FINAL

PHASE III SAMPLING AND ANALYSIS PLAN

Remedial Investigation
Former Camp Hero, Montauk, New York

Revision: 0

Prepared for:

Department of the Army
U.S. Army Corps of Engineers
New York District
26 Federal Plaza
New York, New York, 10278

and

U.S. Army Corps of Engineers
New England District
696 Virginia Road
Concord, Massachusetts 01742

Prepared By:

A Joint Venture of AECOM – Tidewater
3101 Wilson Boulevard
Suite 900
Arlington, VA 22201

TABLE OF CONTENTS

LIST OF FIGURES (APPENDIX A)

LIST OF TABLES (APPENDIX B)

LIST OF APPENDICES

This page intentionally left blank.

ACRONYMS AND ABBREVIATIONS

ACWS	Aircraft Control and Warning Squadron
ADR	Automated Data Review
AST	aboveground storage tank
ASTM	American Society for Testing and Materials
AOC	Area of Concern
APP	Accident Prevention Plan
ARAR	applicable or relevant and appropriate requirement
BAF	bioaccumulation factor
bgs	below ground surface
BOD	biochemical oxygen demand
BSAF	biota-sediment accumulation factor
BTV	Background Threshold Value
CAS	Chemical Abstracts Service
CAMP	Community Air Monitoring Plan
CERCLA	Comprehensive Environmental Response, Compensation, and Liability Act
CFR	Code of Federal Regulation
COC	chain of custody or chemical or concern
COPC	chemical of potential concern
COPEC	chemical of potential ecological concern
CSM	conceptual site model
CWM	Chemical Warfare Materiel
CX	Center of Expertise
DEM	Digital Elevation Model
DD	Decision Document
DDESB	Department of Defense Explosives Safety
DL	detection limit
DO	dissolved oxygen
DoD	Department of Defense
DOT	Department of Transportation
DPT	Direct-Push Technology
DQI	data quality indicator
DQO	data quality objective
DU	decision unit
EB	equipment blank
ECD	electron capture device
EPA	Environmental Protection Agency

EPC	exposure point concentration
ERA	Ecological Risk Assessment
EM	Engineering Manual or Environmental and Munitions
eQAPP	electronic Quality Assurance Project Plan
FD	field duplicate
FPS	Fixed-Pulse Radar Surveillance
FPH	Fuel Pump House
FS	Feasibility Study
FT	feet
GC	gas chromatograph
GC-ECD	gas chromatograph-electron capture detector
GPS	global positioning system
HHRA	Human Health Risk Assessment
ICP	inductively coupled plasma
IDW	investigation-derived waste
ISM	incremental sampling method
LCS	laboratory control sample
LCSD	laboratory control sample duplicate
LIDAR	Light Detection and Ranging
LIF	Laser Induced Fluorescence
LNAPL	light non-aqueous phase liquid
LOD	limit of detection
LOQ	limit of quantitation
MCL	maximum contaminant level
MDL	method detection limit
MEC	munitions and explosives of concern
MNA	Monitored Natural Attenuation
MP	Motor Pool
MPC	measurement performance criteria
MS	matrix spike
MSD	matrix spike duplicate
N/A	not applicable
NFA	no further action
NOAEL	No Observed Adverse Effect Level
NRHP	National Register of Historic Places

NTU	nephelometric turbidity unit
NY	New York
NYSDEC	New York State Department of Environmental Conservation
ORP	oxidation-reduction potential
OSHA	Occupational Safety and Health Administration
PAH	polycyclic aromatic hydrocarbon
PCB	polychlorinated biphenyl
PDF	portable document format
PID	Photo Ionization Detector
PP	Proposed Plans
PSLs	project screening levels
PWS	Project Work Statement
QA	quality assurance
QAPP	Quality Assurance Project Plan
QC	quality control
QSM	Quality Systems Manual
RAO	remedial action objective
RI	Remedial Investigation
RL	reporting limit
RPD	relative percent difference
RSL	regional screening level
RTC	response to comment
SAP	Sampling and Analysis Plan
SC	specific conductivity
SDG	sample delivery group
SEDD	Staged Electronic Data Deliverable
SIM	Selective Ion Monitoring
SLERA	Screening Level Ecological Risk Assessment
SOP	standard operating procedure
SS	Site Supervisor
SSHO	Site Safety and Health Officer
STB	Suspected Tank B
SU	sampling unit
SVOC	semi-volatile organic compound
TB	trip blank
TBD	to be determined

TCLP	toxicity characteristic leaching procedure
TDD	Total Daily Dose
TSERAWG	Tri-Services Environmental Risk Assessment Work Group
TOC	total organic carbon
UCL	upper confidence limit
UFP	Uniform Federal Policy
USACE	United States Army Corps of Engineers
USCS	Unified Soil Classification System
USFWS	United States Fish and Wildlife Service
UST	underground storage tank
UU/UE	unlimited use/unrestricted exposure
UXO	unexploded ordnance
VOC	volatile organic compound
WP	Work Plan

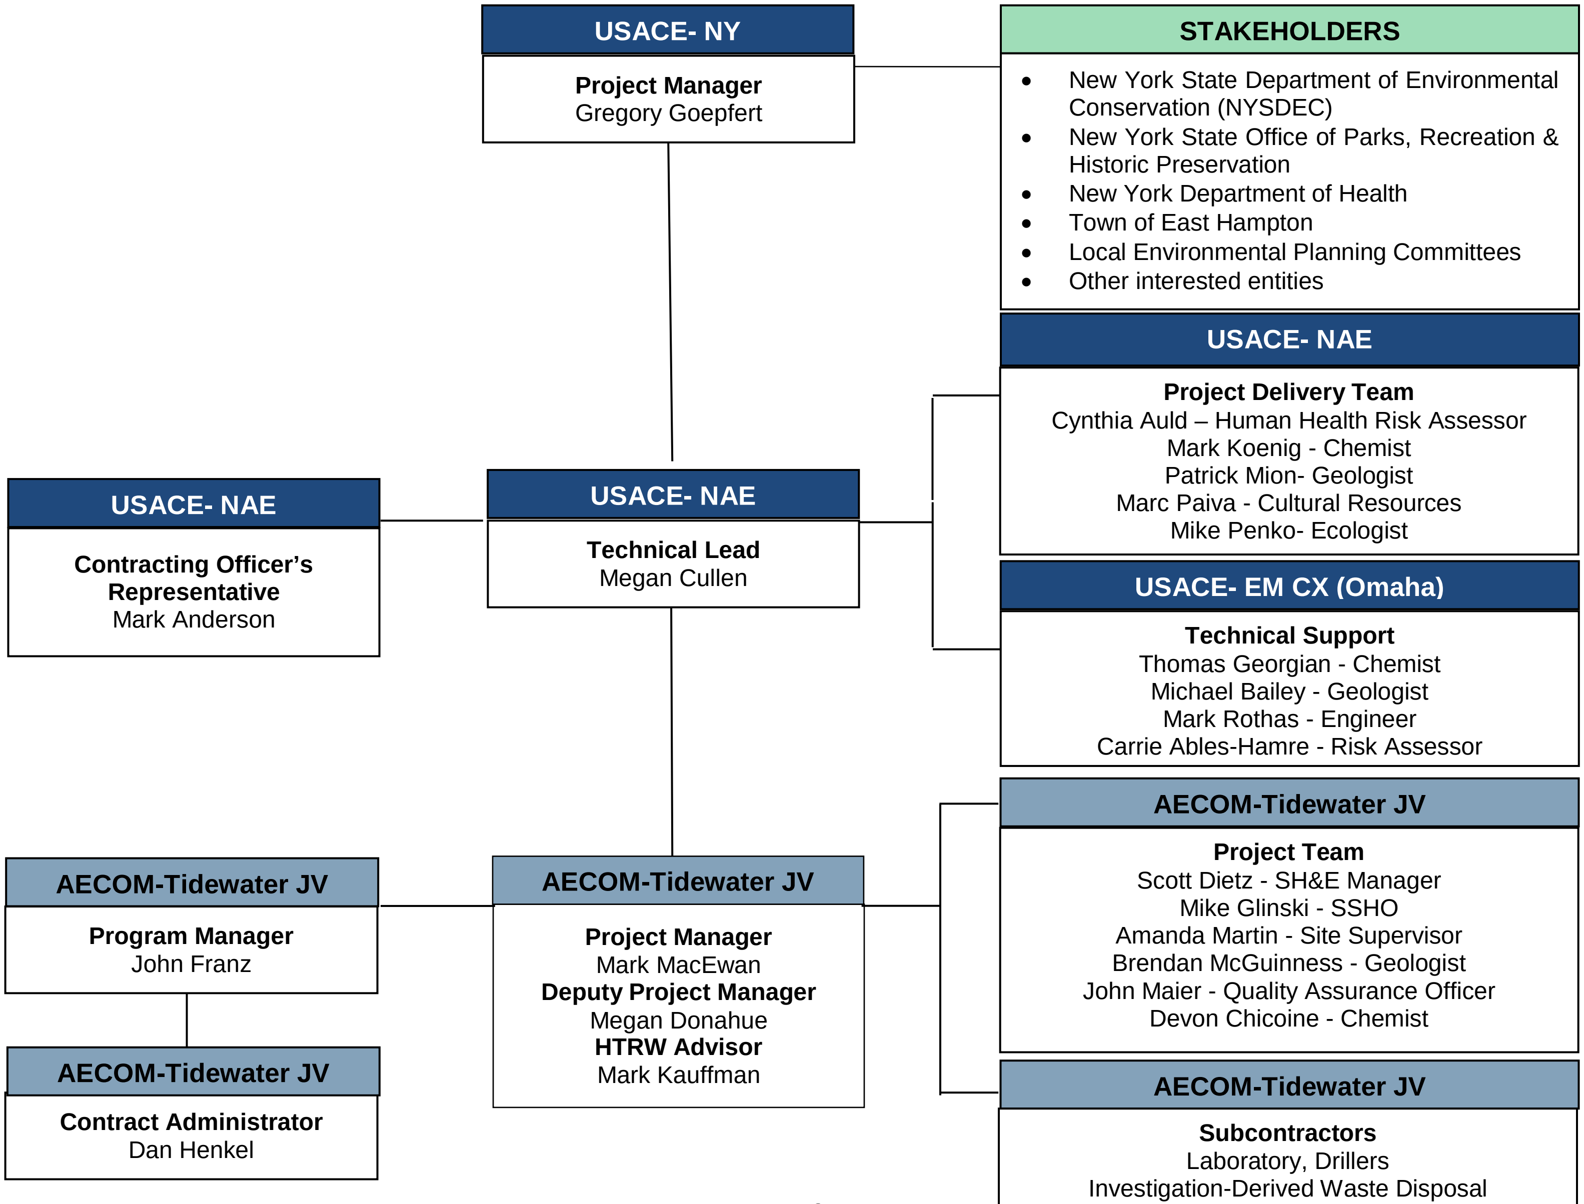
Worksheet #5: Project Organizational Chart



This page intentionally left blank.

Worksheet #6: Communication Pathways

Communication Drivers	Responsible Entity	Name	Phone Number	Procedure (Timing, Pathways, etc.)
Point of Contact with USACE	AECOM Project Manager	Mark MacEwan	703-682-9092	Reporting of project information to the USACE Project Manager through WPs, monthly progress reports, e-mail updates, teleconference calls, and meetings.
Manage All Project Phases	AECOM Project Manager AECOM Field Sampling Team Leader	Mark MacEwan Amanda Martin	703-682-9092 434-664-8047	Primary modes of communication are telephone, e-mail, letter, document submittal; timing dependent on nature of communication and predefined schedules, as applicable and as requested by agencies.
QAPP changes in the field	AECOM Field Sampling Team Leader	Amanda Martin	434-664-8047	Notify AECOM Project Manager and Project Chemist of changes to QAPP in the field and rationale for changes. Document changes in field daily progress reports and memoranda to AECOM and USACE Project Managers.
Daily Field Progress Reports	AECOM Field Sampling Team Leader	Amanda Martin	434-664-8047	Field Sampling Team Leader will complete daily field progress reports and forward to AECOM and USACE Project Managers on a weekly or as needed basis.
Field Corrective Action	AECOM Project Chemist	Devon Chicoine	703-682-9069	Need for field corrective action will be determined by the Project Chemist and will be communicated to the Field Sampling Team Leader and in memoranda to AECOM and USACE Project Managers.
Reporting Laboratory Data Quality Issues	Eurofins Laboratories Project Manager	Stephen Gordon	717-656-2300	All QA/QC issues with project field samples will be reported by the laboratory to the Project Chemist/QA Officer.
Laboratory Analytical Corrective Actions	AECOM Project Chemist Eurofins Laboratories Project Manager	Devon Chicoine Stephen Gordon	703-682-9069 717-656-2300	Need for laboratory corrective actions will be determined by the Project Chemist and/or laboratory Project Manager or QA Manager and will be documented in memoranda to AECOM and USACE Project Managers.
Data Tracking and Management	AECOM Project Chemist	Devon Chicoine	703-682-9069	Project Chemist (or delegated representative) will track data from collection of samples through login at laboratory to delivery by technical report/sample data group and electronic data delivery into database.

Worksheet #6: Communication Pathways (Continued)

Communication Drivers	Responsible Entity	Name	Phone Number	Procedure (Timing, Pathways, etc.)
Release of Analytical Data	AECOM Project Chemist	Devon Chicoine	703-682-9069	Final analytical data cannot be released until validation is complete and Project Chemist has approved release.
QAPP Amendments	AECOM Project Chemist	Devon Chicoine	703-682-9069	Changes to the QAPP will be approved by the AECOM and USACE Project Managers.
Data Validation Issues	AECOM Data Validator	Devon Chicoine	703-682-9069	The Data Validator will coordinate with the Project Chemist and analytical laboratory to ensure data packages provided by the laboratory are complete. The Data Validator will immediately notify the Project Chemist of data that are qualified as rejected, or R-flagged.
Human Health Risk Assessment	AECOM Human Health Risk Assessor	Gretchen Welsholfer	301-820-3148	The Risk Assessor will coordinate with the Project Chemist, database manager, and statistician to complete risk assessment.
Ecological Risk Assessment	AECOM Ecological Risk Assessor(s)	Jeff Briggs Christine Archer	518-951-2280 603-622-1556	The Risk Assessor will coordinate with the Project Chemist, database manager, and statistician to complete risk assessment.

Worksheet #9-1: Project Scoping Session Participants Sheet

Project Name: Phase III Remedial Investigation

The following bullets summarize the significant topics that were discussed and decisions made during the TPP session that contribute to the Phase III RI SAP.

CERCLA Process

- The team concurred to designate areas of concern (AOCs) that warrant no further action (NFA) by comparing the available dataset collected to date to preliminary screening criteria and background threshold values (BTVs). The team agreed to present the outcome of that screening process as an appendix to the Phase III remedial investigation (RI) field investigation Sampling and Analysis Plan (SAP), to document and support which AOCs will be further investigated as part of the Phase III RI field investigation. The team also agreed to include that same appendix in forthcoming Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) documents as required, such as the RI report after the Phase III RI is completed. The team agreed not to prepare a separate "Site Inspection" document at this point in the CERCLA process.

- The team agreed to consider two separate Proposed Plans (PPs) and Decision Documents (DDs), one for the AOCs recommended for NFA and the other for those AOCs that warrant further action. The team agreed to consider presenting the PPs for both categories simultaneously to be efficient with public outreach and hearings, as well as to be efficient in securing the DD signatures. The basis for two separate DDs is to minimize the 5-year review requirements to only the DD that includes AOCs that warrant further action.

- The team agreed to use a streamlined Tier II Uniform Federal Policy for Quality Assurance Project Plan (UFP-QAPP) format for the Phase III RI SAP, rather than prepare multiple project work plans.

- The team will streamline the SAP document refinement process by: (1) submitting UFP-QAPP Worksheets 10, 11, and 17 to the USACE New England, New York, and Environmental and Munitions (EM) Center of Expertise (CX) in advance of the SAP, (2) reviewing USACE comments together during a working TPP session scheduled for 13 April 2017, rather than preparing response to comments (RTCs), and (3) refining the document together to expedite document finalization and ensuring on-schedule field mobilization.

- The team agreed to expedite the SAP process and set a team goal to mobilize for the field program in June 2017 with an objective to demobilize prior to the July 4th weekend.

Grouping of AOCs and Selection of Decision Units (DUs)

- The team agreed with the concept to group contiguous AOCs to create larger DUs that have a more robust dataset and are more representative of potential human health and ecological exposures.

- AOCs will be grouped into DUs that are approximately ½ acre (or up to 1 acre if feasible). The DUs may be subdivided into sampling units (SUs) if necessary based on variations within the DUs, such as areas where light non-aqueous phase liquid (LNAPL) is present. In general, the DUs will be geometric squares, but may be adjusted slightly in some locations to account for nearby fences, roads, steep slopes, drainage channels, or similarly significant geographic features.

- Unbiased samples will be collected from within the DU to obtain a sufficient dataset for statistical calculations (a minimum of 15 points) and to calculate representative exposure point concentrations (EPCs) for use in risk assessments.

- The team agreed that DUs should be contiguous. A DU cannot include multiple, geographically separate areas even if they have similar sources/impacts, because that would not be representative of an exposure area.

- Samples will not be collected from inaccessible areas within each of the DUs; however, the entire DU boundary will still be considered the "exposure area" for quantification of potential risks to receptors. The basis for this decision is that if areas within the DU are inaccessible for sampling, then they would generally provide limited accessibility to potential receptors.

Preliminary Screening Evaluation

- The team agreed to revisit relevant preliminary screening criteria to ensure that it would include a conservative assumption of residential use and include both Environmental Protection Agency (EPA) and New York State Department of Environmental Conservation (NYSDEC) criteria.

- Other considerations would include ecological screening criteria for the representative receptors given the generally dry conditions of the majority of intermittent drainage channels.

- As part of the preliminary screening evaluation of the existing dataset, the maximum concentration for each analyte will be compared against the residential screening criteria and BTVs. This is acceptable on a per-AOC basis because the dataset is small (less than 20 samples) for each parameter.

- If the result is below the screening criteria and/or BTV, it will not be retained as a parameter of concern. If no analytes exceed the conservative screening criteria or BTV, then NFA will be warranted for that particular AOC.

- The team discussed applying a comparison of mean values as a statistical approach, considering a two-tailed hypothesis test, and the logistics of obtaining and applying uncensored analytical data. The team concurred that with the limited dataset, such as for groundwater (in many cases less than 3 samples), site concentrations will be compared with BTVs during the data analysis phase of the RI.

- The team reiterated that this preliminary screening step is very conservative, and the screening criteria selected will not necessarily be the same criteria used to define project screening levels (PSLs) in the Phase III RI SAP, will not necessarily be the same criteria and/or exposure scenarios used in the human health and ecological risk assessments, and will not necessarily be the same criteria applied in the feasibility study to define applicable or relevant and appropriate requirements (ARARs) and develop project-specific remedial action objectives (RAOs). This is a critical team concept to document and apply throughout the CERCLA process.

- The team concurred to build in the delivery of uncensored analytical data as part of the forthcoming Phase III RI field investigation in the event that it could be used for statistical evaluation as part of the RI report.

<u>Risk Assessment Scenarios and Pathways</u>

- The team discussed relevant exposure scenarios and screening criteria, relative to groundwater potability, the recently updated EPA polycyclic aromatic hydrocarbon (PAH) toxicity values, and an evaluation of the most conservative, but realistic, future scenarios for this project. The current and future land use scenarios and pathways to be considered will be presented in the SAP for team review and concurrence, and then applied to the risk assessments that will be part of the RI report. These exposures are expected to be different (most likely less conservative) than those being used for the preliminary screening evaluation.

- The future use human health receptor scenarios and pathways will be finalized after the Land Use Letter is submitted by New York State Park personnel, and it can be considered in determining the most conservative, but realistic, potential future use scenarios. The team acknowledged that it is possible that a small parcel within the investigation area may be designated for residential use. If so, the team may consider evaluating the future use residential scenario for DUs (if any) that are within that designation.

