**Re: Circuitron Corporation Superfund Site
2010 Annual Performance Monitoring Report**

Please find enclosed your copy of the 2010 Annual Performance Monitoring Report, for the above referenced Site, prepared by URS in accordance with the terms outlined in the scope of work for the current contract mod (W9128F-04-D-0001-DH02 Year 3). This report evaluates the 2010 monitoring well sampling results and water levels obtained through the July 2010 Performance Monitoring Period.

Please do not hesitate to contact Mr. Doug Gray directly via phone at 216-622-2283 or via e-mail at doug_gray@urscorp.com if you have any questions.

Very truly yours,

Anping Zheng
Water Resources Specialist

1.0 Introduction

This is the 2010 Annual Performance Monitoring Report for the Circuitron Corporation Superfund Site (Site) located in East Farmingdale, New York (Figure 1-1). This report presents an assessment of the groundwater data collected from January 1999 through July 2010, in accordance with the selected remedy for the Site as described in the Record of Decision (ROD) (United States Environmental Protection Agency [USEPA], 1994) for Operable Unit Two (OU-2). The annual report, documented herein, is prepared on a regular schedule incorporating new performance monitoring data. It is also noted that since metals analyses were eliminated after the 2003 sampling event, this report does not contain the historical metals data. Refer to the 2003 Annual Performance Monitoring Report for the metals data collected from January 1999 through April 2003.

This section of the report provides background information for the Site, including a description of the former and presently non-operational groundwater extraction well system, the network of performance monitoring wells, and the monitoring schedule. Section 2 discusses the technical approach for the performance monitoring evaluation. Section 3 presents an assessment of the groundwater flow patterns for the Site over time (i.e., with and without the groundwater extraction system in operation). Section 4 provides a summary of groundwater quality data collected at the Site. Section 5 presents a summary of the findings and conclusions. Section 6 presents recommendations for the Site, and Section 7 provides the reference materials used for the preparation of this report.

1.1 Background

Based on the results of the Focused Feasibility Study (FFS) for OU-2, completed by Roy F. Weston (Weston, 1994), elevated levels of both organic and inorganic compounds were detected in the Upper Glacial Aquifer below and near the Site. The Upper Glacial Aquifer is described as the water table aquifer that extends to a depth of 70 to 80 feet below the ground surface (bgs) at the Site and overlies the Magothy Aquifer. Elevated levels (exceeding Federal and State Groundwater Drinking Water Standards) of 1,1,1-trichloroethane (1,1,1-TCA), 1,1-dichloroethene (1,1-DCE), chromium (Cr), and copper (Cu) were detected in the groundwater in the upper portions (less than 40 feet bgs) of the Upper Glacial Aquifer. These detections were attributed to the historical activities at the Site (see Figure 1-2). Similar compounds were also detected at elevated levels in the deeper portions (greater than 60 feet bgs) of the Upper Glacial Aquifer and in the underlying Magothy Aquifer in wells located on-site in addition to the wells

Site Map

Circuitron Corporation Superfund Site
East Farmingdale, New York

URS

located upgradient and downgradient of the Site. These detections in the deeper zone are believed to be the result of off-site sources (Weston, 1994). After the FFS was completed, a ROD for OU-2 was signed on September 30, 1994. The selected remedy consisted of the removal of organics and inorganics from the groundwater within the upper portion of the Upper Glacial Aquifer via air stripping and metal precipitation, respectively, and re-injection of the treated groundwater. Groundwater extraction for treatment from the deeper portion of the Upper Glacial Aquifer, and the Magothy Aquifer was not included as part of the OU-2 remedy for the Site. The major components of the OU-2 remedy include the following:

- Extraction of the site-related groundwater contaminant plume present in the upper 40 feet (top portion) of the saturated Upper Glacial Aquifer;
- Treatment, via precipitation and air stripping, of contaminated groundwater to drinking water standards;
- Re-injection of the treated groundwater into the Upper Glacial Aquifer via an infiltration gallery, and
- Disposal of treatment residuals at a Resource Conservation Recovery Act (RCRA) Subtitle C Facility.

1.2 Groundwater Extraction System

For the OU-2 remedy, groundwater flow and contaminant transport modeling was performed (Radian, 1999) to assist in the final design of the treatment system. Specifically, modeling was used to determine the placement and pumping rates of proposed extraction wells. Several scenarios of groundwater extraction well placement and pumping rates were considered for the OU-2 remedy design. The selected design consists of three (3) extraction wells pumping at a total rate of 80 gallons per minute (gpm), a treatment system, and re-injecting treated groundwater into a trench located at the northern (upgradient) end of the Site. The system began operations on June 28, 2000.

Additional groundwater modeling was performed by URS in 2005 to evaluate the effect of halting pumping at downgradient extraction wells RW-2 and RW-3 as recommended in the Streamlined Remediation System Evaluation (RSE-Lite) report (GeoTrans, 2005). The results of the additional modeling and the RSE-Lite report were included as Appendices D and E, respectively, in the 2005 Annual Groundwater Report, and are not re-iterated herein.

Both URS and the USEPA concurred that extraction well RW-3 could be shut off in 2005 and that prior to shutdown of RW-3, groundwater from all three of the extraction wells

would be sampled. The analysis showed that with the exception of 1,1-dichloroethane (1,1-DCA) and 1,1,1-TCA, all volatile organic compounds (VOCs) were below method detection limits in groundwater obtained from extraction wells RW-1, RW-2 and RW-3. The level of 1,1-DCA detected in well RW-2 was 19 micrograms per liter ($\mu\text{g/l}$). The level of 1,1,1-TCA detected was 4 $\mu\text{g/l}$ from well RW-1, 18 $\mu\text{g/l}$ from RW-2, and 3 $\mu\text{g/l}$ from RW-3. Based on these results, USEPA agreed that RW-2 should not be turned off.

The additional groundwater modeling performed by URS evaluated several alternative pumping scenarios, the first with wells RW-1 and RW-2 pumping, and RW-3 shut down; and another with only well RW-1 pumping. The resulting capture zones were compared to the current area where concentrations of 1,1,1-TCA exceed the standard of 5 $\mu\text{g/L}$. The modeling concluded that the capture zone created by wells RW-1 and RW-2 is sufficient to maintain hydraulic control of the affected area. Based on the recommendation of the RSE-Lite report to stop pumping at well RW-3 and supported by the groundwater modeling, well RW-3 was shut down on January 5, 2005.

Since 2005, the groundwater extraction system consisted of two extraction wells (RW-1 and RW-2) each equipped with a submersible well pump and piping that discharges groundwater to an on-site treatment plant. The extraction wells are positioned to pump groundwater from two areas to accomplish groundwater capture around the subject site area. Each well is constructed with a 15-feet long ASTM-A-304 stainless steel screen connected to ASTM-A-304 Schedule 40 stainless steel riser. The bottoms of the well screens for RW-1 and RW-2 were both installed to a depth of 56 feet bgs. The extraction well locations are presented in Figure 1-2. Each extraction well is pumped intermittently based on water levels in the extraction wells and the water levels in both the equalization tank and in the building sump inside the groundwater treatment plant (remediation system) building. The results of the 2005 modeling indicate that the combined flow rate of the two extraction wells should be operated at a total flowrate of 40 gpm. Currently, the system is not actively recovering groundwater; the system is “exercised” approximately four to six hours every month, concurrent with URS visits to the Site.

1.3 Groundwater Monitoring System

Presently, there is a network of 19 monitoring wells located at and around the Site that are used for groundwater monitoring of the OU-2 remedy. Shallow wells are those wells screened in the shallow portion of the Upper Glacial Aquifer (i.e., approximately 34 to 40 ft-bgs). Deep wells are those wells screened in the deep Upper Glacial Aquifer or Magothy Aquifer

(i.e., approximately 99 to 101 ft-bgs). Of the existing 19 wells, 12 wells are shallow and seven (7) are deep. For the Performance Monitoring period of June 2000 through July 2010, water level data and groundwater quality data were collected from each well in the network. Water levels were measured monthly from each well in the network and groundwater samples were collected quarterly for VOCs and semi-annually for inorganic analyses. In 2003, the monitoring well sampling frequency was reduced to annual sampling for VOCs and metals.

Based on URS's recommendations in the 2003 Annual Performance Monitoring Report, USEPA eliminated the requirement for annual metals sampling in the monitoring wells. The sampling method was also changed from the low-flow method to the diffusive bag method. The water level data and groundwater quality data (VOCs) have been collected annually since the mothballing of the treatment system in August 2007. These data are used to assess the performance of the treatment system and are discussed in Sections 3 and 4 of this report.

1.4 Process Observations and Changes

The Circuitron Project Team evaluated the recommendations of the RSE-Lite Report (January 2005) and with USEPA approval, implemented during 2005, those recommendations deemed appropriate. Prior to implementing the recommendation to install extra sets of filter bags, URS performed further evaluation. Based on successful histories at other Operation & Maintenance (O&M) sites with citric acid treatment, URS, with the concurrence of the USEPA, started on July 6, 2005 to introduce citric acid after the influent tank. The micron size of the filter bags was increased from 10 microns to 100 microns. In general, the results indicated that the reduction in the frequency of the filter bag changes caused no major decrease in the pH of the effluent. Acetone was detected in the effluent during the months after citric acid was introduced into the system.

With the introduction of the citric acid, the fouling of the reinjection trench occurred. The Project Team decided that the best solution was to waterjet the trench 3 – 4 times a year and to treat the reinjection trench with citric acid on an as-needed basis. This method continued until the mothballing of the groundwater treatment system in August 2007. On December 8, 2009, URS, with the concurrence of the USEPA, introduced 20 bags of 50-lb citric acid powder into the reinjection vault due to the fact that the water in the reinjection trench did not drain satisfactorily during the previous month's system exercise period, causing water overflow in the vault. The result of the citric acid injection lasted about 1 week before URS observed the water started to rise again when the system was running again. Although there has been no reinjection

trench fouling observed in 2010, a continued water jetting treatment program on the reinjection trench is recommended if the system is re-started in a full operational mode. In June 2010, URS noted a leak in the water supply line to the Site and the leak was subsequently repaired with water service being returned to the Site.

1.5 Summary of Investigation of Chlorinated Source

Response Engineering and Analytical Contract (REAC) personnel provided technical assistance to EPA Region II and performed an investigation of the unsaturated/saturated zone in the southwestern corner of the Circuitron Corporation Site, near wells MW-4S and MW-4D. The objective of the REAC investigation was to determine if a residual source of 1,1,1-TCA remains. The results of this investigation were published by REAC in April 7, 2006 and are briefly summarized below.

During November 2005, REAC utilized direct push to install and sample 40 soil borings and 22 temporary monitoring wells located in the southwestern corner of the Circuitron Corporation Site, predominately near wells MW-4S and MW-4D. The soil borings provided continuous cores to a total depth of between 25 and 35 feet bgs. Based on screening of the soil cores for total VOCs using a Flame Ionization Detector (FID), 63 soil samples were analyzed using an on-site portable gas chromatograph/mass spectrometer (GC/MS) for VOC Target Compound List, which included trichloroethylene (TCE) and tetrachloroethylene (PCE). Six of these soil samples were sent to an analytical laboratory for confirmation. Twenty-two (22) one-inch diameter temporary monitoring wells were installed to a depth of 5 feet below the water table (total depth of 35 feet bgs). Groundwater was obtained using disposable bailers from each of these 22 wells plus existing wells MW-1S, -1D, -4S and -4D. The groundwater samples were analyzed for VOCs using an on-site GC/MS and six samples were sent to an analytical laboratory for confirmation.

The results of this effort indicated:

- a) An accumulation of 1,1,1-TCA dissolved in groundwater surrounding well MW-4S, with a maximum 1,1,1-TCA concentration of 1,600 µg/l from temporary monitoring well SD-3, which is located 5 to 10 feet north of well MW-4S.
- b) An accumulation of PCE dissolved in groundwater located approximately 50 feet north of well MW-4S, with a maximum concentration of 150 µg/l from temporary well R3.

- c) An approximate 15-20 foot diameter area of soil, generally centered around well MW-4S, where 1,1,1-TCA has been detected with a maximum soil concentration of 21,900,000 µg/kg at a depth of 15 feet bgs.
- d) An approximate 10-15 foot diameter area of soil, located approximately 50 feet north of well MW-4S, where PCE has been detected with a maximum soil concentration of 17,200 µg/kg.

In August 2007, USEPA and its contractor, under a separate contract, installed a soil vapor extraction (SVE) system for a pilot study. During the pilot study, the groundwater extraction and treatment system have been operated for approximately four to six hours every two weeks. The pilot SVE system continued to be in operation throughout 2010.

2.0 Technical Approach

The performance monitoring evaluation assesses changes in the concentrations of compounds dissolved in groundwater relative to the observed zone of capture using hydraulic and water quality data collected throughout the Performance Monitoring period, extending from January 1999 through July 2010. Isoconcentration maps, groundwater elevation contour and flow maps, and geochemical time-series graphs are used to assess the effectiveness of the remediation system for treating the groundwater present in the shallow portion of the Upper Glacial aquifer. Portions of the deep Upper Glacial Aquifer and the Magothy Aquifer are being monitored for changes in groundwater chemistry over time; therefore, time-series graphs have also been prepared for wells screened within this zone. However, the overall effectiveness of the remediation system is based solely on the results in the Upper Glacial Aquifer, as described in the ROD.

2.1 Groundwater Contour and Flow Maps

Groundwater elevation contour maps were prepared for the shallow portion of the Upper Glacial Aquifer beneath the Site. When the groundwater extraction system was operational, the effectiveness of the remediation system to induce groundwater capture was evaluated by comparing the groundwater flow pattern under pumping conditions to the modeled capture zone. Compounds dissolved in groundwater obtained from wells within the capture zone will be transported toward one of two pumping wells. Groundwater capture was demonstrated if groundwater flow lines were directed toward one of the two extraction wells, as indicated by groundwater elevation contour maps prepared under pumping conditions. However, since the groundwater extraction system has not been operational since 2007, the assessment on groundwater capture zone is not presented in this report. It is noted that the groundwater extraction and treatment system was only operated (i.e., “exercised”) for approximately four to six hours every month in 2010. For additional details and documentation of assessments on groundwater capture zones, please refer to Section 3 of previously submitted Annual Performance Monitoring Reports.

2.2 Groundwater Quality

Groundwater quality was evaluated by preparing isoconcentration maps and geochemical time-series graphs from the sampling data obtained during the Performance Monitoring Period. Data from sampling events that occurred prior to startup of the remediation system (i.e., May 1993, February 1994 and mid-June 2000) were used as the benchmark to

represent pre-remediation baseline groundwater quality conditions. These data were used to identify which VOCs are potentially related to historical activities at the Site (site-related) or believed to not have been related to historical activities at the Site (non site-related). This is discussed more fully in Section 4 of this report.

- Isoconcentration contour maps were prepared using data obtained from the June 2000, January/February 2002, April 2003, June 2004, June 2005, July 2006, August 2007, July 2008, July 2009 and July 2010 sampling events for various VOCs and inorganic analytes for groundwater obtained from the shallow portion of the Upper Glacial Aquifer. Beginning in June 2004, only VOC samples were collected for analysis as agreed to by USEPA. Based on USEPA's request, only one diffusion bag was utilized for sampling the wells since June 2005. The bag was placed at one foot above the bottom of the well.

Previous data were submitted to the USEPA and United States Army Corps of Engineers (USACE) as part of the Operation and Maintenance Monthly Progress Reports for the Site. Comparison of the isoconcentration maps to groundwater flow paths can be used to document that the remediation system is effectively remediating compounds dissolved in groundwater. This evaluation is presented in Section 4 of this report.

Geochemical time-series graphs provide an effective technique for documenting trends over time in groundwater quality from a given well. Time-series graphs were prepared by plotting concentration levels versus time for compounds detected in groundwater samples from both the shallow and deep monitoring wells. Data obtained from the deeper Upper Glacial and Magothy Aquifer wells were prepared to document changes in groundwater chemistry over time because these wells are included in the Performance Monitoring program. However, the assessment of the OU-2 remedy is solely based on the results from the shallow Upper Glacial Aquifer.

3.0 Groundwater Flow

Water levels measurements from each accessible monitoring well were collected in January 1999, prior to the startup of the full-scale remediation system operation in late June 2000. Groundwater level data from January 1999 (Figure 3-1a) and mid-June 2000 (Figure 3-1b) were used to establish baseline conditions of groundwater flow within the upper portion of the Upper Glacial Aquifer under non-pumping conditions. After commencement of the remediation system operation in late June 2000, water level measurements were collected monthly from each accessible monitoring well. Beginning in January 2005, pumping was halted at the most downgradient extraction well RW-3. Groundwater level data was collected monthly through June 2006, after which groundwater level data was collected quarterly at the request of the USEPA. Since 2008 the groundwater level data has been collected annually, at the same time as the annual performance sampling event. All these groundwater elevation contour maps are presented in Figures 3-1a to 3-1k.

Hydrographs showing groundwater elevation over time were prepared for each well (Appendix C). These graphs indicate that the hydrographs for the individual wells generally (with a few notable exceptions) parallel one another and the hydraulic gradient has remained essentially constant during this Performance Monitoring Period.

3.1 Baseline Conditions

The baseline groundwater flow pattern recorded in January 1999 (Figure 3-1a) and June 2000 (Figure 3-1b) represents hydraulic conditions prior to operating the remediation system. These data show that groundwater flow is to the south/southeast with a hydraulic gradient between 0.002 ft/ft and 0.004 ft/ft within the upper portion of the Upper Glacial Aquifer during January 1999 and June 2000.

3.2 Pumping Conditions

Figures 3-1c to 3-1h show the groundwater contour map within the upper portion of the Upper Glacial Aquifer under pumping conditions during August 2002, April 2003, March 2004, June 2005, June 2006, and July 2007 while the system was fully operational. During the period from July 2008 through July 2010, the system was not operated continuously and groundwater contour maps (Figures 3-1i to 3-1k) are based on water level measurements in monitoring wells.