Background Samples and Comparison

- The team acknowledged the need for permanent, developed monitoring well network within the Camp Hero investigation area for groundwater sample collection via low-flow methods to compare with groundwater BTVs. The existing groundwater data (with the exception of Building 203) was collected via well points, exhibited a high level of turbidity and suspended solids, and thus is not suitable for comparison to BTVs for formation groundwater. The existing groundwater data is useful, however, for refining the conceptual site model (CSM) relative to potential groundwater impacts, identifying parameters of concern, and assisting in placement of the permanent monitoring well network that will be installed during the Phase III RI field investigation.

- The team acknowledged that the results of PAHs and polychlorinated biphenyls (PCBs) in the well point groundwater data is another indication that suspended solids are present and contributing to the analytical results, rather than representing the potential potable groundwater condition of the formation.

- The team agreed that the statistical approach to background comparisons after the Phase III RI field investigation will be more robust than the discrete-based approach used in the preliminary screening evolution. The team also acknowledged that per CERCLA guidance, the next background screen will be conducted as part of the uncertainty evaluation to support risk-based decisions after the human health and ecological risk assessments are completed.

Surface and Subsurface Soil Samples

- The team agreed to collect surface soil samples from a depth of 0 to1 foot (ft) below ground surface (bgs), and subsurface soil samples from a composited depth of 1 to10 ft bgs. If discrete samples area analyzed, rather than incremental sampling method (ISM) samples, total soil (0 to10 ft bgs) results could be derived if needed during the RI or feasibility study (FS) phase. The concept was that exposure to subsurface soil would be across the 1 to 10 ft bgs depth horizon; therefore, a composite samples collected from that horizon at each sample location would be most representative for assessment of potential risks.

- Subsurface soil will also be evaluated as part of individual DUs, not as a sitewide DU.

- The analyses will vary for each DU, and will be limited to those analytes that exceeded the preliminary screening evaluation.

- The approach to establishing sampling grids for surface soil will consist of applying a ISM or collecting a minimum of 15 discrete samples from each of the DUs. The team concurred to research which of those sample collection methods would be best suitable for the site conditions expected, as well as the costs for sample collection, processing, and laboratory analysis. An additional factor the team discussed was ensuring that analytical data is comparable to BTVs. The team noted that because the BTVs were calculated using discrete samples, the team may need to collect discrete samples rather than ISM sampling for continued comparison to BTVs.

- The team concurred that the soil dataset available to date was intended to identify source areas, not to establish EPCs for larger exposure areas. Thus, the team will use the existing dataset for defining DU boundaries and selecting parameters of concern, but will not include existing biased data in calculating EPCs at the completion of the Phase III RI field investigation. The EPC calculations will be limited to only those samples collected from the unbiased grid to be designed within each of the DUs.

Surface Water and Sediment Samples

- Surface water and sediment samples will be collected from drainage channels that are adjacent and downgradient of DUs with the potential for surface water and sediment impacts. Similar to surface and subsurface soil, unbiased samples will be collected from the drainage channels to obtain a sufficient dataset for statistical calculations (a minimum of 15 points) and to calculate representative EPCs for use in risk assessments.

- Surface water and sediment samples will be analyzed for the same parameters that will be analyzed in soil, subsurface soil, and/or groundwater associated with the associated DUs being investigated.

- Background/reference surface water and sediment samples will consist of a minimum of 15 upstream samples collected on a sitewide basis. This includes both steam type (revetted and non-revetted) to the extent possible given the relative precipitation since these streams are mostly intermittent. The team recognized that if there are insufficient reference locations for background sample collection, local upstream sediment and surface water conditions local to each relevant DU would be used to support the individual CSMs.

- The team acknowledged that there are insufficient aquatic ecological receptors in the surface water given the generally dry conditions of the drainage channels. However, surface water data is still necessary to support potential human health risk assessment exposures that include wading or other types of surface water contact or incidental ingestion pathways.

Groundwater Samples

- A network of wells across the site will be installed to build a representative groundwater monitoring well network. In addition, DU-specific wells will be installed, as required, for those DUs with demonstrated or potential groundwater impacts (such as Building 203).

- The selection of monitoring well locations will be biased to establish sufficient data points for refining the CSM. Groundwater is considered to be spatially correlated, which allows this biased approach. This is different from the soil sampling concepts discussed earlier, because soil is not spatially correlated.

- The team agreed to avoid drilling through the clay layer during this RI program. There is insufficient data to justify penetrating the clay layer and risking the potential downward spreading of site impacts. This decision could impact the availability of suitable monitoring well locations, given that there will be portions of the site where groundwater will not be encountered above the clay layer.

- The analyses will include parameters that were previously detected above screening values and BTVs, as well as mercury (which was not included in prior groundwater sampling events), and select monitored natural attenuation (MNA) and geochemical parameters. The team's intent is to provide sufficient groundwater data to assess risks, support the FS evaluation of remedial alternatives, and focus the remaining CERCLA process on those areas that warrant further consideration relative to groundwater quality.

- The team will evaluate whether groundwater at the site is potable. The team discussed the possibility of saline conditions, insufficient yields, and potential lack of connection to the lower productive aquifer as possible reasons to render groundwater as non-potable at the site. The team agreed that the drinking water pathway is appropriate for the preliminary screening evaluation, but may not be appropriate for the current or future use scenarios and pathways to be applied in the forthcoming human health risk assessment after the collection of Phase III RI data.

- The team agreed to review the available data collected to date for the mobility of LNAPL and to include measurements and parameters as needed during the Phase III RI field investigation to provide sufficient information for the evaluation of LNAPL remedial options in the FS. References to review include Interstate Technology and Regulatory Council and American Society for Testing and Materials guidance.

- The team acknowledged that there may be difficulty obtaining true formation groundwater if well construction, development, and low-flow sampling does not yield groundwater with < 10

NTU turbidity. The team will conduct field-filtering for non-volatile organic parameters [such as Semi-Volatile Organic Compound (SVOCs) and PCBs) and metals, if collected. It is not appropriate to field-filter samples for Volatile Organic Compound (VOCs).

Potential Acetone Impacts in Soil

- The team agreed that there was a low probability that acetone was still present even though there were acetone detections from the Phase I RI. The age of the potential releases are long ago and acetone is one of the more volatile organic compounds. The team acknowledged that if acetone is present in surface soil in particular, its presence is even more questionable. The team agreed to revisit screening criteria (as described above) and to conduct a more thorough evaluation of the reported acetone concentrations relative to the screening criteria, as well as to further explore the conditions in which acetone was reported, such as soil type, depth, and field measurements.

- If re-evaluation of the screening criteria does not eliminate acetone as a parameter of concern, the team discussed the potential option of field verification of acetone by collecting biased confirmatory samples.

This page intentionally left blank.

The following bullets summarize the significant topics that were discussed and decisions made during the TPP session that contribute to the Phase III RI SAP.

Preliminary Screening Evaluation

- The team concurred that it was accurate to have separate screening criteria for non-petroleum impacted AOCs vs. petroleum impacted AOCs. The team noted that there are some parameters on the NYSDEC STARs list that are not on the other HHRA or ERA criteria lists. There are also lower values in some cases for parameters on the STARs list. The team concurred to organize the criteria tables more clearly to sort parameters by parameter group for easier review. The team also concurred to simplify Tables 3 and 5 to show only those parameters that have NYSDEC STARs criteria, since all other parameters with HHRA and ERA screening criteria are shown in Tables 1, 2, and 4.

Risk Assessment Approach

- For the discussion of groundwater potability and the discussion of future site use, reference the recent figures received from Brian X. Foley, Deputy Regional Director, Long Island State Parks Region on April 3, 2017. Clarify that there are no plans for future residential use. This applies to both soil and groundwater. This will be added to Worksheet #10
- Correct the definition of UU/UE to "unlimited use/unrestricted exposure."
- For discussions of the CERCLA "hypothetical" future use scenario relative to groundwater being used as a drinking water source, clarify that the project team completed a groundwater potability analysis to support the selection of potential exposure pathways, as well as subsequent risk-based decision throughout the CERCLA process (refer to Appendix G). The analysis revealed that the shallow perched groundwater at Camp Hero is not suitable as a potable water source. However, the drinking water exposure pathway will be assessed as a potential use, however unlikely, in the HHRA to assess the potential unlimited use/unrestricted exposure (UU/UE).
- Use the meadow vole instead of muskrat in the ERA, as it is expected to be a better habitat match for the Camp Hero site.
- The team agreed to host a separate call with the risk assessors and other involved team members to discuss details of the HHRA and ERA approaches including exposure assumptions, BTV comparisons, background population comparisons, and calculations of EPCs.

Analytical Parameters

- The team agreed to consider eliminating SVOCs other than PAHs from laboratory analysis at DUs where no other SVOCs exceeded the preliminary screening evaluation, except at DUs with potential petroleum impacts where the NYSDEC STARs list SVOCs would be required. The team would evaluate which DUs would potentially apply to this protocol. However, in considering the logistical details of this suggested change, the AECOM team is recommending to keep the same SVOC/PAH parameter list for all DUs. The team chemist confirmed that all SVOCs (including PAHs) will be analyzed by the same initial method (SW846 Method 8270), after which PAHs will be subsequently re-analyzed by SIM only if the detections are in the vicinity of the LOD or not detected. In addition, if there were different parameters within parameter groups at certain DUs, there would be a different eQAPP required in ADR to assess the data. There would be different COCs required, different SDGs, increased data management, and a higher potential for error.

Background Data and Comparisons

- The team clarified the use of BTVs and the background dataset, and the sequence of background screening relative to the risk assessments for soil, sediment, and surface water media as recommended by the CX is as follows:
  - Step 1: Compare Phase I and II data to BTVs as a preliminary screening evaluation to identify DUs and chemicals requiring analysis in Phase III (this step has been completed; refer to Phase III RI SAP Appendix E).
  - Step 2: Compare Phase III data to human health and ecological screening values and BTVs as the first step in the risk assessments.
  - Step 3: If Phase III data is in exceedance of BTVs, conduct a statistical population comparison of the DU (or exposure area for surface water and sediment) dataset to the background dataset (referred to by some as a "means" comparison).
  - Step 4: If Phase III DU or exposure area data is in exceedance of the background data and screening values, then the chemical is identified as a chemical of potential concern (COPC) and EPCs are calculated to conduct the HHRA and ERA for that DU or exposure area.
- This approach is generally consistent with DoD guidance (2011 Tri-Service Position Paper on Background Levels in Risk Assessment) which considers background conditions early in the evaluation to focus the risk assessments on potentially site-related COPCs. However, the approach agreed to by the team considers background conditions earlier in the ERA process than is recommended in the 2011 DoD guidance. It is recognized that for CERCLA sites, background conditions are typically used in the ERA to refine COPCs in Step 3a (USEPA,

2001), rather than in the upfront selection of COPCs, and that the background evaluation is typically conducted at the end of the HHRA (USEPA, 2002a). The team agrees with the CX recommendation to include background prior to the selection of COPCs as part of the sequential evaluation of the DUs and exposure areas in order to focus on potentially site-related COPCs.

- The team clarified that groundwater data from each well will be individually compared with the groundwater BTVs and human health screening levels to identify COPCs. Each well will be evaluated separately in the HHRA.
- For the preliminary screening evaluation, the lowest BTV was used when two values were generated for the two different soil types. There was non-concurrence from the EM CX that the smallest BTVs should be used. The EM CX recommendation was to compare the data sets properly prior to pooling them and recalculate the BTVs (using the new pooled data sets), or use the largest BTVs to minimize false positives. Upon discussion, the team decision was to use lowest of the two BTVs in preliminary screening as a conservative screening step. However, the team may consider applying the higher BTV during the subsequent background evaluation steps (refer to stepwise approach above) to minimize false positives in the risk evaluations.
- The team discussed the sampling of wetlands and whether a wetland soil background dataset is required. The team agreed that a separate wetland soil background dataset was not warranted due to the limited DUs that contain wetland soil. Additionally, the wetlands within DUs will be sampled from 0 to1 and 1 to 2 feet, and the data would be compared to both soil and sediment BTVs and relevant HHRA and ERA criteria. The team may consider collecting wetland soil background data in the future if the comparison to the soil and sediment BTVs are determined to be non-representative of wetland conditions.
- The team discussed potentially collecting a second round of groundwater samples from the background wells to increase the background groundwater dataset. Chemical testing of groundwater samples from the background wells was also recommended by the EM CX to determine whether results are consistent with the current set of BTVs (i.e., as a check that verifies the metal concentrations are less than the current calculated BTVs). However, the team decision was that it was not necessary at this time because the first round of samples yielded a background groundwater dataset that was generally normally distributed and representative of background conditions.
- The team agreed to include the background monitoring wells in the Phase III field program groundwater gauging event to support the groundwater flow evaluation and mapping.

Surface and Subsurface Soil Evaluation

- The team concurred that either ISM or discrete sampling could be considered for this site and phase of work. The team will still implement discrete sampling, but will revise the text to indicate that ISM could have been used as well. The team will refine the basis for this decision in Worksheet #17.
- The team agreed that surface soil samples will be collected for the same parameters as subsurface soil where subsurface soil samples are collected, to allow for the calculation of total soil values as needed for some of the HHRA exposure scenarios. Subsurface soil samples will not be collected at DUs where the Preliminary Screening Evaluation (refer to Appendix E) indicates that subsurface soil warrants no further action. Additionally, surface soil samples will not be collected during the Phase III effort at Building 203 because an unbiased grid of surface soil samples was already collected during Phase II calculation of EPCs and use in the HHRA (including total soil evaluations).
- Clarify in the text and figures the rationale for designing the DU boundaries. It appears that some of the DUs are not centered on the source areas. Specific examples noted during the meeting were DU02, DU04, and DU14. The text and figures will be clarified to present the potential source area being evaluated and site features that contributed to selecting the DU boundaries (such as nearby fence, drainage channel, steep slope, etc.), resulting in some DUs not being centered on the source areas.
- The team agreed to use 16-point grids for all DUs (whether 0.5 or 1 acre), rather than using an increased number of points for the larger DUs.
- If areas within a DU are inaccessible for the intended sampling design (such as shallower depths due to wet conditions or refusal), the subsurface sampling location can be terminated at the shallower depth and still be incorporated into the subsurface soil dataset for that DU. Similarly, if a steep slope prevents access by a drilling rig, the team can offset that location to an accessible area within the DU (in an unbiased fashion) or use hand-augering to collect subsurface soil to the depth possible. In general, the team expects that the maximum depth of hand-augering will be in the range of 2 to 4 feet.

Groundwater

- The team clarified that there is not a need to differentiate between the East and West Basin. The background groundwater evaluation revealed similar groundwater conditions across both of the basins. The text will be revised to remove implied rationale to differentiate groundwater collected from each of the basins.

- The team agreed to increase the specificity of groundwater well placement rationale to Table 17-4. The specific DU(s) in the vicinity of each proposed well will be listed in the rationale table.

Surface Water and Sediment

- The team agreed to clarify the rationale for surface water and sampling locations. The surface water and sediment exposure areas are intended to be upstream, adjacent, and/or downstream of groups of soil DUs, and are intended for assessment of potential DU contributions, as well as broader drainage channel conditions along longer stretches of the channels. The grouping of datasets into exposure areas may consider factors such as the analytical results, physical characteristics of the drainage channel sediment, surface water conditions at the time of sampling (i.e., wet or dry), and proximity to nearby DUs. Separate EPCs will be generated for each exposure area.
- The team agreed to increase the number of surface water and sediment samples to a minimum of 15 in all exposure areas.

Analytical Details

- The team discussed the analysis of hexavalent chromium and concurred with analyzing 10% of the samples. The team agreed that it is acceptable to pre-select a generally well-distributed set of locations intended for this additional analysis. The team will refine the text that the analysis of hexavalent chromium is intended to verify the absence of hexavalent chromium. The New York District offered to provide a study of hexavalent chromium by Cornell University to consider as the analytical results arrive.
- The team agreed to use the hexavalent chromium data (if detected in any of the locations) to generate ratios of hexavalent to total chromium for the remainder of the dataset where hexavalent chrome was not analyzed. The ratios can then be used in the HHRA and ERA, rather than defaulting to the conservative presumption that all chromium could be hexavalent chromium.
- The team agreed that Dissolved Oxygen (DO) was missing from the list of low-flow field parameters for groundwater sampling, and it will be included in the draft SAP.
- The team discussed the necessity of collecting Matrix Spike Duplicate (MSD) samples or Field Duplicate (FD) samples. The EM CX recommended matrix spike duplicates and field duplicates not be collected for the soil DUs, as n = 15 – 20 independent replicates are planned. The variance of these replicates will measure total precision. Owing to the small sample size (n = 2) and the lack of statistical independence for the subject duplicates, they will be of little or no value for characterizing total precision, which they will likely underestimate. However, the

team decision was to not eliminate MSD and FD samples because they are required by the project chemist to comply with the DoD QSM data validation requirements.

- The team followed-up on the assessment of acetone. After the updated preliminary screening evaluation, it was apparent that acetone was well below the screening criteria. The team also noted that because acetone was reported in surface soil, given the volatility of acetone and timeframe since a possible release could have occurred, it is unlikely that acetone is actually present at the site.

Workflow and Schedule

- The team agreed that because preliminary worksheets (Worksheets 10, 11, and 17) were reviewed by USACE, and informal comments were presented for team discussion, no "formal" comments or response-to-comments (RTCs) are required prior to USACE review of the full draft SAP. The team expects the full draft SAP to be provided by April 20th, with an expedited USACE review by April 27th. The team expects formal comments, formal responses, and a subsequent "final" SAP to position the team for presentation of the SAP to stakeholders in mid-May, field mobilization by early June, and field completion by the end of June.
- The team agreed to review prior comments from the NYSDEC and NYSDOH to anticipate the types of input they may offer in reviewing the Phase III RI SAP. The team will pre-emptively address that input to the extent possible. Upon further review, NYSDEC input was provided on May 26, 2016 relative to the Phase I RI Work Plan, and included NYSDOH input. Two of the following five items were identified and have already been addressed. The Phase III RI SAP also incorporates these items:
  - (NYSDEC) Contaminant migration relative to soil vapor. The Phase III RI SAP incorporates potential vapor migration as part of the HHRA exposure pathways presented in Tables 10-1 and 10-2.
  - (NYSDEC) Depth of subsurface soil sampling. The depth of subsurface soil sampling will be 1 to 10 feet, or 1 to 2 feet in wetland areas (per earlier team discussion during this TPP discussion). This detail is provided in the Phase III RI SAP Worksheet #17 and the associated rationale tables.
  - (NYSDEC) Expanded list of VOCs for the Motor Pool. The list of VOCs for the Motor Pool will consist of all VOCs on the NYSDEC STARs list for petroleum-related investigations. This detail is provided in the Phase III RI SAP Worksheet #15, as well as Worksheet #17 and the associated rationale tables.

- (NYSDOH) Modification to the Community Air Monitoring Plan (CAMP). The CAMP was previously modified to incorporate NYSDOH requirements and is provided as Appendix H to the Phase III RI SAP.
- (NYSDOH) Incorporation of NYSDOH screening criteria for groundwater. As part of the HHRA process, groundwater results from the Phase III RI field effort will be compared to relevant screening criteria (which will include NYSDOH screening criteria), as well to the background groundwater BTVs.

This page intentionally left blank.

Worksheet #10: Conceptual Site Model

10.1 Overview

This worksheet presents general background information and working CSMs of environmental study areas, referred to as DUs, within Camp Hero. The CSMs are intended to provide the basis for developing the sampling and analysis program to complete the RI phase of the CERCLA process.

10.2 Description and Current Use

Camp Hero State Park is located on the eastern tip of the south fork of Long Island, New York, approximately five miles east of the Village of Montauk (Figure 10-1). The park consists of 469 acres and is bound by Montauk Highway (Route 27) to the north, the Atlantic Ocean to the south, Montauk Point State Park to the east, and Camp Hero State Park's undeveloped sanctuary area to the west. The landscape includes wooded areas, freshwater wetlands, and sea-side bluffs (Figure 10-2).

Camp Hero State Park is owned by the New York State Office of Parks, Recreation, and Historic Preservation and is operating as the public recreational area (USACE 2003). The park contains hiking trails and roadways leading to former military buildings, picnic areas, and recreational areas. Although the Fixed-Pulse Radar Surveillance (FPS)-35 Radar Tower and Antenna ("Radar Tower") was listed under the National Register of Historic Places (NRHP) in 2002, only two facilities on the park are active at this time: a vehicle maintenance shop used by the New York State Office of Parks, Recreation, and Historic Preservation, and a New York State Park Police building utilized as a residence for a park officer. The developed portion of the site is fenced and the inactive buildings and bunkers have been sealed; however, some portions of these areas may be accessible to trespassers.

10.3 Topography and Geology

Montauk Point is at the eastern extremity of the Ronkonkoma moraine, which forms a ridge of coalescing hills traversing Long Island from west to east. The land surface is characterized by knob-and-kettle topography and ranges in elevation from sea level to about 100 ft above sea level, with steep terrain and thickly wooded areas throughout the park. Along the south shore, steep bluffs rise abruptly from 30 to 80 ft above narrow, rock-strewn beaches.

The Montauk Point area is underlain by crystalline bedrock of Pre-Cambrian age upon which rest, in succession, un-consolidated deposits of Cretaceous, Pleistocene, and Recent age. The bedrock likely consists of gneiss and schist and is about 1,000 to 1,300 ft below sea level. The Pleistocene deposits of Long Island are end products of the advance and retreat of several glaciers during the Pleistocene Epoch. Most of the material carried from the glacier was sand and well-rounded gravel, which was redeposited as stratified sand and gravel glacial till deposits, which make up the substratum of most of the soil in Suffolk County. Upon further retreat of the ice, most of the till and parts of the outwash and morainic deposits were covered by water or wind-deposited silt, clay, and fine sand to varying depths, resulting in lenses and beds of silt and clay. These deposits comprise the upper soil found at Camp Hero.

10.4 Hydrology and Hydrogeology

Surface water features in the Montauk Point area include lakes, ponds, streams, and small marsh areas, many of which occupy kettle holes formed by retreating glaciers. The major lakes in the Montauk area include Fresh Pond, Fort Pond, Big Reed Pond, Little Reed Pond, and Lake Montauk. Oyster Pond is the closest lake, located approximately 1,200 ft northwest of Camp Hero (USGS 1986).

Surface runoff at Camp Hero is primarily through four small un-named streams. Three of the streams flow northwestward to Oyster Pond; the fourth flows southward to the Atlantic Ocean. Much of the area precipitation runs off in temporary channels and in gullies to the Atlantic Ocean, to Block Island Sound, and into kettle holes. Intermittent streams form in the channels and gullies after rain events. Many of the primary and intermittent streams throughout the park are channelized with narrow, wooden stream revetments along the sides of the stream beds, which appear to have been installed to control surface water flow across the facility.

Groundwater is contained in the upper 200 ft of deposits, which are broadly divided into an upper unit of undifferentiated till and stratified drift and a lower unit of stratified drift. Groundwater is obtained primarily from the principal aquifer in the lower unit of stratified drift. The principal aquifer is a lens shaped body, which lies above saline water. The fresh water in the principal aquifer is under artesian pressure and has a head ranging from about sea level to 3.5 ft above sea level.

Scattered perched water bodies are found above the principal water table, owing to lenses and beds of silt and clay, which retard downward movement of water. The perched water bodies are generally small isolated bodies of water temporarily stored above the principal aquifer in scattered lenses of permeable material underlain by clay and silt (USGS 1960). During the drilling of previous monitoring and observation wells at Camp Hero, perched groundwater was reported at depths ranging from approximately 5 to 25 ft bgs. Groundwater elevations measured in June 2016 during the Phase I field effort, in conjunction the 2014 Light Detection and Ranging (LIDAR)-derived Digital Elevation Model (DEM) surface (NAVD88 vertical datum), were utilized to establish a sitewide perched groundwater elevation map. Perched groundwater flow direction appears to be within two basins in the park, the "East Basin" and the "West Basin," with a North-to-South groundwater divide splitting the park. Perched groundwater flow within the "East Basin" is to the south, while flow in the "West Basin" is to the northwest.

A groundwater potability analysis was completed as part of this RI to assess whether perched groundwater at Camp Hero should be considered a potential potable water supply. The results of this analysis indicate that the shallow perched groundwater at Camp Hero is not suitable as a potable water source and should be considered unsuitable for drinking based on the groundwater characteristics and local drinking water standards. The potability analysis is provided in Appendix G.

10.5 Operational History and Environmental Areas of Concern

Camp Hero was established in early 1942 as a Coastal Defense Installation and continued to be used for military purposes throughout the Cold War period. Military development included a series of underground bunkers associated with the many gun batteries that were used as part of a coastal defense system installed during World War II. Other developments on the site included supporting facilities (barracks, mess halls, hospital facilities, a motor repair shop, a recreation facility, sentry boxes, and water supply and sewage facilities) and a radar tower that was the main component of an air defense system in operation during the Cold War.

In 1952, the Air Force property was renamed the Montauk Air Force Station and was occupied by the Aircraft Control and Warning Squadron (ACWS). In 1974, when some of the on-site military uses were still active, portions of the property were transferred from Department of Defense (DOD) to the State of New York. With the departure of the last military personnel from the site in 1980, the DOD declared the remainder of the property to be surplus Federal land. Over the next few years the property was divided and deeded to the State of New York and Town of East Hampton. The ACWS facility was permanently closed in 1982 and the final land transfer to the State occurred in 1984.

A historical records review was conducted as part of this RI which identified 47 Areas of Concern (AOCs) at Camp Hero. The AOCs included former waste disposal areas, former coal storage areas, abandoned drum locations, possible and former underground storage tanks (USTs), former aboveground storage tanks (ASTs), and a Motor Pool building, among others. The AOCs included in the Phase I RI field investigation are shown on Figure 10-3.

10.6 Previous Site Investigations and Available Dataset

Previous investigations at Camp Hero have included UST and AST closures and reports, focused site assessments, and sitewide surveys and reports. Key reports that provide historical data for Camp Hero are briefly summarized below.

- *UST and AST Closure Reports.* With the exception of four USTs and ASTs (and one drum area) that are currently listed as in use at Camp Hero by Suffolk County OPS, all the USTs and ASTs have been removed at Camp Hero. All USTs and ASTs with reported petroleum releases and respective NYSDEC spill case numbers have a case closed status with NYSDEC. Analytical data from the closure reports at USTs 30 and 34 indicated that lead was present at concentrations that exceed screening criteria and further characterization is required.

- *Building 203 Site Assessment Report (1994).* The 1994 Site Assessment Report documents the excavation of former diesel USTs 16 and 18 at former Building 203, where 2,500 yards of diesel-impacted soil were removed. Geoprobe® borings were conducted around and within excavation and confirmatory soil and groundwater samples were collected. The results of the soil and groundwater samples were below screening criteria (USACE 1994). The Spill Report Case was closed by the NYSDEC in July 1995.
- *Hazardous Materials Survey and Preliminary Report (1998).* The 1998 Camp Hero Feasibility Study, Hazardous Materials Survey, Preliminary Report Identified areas needing further investigation but did not collect any analytical samples, with the exception of one PCB sample collected in an area of oil staining under electrical equipment in Battery 113 (Cashin Associates 1998).
- *Data Collection Report (2000).* The 2000 Data Collection Report investigated potential soil and water contamination within select areas at Camp Hero on a sitewide basis in support of a decision regarding whether further environmental action was required. Concrete chip samples, soil (surface and subsurface), groundwater and sediment samples were collected and compared against applicable regulatory criteria or guidelines (Weston, Inc. 2000). Conclusions from the investigation included:
  - The oil stains on the concrete floors of Building 107 and the Radar Tower (Building 201) contained concentrations of PCBs that exceed the TSCA unrestricted use limit of 1 mg/kg; however, the oil stains provided no significant ecological or human health threats via migration.
  - PCBs were detected in one surface soil sample above criteria near the radar tower, but no PCBs were detected above the regulatory criteria in adjacent samples collected within 50 ft.
  - Subsurface soil samples at H-11 (former Power Plant) indicated elevated levels of beryllium. Groundwater samples at H-11 indicated elevated levels of chromium and lead.
- *Phase I RI Field Investigation (AECOM-Tidewater JV 2017a).* The Camp Hero RI established 47 AOCs, based on records review and previous investigations. The Phase I RI field investigation was conducted to determine the presence or absence of contamination at the AOCs, to establish which AOCs needed additional investigation. Phase I activities included a geospatial survey utilizing archived aerial photography, digital geophysical mapping of select AOCs, and collection of surface soil, subsurface soil, and grab (unfiltered) groundwater samples. The Phase I RI field investigation activities are documented in the Phase I Field Investigation

Report (AECOM-Tidewater JV, 2016), which provides the laboratory analytical data reports from the Phase I RI field investigation. The results of the geophysical mapping are included as Appendix D, Geophysical Survey Report.

- *Phase II RI Field Investigation (AECOM-Tidewater JV 2017b).* The Phase II RI field investigation activities included the installation, development, and sampling of fifteen permanent background monitoring wells for collection of a sitewide background groundwater data. Phase II activities at the former Building 203 AOC included subsurface screening for LNAPL with Laser Induced Fluorescence (LIF); surface soil sample collection on discrete, unbiased grids within two SUs; discrete biased subsurface soil sampling within two SUs to further evaluate the extent of LNAPL impacts; and groundwater sample collection from six newly-installed permanent monitoring wells. Additionally, a sitewide surface water drainage survey was conducted and habitat surveys of multiple AOCs were conducted. The Phase II RI field investigation activities are documented in the Phase II RI Field Investigation Report (AECOM-Tidewater JV 2017b), which provides the laboratory analytical data reports from the Phase II RI field investigation.

10.7 Preliminary Screening Evaluation

A preliminary screening evaluation of the existing Camp Hero dataset was conducted to (1) determine which AOCs needed further evaluation and sampling during the Phase III RI field investigation and (2) refine the list of analytes for sample collection during the Phase III RI field investigation. Results of the preliminary screening evaluation are presented in Appendix E. Additional supplemental analytical results are provided in Appendix F.

10.8 Potential Exposure Pathways and Receptors

The following subsections describe the potential human health and ecological exposure pathways and receptors to be considered for Camp Hero. Refer to Tables 10-1 and 10-2 for a graphical presentation of the potential current and future human health risk pathways, respectively, and Tables 10-3 and 10-4 for potential ecological risk pathways.

10.8.1 Human Health Potential Exposure Pathways and Receptors

The receptors and exposure pathways that will be evaluated in the human health risk assessment (HHRA) based on current and potential future land use are summarized below. Information provided by Brian X. Foley, Deputy Regional Director of the Long Island State Parks Region on April 3, 2017 was used to identify current and potential future land uses that could be relevant to the HHRA. Figures provided by Mr. Foley identified current activities consistent with the use of the area as a state park used for recreational purposes (e.g., camping areas, hiking trails) and that future uses included similar activities with the potential for the addition of more camping areas and trails. No plans for future residential use of the area or groundwater were identified.

As indicated in Section 10.4, a potability evaluation concluded that the shallow perched groundwater at Camp Hero is not suitable as a potable water source. However, the drinking water exposure pathway will be conservatively included in the evaluation of potential future residential exposures, however unlikely, to assess the potential unlimited use/unrestricted exposure (UU/UE). The deeper groundwater zone is not proposed for sampling as the CSM does not indicate that it is expected to be impacted by site activities. The lower productive aquifer in this deeper zone may be potable, but is not currently being used for residential purposes and there are no future-use plans that anticipate using the deeper aquifer for residential purposes.

For future land-use scenarios, it is assumed that there would be some level of construction to convert the area to the desired use. Therefore, it is assumed that current subsurface soil may be brought to the surface and become available for exposure by future receptors. Table 10-1 identifies the current potentially complete human health exposure pathways and Table 10-2 identifies potential future human health exposure pathways.

Human health exposure parameters and equations for the current and future scenarios will be derived primarily from USEPA resources including the Human Health Evaluation Manual, Supplemental Guidance: Update of Standard Default Exposure Factors (USEPA 2014 and 2015), Exposure Factors Handbook (USEPA 2011), Risk Assessment Guidance for Superfund Parts E and F (USEPA 2004 and 2009), and Supplemental Soil Screening Guidance (USEPA 2002b).

<u>Current and Future On-Site Outdoor Maintenance Worker</u>

Information on current outdoor maintenance workers indicates that employees may repair park equipment or perform grounds maintenance across the park.

Therefore, the HHRA will evaluate an adult park worker scenario for the following pathways:

- Exposure to surface soil (0 to 1 ft bgs) through incidental ingestion, dermal contact, inhalation of airborne particles (i.e., fugitive dust) in outdoor air, and inhalation of vapors from soil;
- Exposure to surface water dermal contact; and
- Exposure to sediment through incidental ingestion and dermal contact.

<u>Current and Future On-Site Park Employee</u>

Information on current on-site workers present at Camp Hero indicates employees (e.g., park police or naturalist) may travel across the park to check abandoned buildings, fences, or environmental study areas.

Therefore, the HHRA will evaluate an adult park worker scenario for the following pathways:

- Exposure to surface soil (0 to 1 ft bgs) through incidental ingestion, dermal contact, inhalation of airborne particles (i.e., fugitive dust) in outdoor air, and inhalation of vapors from soil;
- Exposure to surface water dermal contact; and
- Exposure to sediment through incidental ingestion and dermal contact.

Current and Future Indoor Worker

Information on current on-site indoor workers present at Camp Hero indicates workers that spend time in existing buildings and possible future buildings if land re-development occurs. This receptor is used to address the vapor intrusion exposure pathway only, if volatiles are detected in the groundwater. USEPA (2015a and b) guidance does not recommend using subsurface soil to quantify the vapor intrusion exposure pathway.

Therefore, the HHRA will evaluate an adult indoor worker scenario for the following pathway:

- Exposure to indoor air via volatilization from groundwater (i.e., vapor intrusion).

Current and Future On-Site Recreational Adult and Child

Camp Hero is currently used as a public park. It is anticipated that visitors may spend time walking on trails, picnicking, camping, and wading in stream beds. Streams are intermittent so wading, but not swimming, is possible.

Therefore, the HHRA will evaluate a recreational adult and child scenario for the following pathways:

- Exposure to surface soil (0 to 1 ft bgs) through incidental ingestion, dermal contact, inhalation of airborne particles (i.e., fugitive dust) in outdoor air, and inhalation of vapors from soil;
- Exposure to surface water dermal contact; and
- Exposure to sediment through incidental ingestion and dermal contact.

Current On-Site Trespassing Youth

It is anticipated that trespassers (ages 6 to 16 years old) may climb fences into restricted areas of a DU where current access is restricted. The teen trespasser is used to evaluate current land use exposure to soil, surface water and sediment instead of the recreational user. However, the recreational user is used to evaluate future land use, assuming the fences are removed from the DU.

Therefore, the HHRA will evaluate current trespassing teenager scenarios for the following pathways:

- Exposure to surface soil (0 to 1 ft bgs) through incidental ingestion, dermal contact, inhalation of airborne particles (i.e., fugitive dust) in outdoor air, and inhalation of vapors from soil;
- Exposure to surface water dermal contact; and
- Exposure to sediment through incidental ingestion and dermal contact.

Future On-Site Construction Worker

A construction worker exposure scenario will be evaluated in the HHRA assuming that construction activities may occur in the future. Future excavation activities may result in the subsurface soil being brought to the surface and "mixed" together. Therefore, a total soil data set (0 to 10 ft bgs; or to depth at which groundwater is encountered) will be derived as-needed for surface soil and/or subsurface soil chemicals of potential concern (COPCs), assuming future land re-development occurs.

The exposure pathways that will be evaluated for a construction worker are as follows:

- Exposure to combined surface soil and subsurface soil up to maximum likely depth of excavation through incidental ingestion, dermal contact and inhalation of airborne particles (i.e., fugitive dust) in outdoor air; and inhalation of vapors from soil;
- Exposure to groundwater in an excavation trench through incidental ingestion, dermal contact, and inhalation of air within the trench. Inhalation of excavation trench air will only be evaluated where volatiles in groundwater are identified as COPCs and where groundwater is present within 10 ft bgs.
- Exposure to surface water dermal contact; and
- Exposure to sediment through incidental ingestion and dermal contact.

Potential Future On-Site Resident

There are currently no residential receptors on the site, the area is not currently zoned for residential use, and there are no plans for future residential use (per Mr. Foley of the Long Island State Parks Region on April 3, 2017). However, a residential exposure pathway will be evaluated in the HHRA as a conservative measure of a potential future site use, however unlikely.

The project team completed a groundwater potability analysis of the perched groundwater to support the selection of potential exposure pathways, as well as subsequent risk-based decision throughout the CERCLA process (refer to Appendix G). The analysis revealed that the shallow perched groundwater at Camp Hero is not suitable as a potable water source. However, the drinking water exposure pathway will be assessed in the HHRA to assess the potential UU/UE. If the UU/UE evaluation identifies the potential for unacceptable risk, the exposure pathways for potable water may be removed and the risks re-calculated. Given that there are no future residential land use plans and that the perched groundwater is not potable for several reasons (see Appendix G), the inclusion of this exposure pathway is highly conservative.

The HHRA will evaluate a potential future on-site adult and child residential scenario for the following pathways:

- Exposure to combined surface and subsurface soil (0 to 10 ft bgs, or depth at which groundwater is encountered) through incidental ingestion, dermal contact and inhalation of airborne particles (i.e., fugitive dust) in outdoor air; and inhalation of vapors from soil;
- Exposure to groundwater through ingestion of drinking water and dermal contact and inhalation during bathing;
- Exposure to indoor air via volatilization from the subsurface (i.e., vapor intrusion);
- Exposure to surface water dermal contact; and
- Exposure to sediment through incidental ingestion and dermal contact.

Potential Future Off-Site Resident

Similar to the on-site resident exposure pathway, groundwater is not considered a potable water source for off-site residents. However, to support the evaluation of UU/UE, if groundwater flow reveals downgradient pathways in the direction of off-site residents, then the HHRA will evaluate the off-site use of groundwater by nearby residents. Given that the perched groundwater is not potable for several reasons (see Appendix G), the inclusion of this exposure pathway is highly conservative. If the UU/UE evaluation identifies the potential for unacceptable risk, the exposure pathways for potable water may be removed and the risks re-calculated.

The HHRA will evaluate a potential future off-site adult and child residential scenario for the following pathways:

- Exposure to groundwater through ingestion of drinking water and dermal contact and inhalation during bathing; and
- Exposure to indoor air via volatilization from the subsurface (i.e., vapor intrusion).

10.8.2 Ecological Potential Exposure Pathways and Receptors

The receptors and exposure pathways that will be evaluated in the ecological risk assessment (ERA) based on current and potential future land use are summarized below. The ERA will be conducted in accordance with USEPA's eight-step process for ecological risk assessments under CERCLA (USEPA 1997) and additional guidance including Guidelines for Ecological Risk Assessment (USEPA 1998), The Role of Screening-Level Risk Assessments and Refining Contaminants of

Concern in Baseline Ecological Risk Assessments (USEPA, 2001), and A Guide to Screening Level Ecological Risk Assessment (Tri-Services Environmental Risk Assessment Work Group [TSERAWG] 2008). As agreed to by the team, background conditions will be considered earlier in the ERA process than is typically recommended in ERA guidance (i.e., in Step 2 of the ERA, rather than in Step 3).

The project area includes upland habitats that have been disturbed by past site activities, intermittent and perennial streams, and wetlands. Based on this description, it is anticipated that ecological receptors may come in contact with surface soil (0 to 1 ft bgs) associated with the DUs and surface sediment (0 to 0.5 ft bgs) and surface water associated with exposure areas upstream, adjacent, and/or downstream of groups of soil DUs. Table 10-3 identifies the potentially complete ecological exposure pathways and receptors and Table 10-4 presents ecological assessment and measurement endpoints.

Ecological receptors are not typically directly exposed to groundwater so the pathway to this medium is considered not complete and will not be directly evaluated in the ERA. Ecological receptors are not expected to have significant contact with subsurface soil. The majority of bird and mammal exposure to chemicals of potential ecological concern (COPECs) comes from ingestion of food (plants and soil invertebrates). The majority of plant and invertebrate chemical exposure is from uptake in the upper soil horizon; therefore the exposure pathway for subsurface soil is considered incomplete and will not be evaluated.