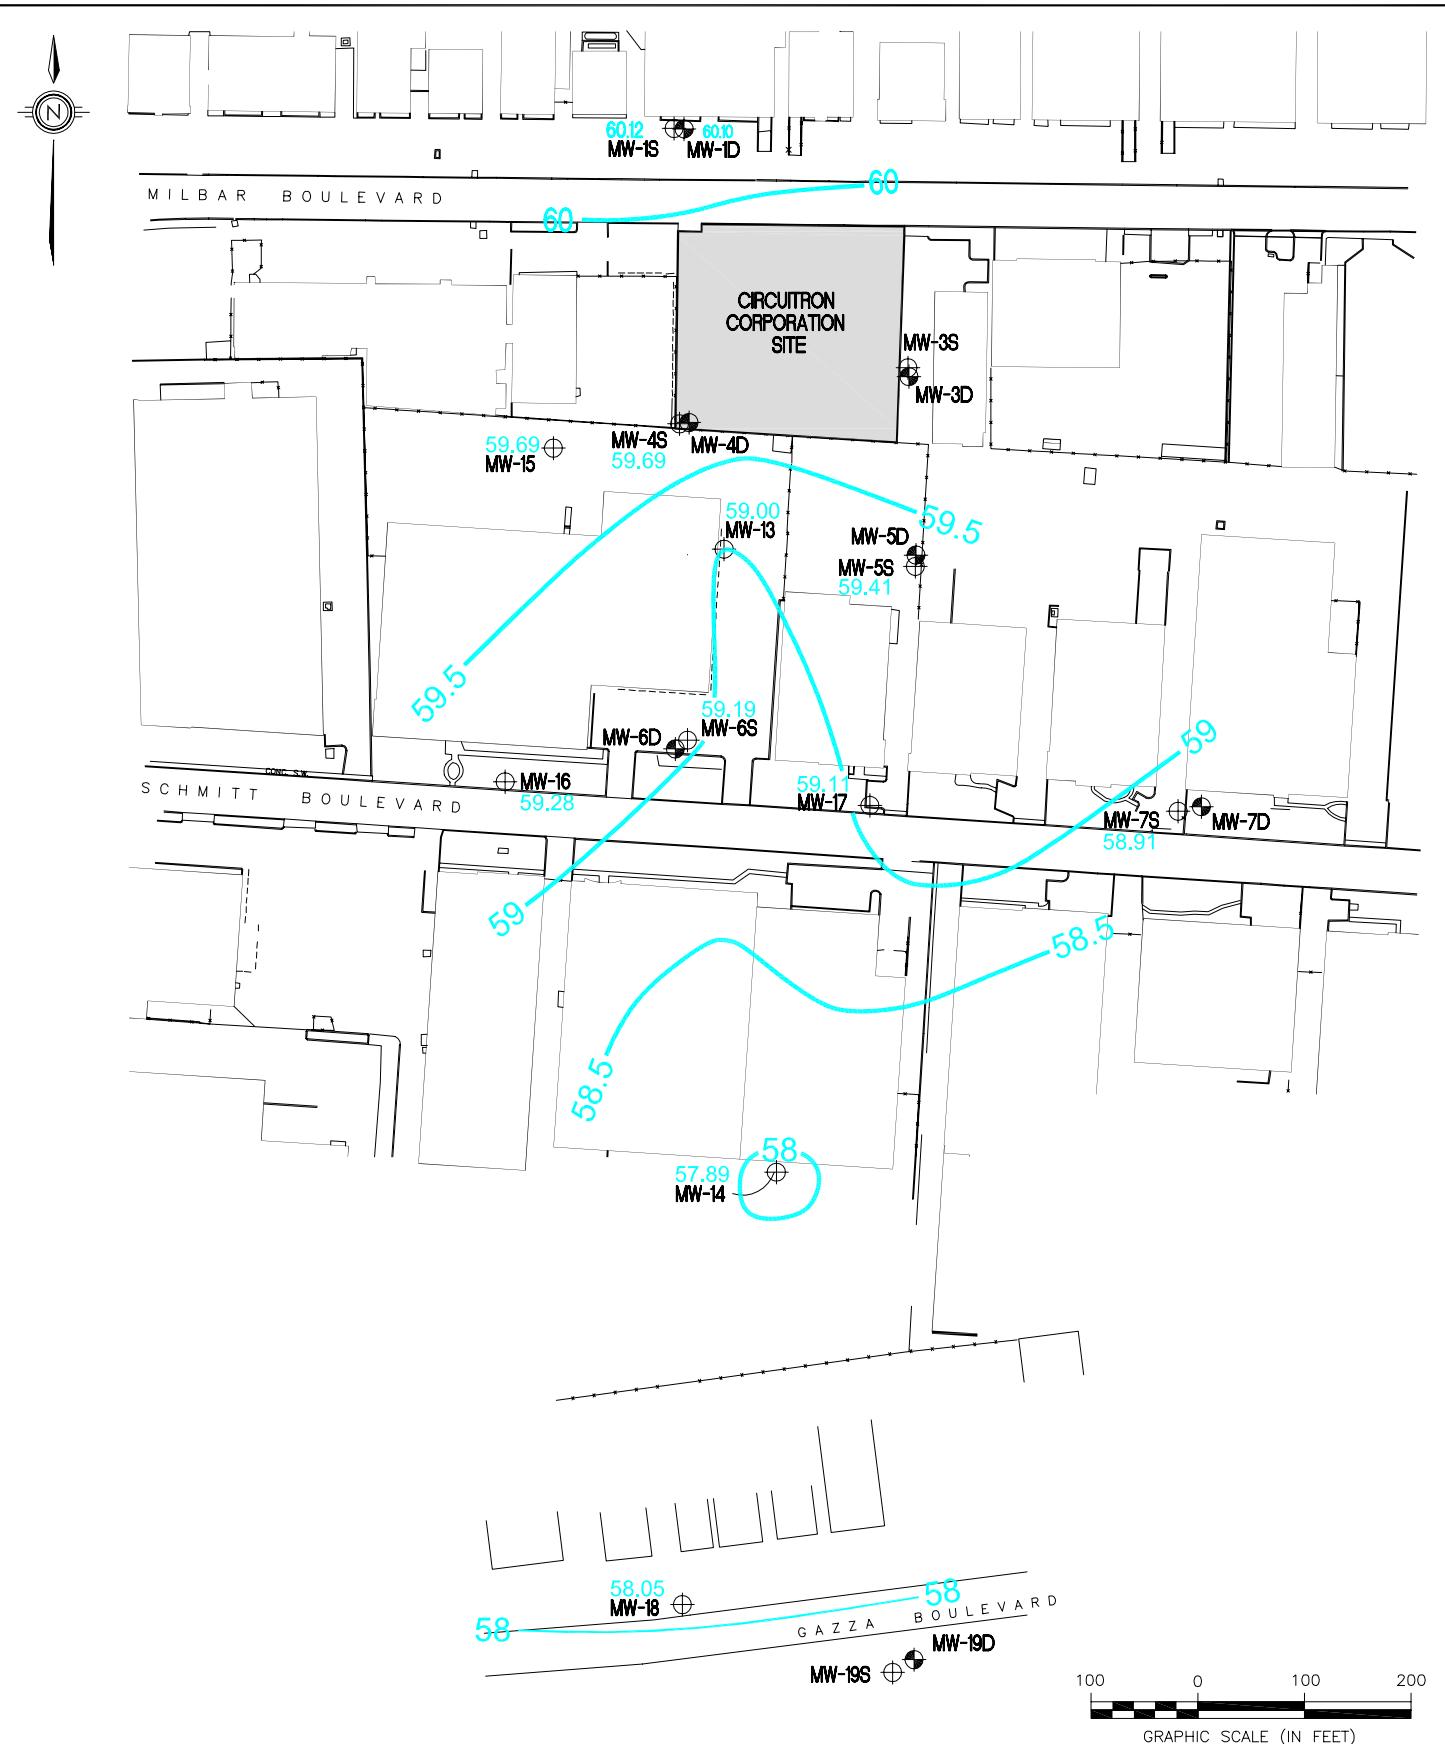

The groundwater flow pattern indicates transport toward the south with a slight bi-directional flow component on either side of a north-south line connecting the recovery wells. West of this line, flow is predominantly to the southeast. East of this line, flow is to the southwest. The effects of the groundwater extraction system, when operational, are evident as groundwater contours are partially wrapped around each recovery well. Pumping well RW-3 was turned off in January 2005. Pumping wells RW-1 and RW-2 have been operated four to six hours every two weeks since August 2007 because of a pilot test of a SVE system near MW-4S and MW-4D. It is noted that since the groundwater extraction system has been non-operational, groundwater flow direction has generally returned to baseline (pre-pumping) conditions with groundwater flow in an apparent south/southeast direction.

Table 3-1 presents hydraulic gradients observed in June 2000 (pre-pumping), August 2002, April 2003, March 2004, June 2005 (pumping), June 2006 and July 2007 conditions. A comparison of the gradients measured in August 2002, April 2003, March 2004, June 2005, June 2006 and July 2007 at which time the treatment system was operational, shows that gradients in the northern portion of the Site are very similar; but that gradients are steeper around well MW-14 during the April 2003 measurements.

**Table 3-1. Horizontal Gradients (feet/feet) Upper Glacial Aquifer,
Circuitron Corporation Superfund Site**

Date	Traverse*			
	MW-15 (Northwest)	MW-5 (Northeast)	MW-14 (Southwest)	MW-14 (Southeast)

4.0 Groundwater Quality

During the period from June 2000 through July 2010, when the OU-2 remedy was operating (fully or partially), groundwater samples were collected from up to 19 monitoring wells at the Site. These data, as presented in Appendices A-1, A-2, and A-3, were used to evaluate changes of the dissolved phase VOC concentrations in the groundwater during the Performance Monitoring Period. Data from sampling events that occurred prior to startup of the remediation system (i.e., May 1993, February 1994 and mid-June 2000) were used as the benchmark to represent pre-remediation baseline groundwater quality conditions.