The following exposure pathways will be evaluated quantitatively in the ERA:

- Terrestrial plants directly exposed to surface soil within the DUs;
- Soil invertebrates directly exposed to surface soil within the DUs;
- Aquatic organisms (e.g., aquatic invertebrates and amphibian larvae) directly exposed to surface water in the streams/wetlands;
- Benthic invertebrates directly exposed to surface sediments in the streams/wetlands;
- Terrestrial herbivorous birds and mammals exposed through incidental ingestion of surface soil and/or by ingestion of plant parts (e.g., leaves, seeds, roots) that may have taken up COPECs from the soil into their tissues;
- Terrestrial insectivorous birds and mammals exposed through incidental ingestion of surface soil and/or by ingestion of prey items (e.g., earthworms) that may have taken up COPECs from the soil into their tissues;

- Semi-aquatic herbivorous mammals exposed through ingestion of aquatic plant parts that may have taken up COPECs from the soil into their tissues; and
- Semi-aquatic insectivorous birds and mammals exposed through incidental ingestion of surface sediment and/or by ingestion of prey items (e.g., benthic invertebrates) that may have taken up COPECs from the sediment or surface water into their tissues.

Based on the intermittent nature of the stream and the shallow water conditions within the wetland, fish are not expected to be present. Therefore, evaluation of piscivorous wildlife is not warranted. Semi-aquatic herbivorous birds such as ducks and geese are also not expected to spend a significant amount of time within the aquatic habitat available on-site.

In general, ingestion of food items and, in some cases, incidental ingestion of soil or sediment are typically primary exposure pathways for birds and mammals. Other exposure pathways may be complete, but are not evaluated quantitatively. Inhalation of contaminated dust by birds and mammals is expected to be insignificant because the site is well vegetated and dust generation is minimal. VOCs may volatilize into soil air spaces from soil and migrate to the soil surface where they may be emitted to the atmosphere, but scientific data to estimate exposure of wildlife is lacking, so the pathway is not evaluated quantitatively. Exposure to VOCs by breathing contaminated air is expected to be insignificant compared to exposure by ingestion pathways. Dermal absorption of surface soil contaminants is potentially complete for ecological receptors, but scientific data to estimate exposure of wildlife is lacking, so the pathway is not evaluated quantitatively. Exposure to COPECs by dermal absorption or via the drinking water pathway for wildlife is expected to be insignificant compared to exposure by food ingestion pathways.

The following wildlife receptors will be considered in the ERA:

- American robin (*Turdus migratorius*) - insectivore foraging in upland areas and in stream/wetland areas;
- Mourning dove (*Zenaida macroura*) - herbivore foraging in upland areas;
- Meadow vole (*Microtus pennsylvanicus*) - herbivore foraging in upland areas and in stream/wetland areas; and
- Masked shrew (*Sorex cinereus*) - insectivore foraging in upland areas and in stream/wetland areas.

Table 10-4 summarizes the assessment and measurement endpoints that will be included in the Screening Level Ecological Risk Assessment (SLERA). The soil screening benchmarks for plants and soil invertebrates will be consistent with those used to screen the existing data in Appendix D. The surface water and sediment screening benchmarks will be obtained from NYSDEC guidance documents (NYSDEC, 1998 and 2014). If screening benchmarks are not available from NYSDEC sources, then other literature sources will be considered.

Risks to mammals and birds from exposure to COPECs will be evaluated using food chain models to estimate the Total Daily Dose (TDD) which will be compared to TRVs representing acceptable daily doses in mg/kg-day. Detected chemicals will be evaluated using a food chain model if the chemicals is identified as an 'important bio-accumulative compound' by USEPA (2000; Table 4-1).

TRVs incorporated into the quantitative evaluation of potential ecological risks to wildlife will be obtained from the following sources: TRVs derived according to USEPA guidance (USEPA, 2005) during the development of Eco-SSLs, ORNL publication Toxicological Benchmarks for Wildlife: 1996 Revision (Sample et al,. 1996), and the LANL EcoRisk Database (LANL, 2015). When TRVs are not derived in these documents, the literature will be reviewed for relevant data and TRVs will be derived using the methodology of ORNL (Sample et al., 1996). TRVs used in the SLERA will be based on No Observed Adverse Effect Levels (NOAELs).

Chemical concentrations in food items will be calculated using bioaccumulation factors (BAFs) and other uptake factors from published sources or regression equations from the USEPA Eco-SSL Guidance (USEPA, 2007) and other literature sources (e.g., Bechtel Jacobs, 1998a,b). The USEPA's Biota-Sediment Accumulation Factor (BSAF) database will be used as a primary source to identify sediment-to-invertebrate uptake factors for organic chemicals. Soil-based uptake factors may be used when sediment-specific uptake factors are not identified.

Exposure assumptions (e.g., body weights, relative consumption of food items, foraging range, exposure duration, etc.) for wildlife species will generally be obtained from the USEPA's Wildlife Exposure Factors Handbook (USEPA, 1993). Allometric equations (Nagy, 2001) will be used to estimate food ingestion rates.

10.9 Selection of Decision Units for Further Investigation

A total of 21 AOCs, plus 6 segments of the WDS AOC, warrant further assessment based on the results of the preliminary screening evaluation (Appendix E). AOCs warranting additional sampling were grouped into 18 geometric DUs for the Phase III investigation. DUs will create a more robust dataset and will establish representative EPCs from a realistic exposure area for potential human health and ecological receptors.

The DUs will be approximately 0.5 acre or 1 acre exposure areas, consistent with the extent of potential impacts from prior investigations and the range of human health and ecological receptor potential exposure areas. In general, the DUs will be designed as geometric squares, but the sampling protocol within the DUs may be adjusted, were appropriate, to account for nearby fences, roads, steep slopes, drainage channels, or similarly significant geographic features. Sample collection and sample depths may vary in areas with limited accessibility within each of the DUs; however, the entire DU boundary will still be considered the "exposure area" for quantification of potential risks to receptors. Table 10-5 and Figure 10-4 present the DU groupings for the Phase III RI field investigation.

10.10 Conceptual Site Models of Decision Units

The following subsections briefly summarize the DU-specific CSMs that provide the basis and framework for developing the sampling and analysis plan to complete the RI phase of the CERCLA process. For simplicity, analytical parameter groups warranting further analysis are referred to as VOCs, SVOCs, PCBs, and metals in this worksheet. However, the specific analytes to be evaluated within each parameter group have been refined based on the Preliminary Screening Evaluation (Appendix E) and other specific project needs. Refer to Worksheet #15 for specific details on the parameter groups and specific parameters selected for this Phase III RI field investigation. Refer to Worksheet #17 and specifically Figures 17-1 through 17-20 for the sampling design associated with the Phase III RI field investigation.

Sitewide Surface Water and Sediment

- Study Area: Sitewide surface water and sediment samples grouped into exposure areas, which are intended to be upstream, adjacent, and/or downstream of groups of soil DUs, and are intended for assessment of potential DU contributions, as well as broader drainage channel conditions along longer stretches of the channels. The grouping of datasets into exposure areas may consider factors such as the analytical results, physical characteristics of the drainage channel sediment, surface water conditions at the time of sampling (i.e., wet or dry), and proximity to nearby DUs. Separate EPCs will be generated for each exposure area.
- Potential Impacts: Surface water and sediment has not yet been assessed. It is unclear if environmental impacts from the various DUs have impacted the local network of drainage channels. Based on the preliminary screening evaluation of soil, metals and SVOCs warrant further assessment in surface and subsurface soil at the majority of the DUs. Additional parameters warrant further assessment in surface and subsurface soil at select DUs, including PCBs at DU15 and VOCs at DU01. Based on these results, surface water and sediment in the vicinity of the DUs warrant further assessment for metals (dissolved and total) and SVOCs (total) sitewide and additional parameter groups identified at select DUs, as described below in the DU-specific CSMs.
- Potentially Impacted Media and Data Needs: Surface water and sediment sampling is required on a sitewide scale upstream of all of the DUs to assess reference upstream drainage channel

conditions and to establish BTVs. In addition, surface water and sediment sampling is required in multiple exposure areas upstream, adjacent, and/or downstream of groups of soil DUs.

- Sampling Design Considerations: Because many of the streams and drainage channels transect multiple DUs, surface water and sediment should be evaluated at a sitewide scale and within specific exposure areas (stream segments). Upstream locations should be selected which are upstream of all DUs. Additionally, due to the presence of wooden revetments along the stream channels, one set of upstream samples should be collected from streams with wooden revetments; an additional set of upstream samples should be collected from streams without wooden revetments. Other sampling locations could be downstream of one DU but upgradient of another DU. Refer to Worksheet #17 for a discussion of how the surface water and sediment EPCs should be calculated on a sitewide scale and within exposure areas. To ensure data is comparable at a sitewide scale, all surface water and sediment samples should be evaluated for selected SVOCs and metals at minimum. Additional parameters for surface water and sediment should be evaluated at individual exposure areas as necessary depending on each CSM. Refer to the DU-specific CSMs provided below for more detail.

Sitewide Groundwater

- Study Area: Sitewide groundwater, with specific focus in the near-vicinity of DUs that have exhibited the potential for groundwater impacts..
- Potential Sitewide Impacts: Background groundwater monitoring wells were constructed in upgradient locations of Camp Hero and were used to derive groundwater BTVs. DU-specific groundwater monitoring wells were constructed in the vicinity of DU01. There are no other permanent groundwater monitoring wells at Camp Hero, and an assessment of sitewide groundwater has not yet been conducted. Grab groundwater samples were collected during prior investigations, which were useful to support the DU-specific CSMs; however, because the grab groundwater samples were not collected from developed wells, were not sampled via low-flow sampling procedures, and exhibited extreme turbidity, they are not considered suitable for assessing true groundwater conditions. Based on the preliminary screening evaluation of soil, as well as field screening of the grab groundwater samples collected during prior investigations, potential sitewide groundwater impacts could include SVOCs and metals, as well as some additional parameters in focused areas, as described below.
- Potential Focused Impacts: VOCs warrant further assessment in groundwater near DU01 due to the presence of LNAPL. Additionally, VOCs warrant further assessment in the vicinity of the former AOCs AST-35, Fuel Pump House (FPH), and Suspected Tank B (STB) due to field observations (including petroleum odor, staining of soil cores, and sheen on turbid groundwater from temporary wells) indicating potential petroleum impacts to groundwater. PCBs warrant

assessment at DU15 to refine the CSM relative to prior detections of PCBs in the turbid grab groundwater samples.

- Sample Design Considerations: A network of groundwater monitoring wells should be constructed across Camp Hero, with specific focus in the near-vicinity of DUs that have exhibited the potential for groundwater impacts. The well network will include the existing background wells (which do not require further sampling), as well as the existing DU01 wells (which should be sampled for a second round of groundwater data). It is expected that all new wells will be constructed within perched groundwater, not the lower productive aquifer. The sample design should consider an appropriate depth of each well, as well as the specific screen interval to intersect sufficient groundwater for well development and low-flow sampling.

DU01: Former Building 203 Area

- Associated Former AOCs: Former Building 203. The DU boundary encompasses LNAPL impacts and the prior surface soil sampling grid. It is bounded by a nearby fence to the west and includes an area of limited accessibility due to steep terrain. The northwest and western portions of the DU include steep terrain. The sample locations in those areas may be offset to avoid the steep terrain.
- Potential Site Impacts: VOCs, SVOCs, PCBs, and TAL metals were assessed in surface soil and subsurface soil during previous investigations. VOCs, SVOCs, and TAL metals were assessed in groundwater from permanent monitoring wells during previous investigations. Based on the preliminary screening evaluation for soil, VOCs, SVOCs, and metals warrant further assessment. In addition, field observations from previous investigations indicate the residual presence of LNAPL in the subsurface of this area, ranging from approximately 8 to 34 ft bgs.
- Potentially Impacted Media and Data Needs: An unbiased grid of surface soil samples was collected and analyzed during the Phase II RI, which is sufficient for calculating EPCs and conducting risk assessments. No further surface soil characterization is necessary to support the RI/FS phase of study. Subsurface soil and associated groundwater warrant further evaluation of VOCs based on the detection of chlorinated VOCs in groundwater and petroleum-related VOCs in soil and groundwater (from existing permanent monitoring wells). Subsurface soil and groundwater also warrant further evaluation of SVOCs and metals based on the preliminary screening evaluation. In addition, a more detailed evaluation of physical subsurface characteristics is warranted to support the FS in developing and evaluating candidate response actions for LNAPL. Groundwater will also be analyzed for selected geochemical and MNA parameters to support the FS.
- Sampling Design Considerations: Subsurface soil in a portion of this DU, from an approximate depth range of 0 to 20 ft bgs, was excavated and backfilled during the removal of two former

petroleum-related USTs. Although it is not typical to collect samples of backfill, in this case, samples of backfill within DU01 will be included in the unbiased 1 to 10 ft bgs subsurface sampling grid to generate a representative EPC for the entire subsurface soil exposure area. LNAPL is not expected to be encountered in the majority of the 1 to 10 ft bgs subsurface soil sampling horizon because the LNAPL has generally been encountered below that depth. There was petroleum-impacted subsurface soil reported in the 1 to 10 ft bgs depth range during prior investigations, but those impacts are not expected to include LNAPL. Based on the working CSM for this area, the extent of LNAPL impacts is expected to be primarily within the 8 to 34 ft bgs depth range.

DU02: H-2 Drum Area

- Associated Former AOCs: Drum Location (H-2). The DU boundary encompasses an existing drum remnant that is bounded by a fence on the east. This DU is intended to assess potential impacts and exposures west of the fence in the direction of overland surface water flow and groundwater flow. An adjacent DU (DU01) will assess the area east of the fence.
- Potential Site Impacts: Potential drum contents (unknown). VOCs, SVOCs, PCBs, and TAL metals (except mercury) were assessed in surface and shallow subsurface soil during previous investigations. Based on the preliminary screening evaluation, metals in surface soil warrant further assessment. The presence of some metals in excess of screening criteria and BTVs could be an indication that other metals could pose potential environmental impacts.
- Potentially Impacted Media and Data Needs: Surface soil warrants further evaluation for metals. Surface water and sediment downgradient of this DU also warrant further evaluation of metals associated with potential soil impacts, as well as SVOCs to be consistent with the sitewide evaluation of SVOCs and metals in surface water and sediment. SVOCs from DU01 or DU03 could be a potential source of SVOCs in this surface water and sediment exposure area. There is no evidence of potential DU-specific groundwater impacts; however, groundwater will be assessed sitewide with a network of groundwater monitoring wells.

DU03: Drum Location H-1

- Associated Former AOCs: Drum Location (H-1). The DU boundary encompasses an existing drum remnant to assess potential impacts and exposures. The southern portion of the DU includes wetlands. The sample depths within the wetlands may be shallower to avoid impacts to the wetlands and to match the most likely exposure depths to potential human health and ecological receptors (i.e., 0 to 1 foot and 1 to 2 feet).
- The DU boundary encompasses LNAPL impacts and the prior surface soil sampling grid. It is bounded by a nearby fence to the west and includes an area of limited accessibility due to steep

terrain. The northwest and western portions of the DU include steep terrain. The sample locations may be offset to avoid the steep terrain.

- Potential Site Impacts: Potential drum contents (unknown). VOCs, SVOCs, PCBs, and TAL metals (except mercury) were assessed in surface and shallow subsurface soil during the previous investigations. Based on the preliminary screening evaluation, metals and SVOCs in surface soil warrant further assessment. The presence of cadmium in excess of screening criteria and BTVs could be an indication that other metals could pose potential environmental impacts. Additionally, the presence of SVOCs in subsurface soil warrant further investigation.
- Potentially Impacted Media and Data Needs: Surface soil warrants further evaluation for metals; surface and subsurface soil warrant further evaluation of SVOCs. Surface water and sediment transecting and downgradient of this DU also warrant further evaluation of metals and SVOCs associated with potential soil impacts. These parameter groups are also consistent with the sitewide evaluation of SVOCs and metals in surface water and sediment. There is no evidence of potential DU-specific groundwater impacts; however, groundwater will be assessed as part of the sitewide network of groundwater monitoring wells.

DU04: H-18 Drum Area

- Associated Former AOCs: Drum Location (H-18). The DU boundary encompasses an existing drum remnant at the top of the slope in the western portion of the DU. This DU is intended to assess potential impacts and exposures in the operational and recreational area along the gravel access road and other unmarked paths, north of Battery 112. The DU is bounded by steep terrain on the east and west boundaries, which have a more limited potential for exposure.
- Potential Site Impacts: Potential drum contents (unknown). VOCs, SVOCs, PCBs, and metals (except mercury) were assessed in surface and shallow subsurface soil during the previous investigations. Based on the preliminary screening evaluation, metals in surface soil warrant further assessment. The presence of thallium in excess of screening criteria and BTVs could be an indication that other metals could pose potential environmental impacts.
- Potentially Impacted Media and Data Needs: Surface soil warrants further evaluation for metals. No drainage channels or streams directly transect or are directly downgradient of this DU; surface water and sediment will be assessed at a sitewide scale. Additionally, no sources to groundwater impacts are anticipated in this DU; groundwater will be assessed at a sitewide scale.

DU05: WDS Cesspool Area

- Associated Former AOCs: WDS Borings -SB25 through -SB27. The DU boundary encompasses the former cesspool area. This DU is intended to assess potential impacts and exposures in the vicinity of the cesspool area and to the east of that area, in the direction of overland surface water flow and groundwater flow. It is bounded by a nearby road (Camp Hero State Park Road) to the west and includes an area of limited accessibility due to steep terrain. The western portion of the DU includes steep terrain. The sample locations in that area may be offset to avoid the steep terrain.

- Potential Site Impacts: Cesspools associated with the former sitewide waste disposal system. VOCs, SVOCs, PCBs, and TAL metals (except mercury) were assessed in subsurface soil during the previous investigations. Based on the preliminary screening evaluation, metals in subsurface soil warrant further assessment. The presence of arsenic and iron in excess of screening criteria and BTVs could be an indication that other metals could pose potential environmental impacts.
- Potentially Impacted Media and Data Needs: Surface and subsurface soil warrant further evaluation for metals based on exceedances in subsurface soil. Surface water and sediment downgradient of this DU also warrant further evaluation of metals associated with potential soil impacts, as well as SVOCs to be consistent with the sitewide evaluation of SVOCs and metals in surface water and sediment. SVOCs from DU06 could be a potential source of SVOCs in this surface water and sediment exposure area. There is no evidence of potential DU-specific groundwater impacts; however, groundwater will be assessed in this area as part of the sitewide network of groundwater monitoring wells.

DU06: Former Power Plant Area

- Associated Former AOCs: Former Power Plant (H-11), former Sewage Ejector Station (H-12), WDS Borings -SB23 through -SB24 (Tile Field). The DU boundary encompasses these former operational areas to assess potential impacts and exposures. The southern portion of the DU includes coal fragments. The sample locations and depths within the coal fragments will be the same as the rest of this DU.
- Potential Site Impacts: At the former Power Plant (H-11), SVOCs (PAHs only), PCBs, and TAL metals (except mercury) were assessed in surface and subsurface soil during the previous investigations. At the former Sewage Ejector Station (H-12), VOCs, SVOCs, PCBs, and TAL metals (except mercury) were assessed in surface and subsurface soil during the previous investigations. At the WDS Borings -SB23 through -SB24 (Tile Field), VOCs, SVOCs, PCBs, and TAL metals (except mercury) were assessed in subsurface soil during the previous investigations. Based on the preliminary screening evaluation, lead in surface soil warrants further assessment. In addition, the presence of lead in excess of screening criteria and BTVs could be an indication that other metals (mercury not previously analyzed) could also pose potential environmental impacts. Based on the preliminary screening evaluation, PAHs and metals in subsurface soil warrant further assessment. In addition, the presence of PAHs in subsurface soil could be an indication that PAHs in surface soil pose potential environmental impacts. The exceedance of PAHs is also consistent with the field observation of coal at the site.