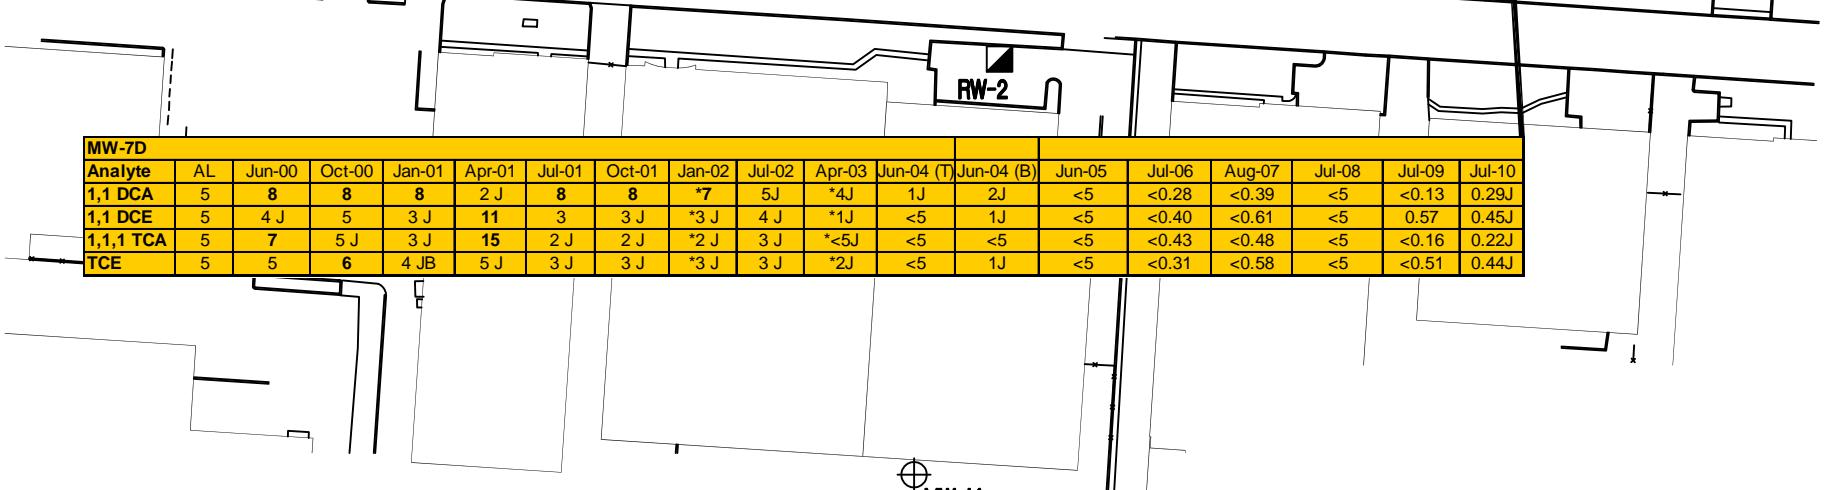

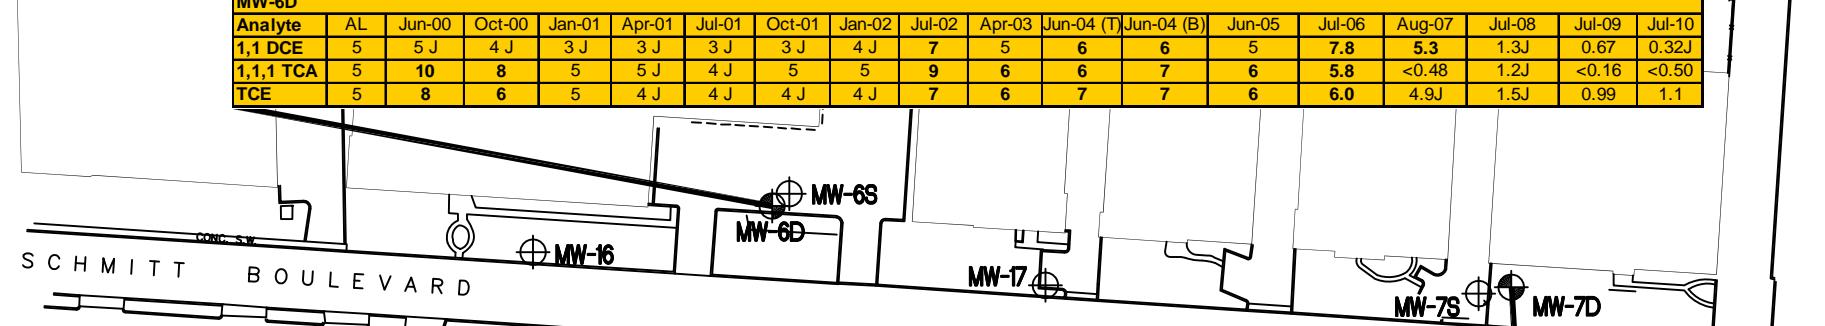

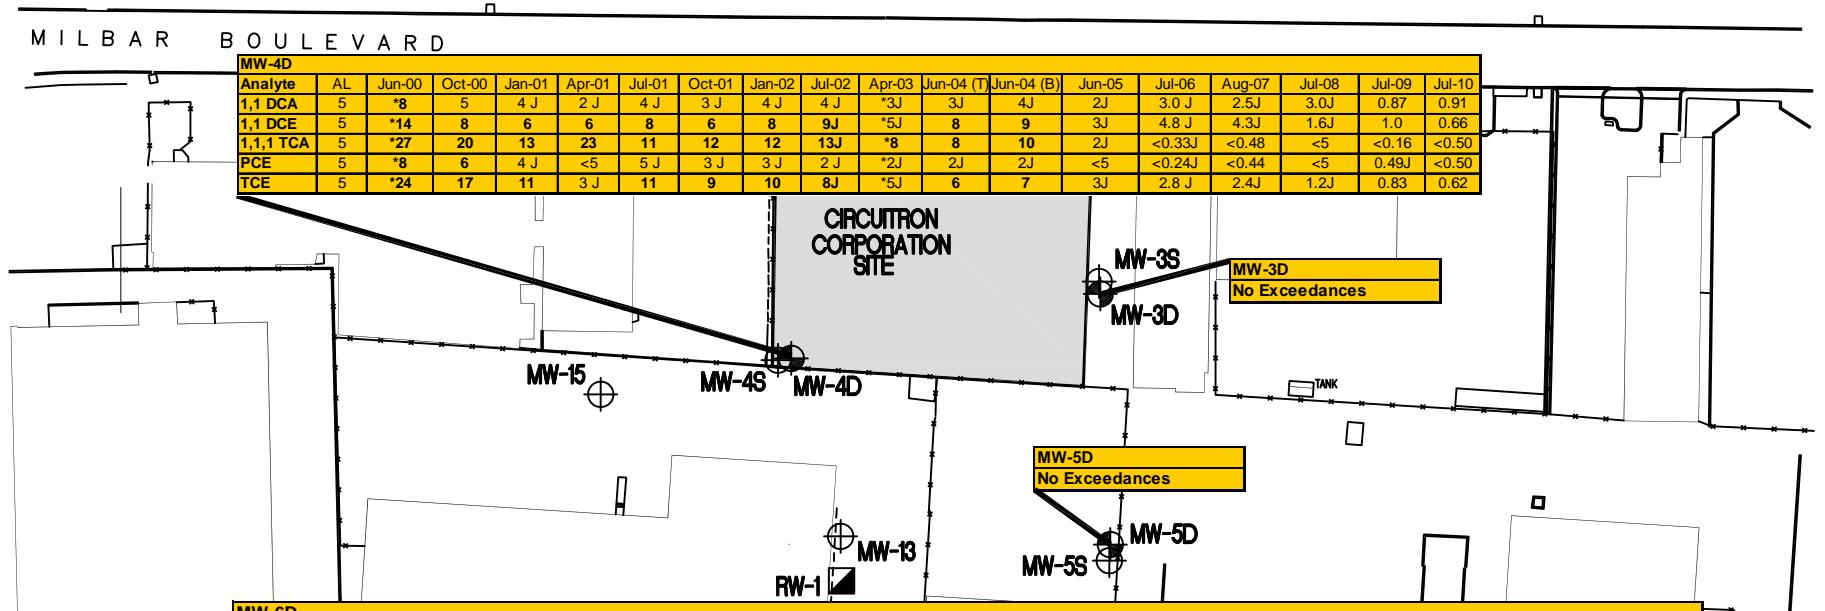

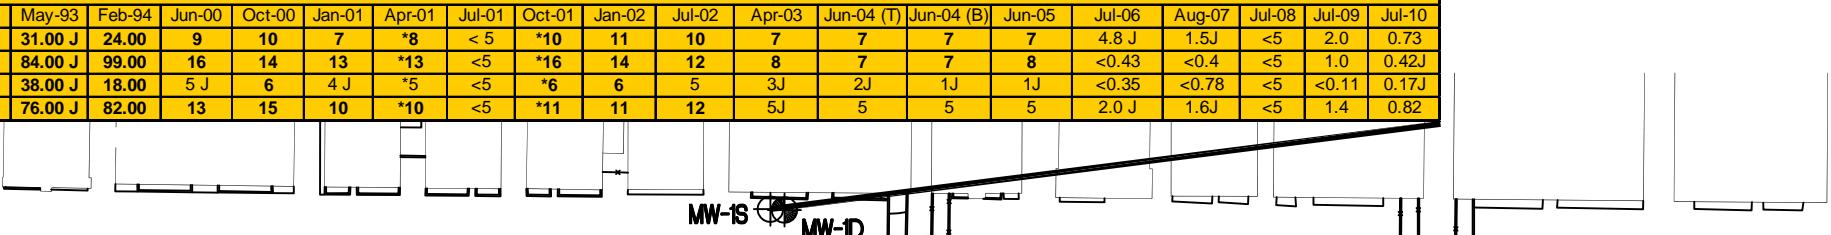

The following sections discuss the distribution of compounds detected in the shallow groundwater using isoconcentration contour maps and time-series graphs (as presented in Appendix B). Time-series graphs for seven deep wells included in the Performance Monitoring program were also prepared to show trends in the deeper zone of the Upper Glacial Aquifer over time and are also presented in Appendix B.