- Potentially Impacted Media and Data Needs: Surface and subsurface soil warrant further evaluation for metals based on the exceedances of metals in surface and subsurface soil. Surface and subsurface soil warrant further evaluation for SVOCs based on the field observations of coal and the exceedance of PAHs in subsurface soil. Surface water and sediment transecting and downgradient of this DU warrant further evaluation of SVOCs and metals associated with potential soil impacts. These parameter groups are also consistent with the sitewide evaluation of SVOCs and metals in surface water and sediment. There is no evidence of potential DU-specific groundwater impacts; however, groundwater will be assessed in this area as part of the sitewide network of groundwater monitoring wells.

DU07: H-19, H-20 AST/Drum Area

- Associated Former AOCs: Former AST (H-19), Drum Location (H-20), Possible Boiler (H-9). The DU boundary encompasses these former items to assess potential impacts and exposures. The eastern portion of the DU includes wetlands. The sample depths within the wetlands may be shallower to avoid impacts to the wetlands and to match the most likely exposure depths to potential human health and ecological receptors (i.e., 0 to 1 foot and 1 to 2 feet).
- Potential Site Impacts: Potential drum, boiler, and AST contents (unknown). During previous investigations, VOCs, SVOCs (PAHs only), and metals were assessed in surface soil at the former AST (H-19); VOCs, SVOCs, PCBs, and TAL metals (except mercury) were assessed in surface and shallow subsurface soil at Drum Location H-20; and SVOCs (PAHs only) and TAL metals (except mercury) were assessed in surface soil at the Possible Boiler (H-9). Based on the preliminary screening evaluation, metals in surface and subsurface soil warrant further assessment. The presence of some metals in excess of screening criteria and BTVs could be an indication that other metals (mercury not previously analyzed) could also pose potential environmental impacts. In addition, PAHs in subsurface soil warrant further assessment based on the preliminary screening evaluation. The presence of PAHs in subsurface soil could be an indication that PAHs in surface soil pose potential environmental impacts.
- Potentially Impacted Media and Data Needs: Surface and subsurface soil warrant further evaluation for metals based on the exceedances of metals in surface and subsurface soil. Surface and subsurface soil warrant further evaluation for SVOCs based on the exceedance of SVOCs in subsurface soil. Surface water and sediment transecting and downgradient of this DU warrant further evaluation of SVOCs and metals associated with potential soil impacts. These parameter groups are also consistent with the sitewide evaluation of SVOCs and metals in surface water and sediment. There is no evidence of potential DU-specific groundwater impacts; however, groundwater will be assessed in this area as part of the sitewide network of groundwater monitoring wells.

DU08: WDS Chlorine Contact Chamber Area

- Associated Former AOCs: WDS Borings -SB01 through -SB03 (Chlorine Contact Chamber). The DU boundary encompasses the former chlorine contact chamber. This DU is intended to assess potential impacts and exposures in the vicinity of the chamber and north of the chamber along the waste disposal system pipeline. The northern portion of the DU includes wetlands. The sample depths within the wetlands may be shallower to avoid impacts to the wetlands and to match the most likely exposure depths to potential human health and ecological receptors (i.e., 0 to 1 foot and 1 to 2 feet).

- Potential Site Impacts: The sitewide sanitary sewer system was connected to a chlorine contact chamber for treatment prior to discharging into the Atlantic Ocean at a headwall outfall. VOCs, SVOCs, PCBs, and TAL metals (except mercury) were assessed in surface soil and shallow subsurface soil during the previous investigations. Based on the preliminary screening evaluation, metals in surface soil warrant further assessment. The presence of some metals in excess of screening criteria and BTVs could be an indication that other metals (mercury not previously analyzed) could also pose potential environmental impacts. In addition, SVOCs in surface and subsurface soil warrant further assessment based on the preliminary screening evaluation.

- Potentially Impacted Media and Data Needs: Surface soil warrant further evaluation for metals based on the exceedances of metals in surface soil. Surface and subsurface soil warrant further evaluation for SVOCs based on the exceedance of SVOCs in subsurface soil. Surface water and sediment transecting and downgradient of this DU warrant further evaluation of SVOCs and metals associated with potential soil impacts. These parameter groups are also consistent with the sitewide evaluation of SVOCs and metals in surface water and sediment. There is no evidence of potential DU-specific groundwater impacts; however, groundwater will be assessed in this area as part of the sitewide network of groundwater monitoring wells.

DU09: H-15 Coal Storage Area

- Associated Former AOCs: Former Coal Storage (H-15). The DU boundary encompasses a former coal storage area to assess potential impacts and exposures. There are no anticipated access limitations within this DU.

- Potential Site Impacts: Former coal storage area. SVOCs (PAHs only) and TAL metals (except mercury) were assessed in surface soil during the previous investigations. Based on the preliminary screening evaluation, metals in surface soil warrant further assessment. The presence of some metals in excess of screening criteria and BTVs could be an indication that other metals (mercury not previously analyzed) could also pose potential environmental impacts.

- Potentially Impacted Media and Data Needs: Surface soil warrant further evaluation for metals based on the exceedances of metals in surface soil. No drainage channels or streams directly transect or are directly downgradient of this DU; surface water and sediment will be assessed at a sitewide scale. There is no evidence of potential DU-specific groundwater impacts; groundwater will be assessed at a sitewide scale.

DU10: H-5 Drum / Debris Area

- Associated Former AOCs: Drum Location with Construction Debris (H-5). The DU boundary encompasses a former drum remnant area to assess potential impacts and exposures. There are no anticipated access limitations within this DU.
- Potential Site Impacts: Potential former drum contents (unknown) and construction debris. VOCs, SVOCs, PCBs, and TAL metals (except mercury) were assessed in surface soil and shallow subsurface soil during the previous investigations. Based on the preliminary screening evaluation, metals in surface soil warrant further assessment. The presence of some metals in excess of screening criteria and BTVs could be an indication that other metals (mercury not previously analyzed) could also pose potential environmental impacts.
- Potentially Impacted Media and Data Needs: Surface soil warrant further evaluation for metals based on the exceedances of metals in surface soil. Surface water and sediment in intermittent drainage transecting and downgradient of this DU also warrant further evaluation of metals associated with potential soil impacts, as well as SVOCs to be consistent with the sitewide evaluation of SVOCs and metals in surface water and sediment. SVOCs from DU11 could be a potential source of SVOCs in this surface water and sediment exposure area. There is no evidence of potential DU-specific groundwater impacts; groundwater will be assessed at a sitewide scale.

DU11: H16 / WDS Septic / former Building 34 Area

- Associated Former AOCs: Former Building 34, Former Sewage Treatment Area (H-16), Motor Pool Boring –SB02 (Drain) and –SB03 (Cesspool). The DU boundary encompasses these former operational areas to assess potential impacts and exposures. This DU is bounded by a road to the north (Camp Hero State Park Road) and a fence to the west. There are no anticipated access limitations within this DU.
- Potential Site Impacts: At former Building 34, SVOCs (PAHs only), PCBs, and TAL metals (except mercury) were assessed in surface soil and subsurface soil during the previous investigations. At the former Sewage Treatment Area (H-16), VOCs, SVOCs, PCBs, and TAL metals (except mercury) were assessed in surface soil and subsurface soil during the previous investigations. At Motor Pool Borings –SB02 (Drain) and –SB03 (Cesspool), VOCs, SVOCs, PCBs, and energetics were assessed in surface soil and subsurface soil during the previous investigations. Based on

the preliminary screening evaluation, SVOCs and metals warrant further evaluation in surface soil. The presence of some metals in excess of screening criteria and BTVs could be an indication that other metals (mercury not previously analyzed) could also pose potential environmental impacts.

- Potentially Impacted Media and Data Needs: Surface soil warrants further evaluation for metals and SVOCs based on the exceedances in surface soil. Surface water and sediment in the exposure area transecting and downgradient of this DU warrant further evaluation of SVOCs and metals associated with potential soil impacts. These parameter groups are also consistent with the sitewide evaluation of SVOCs and metals in surface water and sediment. There is no evidence of potential DU-specific groundwater impacts; however, groundwater will be assessed in this area as part of the sitewide network of groundwater monitoring wells.

DU12: WDS Manhole Area 1

- Associated Former AOCs: WDS Borings -SB08 through -SB09 (Box and Manhole). The DU boundary encompasses portions of the former waste disposal system and storage area. This DU boundary was generated to encompass both sides of the road (Camp Hero State Park Road) to create the minimum exposure area (1/2 acre) to assess potential impacts and exposures. Sample locations in the vicinity of the roadway may be offset to avoid the roadway.
- Potential Site Impacts: An underground box and manhole associated with the former sitewide waste disposal system. VOCs, SVOCs, PCBs, and TAL metals (except mercury) were assessed in subsurface soil during the previous investigations. Based on the preliminary screening evaluation, SVOCs in subsurface soil warrant further evaluation. Presence of SVOCs in subsurface soil could be an indication that SVOCs in surface soil may also pose an environmental concern.
- Potentially Impacted Media and Data Needs: Surface and subsurface soil warrant further evaluation SVOCs based on the exceedances in subsurface soil. Surface water and sediment transecting and downgradient of this DU warrant further evaluation of SVOCs associated with potential soil impacts, as well as metals to be consistent with the sitewide evaluation of SVOCs and metals in surface water and sediment. There is no evidence of potential DU-specific groundwater impacts; however, groundwater will be assessed in this area as part of the sitewide network of groundwater monitoring wells.

DU13: H-14 Coal Storage Area

- Associated Former AOCs: Former Coal Storage (H-14). The DU boundary encompasses a former coal storage area to assess potential impacts and exposures. This DU is bounded by a road to the north (Camp Hero State Park Road). There are no anticipated access limitations within this DU.

- Potential Site Impacts: Former coal storage area. SVOCs (PAHs only) and TAL metals (except mercury) were assessed in surface soil during the previous investigations. Based on the preliminary screening evaluation, metals warrant further evaluation in surface soil. The presence of some metals in excess of screening criteria and BTVs could be an indication that other metals (mercury not previously analyzed) could also pose potential environmental impacts. The exceedance of metals is also consistent with the historic use of coal storage at the site.
- Potentially Impacted Media and Data Needs: Surface soil warrants further evaluation for metals based on the exceedances in surface soil. No streams or drainage features directly transect this DU, but surface water and sediment in the vicinity will be included in the sitewide evaluation of SVOCs and metals in surface water and sediment. There is no evidence of potential DU-specific groundwater impacts; however, groundwater will be assessed in this area as part of the sitewide network of groundwater monitoring wells.

DU14: WDS Septic Tank Area

- Associated Former AOCs: WDS Borings -SB06 through -SB07 (Suspected Septic Tank). The DU boundary encompasses a suspected septic tank area associated with the former site-wide waste disposal system to assess potential impacts and exposures. This DU is bounded by a road to the south (Camp Hero State Park Road). There are no anticipated access limitations within this DU.
- Potential Site Impacts: A suspected septic tank associated with the former sitewide waste disposal system. VOCs, SVOCs, PCBs, and TAL metals (except mercury) were assessed in subsurface soil during the previous investigation. Based on preliminary screening evaluation, SVOCs in subsurface soil warrant additional investigation. Presence of SVOCs in subsurface soil could be an indication that SVOCs in surface soil may also pose an environmental concern.
- Potentially Impacted Media and Data Needs: Surface and subsurface soil warrant further evaluation SVOCs based on the exceedances in subsurface soil. Surface water and sediment in the exposure area transecting and downgradient of this DU warrant further evaluation of SVOCs associated with potential soil impacts, as well as metals to be to be consistent with the sitewide evaluation of SVOCs and metals in surface water and sediment. There is no evidence of potential DU-specific groundwater impacts; however, groundwater will be assessed in this area as part of the sitewide network of groundwater monitoring wells.

DU15: H-6 Debris Area

- Associated Former AOCs: Construction Debris Area (H-6). The DU boundary encompasses a former drum remnant area to assess potential impacts and exposures. The southern portion of the DU potentially includes wetlands. If present, the sample depths within the wetlands may be shallower to avoid impacts to the wetlands and to match the most likely exposure depths to potential human health and ecological receptors (i.e., 0 to 1 foot and 1 to 2 feet).

- Potential Site Impacts: An area of construction debris. PCBs and lead were assessed in surface soil during the previous investigation. Based on the preliminary screening evaluation, lead in surface soil warrants further assessment. In addition, the presence of lead in excess of screening criteria and BTVs could be an indication that other metals (not previously analyzed) could also pose potential environmental impacts. In additional to surface soil data, Arochlor-1254 was detected in shallow groundwater in a turbid grab-groundwater sample, which could indicate potential PCBs in soil.
- Potentially Impacted Media and Data Needs: Surface soil warrants further evaluation for metals based on the exceedance of lead. Surface and subsurface soil warrant further evaluation for PCBs. Nearby surface water and sediment warrants further evaluation of metals and PCBs downstream of potential soil impacts, as well as SVOCs to be consistent with the sitewide evaluation of SVOCs and metals in surface water and sediment. Groundwater warrants further evaluation for metals and PCBs, to validate the absence of PCBs if they are due to TSS in the prior turbid grab-groundwater sample, as well as SVOCs and metals to be consistent with the sitewide groundwater evaluation.

DU16: WDS Manhole Area 2

- Associated Former AOCs: WDS Boring -SB13 (Manhole). The DU boundary encompasses a portion of the former waste disposal system to assess potential impacts and exposures. This DU is bounded by roads to the west and south (Camp Hero State Park Road). There are no anticipated access limitations within this DU.
- Potential Site Impacts: A manhole associated with the former sitewide waste disposal system. VOCs, SVOCs, PCBs, and TAL metals (except mercury) were assessed in subsurface soil during the previous investigation. Based on preliminary screening evaluation, SVOCs in subsurface soil warrant additional investigation. Presence of SVOCs in subsurface soil could be an indication that SVOCs in surface soil may also pose an environmental concern.
- Potentially Impacted Media and Data Needs: Surface and subsurface soil warrant further evaluation SVOCs based on the exceedances in subsurface soil. No streams or drainage features directly transect this DU. There is no evidence of potential DU-specific groundwater impacts; however, groundwater will be assessed in this area as part of the sitewide network of groundwater monitoring wells.

DU17: H-4 Debris Area

- Associated Former AOCs: Construction Debris Area (H-4). The DU boundary encompasses an area of former debris to assess potential impacts and exposures. This DU is bounded on the south by an existing concrete foundation from a former building, as well as an existing fenced municipal waste storage area. There are no anticipated access limitations within this DU.
- Potential Site Impacts: An area of construction debris. PCBs and lead were assessed in surface and subsurface soil during the previous investigation. Based on the preliminary screening evaluation, lead in surface soil warrants additional investigation. The presence of lead in excess of screening criteria and BTVs could be an indication that other metals could pose potential environmental impacts.
- Potentially Impacted Media and Data Needs: Surface soil warrants further evaluation for metals. Surface water and sediment transecting and downgradient of this DU also warrant further evaluation of metals associated with potential soil impacts, as well as SVOCs to be consistent with the sitewide evaluation of SVOCs and metals in surface water and sediment. There is no evidence of potential DU-specific groundwater impacts; however, groundwater will be assessed in this area as part of the sitewide network of groundwater monitoring wells.

DU18: H-3 Drum Area

- Associated Former AOCs: Drum Area (H-3). The DU boundary encompasses a former drum remnant area to assess potential impacts and exposures. The western portion of the DU includes wetlands. The sample depths within the wetlands may be shallower to avoid impacts to the wetlands and to match the most likely exposure depths to potential human health and ecological receptors (i.e., 0 to 1 foot and 1 to 2 feet).
- Potential Site Impacts: Potential drum contents (unknown). VOCs, SVOCs, PCBs, and TAL metals (except mercury) were assessed in surface and shallow subsurface soil during the previous investigations. Based on the preliminary screening evaluation, metals in surface soil warrant additional investigation. The presence of some metals in excess of screening criteria and BTVs could be an indication that other metals could pose potential environmental impacts.
- Potentially Impacted Media and Data Needs: Surface soil warrants further evaluation for metals. No streams or drainage features directly transect this DU. There is no evidence of potential DU-specific groundwater impacts; however, groundwater will be assessed in this area as part of the sitewide network of groundwater monitoring wells.

Worksheet #11: Data Quality Objectives/Systematic Planning Process Statements

The planned Phase III RI field investigation is designed to complete the RI phase of the CERCLA process, as well as provide data to support risk-based decisions and the subsequent sitewide FS. In general, this Phase III RI field investigation will refine the CSMs for the individual DUs established at the site, as well as provide a regional depiction of sediment quality and establish a representative network of sitewide groundwater monitoring wells. Data quality objectives (DQOs) are developed in this worksheet based on the Guidance on Systematic Planning Using the Data Quality Objectives Process (EPA QA/G4, EPA/240/B-6/001) (EPA, February 2006) and are presented below.

11.1 Problem Statement

The project team initially identified 47 AOCs based on prior site operations and uses, completed a preliminary screening evaluation of available analytical results, and subsequently defined 18 individual Decision Units (DUs). Current data for the 18 DUs is insufficient and does not adequately define the nature and extent of potential contamination in support of the following RI components: 1) Fate & transport, 2) SLERA, and 3) HHRA.

11.2 Study Goals

The project team will collect surface soil, subsurface soil, groundwater, surface water, and sediment samples, as well as analytical parameters, to establish representative datasets and EPCs for quantifying potential human health and ecological risks. Sampling locations for groundwater, surface water, and sediment will be established on a sitewide scale, along with DU-specific or exposure area-specific sampling locations where necessary to assess potential local impacts from upgradient or upstream DUs. Sampling locations for surface soil and subsurface soil will be collected only within the DUs.

Parameters selected for analysis will be based on (1) parameters that exceed the preliminary screening evaluation of Phase I and II sampling and analysis results (refer to Appendix E), (2) the CSM for each DU relative to additional parameters that could be present but have not yet been analyzed, and (3) data needs for the FS, such as geochemical and MNA parameters. To achieve these overall project objectives, the following specific DQOs are appropriate:

- Goal 1 – Collect a representative dataset for potentially impacted surface and subsurface soil associated with each of the individual DUs. Calculate EPCs to quantify potential risks.

- Goal 2 – Collect a representative dataset for surface water and sediment at a sitewide scale, as well as in exposure areas the vicinity of DUs that could potentially impact downgradient surface water and sediment. Calculate EPCs to quantify potential risks.

- Goal 3 – Establish a representative groundwater monitoring well network and collect groundwater samples on a sitewide scale, as well as on a local scale in the vicinity of DUs that could potentially (or have been demonstrated to) have localized groundwater impacts.
- Goal 4 – Collect additional physical and chemical data to support the CSM, risk assessments, and FS.

11.3 Information Inputs

Information inputs used to develop this SAP consist of prior study reports, available analytical data, available site-specific background data, preliminary screening criteria, consideration of potential human health and ecological exposure pathways and receptors, and consideration of potential data needs to support the FS. Refer to Worksheet #10 for an inventory of prior investigations and reports. Additional information inputs that will be generated from the Phase III RI field investigation described in this SAP will include the following items:

- Field observations and measurements, including geologic logs, ambient air [Photo Ionization Detector (PID)) measurements, water quality parameters, GPS coordinates, and survey data.
- Surface soil samples (0 to 1 ft bgs).
- Subsurface soil samples (1 to 10 ft bgs or 1 to 2 ft bgs in wetland soils).
- Groundwater samples from permanent monitoring wells.
- Surface water and sediment samples.
- Chemical and physical data to support the FS.

11.4 Study Area Boundaries

Camp Hero State Park is located on the eastern tip of the south fork of Long Island, NY, approximately 5 miles east of the Village of Montauk (Figure 10-1). The park consists of 469 acres and is bound by Montauk Highway (Route 27) to the north, the Atlantic Ocean to the south, Montauk Point State Park to the east, and Camp Hero State Park's undeveloped sanctuary area to the west. General spatial and temporal boundaries are described below.

Spatial Boundaries

A total of 18 separate DUs have been identified at Camp Hero for sampling during the Phase III RI field investigation, as established in Worksheet #10 of this SAP (refer to Table 10-5 and Figure 10-4). In general, some DUs are bound by nearby fences, roads, steep slopes, drainage channels, or similarly significant geographic features which create areas with limited accessibility. Sample collection and sample depths may vary in areas with limited accessibility within each of the DUs; however, the entire DU boundary will still be considered the "exposure area" for quantification of potential risks to receptors

Specifically, areas of limited accessibility are anticipated at DU01, DU03, DU05, DU08, and DU17. At DU01, steep terrain and heavy vegetation in the North and West portions will be inaccessible to the direct push drill rig. At DU05, steep terrain along the center of the DU may be inaccessible to the direct push drill rig. At DU17, a small portion of the DU is covered with cement; surface soil samples will not be collected from this area. At DU03 and DU08, wetland and marsh conditions paired with heavy vegetation may create inaccessible areas for the direct push drill rig throughout the majority of the DU. Alternate sampling approaches for these areas are described in Section 11.5 below.

Temporal Boundaries

The temporal boundaries for this study will be the Phase III RI field investigation, anticipated to begin after Memorial Day 2017 and end during June 2017, with an objective to demobilize prior to the July 4th holiday.

11.5 Sampling Strategy

The sampling strategy for this Phase III RI field investigation is to implement a comprehensive field investigation to complete the RI phase of the CERCLA process. Refer to Worksheet #17 for the specific sampling design and rationale. In general, unbiased sampling grids will be established for surface soil and subsurface soil sampling locations within applicable DUs. Surface water and sediment samples will be collected in a linear fashion within streams in exposure areas upstream, adjacent, and/or downstream of groups of soil DUs. These datasets will be used to generate a robust dataset that will be considered representative of the conditions to which potential receptors could be exposed. Human health receptors could be exposed to surface soil (0 to 1 ft bgs) for potential surface soil exposure pathways and receptors, and exposed to subsurface soil (1 to 10 ft bgs or 1 to 2 ft bgs in wetland soils) for potential subsurface exposure pathways and receptors. Ecological receptors could be exposed to surface soil (0 to 1 ft bgs) for potential exposure pathways and receptors. Refer to Tables 10-1 through 10-4 or the selected human health risk assessment and ecological risk assessment potential exposure pathways and receptors.

As described above, areas of limited accessibility areas are anticipated at DU01, DU03, DU05, DU08, and DU17 due to steep terrain, heavy vegetation, or wetland/marsh conditions. At DU03 and DU08, wetland and marsh conditions paired with heavy vegetation may create inaccessible areas for a drill rig throughout the majority of the DU. At areas inaccessible for a drill rig due to steep terrain, sample locations may be off-set within the DU boundary or collected with a hand auger to shallower depths. In wetland areas, hand augers will be used to collect subsurface soil to the depth possible, to avoid damage to the wetlands. In general, the team expects that the maximum depth of hand-augering will be in the vicinity of 2 to 4 ft bgs. If unanticipated inaccessible areas are encountered during the Phase III RI field investigation (either horizontally or vertically), the sampling locations will be adjusted as necessary to ensure collection of the minimum number of samples.

Biased sample locations will be selected for the placement and construction of groundwater monitoring wells. Groundwater across the site and within the vicinity of DUs is considered to be generally spatially correlated, which allows a biased sampling design while still achieving a representative dataset.

11.6 Analytical Approach

The analytical approach for the planned Phase III RI field investigation includes specific "if… then…" statements to expand upon the study goals established earlier in this worksheet. These decision statements will guide the sampling design, and will be continually referenced by the team in evaluating the results of the investigation and proceeding with risk-based decisions.

Goal 1 – Collect a representative dataset for potentially impacted surface and subsurface soil associated with each of the individual DUs. Calculate EPCs to quantify potential risks.

- For each DU, design a uniform 0.5 to 1 acre geometric exposure area to encompass impacted surface and subsurface soil identified through prior investigations and the preliminary screening evaluation.
- Design an unbiased sampling grid consisting of a minimum of 15surface soil sampling locations and a minimum of 15 subsurface soil sampling locations, to generate a representative dataset for surface soil and subsurface soil, which will be suitable for statistical evaluation and calculation of EPCs.
- Collect a surface soil sample from a depth of 0 to 1 ft bgs, and collect a composited subsurface soil sample from a blended depth of 1 to 10 ft bgs (or 1 to 2 ft bgs in wetland soils), at DUs as specified in Worksheets #10 and #17, based on the preliminary screening evaluation. Specific analytes as specified in Worksheet #17 and may include SVOCs, PCBs, and metals, including Cr^{6+} and mercury. Per team agreements, depth-discrete subsurface soil sampling is not required; a composite subsurface soil sample is appropriate to assess potential risks from exposure to subsurface soil within that depth horizon.

- If Cr6+ or Hg are detected in soil during this Phase III RI filed investigation, and they pose unacceptable risks, they are considered as risk drivers for either human or ecological receptors, and they could be attributable to background conditions, then the team will consider sampling background locations where Cr^{6+} and Hg are potentially present.

- Anticipate areas of limited accessibility within selected DUs (refer to Figures 17-3 through 17-20) and design an appropriate sampling grid to avoid those areas. As described above, areas of limited accessibility are anticipated at DU01, DU03, DU05, DU08, and DU17 and appropriate sample grids have been designed. If unanticipated areas of limited accessibility are encountered during the Phase III RI field investigation (either horizontally or vertically), adjust the sampling locations as necessary to ensure collection of the minimum number of samples.

Goal 2 – Collect a representative dataset for surface water and sediment at a sitewide scale, as well as from exposure areas the vicinity of DUs that could potentially impact downgradient surface water and sediment. Calculate EPCs to quantify potential risks.

- Collect a sitewide network of sediment and surface water samples upstream of the DUs. Consider background/reference locations for revetted drainage channels, as well as background/reference locations for non-revetted drainage channels. Collect a minimum of 15 samples in background/reference sampling locations, which will be suitable for statistical evaluation and generation of sediment BTVs.

- Collect a minimum of 15samples from the near-vicinity of DUs that exhibit the potential for surface water or sediment impacts. Locations should consist of adjacent and downstream segments of drainage channels that are within or in the near-vicinity of DUs. If associated upstream samples are not already included in the background/reference surface water and sediment sampling locations, then collect local upstream samples in the near-vicinity of the DU. If sufficient water is in the drainage channel during the Phase III RI field investigation, then collect associated surface water samples at that particular sediment sampling location.

- Collect both filtered (dissolved) and unfiltered (total) surface water samples for metals (including Cr^{6+} and mercury) from both site and background locations for use during risk assessment and for refining the CSM. Filtered samples will be collected for organic parameter groups (SVOCs, PAHs, PCBs) in surface water when the turbidity is elevated (>10 NTU).

Goal 3 – Establish a representative groundwater monitoring well network and collect groundwater samples on a sitewide scale, as well as on a local scale in the vicinity of DUs that could potentially (or have been demonstrated to) have localized groundwater impacts.

- Select biased locations within the perched groundwater for additional groundwater monitoring wells on a sitewide scale. Include sufficient sitewide coverage to quantify perched groundwater flow directions and groundwater conditions across the site.

- Select biased locations for additional groundwater monitoring wells in the vicinity of DUs that could potentially (or have been demonstrated to) have localized groundwater impacts. Include sufficient coverage to assess upgradient, source area, and downgradient groundwater conditions.

- Construct all new monitoring wells with the appropriate total well depth and screen interval to enable well development and low-flow groundwater sampling per EPA guidelines.

- Collect total (unfiltered) and dissolved (filtered) groundwater samples for use in refining the groundwater CSM, with the exception of VOCs; field-filtering is not appropriate for VOCs.

Goal 4 – Collect additional physical and chemical data to support the CSM, risk assessments, and FS.

- Collect the required field parameters (pH, DO, ORP, temperature, and specific conductance) during groundwater monitoring well development and sampling per low-flow sampling guidance to assess groundwater stability prior to sampling.

- Analyze for TOC in sediment samples and hardness in surface water samples to support the ecological risk assessment.

- Collect hexavalent chromium (Cr^{6+}) data at 10% of samples analyzed for metals in all media to assess what, if any, fraction of total chromium is present in the more toxic Cr^{6+} form. The analysis of Cr^{6+} is an exercise to verify the absence of Cr^{6+}. The Cr^{6+} data can be used to generate ratios of hexavalent to total chromium, which can then be used in the HHRA and ERA, rather than defaulting to the conservative presumption that all chromium could be Cr^{6+}.

- Analyze additional geochemical parameters (pH and ORP) for samples that will be analyzed for Cr^{6+}, to validate the analytical results relative to field conditions.

- Analyze for selected geochemical and MNA parameters in groundwater to support the CSM, as well as to evaluate the potential for MNA in the FS.

- Collect physical/geotechnical characteristics of soil and groundwater, including hydraulic conductivity and soil permeability, to support potential LNAPL response actions in the FS.

11.7 Performance Criteria

The selection of performance criteria is based on potential sources of study error (i.e., field error, analytical error), methods that will be applied to reduce the potential sources of error, and an approach on how team decisions will be managed relative to potential occurrences of error.

Sources of Error

For this field program, sources of error consist of two main categories: sampling errors and measurement errors. A sampling error occurs when the sampling design, planning, and implementation do not provide for a representative range of heterogeneity at the site. A measurement error occurs when there is a performance variance from laboratory instrumentation, analytical methods, and/or operator error. EPA identifies the combination of all these errors as a "total study error" (EPA 2006). For this Phase III RI field investigation, the team has prepared this SAP to reduce (and essentially eliminate) the potential for total study error by documenting the DQOs, decision strategy, sampling design, analytical requirements, and other details, all of which provide team alignment with the study objectives and goals.

Managing Decision Error

This investigation will use decision-error minimization techniques in sampling design, sampling methodologies, and laboratory measurement of constituents of potential concern. Possible decision errors will be minimized during the Phase III RI field investigation by using the following methods:

- Use standard field sampling methodologies (as discussed in Worksheets #14, #18, and #21).
- Use applicable analytical methods and standard operating procedures (SOPs) for sample analysis by a competent analytical laboratory having state appropriate National Environmental Laboratory Accreditation Program accreditation, and be accredited through the DoD Environmental Laboratory Accreditation Program.
- Confirm analytical data to identify and control potential laboratory error and sampling error by using matrix spikes, blanks, and duplicate samples.

Decision Error

Decision errors associated with judgmental sampling are based on sample design and measurement errors. Assuming that the best possible professional judgment was used to develop the judgmental sampling plan (e.g., selection of sampling locations, depths, and analytical parameters), remaining decisions and opportunities to mitigate potential errors will be associated with field decisions on refined sampling locations and depths, managing insufficient groundwater yields or quality, managing and packaging analytical samples, and managing analytical results through the data validation process and statistical analysis to derive EPCs and conduct risk assessments. Analytical data will be considered acceptable if they meet the appropriate data validation criteria presented in Worksheet #34, 35, and 36. Estimates of the mean within a DU or exposure area will be calculated using ProUCL software to obtain a 95% upper confidence limit (UCL) on the arithmetic mean (alpha = 0.05). Data from within DUs or exposure areas will be evaluated relative to background conditions using hypothesis testing with alpha set at 0.05 to limit the potential for Type I (false positive) errors.

11.8 Analytical Laboratory Sample Management

The sample matrix, number of samples, and number and type of laboratory quality assurance and quality control (QA/QC) samples are summarized in the "Sample Details Tables" of this SAP. Details on the analytical group, sample volumes, sample container specifications, preservation requirements, and maximum holding times are identified in Worksheets #19 and #20 of this SAP.

The laboratory will provide staged electronic data deliverable (SEDD) files, as specified below, which will be compatible with the EQuiS database. Additionally, the laboratory will provide portable document format (PDF) files of the data deliverables for all project data and a hard copy of data deliverables for all results including results from secondary subcontract laboratories. The team may also consider requesting uncensored results from the laboratory as a separate electronic deliverable for selected methods. Designated samples will be used to obtain necessary subsamples for laboratory QC measurements, which includes analytical sample duplicate and sample matrix spike/matrix spike duplicate (MS/MSD). Tasks will be completed using the laboratory SOPs. AECOM will provide data validation services and verify and evaluate the usability of the data as identified in Worksheets #31 through #37.

PDF copies of all analytical data packages will be stored on CD-ROM, archived in the Administrative Record, and uploaded to the FUDSChem Database. All other data generated in the field and reports generated for the project will be stored as computer readable data files by AECOM and the native files will be provided to USACE.

11.9 Staged Electronic Data Deliverable (SEDD) File Specifications

The laboratory will provide SEDD version 5.2 Stage 2a files for the project. The SEDD files will comply with the EPA published specifications, be in extensible mark-up language (XML) and be provided on a sample delivery group (SDG) basis.

The USACE Automated Data Review (ADR) web-based program will be used for this project. AECOM will provide the contract laboratory (Eurofins Laboratories) with a project specific ADR electronic Quality Assurance Project Plan (eQAPP) for their review. The laboratory will utilize the eQAPP to verify compliance of the laboratory SEDD files prior releasing the SEDD files.

The SEDD files will consist of project and laboratory QC samples. The ADR program will check for format and content compliance. ADR will perform an automated data review of the project samples including but not limited to: holding times: sample temperature upon laboratory receipt; laboratory and field blank contamination; and accuracy and precision of laboratory control samples, MS/MSD, surrogates, field duplicates, and laboratory duplicates. ADR will produce validation outlier reports and assign qualifiers; the reports and qualifiers will be reviewed and approved by the AECOM project chemist.

Worksheet #12.1: Measurement Performance Criteria – Field Quality Control (QC) SAMPLES

QC Sample	Analytical Group	Frequency	Data Quality Indicators (DQIs)	Measurement Performance Criteria (MPC)
Equipment Rinsate Blank	VOCs, SVOCs, PCBs, metals/mercury, hexavalent chromium	One per 10 samples per matrix per sampling equipment	Accuracy/Bias/ Contamination	No analytes > ½ Limits of Quantification (LOQ)
Field Duplicate	VOCs, SVOCs, PCBs, metals/mercury, hexavalent chromium	One per 10 field samples	Precision	Relative Percent Difference (RPD) ≤ 30 for aqueous samples or ≤ 50 for solid samples if both results are ≥2 x LOQ
Trip Blank	VOCs	One per cooler	Accuracy/ Bias/ Contamination	No target analytes ≥ ½ LOQ (>LOQ for common laboratory contaminants), unless target analytes in field samples are > 10x those in trip blank.
Cooler Temperature Indicator	VOCs, SVOCs, Metals and Mercury (total and dissolved), PCBs, hexavalent chromium	One per cooler	Representativeness	Temperature must be above freezing and ≤ 6 ˚C.
Matrix Spike/ Matrix Spike Duplicate	VOCs, SVOCs, PCBs, metals/mercury, hexavalent chromium	One pair per 20 field samples	Accuracy/Bias/ Precision	See Worksheet #28 for percent recoveries and RPDs RPD ≤30

Notes:

(1) Collect only if non-dedicated, non-disposable equipment is used.

This page intentionally left blank.

Worksheet #14: Summary of Project Tasks

The following project tasks are to be performed as a part of the Camp Hero Phase III RI field investigation, as summarized below:

- Field Tasks
- Analytical Tasks
- Data Management and Review
- Report Preparation

Field Tasks

The following subsections present field tasks that will be completed as part of the Phase III RI field investigation at Camp Hero. All field tasks will be completed following the SOPs listed in Worksheet #21 and provided in Appendix I.

Personnel Qualifications – As established in the Accident Prevention Plan/Site Safety and Health Plan (APP/SSHP), personnel mobilized to the site will meet applicable Occupational Safety and Health Administration (OSHA) training including hazardous waste operations and emergency response training, medical surveillance requirements, and First Aid/automated external defibrillator/cardiopulmonary resuscitation certification.

The Site Safety and Health Officer (SSHO) will have completed the 30-hour OSHA General Industry or Construction Industry Safety Class, as specified in Engineering Manual (EM)-385 (USACE, 2014). The SSHO will be responsible for managing, implementing, and enforcing the health and safety program in accordance with the accepted APP. The SSHO will be a competent person that can identify existing and predictable hazards in the working environment or working conditions that are dangerous to personnel, and who has authorization to take prompt corrective measures to eliminate them.

The Site Supervisor (SS) will have completed the 8-hour OSHA SS training, as specific in EM-385. The SS will lead field operations, coordinate field activities, and act as the liaison between site and laboratory personnel, among other responsibilities. The Unexploded Ordnance (UXO) Technician II will have the appropriate level of training and experience as stated in Department of Defense Explosives Safety Board (DDESB) Technical Paper 18.

Site-Specific Training – As part of the mobilization process, site-specific training for on-site personnel will be conducted by the SSHO prior to performance of work. Site-specific training will include, but is not limited to, Ordnance Recognition Training to identify potential explosive hazards and react appropriately, by all employees and the subcontract employees. **Stop work authority will be used immediately if ordnance or Chemical Warfare Materiel (CWM) is suspected.**

Training will be provided by the SSHO and the other project staff, as required. The purpose of this training is to ensure that personnel fully understand the operational procedures and methods to be used at Camp Hero, individual duties and responsibilities, and safety and environmental concerns associated with the planned investigation activities.

Digital and paper copies of required project documents will be maintained on site for reference. Site workers, whether arriving at the start of the project or rotating on site as a substitution for another employee, will not be allowed to conduct their daily field operations without receiving site-specific training, reviewing the required documents, and signing off that they have reviewed, understood, and will follow the project SAP.

Site Coordination – In accordance with project kick-off meetings, anticipated work hours will be 0700 to 1900. All Phase II activities conducted under this RI WP will be coordinated with the Camp Hero State Park Superintendent Tom Dess to ensure activities do not impact park visitors and seasonal work restrictions. Additionally, activities under this RI WP will be coordinated with the State Historic Preservation Officer and other interested parties and stakeholders, in accordance with Section 106 of the National Historic Preservation Act of 1996, as amended and 36 CFR 800.

Site Visit – Prior to the initiation of intrusive field work, the team will conduct a site visit to mark out the locations of the discrete soil samples and lay out the sampling locations for the unbiased sampling grids. Selected locations will be marked in the field and coordinates will be recorded using a Global Positioning System (GPS) receiver capable of sub-meter accuracy (Trimble). Obstructions that limit access will be noted and contingent locations identified. The mark out of the locations will be utilized for utility clearance (described below).

Mobilization/Demobilization – The team will schedule the arrival of its workforce, and subcontracted workforce, in a manner that is most effective and designed to allow immediate productivity. Personnel mobilized to the site will meet the OSHA training and medical surveillance requirements specified in the APP. As part of the mobilization process, site-specific training for on-site personnel will be performed.

UXO Anomaly Avoidance – Based on a UXO probability analysis completed by USACE Baltimore District, it has been determined that the Camp Hero site activities have a low probability of encountering munitions and explosives of concern (MEC), except for areas H and K, which will not be entered at any point during RI field activities. Anomaly avoidance will be conducted in accordance with EM 385-1-97 during subsurface investigations. "Anomaly avoidance" is defined as the avoidance of surface MEC and any subsurface anomalies where the specific activity can be moved to another location. A UXO Technician II will conduct anomaly avoidance during RI field activities. The UXO Technician II will have the appropriate level of training and experience as stated in DDESB Technical Paper 18.

Additionally, all field personnel, including project staff, site visitors, and subcontractors, will complete Ordnance Recognition Training prior to the start of field activities. **Stop work authority will be used immediately if ordnance or Chemical Warfare Materiel (CWM) is suspected and the team leader will call 911 to notify authorities.** It should be noted that anomaly avoidance is only applicable to MEC hazards. The CWM Design Center in Huntsville will provide guidance for the potential of encountering CWM.

Brush Clearing and Rare Plant Survey – Portions of Camp Hero are significantly overgrown with vegetation, which will have to be removed to access sample locations and install permanent monitoring wells. To facilitate access, hand tools and mechanized equipment will be used to trim the overgrowth of vegetation along the site access roads and clear paths to the sampling locations. Only small shrubs and brush will be cleared; no hardwood trees. Cut brush will be left on site in the general vicinity of its generation. The vegetation will be cleared prior to the initiation of field activities.

Additionally, a botanist will survey areas needing vegetation removal prior to removal activities, to flag endangered or rare species, including the southern arrowwood. The removal of snags will be avoided, and no large a hardwood trees will be cleared, defined as a tree with greater than or equal to a 3 in diameter, to ensure protected habitat for the endangered Northern long-eared bat and preserve potential bird nesting. Clearing will be minimized to the maximum extent practicable. Also, because many sample locations are near streams, the team will take measures to avoid and minimize impacts to streams and riparian wetlands. Any ruts which may be created when crossing wet areas will be removed.