4.1 Exceedances of Action levels

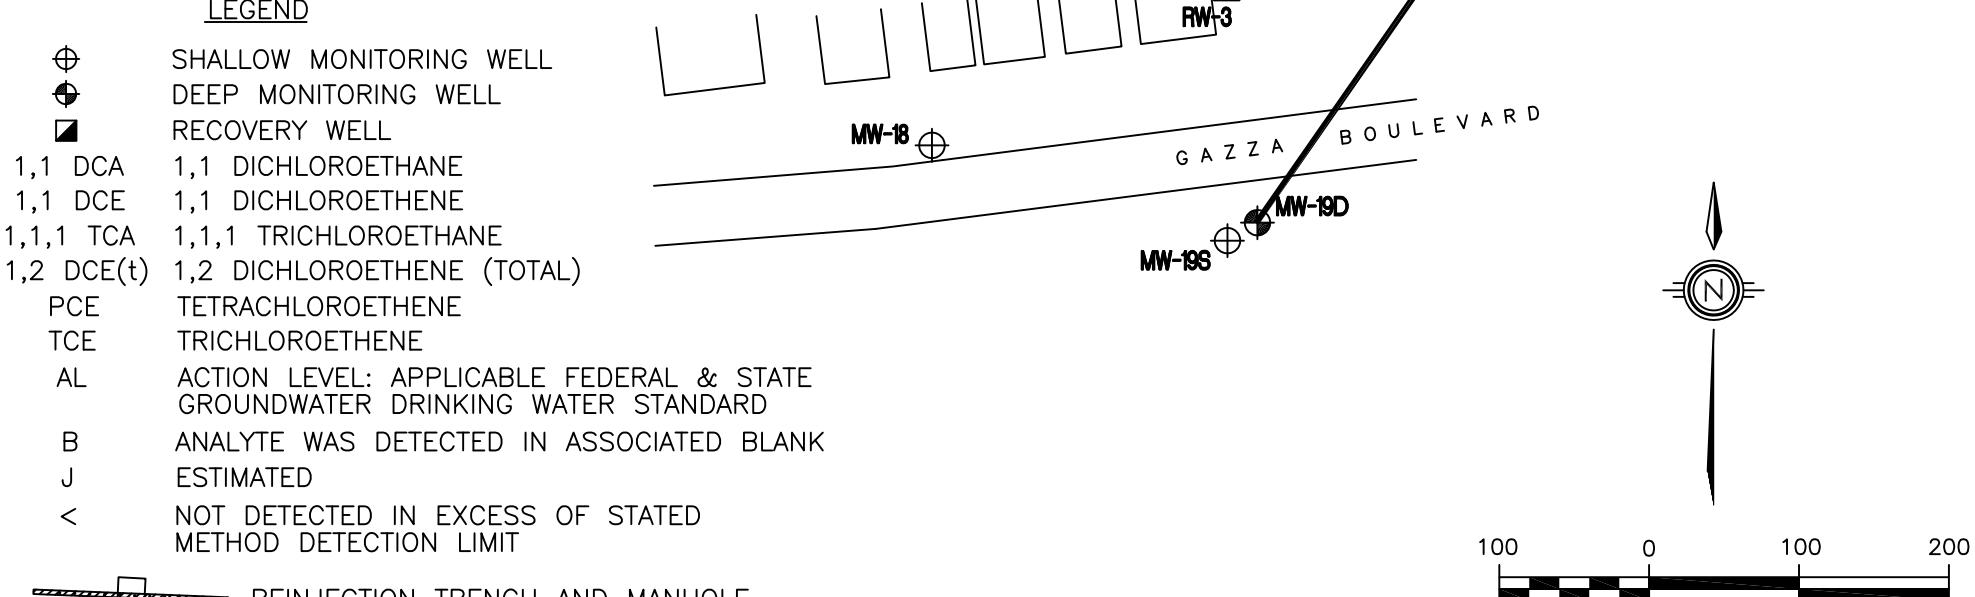

Exceedances are defined for the purposes of this report as groundwater samples analyzed that have VOCs or metals detected at levels exceeding the applicable Federal or State Groundwater Drinking Water Standards. These standards are referred to in this report as Action Levels. Single exceedances may be anomalous and therefore recommendations for changing the operation of the remediation system will be based on only a pattern of multiple exceedances. Table 4-1 summarizes the exceedances observed in groundwater from each well and Figures 4-1a and 4-2a illustrate historical exceedances of VOC compounds observed in groundwater sampled from shallow and deep wells, as well as observed concentrations versus time. Appendix A-1 presents the total VOC concentrations for each monitoring well sampled from June 2000 through July 2010. Appendix A-2 contains the historical VOC analytical results for each monitoring well. Appendix A-3 presents validated laboratory summary data for the 2010 sampling event.

Among all shallow wells, MW-14, MW-18 and MW-19S are located outside the historical capture zone (refer to previous reports about capture zone). Groundwater samples collected from MW-18 showed 2 exceedances of methylene chloride (see Appendix A-2), both occurring in 2001. Groundwater samples collected from MW-19S showed multiple exceedances of methylene chloride, a single exceedance of 1,1-DCA, and 2 exceedances of 1,1,1-TCA. All

these exceedances occurred between 2000 and 2003. However, methylene chloride, a common analytical artifact for VOCs, is not representative of groundwater contamination because most of the associated method blanks also exhibited detections of methylene chloride, and therefore, such exceedances were not used in this evaluation and are not shown on Figure 4-1a. Monitoring well MW-14 has not exhibited any exceedances of VOC standards during the last eight rounds of annual groundwater sampling conducted since 2002.

Based on the most recent July 2010 groundwater analytical data, only two (2) exceedances to Action Levels are noted within the shallow portion of the Upper Glacial Aquifer. These exceedances occurred at monitoring wells MW-4S (1,1,1-TCA @ 54 µg/L) and MW-13 (1,1-DCA @ 8.7 µg/L). None of the other shallow performance monitoring wells indicated any exceedances. Additionally, no exceedances were observed in any of the deep performance monitoring wells, based on the July 2010 data.

4.2 Site-related Compounds versus Non Site-related Compounds

For the purposes of this document, the following criteria were used to determine if a compound is potentially related to historical activities at the Site (site-related) or believed to not have been related to historical activities at the Site (non site-related). The effectiveness of the remediation system will be evaluated by the presence of compounds that are believed to be site-related. Compounds that are judged to be non site-related will not be used to determine the remediation system effectiveness.

A compound will be considered site-related if:

- a) It was not observed as an exceedance in groundwater obtained from the upgradient well prior to remediation system startup (i.e., May 1993, February 1994 and June 2000 sampling events) and was observed as an exceedance in groundwater from a site well during more than one sampling event; or
- b) It formed from naturally occurring biodegradation, such as dichloroethenes and dichloroethanes, if the parent compound (e.g., PCE, TCE or 1,1,1-TCA) is considered to be site-related (i.e., not observed as an exceedance in groundwater from the upgradient well).

A compound will be considered as non site-related if:

- a) It was observed as an exceedance in groundwater from the upgradient well prior to remediation system startup (i.e., May 1993, February 1994 and June 2000 sampling events); such compounds are considered to be background; or
- b) It formed from naturally occurring biodegradation, such as dichloroethenes and dichloroethanes, if the parent compound (e.g., PCE, TCE or 1,1,1-TCA) is considered to be non site-related, (i.e., observed as an exceedance in groundwater from the upgradient well).

4.3 Isoconcentration Maps

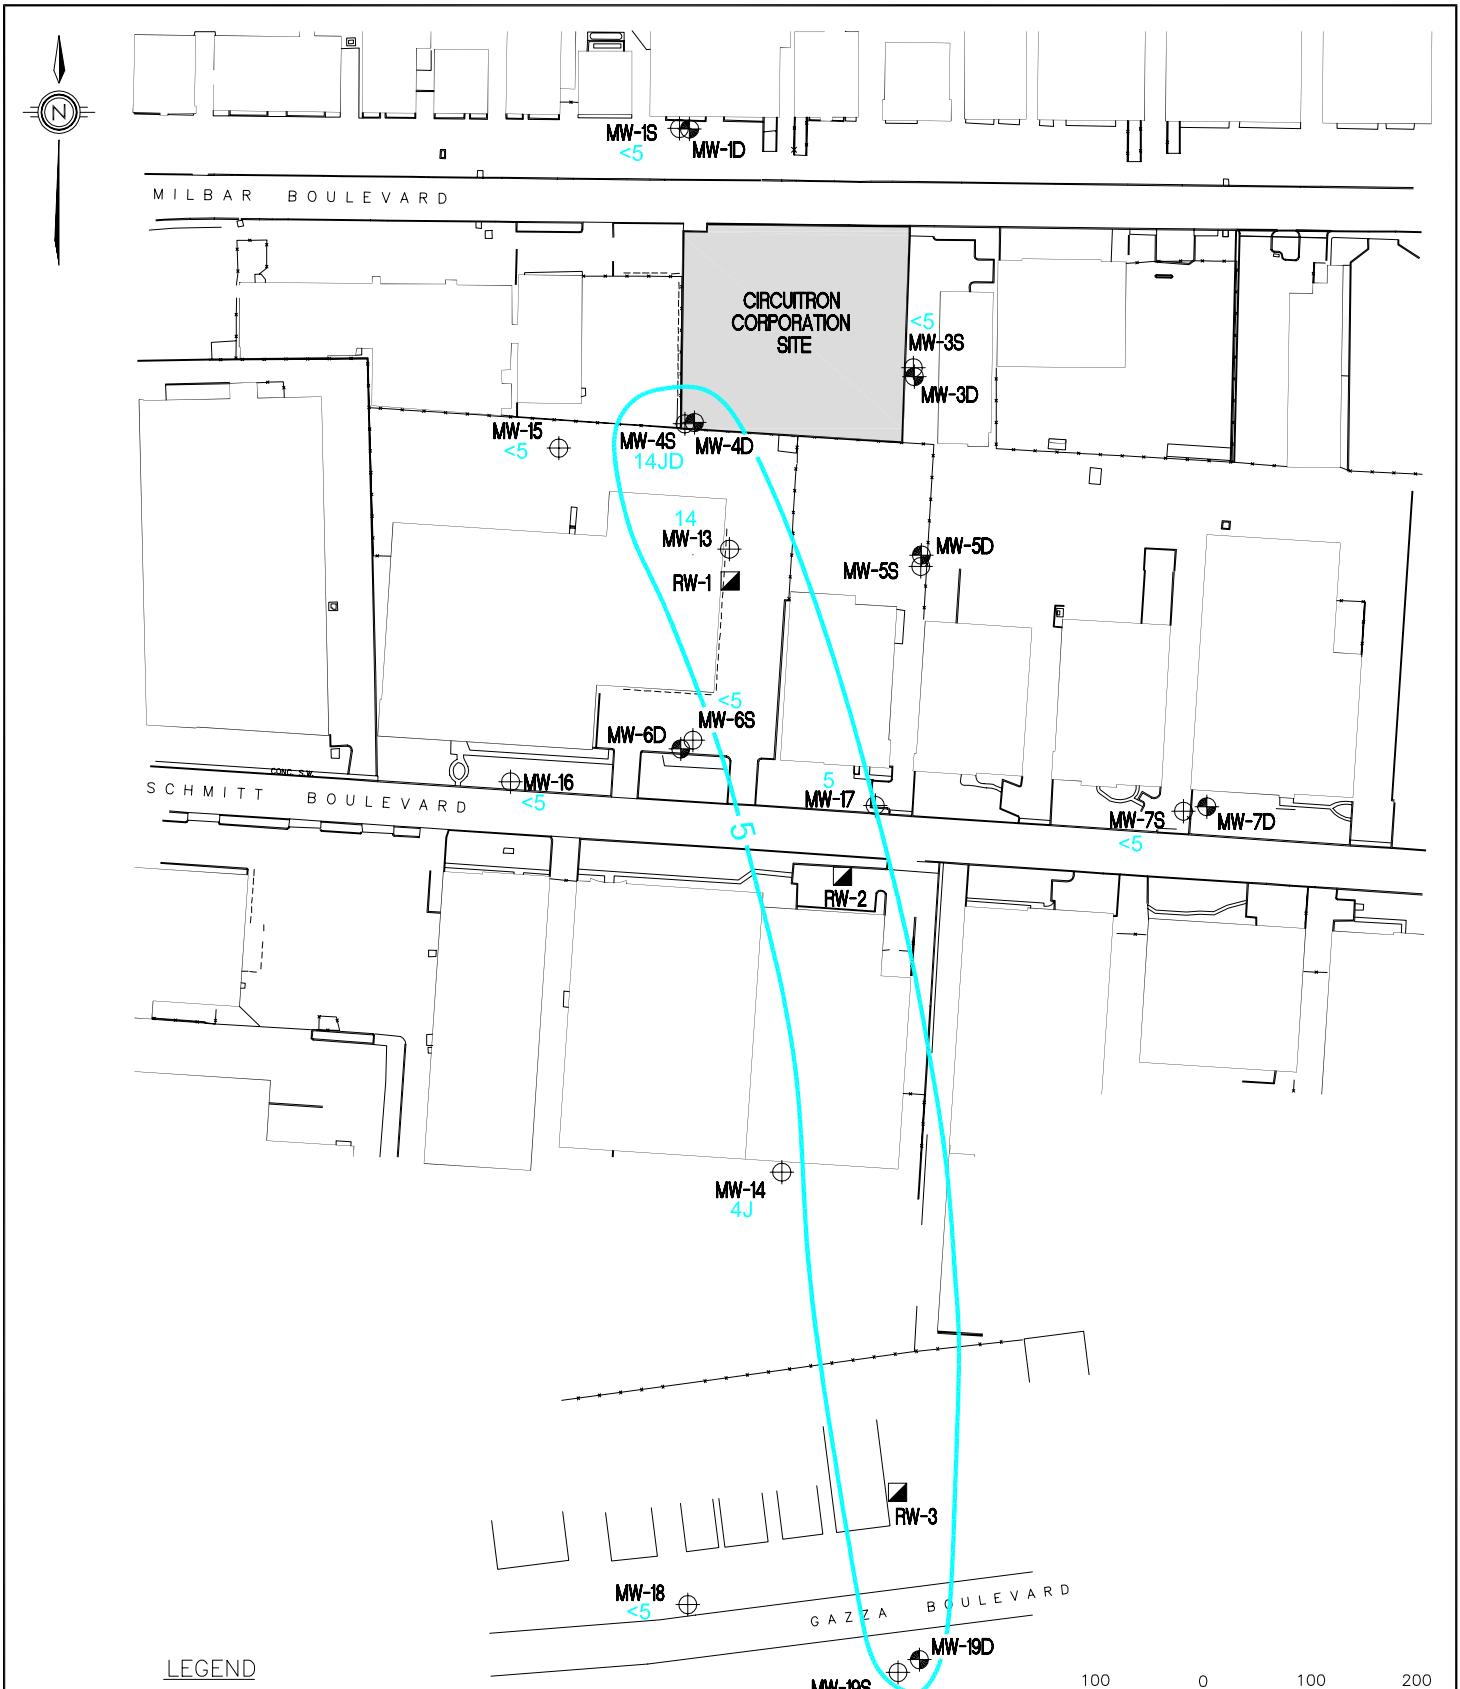

Isoconcentration maps for the shallow portion of the Upper Glacial Aquifer were prepared for sampling events conducted in June 2000, January/February 2002, April 2003, June 2004, June 2005, July 2006, August 2007, July 2008, July 2009 and July 2010 and are presented in Figures 4-3(a-j) and 4-4(a-j) for 1,1-DCA and 1,1,1-TCA, respectively. Data from January/February 2002 was used in place of August 2002 data because dry conditions prevented sampling of shallow monitoring wells (MW-4S, MW-6S, and MW-7S) at that time.

Isoconcentration maps were created for organic compounds (1,1-DCA and 1,1,1-TCA), which had historical exceedances observed in the groundwater from downgradient well MW-19S.

4.3.1 VOC Exceedances in Shallow Wells

Figure 4-1a and Table 4-1 provide a summary of the exceedances of VOCs observed to have been present in the groundwater samples from shallow wells. For the 2010 annual sampling event, there are two exceedances of VOCs: the concentration of 1,1-DCA exceeded its respective action level in the groundwater sample collected from site monitoring well MW-13 (8.7 µg/L); the concentration of 1,1,1-TCA exceeded its respective action level in monitoring well MW-4S (54 µg/L).

Isoconcentration contours of these compounds were prepared for the June 2000, January/February 2002, April 2003, June 2004, June 2005, July 2006, August 2007, July 2008, July 2009 and July 2010 data and are presented in Figures 4-3a to 4-3j (1,1-DCA) and Figures 4-4a to 4-4j (1,1,1-TCA). Concentrations of 1,1-DCA found in groundwater for February 2002, April 2003, June 2004, June 2005, July 2006, August 2007, July 2008, July 2009 and July 2010 are considerably less than the levels present in June 2000 in all cases except monitoring wells

MW-13 and MW-17. The MW-13 sample collected during July 2010 had a 1,1-DCA concentration of 8.7 µg/L, which exceeds the action level of 5 µg/L. This was the first detection of 1,1-DCA in MW-13 since 2003. It is also noted that MW-17 was non-detect for 1,1-DCA compared to samples collected in July 2008 and July 2009 of 20 µg/L and 17 µg/L, respectively.

The data from July 2010 indicate all locations (except for well MW-4S) with less than 2 µg/l of 1,1,1-TCA. For the monitoring well MW-4S, the concentration of 1,1,1-TCA has continuously decreased from 340 µg/L in 2007 to 54 µg/L in 2010, which may be due to the localized treatment conducted by USEPA. While very slight variations might be detected from year to year, the significant reductions in the mass of 1,1,1-TCA dissolved in groundwater are evidence that the remediation system has been effective in capturing this constituent in the shallow groundwater at the Site.