The team has also coordinated with Julie Lundgren (NY Natural Heritage Program of SUNY ESF in partnership with NYS Office of Parks, Recreation and Historic Preservation), the NYSDEC, and the United States Fish and Wildlife Services (USFWS), whom are providing guidance on the known occurrence of rare, threatened, or sensitive species in the vicinity of the RI field and appropriate protection measures. The field team will sweep the path ahead of the drill rig or other equipment at all sampling locations to check for box turtles or other significant species.

Utility and Subsurface Structure Clearance – Per AECOM-Tidewater JV and USACE policies, utility clearance is required for all intrusive work, regardless of planned intrusive depth. Prior to intrusive activities, the Site Supervisor is responsible for marking-out planned intrusive locations and contacting DigSafe per New York (Long Island) pre-notification requirements. Precautionary measures (e.g., geophysical survey, hand-digging to 5 feet, etc.) are required if utility clearance is not confirmed. Lack of confirmation can include urban locations, areas adjacent to roadways, areas not previously assessed, areas with insufficient utility information, or areas with multiple utility lines. The location of utilities will be noted and recorded during the site visits and referenced when selecting investigation locations. Utility Clearance will be conducted in accordance with *SOP 3-01: Utility Clearance* (Appendix I).

<u>Field Instrument Calibration and Quality Control</u> – Equipment, regardless of source, will be checked to ensure its completeness and operational readiness. Any equipment found damaged or defective will be returned to the point of origin, and a replacement will be secured. Instruments and equipment that require routine maintenance and/or calibration will be checked initially upon arrival and then prior to use each day, if needed to support that day's operations. See *SOP 3-20: Operation and Calibration of a PID* (Appendix I) for more details.

This system of checks ensures that the equipment is functioning properly. If an equipment check indicates that any piece of equipment is not operating correctly and field repair cannot be made, the equipment will be tagged and removed from service, and a request for replacement equipment will be placed immediately. Replacement equipment will meet the same specifications for accuracy and precision as the equipment removed from service.

<u>Community Air Monitoring</u> – Community air monitoring will be performed in accordance with the New York State Department of Health Generic Community Air Monitoring Plan (CAMP), Attachment 1A of the NYSDEC Division of Environmental Remediation-10 Technical Guidance for Site Investigation and Remediation (refer to Appendix H). Air monitoring activities will be implemented to protect the community from any potential airborne releases that could result from field activities associated with the RI or remedial action efforts as necessary (NYSDEC 2010).

The field personnel will monitor their breathing zones during project activities using a PID when working at AOCs potentially contaminated with petroleum hydrocarbons and organic solvents. An action level for respiratory protection has been established at 5 ppm as averaged over a 15-minute time period. If this limit is exceeded, work will stop and the SSHO and PM will determine how to proceed. See *SOP 3-20: Operation and Calibration of a PID* (Appendix I) for more details.

<u>Permanent Monitoring Well Installation</u> – Approximately 22 permanent monitoring wells will be installed during the Phase III RI field investigation. Monitoring wells will be installed by a driller licensed by the State of New York via sonic drilling methods. An exclusion zone will be established with cones surrounding the drilling operation. The drilling team will slip a sheet of plastic under the sonic drill rig and pull it up around the tracks to act as a containment barrier. The sonic drill will be

advanced through a tub or surface casing at the ground surface. A 4-inch core barrel and a 6-inch override casing will be utilized to core and case through to the borehole target depth. Soil within each 5-foot long core barrel will be extruded from the core barrel into a plastic sleeve. The plastic sleeve will be placed horizontally on clean plastic for logging and sampling purposes. The geologist will measure to the bottom of the boring within the 6-inch override casing to insure the inside casing is open and clear to the bottom of the borehole.

An unused 2-inch diameter milled slot PVC screen and casing will be installed to the bottom of the borehole. Sand pack will be placed in lifts as the drilling crew pulls the casing back to expose the well screen. The borehole above sand pack will be sealed with 2 feet of bentonite chips. The remaining annular space between the well casing and the 6-inch override casing from the top of the sand pack to the ground surface will be pressure grouted with a bentonite/ cement grout using a tremie pipe. The remaining 6-inch diameter sonic casing will be pulled from the ground. Vibration will be applied to the casing as it is pulled to densify and degas the grout, as well as knit the grout into the borehole wall, creating a superior seal. IDW will be contained and transported to the IDW storage area.

The SSHO will provide oversight of the subcontractor performing Sonic drilling, continuous soil core collection, and monitoring well installation. The geologists will perform soil logging in accordance with USCS and develop the monitoring wells. See *SOP 3-12: Monitoring Well Installation* for more details.

Concrete coring will be conducted prior to drilling at sampling locations situated in concrete covered areas. A 4-inch diameter core barrel will be advanced through the concrete using a stand mounted core drill to access soils for direct push sampling. The core drill will be anchored to the concrete surface either by vacuum or lag bolts during drilling. All cores will be wet drilled and water and slurry will be vacuumed as they are generated.

<u>Permanent Monitoring Well Development</u> – Permanent monitoring wells will be developed at least 24 hours after completion of well installation. Development will be completed by a combination of surging with a surge block and over-pumping with a submersible monsoon pump or Wattera pump and associated HDPE tubing, in accordance with *SOP 3-13: Monitoring Well Development* (Appendix I).

Water clarity will be visually monitored and water quality parameters, including dissolved oxygen (DO), specific conductivity (SC), ORP, pH, temperature, and turbidity will be measured using a flow-through cell per the SOP 3 24 (Water Quality Parameter Testing for Groundwater Sampling) every 5 minutes during purging to determine progress of development. The multi-parameter water quality meter will be calibrated initially and continually throughout its usage each day, as needed. A calibration check will be performed at the end of each day. Each well will be developed until the well produces clear (silt-free) water with a minimum of 3 stable water quality readings as outlined below:

- pH – within ± 0.2 units.
- DO – within ± 10%
- SC – within ± 3 percent (%).
- ORP – within ± 10 millivolts.
- Temperature – within ±1 degree Celsius.
- Turbidity – at or below 10 nephelometric turbidity unit (NTU) or within ± 10% if above 10 NTU.

If the well has slow groundwater recharge and is purged dry, the well will be considered developed when bailed or pumped dry three times in succession and the turbidity has decreased. If any water is added to the well's borehole during development or drilling, three times the volume of water added will also be removed during well development.

Reusable sampling equipment will be properly decontaminated after each use in accordance with *SOP 3-06*. Excess soil or groundwater generated will be containerized, managed and disposed of as IDW. See *SOP 3-13: Monitoring Well Development* for more details.

<u>Soil Sample Collection</u> – Soil samples will be collected from both permanent monitoring well borings, soil boring locations, and surface soil sample locations. At permanent monitoring well locations, a Sonic Drill Rig will be used to collect continuous soil cores to the target depth. At soil boring locations, a Direct Push drill rig will be used. The target depth is specified for each location in Worksheet #17 of this Phase III RI SAP. Concrete coring will be necessary prior to boring at locations with asphalt or cement. The continuous soil sampling will be accomplished by advancing a 5-ft (60-inch) coring barrel. The soil core will be screened for VOCs immediately upon opening the sleeve with a PID. Details regarding the air monitoring procedures and specific action levels are provided in the APP (AECOM-Tidewater JV, 2017c). The soil core will be logged for descriptions by a field geologist. Observations and measurements will be recorded on a soil boring log. At a minimum, depth interval, recovery thickness, PID concentrations, moisture, relative density, color (using a Munsell soil color chart), and texture using the Unified Soil Classification System (USCS) will be recorded. Additional observations to be recorded may include detectable odors, groundwater or perched water depth, organic material, cultural debris, or color changes indicating staining. See *SOP 3-16: Soil and Rock Classification* and *SOP 3-17: Direct Push Sampling Techniques* for more details.

Two soil samples will generally be collected from each boring location unless otherwise specified in the RI WP Addendum. Surface soil samples are considered to be 0 to 1 ft bgs, while subsurface surface samples from unbiased DU grids will be a composite sampled from 1 to 10 ft bgs (or 1 to 2 ft bgs in wetland areas). VOC samples will be collected directly from the recently-exposed soil using a sampling corer (Encore sampler, Terra Core, or equivalent) and in accordance with *SOP 3-21: Surface and Subsurface Soil Sampling* . For other analyses, soil will be removed and transferred to a disposable, re-sealable plastic bag. The sample will then be homogenized, which will consist of mixing the soil until the sample is a uniform color, texture, and particle size. Any non-homogenous particles, organic matter, and projectile debris will be removed from the samples. After homogenization, the sample will be transferred to the appropriate sample container for laboratory analysis and placed in a cooler on ice. The required sample containers, preservatives, and holding times are specified in the QAPP (Appendix B). Sample locations will be marked with a pin flag with sample identification number, photo-documented, and recorded with a hand-held global positioning system. See *SOP 3-21: Surface and Subsurface Soil Sampling* for more details.

At locations where only surface soil samples will be collected, a clean (decontaminated) coring device will be utilized, unless soils are not cohesive, in which case certified clean, disposable sample scoops will be used. Samples will be collected via the same methodology as collecting samples from the soil cores. Non-disposable sampling equipment (i.e., hand auger) will be decontaminated between sample locations according to the procedures in Section 3.16 and *SOP 3-06: Decontamination Procedures*. An equipment blank will be collected from the hand auger for analysis of VOCs only.

<u>Soil Permeability Sample Collection (Shelby Tubes)</u> –Shelby tubes will be collected by the drillers at preselected locations as outlined in Worksheet #17. Each sample will be collected in a 3-inch outer diameter Shelby tube following American Society for Testing and Materials (ASTM) D1587/D1587M. Once the sample has been recovered, the total length will be recorded to the nearest inch and logged on the side of the tube, the borehole log, and the field book. Prior to sealing, approximately 1-inch of material will be removed from the lower end of the tube. The tubes will be sealed on both ends using either expandable packers or waxed wood discs/caps. Electrical tape will be used to seal the caps to the tube. The tubes will be stored in laboratory-provided containers to ensure the tubes are shipped in an upright position. Geotechnical parameter results do not require data validation and are therefore not listed in the analytical worksheets of this RI SAP.

<u>Surface Water and Sediment Sample Collection</u> – Co-located surface water and sediment samples will be collected from permanent, intermittent, revetted, and non-revetted stream exposure areas throughout Camp Hero. Surface water samples will be collected first at each location, prior to sediment sampling. Surface water samples should not be collected directly following a rain event. Every effort will be made to collect surface water samples after several days without precipitation

so that samples will represent baseflow conditions. Sampling will occur from downstream to upstream in locations where surface flow direction can be clearly identified; agitation of the sediment and water at shallow locations will be minimized. Physical characteristics of the sampling locations (e.g., water depth, stream width, etc.) will be documented.

All surface water samples will be analyzed for SVOCs, metals (total and dissolved), and hardness; select surface water locations may be analyzed for additional parameters, depending on the exposure area CSM (refer to Worksheet #17). Filtered surface water samples will be collected for organic parameters (SVOCs, PAHs, PCBs) when the turbidity is elevated (>10 NTU). Filtered samples will be analyzed for metals only (including Cr^{6+} [in 10% of samples] and mercury) as the dissolved phase represents the more bioavailable fraction of metals in the water column for aquatic receptors.

For unfiltered surface water samples, water will be dipped from the source or pumped from the source using a peristaltic pump with disposable tubing and placed into the appropriate laboratory-supplied bottleware containing chemical preservatives, if necessary. For filtered surface water samples, individual disposable single-sample Nalgene vacuum filters or a peristaltic pump with clean, disposable tubing and in-line filters will be used to field-filter water samples. Water will be dipped/pumped from the source and pumped through the filter into the laboratory-supplied bottleware. Each filter will be used once and discarded as non-hazardous waste.

At the end of surface water sampling, field parameters including oxidation-reduction potential, pH, specific conductance, salinity, temperature, dissolved oxygen, and turbidity will be measured with a water quality meter and recorded in the field logbook or sampling form.

Once surface water sampling is complete, sediment samples will be collected from 0 to 0.5 ft bgs using a hand-driven coring barrel with disposable acetate or PVC liner or a clean, disposable scoop. Sediment samples should target fine grained material from depositional areas. All sediment samples will be analyzed for SVOCs, metals, and total organic carbon (TOC); select locations may be analyzed for additional parameters, depending on the exposure area CSM (refer to Worksheet #17). Ten percent of the sediment samples will be analyzed for hexavalent chromium.

Material such as twigs, leaves, and stones will be removed from the samples prior to homogenization and documented in the field log or field forms. Sediment samples will be homogenized in disposable bags prior to filling laboratory-supplied sample containers. Sample jars will be labeled with the appropriate information, placed in a Ziploc bag, and stored in a cooler containing bagged ice to maintain a preservation, as appropriate.

Surface water and sediment sampling locations will be flagged in place and depicted in the field logbook for use during land surveying. Additionally, at each location the depth of water and width of channel will be recorded. Refer to *SOP 3-10 Surface Water and Liquid Sampling* and *SOP 3-22 Sediment Sampling* (Appendix I) for additional details.

Groundwater Sample Collection – Permanent monitoring wells will be sampled at least 72 hours after completion of well development, which is a deviation from the 24-hour wait period referenced in *SOP 3-14: Groundwater Sampling* (Appendix I). The "72 hour window" deviation from the SOP is being adopted in an effort to obtain representative groundwater sample, allow for recently developed wells to equilibrate, and hopefully further reduce turbidity/suspended colloidal content of groundwater samples.

Groundwater levels will be measured in each well prior to sampling using a water level meter (Solonist or equivalent). The monitoring wells will be purged using low-flow sampling techniques using a bladder or peristaltic pump and disposable tubing in accordance with SOP-3-14. Water clarity will be visually monitored and water quality parameters, including dissolved oxygen, SC, ORP, pH, temperature, and turbidity will be measured using a flow-through cell per the SOP 3 24 (Water Quality Parameter Testing for Groundwater Sampling). Readings will be collected every 5 minutes until the well produces clear (silt-free) water with a minimum of 3 stable water quality readings, as outlined above in the Well Development procedures. The multi-parameter water quality meter will be calibrated initially and continually throughout its usage each day, as needed. A calibration check will be performed at the end of each day.

Once the water quality parameters reach stabilization, samples will be collected in laboratory-supplied bottleware for the parameters established in Worksheet #17. Both total (unfiltered) and dissolved (filtered) samples will be collected for SVOCs, PCBs, and metals (including Cr^{6+} and mercury). Filtered samples will be field-filtered using a clean, disposable in-line filter. Ferrous iron (Fe^{2+}) will be analyzed in the field according to the procedures outlined below. The pH of dissolved and total Cr^{6+} samples will be adjusted according to the procedures outlined below. Non-disposable sampling equipment will be decontaminated between each well. *See SOP 3-14: Monitoring Well Sampling* and *SOP 3-24: Water Quality Parameter Testing* for more details.

Hexavalent Chromium Analysis – The pH of groundwater and surface water Cr^{6+} samples (total and dissolved) will be adjusted in the field according to the following procedures:

- If possible, pour approximately 200 mL of the sample into the Chromium 6 sample bottle (roughly 1 inch from the lip). Repeatedly invert for 1 minute.

- Using the pipette, draw a portion of preserved sample and drop onto pH paper. DO NOT dip pH paper into bottle. Only use pH strip ONCE; DO NOT reuse the pH strip.
- Read the pH. The target pH is 9.5; the acceptable pH range is 9.3 to 9.7.
  - If the pH is too high (>9.7), add a small portion of unpreserved sample, invert for a minute, retest using the pipette and pH paper.
  - If the pH is too low (<9.3), add Ammonium Hydroxide/Ammonium Sulfate buffer one drop at a time to the bottle. Add ten drops, invert for a minute, and retest using the pipette and pH paper. Document total drops added.
- Tightly close bottle lid when target pH is achieved, complete documentation, and store in cooler.

Ferrous Iron Analysis – The concentration of ferrous iron (Fe^{2+}) in filtered and unfiltered groundwater samples will be analyzed in the field using the HACH DR890 Colorimeter and HACH Method 8146 according to the procedures in *SOP 3-18 Field Analysis of Ferrous Iron Using the HACH DR890 Colorimeter and HACH Method 8146* (Appendix I). Samples will be analyzed immediately after collection because Fe^{2+} readily oxidizes to ferric iron upon exposure to air.

Hydraulic Conductivity Measurement (Slug Tests) – Hydraulic conductivity will be calculated using slug testing. The slug testing will commence at least a week after installation and a significant enough time after developing and sampling to allow the well to return to equilibrium. Hydraulic conductivity will be conducted in accordance with *SOP 3-35 In-Situ Hydraulic Conductivity Testing via Rising or Falling Head Slug Testing*.

Field Quality Control Samples — Field QC samples will be collected as part of this investigation, including field duplicates (FDs), MS/MSDs, equipment blanks (EBs), trip blanks (TBs), and temperature blanks. FD samples will be collected at a rate of 10% and analyzed for the same parameters as the accompanying samples. MS and MSD samples will be collected at the rate of 5% and analyzed for the same parameters as the accompanying samples.

TBs will accompany each cooler containing samples for VOC analysis and will be analyzed for select VOCs. If non-dedicated sampling equipment is used, an EB will be collected and analyzed for whatever parameters were collected using the non-dedicated sampling equipment. A temperature blank shall be placed in each cooler to ensure that samples are preserved at or below four degrees Celsius during shipment.

Sampling Handling, Storage, and Transport – Samples will be stored on ice, packaged, and submitted to the analytical laboratory for analysis as specified in Worksheet #15. Worksheet #17 provides the soil sampling design and rationale. The combined Worksheets #18, 19, 20, and 30 provide sample identifications, necessary sample volume and preservative requirements, and hold time limitations. Samples will be quality-control checked by the Sample Manager (label correctness, completeness, etc.) and recorded on Chain-of--Custody forms. Samples will be packaged on ice and transported via overnight commercial carrier or a laboratory courier under standard chain-of-custody procedures to the laboratory. See *SOP 3-04: Sample Handling, Storage, and Shipping* (Appendix I) for additional information.

Field Documentation – Field documentation will be performed during this investigation in accordance with SOP 3-02. Sample collection information will be recorded in bound field notebooks, tablet computers, or specific field forms. A summary of field activities will be properly recorded in a bound logbook with consecutively numbered pages that cannot be removed. Logbooks will be assigned to field personnel and stored in a secured area when not in use. All entries will be written in indelible ink, and no erasures will be made. If an incorrect entry is made, striking a single line through the incorrect information will make the correction; and the person making the correction will initial and date the change. Sampling forms and other field forms will also be used to document field activities. See *SOP 3-02: Logbooks* (Appendix I) for additional information.

Borehole Abandonment – Direct push soil sample borings will be abandoned at completion of sampling activities. Borings in grass or sand will be abandoned by backfilling with bentonite chips. Borings in asphalt or concrete shall be abandoned by backfilling with bentonite chips to approximately 6 inches bgs, and the remainder of the borehole will be patched with asphalt cold patch or hydraulic concrete. The surface at each location will be restored to match the surrounding area. *See SOP 3-15: Monitoring Well and Borehole Abandonment* (Appendix I) for more details.

Equipment Decontamination — To the maximum extent possible, the team will utilize dedicated and disposable sampling equipment to avoid the potential for cross contamination of samples due to inadequate decontamination processes. The dedicated/disposable sampling equipment will include disposable polyethylene tubing, disposable gloves, and laboratory-supplied sample bottles.

Non-disposable or non-dedicated sampling equipment (e.g., bladder pumps, water level meters, water quality meters, etc.) will be decontaminated prior to sampling and between samples following AECOM SOPs. Cleaning of equipment is performed to prevent cross-contamination between samples and to maintain a clean working environment for all personnel. Decontamination will generally consist of a water rinse station to remove gross contamination (if needed), followed by a non-phosphate detergent (e.g., Liquinox) water rinse, and a rinse with de-ionized water (provided by the laboratory). For decontamination for samples collected for organics, a solvent rinse will be included (using pesticide-grade methanol or isopropyl alcohol) for non-disposable sampling equipment. Paper towels containing recycled paper content are prohibited. If smaller equipment is to be stored or transported, it will be wrapped in aluminum foil after air-drying. Decontamination activities will be performed in accordance with *SOP 3-06: Decontamination* (Appendix I).