The July 2010 data indicate that only wells MW-4S and MW-13 exhibited levels of VOCs exceeding NY Water Quality Criteria (Figure 4-1a). Overall, historical results indicate the success of the remediation system at capturing VOCs in the shallow portion of the Upper Glacial Aquifer. Groundwater obtained from well MW-4S historically showed greater levels of VOCs than any other monitoring wells (Figure 4-1a). Levels of VOCs (1,1-DCA, 1,1-DCE, 1,1,1-TCA, PCE) detected in groundwater from this well have all declined since October 2000. As noted in Section 1.5, localized treatment (SVE pilot test) around MW-4S was initiated in August 2007 by the USEPA, and operations are presently ongoing in the area of the Site.

4.3.2 VOC Exceedances in Deep Wells

Figure 4-2a and Table 4-1 provide a summary of the exceedances of VOCs present in groundwater samples from the deep wells in the period from June 2000 through July 2010. These data show that multiple exceedances of 1,1-DCA, 1,1-DCE, 1,1,1-TCA, PCE, TCE, 1,2-dichloroethene (total) (1,2-DCE), and methylene chloride had historically been observed in groundwater from various deep wells in various years. The overall trend is towards lower or non-detectable concentrations of VOCs across the entire Site. In fact, it should be noted that none of the deep wells exhibited any VOC exceedances in the July 2010 sampling event.

The historical data show that multiple exceedances of 1,1-DCE, 1,1,1-TCA, PCE and TCE were present in groundwater from upgradient well MW-1D, indicating these specific compounds are non site-related. These same compounds were also shown to have multiple

exceedances in groundwater from downgradient well MW-19D, indicating these compounds had been being transported in deeper groundwater across the Site. As aforementioned, both MW-1D and MW-19D showed no exceedances in the July 2010 sampling event, and MW-19D was non-detect for all analyzed chlorinated organics. Appendix A-2 contains the historical summary data for each monitoring well.

Figure 4-5 presents these VOCs in a cross-sectional view and shows data for wells screened in the Upper Glacial Aquifer and the deeper Magothy Aquifer for select dates from baseline through the July 2010 sampling events. With the exception of MW-4S and MW-13, no exceedances are currently observed within the shallow portion of the Upper Glacial Aquifer in the direction of groundwater flow and downgradient of the former source area (i.e., MW-4S). Within the deeper portion of the aquifer, non site-related impacts from upgradient of the Site have also apparently decreased. It is also noted that it is apparent that the PCE and TCE detected in groundwater in the Magothy Aquifer are being transported within the Magothy Aquifer under the Site, and that these compounds originate from a source upgradient of the subject property.

Multiple exceedances of 1,2-DCE were observed in groundwater from downgradient well MW-19D through July 2006. 1,2-DCE is a daughter-product of natural biodegradation of PCE and TCE (both of which were observed as exceedances in groundwater from upgradient well MW-1D); therefore, 1,2-DCE is not considered a site-related compound.

1,1-DCA, detected as multiple exceedances in groundwater from MW-7D through June 2004, is a daughter-product of natural biodegradation of 1,1,1-TCA. 1,1,1-TCA was observed as an exceedance in groundwater from upgradient well MW-1D; therefore, 1,1-DCA is not considered a site-related compound.

Methylene chloride and acetone are believed not to be representative of groundwater contamination due to their widespread detections in method blank samples, and therefore, these data were not evaluated in this report.

4.4 Geochemical Time-Series Graphs

Trends in groundwater quality over time are apparent in geochemical time-series graphs prepared for each monitoring well. Time-series graphs were prepared by plotting concentration levels versus time for select compounds detected in groundwater samples collected

during the period extending from June 2000 through July 2010. Time-series graphs and the associated data are presented in Appendix B.

- In general, the time-series graphs show either slight decrease or no change in concentrations of VOCs detected in groundwater from the shallow wells over the Performance Monitoring Period up through July 2007, with a rather significant increase in July 2008 and a rather significant decrease in July 2009 and July 2010. This increase on the time-series graphs apparently is attributable to the low method detection limits achieved during other sampling events as compared to the relatively higher detection limit achieved during the July 2008 sampling event. All compounds exhibited lower concentrations in 2010 sampling event where the method detection limit was low, except for 1,1-DCA in MW-13, which has a noted increase from non-detect in previous 3 years to 8.7 µg/l. Considering the detection limit issue, the overall trend appears to be a consistent decrease over the entire Performance Monitoring Period, especially during the latest two years (2009 and 2010). Continued monitoring will be conducted to evaluate the significance, if any, of these results.
- The graphs also show an apparent increase in concentration of VOCs detected in some deep wells and a consistent decrease in other wells over the Performance Monitoring Period. As noted above, the increase may be attributed to the relatively higher detection limit achieved during the July 2008 sampling event. Considering the detection limit issue, the overall trend appears to be slight decrease over the Performance Monitoring Period.

The difference in trends observed in VOC levels between the shallow and the deep groundwater is potentially attributable to the remediation system treating groundwater from the shallow zone, while leaving the deeper zone unaffected.

Trends over time in the levels of compounds observed as exceedances in groundwater from downgradient shallow well MW-19S are also useful to evaluate the effectiveness of the remediation system. No VOC compounds have been detected as exceedances in groundwater from MW-19S since 6 µg/L of 1,1,1-TCA (a non-site related constituent) was detected in April 2003. Therefore, the time-series graph for MW-19S further demonstrates that the remediation system has been effective in mitigating the VOC compounds.

Additionally, trends over time in the levels of compounds observed as exceedances in groundwater from downgradient well MW-19D indicate that the attenuation and degradation of these compounds continue as the non-site related deep groundwater plume migrates across the Site.

		Nickel	5	No	Not site-related in shallow aquifer

Table 4-1. Site-Related and Non Site-Related Compounds, Circuitron Corporation Superfund Site
 (Page 4 of 4)

Media	Location	Compound	Number of Exceedance Occurrences	Site-Related	Rationale ⁽¹⁾
Deep Groundwater (Continued)	MW-7D	1,1 Dichloroethane	6	No	Biodegradation product of 1,1,1-TCA
		1,1 Dichloroethene	1	No	Baseline exceedance in MW-1D
		1,1,1 Trichloroethane	2	No	Baseline exceedance in MW-1D
		Trichloroethene	1	No	Baseline exceedance in MW-1D
		Methylene chloride	2	No	Method blank artifact
	MW-19D	Iron	*3	No	Baseline exceedance in MW-1D
		1,1 Dichloroethene	14	No	Baseline exceedance in MW-1D
		1,1,1 Trichloroethane	14	No	Baseline exceedance in MW-1D
		1,2 Dichloroethene (total)	10	No	Biodegradation product of PCE and TCE
		Tetrachloroethene	14	No	Baseline exceedance in MW-1D
		Trichloroethene	14	No	Baseline exceedance in MW-1D
		Chloroform	6	No	Biodegradation product of 1,1,1-TCA
		Methylene chloride	4	No	Method blank artifact
		Chromium	3	No	Baseline exceedance in MW-1D
		Iron	6	No	Baseline exceedance in MW-1D
		Lead	4	No	Baseline exceedance in MW-1D
		Manganese	5	No	Not site-related in shallow aquifer
		Nickel	1	No	Single exceedance

Notes: Data considered in this table includes volatile organics through July 2010 and inorganics through April 2003. With concurrence from the USEPA, metals analysis was discontinued prior to the June 2004 sampling event.

(1) Rationale:

Method blank artifact: The compound was detected in several method blanks and will not be considered site-related.

Baseline exceedance in MW-1S: The compound was observed to exceed action levels prior to remediation system startup in groundwater samples collected from the upgradient well and will not be considered site-related.

Single exceedance: The compound was observed as an exceedance in groundwater collected from a site well during only one sampling event and will not be considered site related.

Upgradient well: If a compound is observed exceeding action levels in this well, the compound will not be considered site-related in any downgradient well.

Baseline exceedance in MW-1D: The compound was observed to exceed action levels prior to remediation system startup in groundwater samples collected from the upgradient well and will not be considered site-related.

Not site-related in shallow aquifer: If a compound is determined to be non site-related in the shallow groundwater, it will not be considered site-related in deeper groundwater.

Biodegradation product: The compound is a biodegradation product of a compound that has been determined non site-related.

* Values that appear with an asterisk indicate that a duplicate sample showed a detection of the compound exceeding the action level, but analysis of the normal sample showed either a detection less than the action level or was not detected in excess of the detection limit. The number includes the duplicate exceedance.

5.0 Summary and Conclusions

This section presents a summary of the findings and conclusions for the 2010 Annual Performance Evaluation.

5.1 Groundwater Flow

The groundwater flow pattern for the shallow portion of the Upper Glacial Aquifer was altered during remediation system operation, and has generally returned to baseline conditions since the system has been non-operational. During the remediation system operation, shallow groundwater contamination located within the zone of capture was directed to the remediation system for treatment. Previous reports have documented the effective capture zone, however, an assessment of groundwater capture zone is not presented in this report since the groundwater extraction and treatment system was only operated intermittently (i.e., monthly) during 2010.

5.2 Groundwater Quality

Monitoring well MW-1S is located upgradient of the Site with respect to groundwater flow direction and is the background well for the shallow portion of the Upper Glacial Aquifer in the Site. Comparison of the results from each shallow well located downgradient of well MW-1S provides a benchmark to determine if the concentrations detected in the downgradient wells are site-related. A compound is considered site-related if it is observed as an exceedance in groundwater from a site well and not observed as an exceedance in groundwater obtained from the upgradient well prior to remediation system startup (February 1994 and June 2000 sampling events).

Monitoring well MW-1D is located upgradient of the Site and is screened within the deep portion of the Upper Glacial Aquifer. Comparison of the results from each deep well located downgradient of well MW-1D provides a benchmark to determine if the concentrations detected in the downgradient deep wells are site-related. A compound is considered site-related if it is observed as an exceedance in groundwater from a site well and not observed as an exceedance in groundwater obtained from the upgradient well prior to remediation system startup (May 1993, February 1994 and June 2000 sampling events). The May 1993 data were also used along with the February 1994 data in this comparison because of the lead that exceeded the action level during that sampling event. A compound is not considered site-related in

groundwater from the deep aquifer unless it is determined to be site-related in shallow groundwater.

5.2.1 Shallow Wells - VOCs

VOCs present in the groundwater from the shallow portion of the Upper Glacial Aquifer within this area appear to have been reduced by the remediation system. Evidence for this is:

- a) The levels of 1,1,1-TCA and 1,1-DCA present in January/February 2002, June 2004, June 2005, July 2006, August 2007, July 2008, July 2009 and July 2010 are considerably less than the levels present in June 2000.
- b) Both 1,1-DCA and 1,1,1-TCA were observed as an exceedance in groundwater from downgradient well MW-19S sampled prior to remediation system start-up (June 2000) and once again in April 2003 at a concentration just above the detection limit for 1,1,1-TCA of 5 µg/L. Other than this single exceedance in April 2003, these compounds were not detected as exceedances in groundwater sampled from this well during sampling events after the startup of the remediation system.
- c) As of July 2010, the only shallow wells which exhibited levels of VOCs exceeding 5 µg/l are wells MW-4S and MW-13. Exceedances of 1,1,1-TCA and 1,1-DCA were found in the groundwater from well MW-17 at levels exceeding 5 µg/l in both 2008 and 2009, but were non-detect in 2010. Only 1,1,1-TCA has been detected in groundwater as exceedances from well MW-4S since 2008, but concentrations have decreased from 200 µg/l in 2008 to 54 µg/l in 2010. This decrease may be due to the localized treatment pilot study that USEPA conducted at the well. MW-13 has a 1,1-DCA concentration of 8.7 µg/l in 2010, which has not been detected since 2003.
- d) The above, in combination with the evaluation of the overall Site data, indicates the success of the remediation system in reducing VOC concentrations in the shallow portion of the Upper Glacial Aquifer.

5.2.2 Deep Wells - VOCs

Exceedances of 1,1-DCE, 1,1,1-TCA, PCE, and TCE were observed in groundwater from upgradient well MW-1D, sampled prior to start-up of the remediation system, indicating that these compounds are not site-related. VOCs were consistently detected in MW-1D at decreasing concentrations and there has been no exceedance since July 2006. The same compounds have had multiple exceedances in groundwater from downgradient well MW-19D. These results suggest that these chemicals are no longer being released into the deep aquifer

upgradient of the Site and their attenuation and degradation continue as the non-site related deep groundwater plume migrates across the Site.

In addition, multiple exceedances of 1,2-DCE were historically observed in groundwater from downgradient well MW-19D through July 2006. The presence of 1,2-DCE is not considered site-related, because this compound is a breakdown product of PCE or TCE due to naturally occurring biodegradation. Neither PCE nor TCE were shown as site-related.

The level of 1,1-DCA in groundwater from MW-7D has been less than 5 µg/l since July 2002. Historically, 1,1-DCA was observed as a multiple exceedance in groundwater from MW-7D; however, 1,1-DCA will not be considered site-related because this compound is a naturally occurring biodegradation product of 1,1,1-TCA (parent product), which was determined to be non site-related.

5.2.3 Water Quality Trends over Time

Generally, concentrations of VOCs detected in groundwater from both shallow and deep wells are generally observed to consistently decrease over the Performance Monitoring Period. Time-series graphs for shallow and deep wells depict an increase in some wells, especially in Year 2008, generally followed by a decrease over the Performance Monitoring Period. The increases in 2008 on the time-series graphs are attributable to the relatively higher method detection limit achieved during the July 2008 sampling event and consequently, are based on worst-case assumed concentrations rather than on actual detected concentrations. Considering the effect of the high detection limits, the overall trend continues as a consistent decrease. This was further demonstrated by the results from the 2010 sampling event.

6.0 Recommendations

Continued performance monitoring is recommended for the Site to ensure that current groundwater conditions are maintained in the shallow portion of the Upper Glacial Aquifer at the Site. The only VOC compounds that exhibited exceedances in 2010 were MW-4S (for 1,1,1-TCA) and MW-13 (for 1,1-DCA), but the concentrations have decreased consistently and are considerably less than historical highs. This observation may be due to the localized treatment (SVE pilot test) that USEPA is presently conducting in the area of MW-4S. Based on the planned decommissioning of the Site in 2011, no other actions are recommended at this time.

-------	-------	-------	-------	-------	-------	-------	-------	-------	-------	-------	-------	-------	-------	-------	-------

Bottom of Screen Elevation: 52.04 feet

Notes: Volatile and metal concentrations presented in micrograms per liter; turbidity measurements presented in nephelometric turbidity units.

Elevations referenced to mean sea level.

Since June 2004, monitoring wells have been sampled for VOC's only using the diffusion bag sampling method as per USEPA's requirement.

Diffusion bags were placed with the center at 1 ft above the bottom of the well.

NS: Not sampled.

NY Water Quality Criteria: NYSDEC Regulation for Surface Waters and Groundwater, Section 703.5 (August 1998).

NP: No proposed quantification level available.

NR: Not required.

Bolded values exceed the NY Water Quality Criteria.

*Data presented from May 1993 and February 1994 is published in the Record of Decision (USEPA 1994). These data provide a benchmark of pre-remediation conditions for the upgradient area.

Data Qualifiers:

B: The analyte was detected in the blank sample.

J: Associated value is an estimated quantity.

U: Compound was not detected above the associated level.

UJ: Compound is not detected and the associated quantitation limit is uncertain.

R: Rejected during data validation.

Notes: Volatile and metal concentrations presented in micrograms per liter; turbidity measurements presented in nephelometric turbidity units

Elevations referenced to mean sea level

Since June 2004, monitoring wells have been sampled for VOCs only using the diffusion bag sampling method as per USEPA's request.

Diffusion bags were placed with the center at 1 ft above the bottom of the well

NS: Not sampled

NY Water Quality Criteria: NYSDDEC Regulation for Surface Waters and Groundwater, Section 703.5 (August 1999)

NP: No proposed quantification level available

NR: Not required

Bolded values exceed the NY Water Quality Criteria

*Data presented from May 1993 and February 1994 is published in the Record of Decision (USEPA 1994). These data provide a benchmark of pre-remediation conditions for the upgradient wells.

Data Qualifiers:

B: The analyte was detected in the blank sample

J: Associated value is an estimated quantity

U: Compound was measured above the associated level

UJ: Compound is not detected and the associated quantitation limit is uncertain

R: Rejected during data validation

Bottom of Screen Elevation: 52.37 feet

Notes: Volatile and metal concentrations presented in micrograms per liter; turbidity measurements presented in nephelometric turbidity unit

Elevations referenced to mean sea level

Since June 2004, monitoring wells have been sampled for VOC's only using the diffusion bag sampling method as per USEPA's request

Diffusion bags were placed with the center at 1 ft above the bottom of the well

NS: Not sampled

NY Water Quality Criteria: NYSDEC Regulation for Surface Waters and Groundwater, Section 703.5 (August 1995)

NP: No proposed quantification level available

NR: Not required

Bolded values exceed the NY Water Quality Criteria

Data compiled from May 1993 and February 1994 is published in the Record of Decision (USEPA 1994). These data provide a benchmark of pre-remediation conditions for the upgradient well

Data Qualifiers:

B: The analyte was detected in the blank sample

J: Associated value is an estimated quantity

U: Compound was not detected above the associated level

UJ: Compound is not detected and the associated quantitation limit is uncertain

R: Rejected during data validation

Elevations referenced to mean sea level

Since June 2004, monitoring wells have been sampled for VOC's only using the diffusion bag sampling method as per USEPA's request

Diffusion bags were placed with the center at 1 ft above the bottom of the well

NS: Not sample

NY Water Quality Criteria: NYSDEC Regulation for Surface Waters and Groundwater, Section 703.5 (August 1995)

NP: No proposed quantification level available

NR: Not required

Bolded values exceed the NY Water Quality Criteria

*Data presented from May 1993 and February 1994 is published in the Record of Decision (USEPA 1994). These data provide a benchmark of pre-remediation conditions for the upgradient well

Data Qualifiers:

B: The analyte was detected in the blank sample

J: Associated value is an estimated quantit

U: Compound was not detected above the associated level

UJ: Compound is not detected above the associated quantitation limit is uncertain

R: Rejected during data validation

NOTES:

Diffusion bags were deployed July 15, 2010 and were retrieved and sampled on July 29, 2010.

ND: Not Detected

NP: No Proposed SPDES Permit available

<...: Laboratory Detection Limit

BOLD: Value exceeds the SPDES Permit

D: Results are reported for the diluted samples.

U: Indicates the compound was analyzed but not detected.

J: Indicates an estimated value when a compound is detected at less than the specified detection limit.

UJ: Indicates compound is not detected and the associated quantitation limit is uncertain.

B: Indicates the analyte was found in the blank as well as in the sample.

E: Indicates the analyte concentration exceeds the calibration range of the instrument.

R: Indicates the data is unusable.

NY Water Quality Criteria: NYSDEC Regulation for Surface Waters and Groundwater, Section 703.5 (August 1999).