Land Surveying – The horizontal and vertical position of soil sample locations (surficial and subsurface borings) and permanent monitoring wells will be surveyed by a state-registered surveyor to a horizontal accuracy of 0.1 ft and a vertical accuracy of 0.01 ft. These positions will be tied to a permanent benchmark located near the site, and referenced to the NAD83 (horizontal) and NAVD88 (vertical) datums. Land survey of subsurface sample locations will be conducted in accordance with applicable specifications. See *SOP 3-07: Land Surveying* (Appendix I) for more details.

Investigation-Derived Waste (IDW) Management — IDW generated during site field activities will be managed pursuant to applicable Federal, State, and local regulations and guidance, including the USEPA Management of Investigation-Derived Wastes during Site Inspections (USEPA 1992) and USACE guidance (2013). Refer to *SOP 3-05 Investigation-Derived Waste Management* (Appendix I) for procedures related to IDW management. Department of Transportation (DOT) compliant shipping containers will be used to stage IDW prior to off-site transport. Solid IDW (e.g., drill cuttings from boring/monitoring well installation that cannot be returned to the borehole of origin) will be stored in 55-gallon metal drums and/or a 10 cubic yard closed-top roll-off bin; liquid IDW (e.g., monitoring well development water, purge water, decontamination water) will be stored in frac tanks and/or 55-gallon metal drums. The Phase III RI field investigation is anticipated to generate approximately 3 to 4 tons of solid IDW and 2,000 to 3,000 gallons of liquid IDW.

The IDW containers will be properly labeled, sampled for waste characterization, and temporarily staged on-site at a designated secure location until waste characterization is completed. The IDW containers will subsequently be transported to the approved offsite disposal facility; the intended facility will confirm their acceptance of the waste prior to transport. IDW removal from the site will be documented by manifest or bill of lading prepared by the waste disposal subcontractor. Based on the team's understanding of this site and prior field investigations, only non-hazardous IDW is anticipated during this Phase III RI field investigation. Per the expectations in the HTRW Contract and Performance Work Statement (PWS) for this project, as well as per specific direction from USACE, an AECOM-Tidewater JV field representative will complete and sign the non-hazardous manifest or bill of lading on behalf of USACE. However, per discussions with USACE, if hazardous IDW is identified during this Phase III RI field investigation, then USACE will complete and sign the hazardous waste manifest per USEPA and NYSDEC requirements.

Analytical Tasks

AECOM's Project Chemist will track the samples from collection through analysis. Data deliverables will be provided by the laboratory within 15 business days of sample receipt. The laboratory will submit the Level II sample results in PDF via email. Final data deliverables will be submitted in pdf (bookmarked and searchable), and in electronic form using the SEDD version 5.2 Stage 2a format.

Analytical results from the final data deliverables will be reviewed according to the procedures in Worksheet #36. Only results from final data deliverables will be formally validated. ADR will perform an automated data review of the project samples including but not limited to: holding times: sample temperature upon laboratory receipt; laboratory and field blank contamination; and accuracy and precision of laboratory control samples, MS/MSD, surrogates, field duplicates, and laboratory duplicates. ADR will produce validation outlier reports and assign qualifiers; the reports and qualifiers will be reviewed and approved by the AECOM project chemist. The validated data will then be loaded into the AECOM database.

Report Preparation

Following the completion of data collection, laboratory analysis, and data validation, a comprehensive RI Report per CERCLA guidance will prepared. The results of the site characterization will documented in a RI Report, including the Phase I, Phase II, and Phase III RI field investigations. The RI report will present the methods used for the RI, the updated CSM resulting from the investigation, the results of the risk assessment, and a determination of whether further remedial action is needed.

Additionally, the RI Report will include the following elements:

- Restatement of program goals.
- Summary of field investigation conducted (e.g., sampling dates, soil samples collected, wells sampled, parameters analyzed, field procedures, etc.).
- Tables summarizing the samples collected and sample analytical data.
- Figures showing the layout of each sampling area, updated site features, results of geophysical surveys, soil boring locations, and summaries of pertinent analytical results.
- Data validation/QA/QC discussion.
- Deviations from the initial SAP and/or SAP modification.

Notes:
The laboratory limits for Limit of Quantitation (LOQ), Limit of Detection (LOD), and Method Detection Limit (MDL) and the control limits for LCS/MS/MSD (laboratory control sample/matrix spike/matrix spike duplicate) were obtained from Eurofins Lancaster Laboratories (2017) and are meant to be recommended project values. The limits presented above reflect the most recently promulgated values reported by the laboratory.
[1] The highlighted PSLs are not analytically achievable; the LOD will be used as the PSL for non-detects.

mg/kg = milligrams per kilogram
mV = millivolts
NA = not available
The risk-based screening levels used as part of the PSL selection process include the following human health and ecological screening levels listed below:
(a) The lowest of the human health risk-based screening levels are taken from the following sources:
Res Soil RSL - USEPA Regional Screening Levels (RSLs) for Residential Soil that are protective of a target cancer risk of 1E-06 and a target hazard quotient of 0.1 (USEPA 2016a), with updated PAH RSLs calculated from recently-released updated benzo[a]pyrene toxicity values (USEPA 2017).
The following surrogates (in parentheses) were used to derive RSLs for the following chemicals: Acenaphthylene (acenaphthene); benzo(g,h,i)perylene (pyrene); carbazole (fluorene); dimethyl phthalate (diethyl phthalate); methylcyclohexane (cyclohexane): 3/4-Methylphenol (lower of m-cresol and p-cresol); PCB-1262 (PCB-1260); PCB-1268 (PCB-1260); and phenanthrene (anthracene). The hexavalent chromium RSL was used to select limits for chromium that are protective of all forms of chromium that may be present at the site.
NYCRR Res SCO - 6 NYCRR Part 375-1 Remedial Program Residential Soil Cleanup Objectives (SCOs), Table 6.8(b) Residential values (NYCRR 2015).
NYSDEC SCL - NYSDEC CP-51 Soil Cleanup Guidance Soil Cleanup Levels (SCLs) for Gasoline and Fuel Oil, Tables 2 and 3 (NYSDEC 2010a).
NYSDEC Sup Res SCO - NYSDEC CP-51 Soil Cleanup Guidance Supplemental Residential SCOs, Table 1 (NYSDEC 2010a).
http://www.dec.ny.gov/docs/remediation_hudson_pdf/cpsoil.pdf
(b) Ecological screening values were selected from the following sources (parentheses indicate receptor to which the risk-based screening level applies):
Eco-SSL - Ecological Soil Screening Levels (Eco-SSLs) derived by USEPA according to USEPA guidance (2007). Individual Eco-SSL documents are available here - http://www.epa.gov/ecotox/ecossl/

Oxydation Reduction Potential	ORP	NA	--	--	--	--	--	--

Notes:
The laboratory limits for Limit of Quantitation (LOQ), Limit of Detection (LOD), and Method Detection Limit (MDL) and the control limits for LCS/MS/MSD (laboratory control sample/matrix spike/matrix spike duplicate) were obtained from Eurofins Lancaster Laboratories (2017) and are meant to be recommended project values. The limits presented above reflect the most recently promulgated values reported by the laboratory.

[1] The highlighted PSLs are not analytically achievable; the LOD will be used as the PSL for non-detects.

mg/kg = milligrams per kilogram
mV = millivolts
NA = not avilable
The risk-based screening levels used as part of the PSL selection process include the following human health and ecological screening levels listed below:
(a) The lowest of the human health risk-based screening levels were selected from the following sources:
Res Soil RSL - USEPA Regional Screening Levels (RSLs) for Residential Soil that are protective of a target cancer risk of 1E-06 and a target hazard quotient of 0.1 (USEPA 2016a), with updated PAH RSLs calculated from recently-released updated benzo[a]pyrene toxicity values (USEPA 2017). Also, the soil cancer and non-cancer RSLs were multiplied by a factor of 10 to generate sediment RSLs.
The following surrogates (in parentheses) were used to derive RSLs for the following chemicals: Acenaphthylene (acenaphthene); benzo(g,h,i)perylene (pyrene); carbazole (fluorene); dimethyl phthalate (diethyl phthalate); methylcyclohexane (cyclohexane): 3/4-Methylphenol (lower of m-cresol and p-cresol); PCB-1262 (PCB-1260); PCB-1268 (PCB-1260); and phenanthrene (anthracene).
The hexavalent chromium RSL was used to select limits for chromium that are protective of all forms of chromium that may be present at the Site.
(b) Ecological risk-based screening levels were selected based on the following sources:
DEC Sed - New York State Department of Environmental Conservation, 2014. Screening and Assessment of Contaminated Sediment, June.
EPA R4 - USEPA Region 4. 2015. Supplemental Guidance to RAGS: Region 4 Bulletins, Ecological Risk Assessment.

Worksheet #15.3 Reference Limits and Evaluation for Groundwater

		Project Screening Levels [1]		Achievable Laboratory Limits			Precision and Accuracy Method Performance Criteria, Percent	
Analyte	CAS Number	Value	Source	LOQ	LOD	MDL	LCS/MS/MSD Recovery Limits	LCS/MS/MSD Precision Maximum RPD

Notes:
The laboratory limits for Limit of Quantitation (LOQ), Limit of Detection (LOD), and Method Detection Limit (MDL) and the control limits for LCS/MS/MSD (laboratory control sample/matrix spike/matrix spike duplicate) were obtained from Eurofins Lancaster Laboratories (2017) and are meant to be recommended project values. The limits presented above reflect the most recently promulgated values reported by the laboratory.
[1] The highlighted PSLs are not analytically achievable; the LOD will be used as the PSL for non-detects.

ug/l = micrograms per liter
NA = not available
Ecological receptors are not exposed to groundwater so ecological risk-based screening levels were not included in the PSL selection process.
(a) The lowest of the human health risk-based screening levels were selected from the following sources:
Tapwater RSL - USEPA RSLs for Tap Water that are protective of a target cancer risk of 1E-06 and a target hazard quotient of 0.1 (USEPA 2016a), with updated PAH RSLs2017).
calculated from recently-released updated benzo[a]pyrene toxicity values (USEPA
The following surrogates (in parentheses) were used to derive RSLs for the following chemicals: Acenaphthylene (acenaphthene); benzo(g,h,i)perylene (pyrene); carbazole (fluorene); dimethylphthalate (diethylphthalate); ethane (n-hexane); ethene (n-hexane); methane (n-hexane); methylcyclohexane (cyclohexane); 3/4-Methylphenol (lower of m-cresol and p-cresol); PCB-1262 (PCB-1260), PCB-1668 (PCB-1260); phenanthrene (anthracene); and p-isopropyltoluene (cumene).
The hexavalent chromium RSL was used to select limits for chromium that are protective of all forms of chromium that may be present at the Site.
MCL - USEPA Maximum Contaminant Levels (MCLs) (USEPA 2009).
VISL - USEPA Residential Vapor Intrusion Screening Levels (VISLs) (USEPA 2016b). Residential VISLs were derived using a target cancer risk of 1E-6, target hazard quotient of 0.1, and an average groundwater temperature of 9.2 C (per Phase II Camp Hero groundwater monitoring well data).
TOGS 1.1.1 - New York State Technical and Operational Guidance Series (TOGS), 1.1.1. Groundwater Effluent Limitations, Table 5 (Class GA), dated June 1998, January 1999 Errata, April 2000 Addendum, and June 2004 Addendum (NYDEC 1998, 1999, 2000, and 2004).

Worksheet #15.4 Reference Limits and Evaluation for Surface Water

		Project Screening Levels [1]		Achievable Laboratory Limits			Precision and Accuracy Method Performance Criteria, Percent	
Analyte	CAS Number	Value	Source	LOQ	LOD	MDL	LCS/MS/MSD Recovery Limits	LCS/MS/MSD Precision Maximum RPD

Notes:
The laboratory limits for Limit of Quantitation (LOQ), Limit of Detection (LOD), and Method Detection Limit (MDL) and the control limits for LCS/MS/MSD (laboratory control sample/matrix spike/matrix spike duplicate) were obtained from Eurofins Lancaster Laboratories (2017) and are meant to be recommended project values. The limits presented above reflect the most recently promulgated values reported by the laboratory.
[1] The highlighted PSLs are not analytically achievable; the LOD will be used as the PSL for non-detects.
ug/l = micrograms per liter
NA = not available
The risk-based screening levels used as part of the PSL selection process include the following human health and ecological screening levels listed below:
(a) The lowest of the human health risk-based screening levels were selected from the following sources:
Tapwater RSL - USEPA RSLs for Tap Water that are protective of a target cancer risk of 1E-06 and a target hazard quotient of 0.1 (USEPA 2016a), with updated PAH RSLs calculated from recently-released updated benzo[a]pyrene toxicity values (USEPA 2017). Also, the Tap Water cancer and non-cancer RSLs were multiplied by a factor of 10 to generate surface water RSLs.
The following surrogates (in parentheses) were used to derive RSLs for the following chemicals: Acenaphthylene (acenaphthene); benzo(g,h,i)perylene (pyrene); carbazole (fluorene); dimethylphthalate (diethylphthalate); 3/4-Methylphenol (lower of m-cresol and p-cresol); PCB-1262 (PCB-1260), PCB-1268 (PCB-1260); and phenanthrene (anthracene).
The hexavalent chromium RSL was used to select limits for chromium that are protective of all forms of chromium that may be present at the Site.
NRWQC (hh) - USEPA National Recommended Water Quality Criteria - Human Health Criteria that are protective of the consumption of water and organisms (USEPA 2015).
TOGS 1.1.1 (hh gv) - New York State TOGS, 1.1.1. Ambient Water Quality Standards and Guidance Values, Table 1 GA Guidance Values (NYDEC 1998, 1999, 2000, and 2004).
(b) Ecological risk-based screening levels were selected based on the following sources:
DEC Sed - New York State Department of Environmental Conservation, 2014. Screening and Assessment of Contaminated Sediment, June
TOGS 1.1.1 (aq) - New York State Department of Environmental Conservation, 1998. Ambient Water Quality Standards and Guidance Values and Groundwater Effluent Limitations, Division of Water Technical and Operational Guidance Series (TOGS) 1.1.1, June.
NRWQC (aq) - USEPA, 2009. National Recommended Water Quality Criteria. Hardness dependant criteria adjusted to default hardness of 100 mg/L as $CaCO_3$.
EPA R4 - USEPA Region 4. 2015. Supplemental Guidance to RAGS: Region 4 Bulletins, Ecological Risk Assessment.

Worksheet #16: Project Schedule/Timeline Table

The following table presents a summary of the RI schedule, including the RI WP and Addendums , field investigations (Phases I, II, and III), and reporting schedule.

Activities	Dates		Deliverable
	Anticipated Date(s) of Initiation	Anticipated Date of Completion	
Prepare RI WP, SAP (with QAPP), and APP (with SSHP)	December 2015	July 2016	RI WP
RI Field Operations – Phase I	May 2016	June 2016	Phase I Field Investigation Report
Laboratory Analysis	July 2016	August 2016	None
RI WP Addendum – Phase II	November 2016	December 2016	RI WP Addendum – Phase II
RI Field Operations – Phase II	November 2016	December 2016	Phase II Field Investigation Report
Laboratory Analysis	December 2016	January 2016	None
RI WP Addendum SAP – Phase III	February 2017	May 2017	RI SAP – Phase III
RI Field Operations – Phase III	May 2017	June 2017	Phase III Field Investigation Report
Laboratory Analysis	June 2017	July 2017	None
Prepare RI Report	March 2017	December 2017	RI Report

Worksheet #17: Sampling Design and Rationale

17.1 Overview

This worksheet provides the proposed sampling design and rationale based on the CSMs summarized in Worksheet #10 and the DQOs established in Worksheet #11. This worksheet is supported with 4 tables (Tables 17-1 through 17-4) and 20 figures (Figures 17-1 through 17-20). The proposed field investigation is a "Phase III" RI field investigation that is specifically designed to complete the RI phase of the CERCLA process, as well as to provide data to support risk-based decisions and the subsequent sitewide FS. The results of this field investigation will be used to refine the CSMs for the individual DUs established at the site, as well as to provide a sitewide depiction of groundwater, surface water, and sediment through a representative sitewide network of groundwater monitoring wells and surface water and sediment sampling locations.

Analytical parameters have been selected based on parameters that exceed the preliminary screening evaluation (refer to Appendix E), the CSM for each DU relative to additional parameters that could be present but have not yet been analyzed, and data needs for the FS, such as geochemical and MNA parameters. For simplicity, analytical parameter groups warranting further analysis are referred to as VOCs, SVOCs, PCBs, and metals in this worksheet. Refer to Worksheet #15 for specific details on the parameter groups and specific parameters selected for this Phase III RI field investigation. Refer to Worksheet #10 for the CSM and identification of data needs, refer to Worksheet #11 for the DQOs established to achieve project objectives, and refer to Tables 17-1 through 17-4 for the specific sampling rationale and analytical parameters for each location and each medium.

Project Screening Levels (PSLs) have been selected based on potentially relevant regulatory screening values applicable to the media being sampled (soil, subsurface soil, groundwater, surface water, and sediment), and the potential exposure pathways and receptors identified for human health and ecological risk assessment (refer to Tables 10-1 through 10-4). Analytical requirements to achieve project objectives and support the quantification of potential risks are detailed in Worksheet #15. The proposed locations of samples to be collected as part of this Phase III RI field investigation are shown on Figures 17-1 through 17-20. The following subsections provide the specific sampling design and rationale for the selection of sampling locations, depths, and distribution.

17.2 Field Measurements and Data Collection

Field measurements and data collection will consist of observations and measurements, such as geologic logs, ambient air measurements, low-flow sampling parameters, recording of GPS coordinates, and recording of survey data. These observations and measurements will be documented in the field, organized, stored, and uploaded into the project folders and database (as required). Senior review of recorded information will be conducted and sample information will be transcribed into a field logbook, tablet computer, and/or onto field logs and datasheets.

Measurement devices will be calibrated prior to use and per the required periodic frequency dictated by the equipment manufacturer/vendor. Devices are expected to include a PID, hand-held global positioning system (GPS unit), water quality meters, and dust meters.

17.3 Unbiased Sampling Grid Approach

The prior phases of this RI consisted of biased discrete sampling within potential source areas to support the nature and extent of site impacts, define general locations of impacted media, conduct a preliminary screening evaluation, and select parameters for further assessment. With the completion of the preliminary screening evaluation (Appendix E), the team has identified potential risk exposure scenarios and pathways and the need to generate EPCs. A total of 21 AOCs, plus 6 segments of the WDS AOC, warrant further assessment based on the results of the preliminary screening evaluation (Appendix E). Contiguous AOCs warranting additional sampling were grouped into 18 geometric DUs for the Phase III investigation. The team will be implementing an unbiased sampling grid approach (different from the majority of prior investigation phases) to generate robust EPCs for the selected DUs and associated exposure areas and depths. The sampling design for an unbiased sampling grid can consist of an array of discrete samples or an ISM technique. In either case, the resulting EPCs for each DU will provide reasonable values with which to compare to risk-based screening criteria and complete risk assessments under CERCLA.

For this project, the team has elected to collect discrete samples rather than applying ISM techniques. Both approaches would provide data with which to calculate EPCs and quantify potential human health and ecological risks. An ISM approach, however, may not differentiate site impacts within each DU because only blended samples from each DU would be analyzed by the laboratory. The differentiation of site impacts within each DU is required to refine the nature and extent of contamination during the RI, as well as to define more precise boundaries of potential response actions during the FS, if warranted. In addition, the background datasets and resulting BTVs for soil that were generated for Camp Hero are based on discrete sampling. It would be inappropriate to compare ISM-based site results to discrete-based BTVs.

For these reasons, the sampling design for this Phase III RI field investigation will include an unbiased grid of discrete samples, with a sample size of a minimum of 15 samples per media, per DU. This approach will provide data for EPC calculations, as well as allow for comparisons to the existing BTVs. It will also further define the specific areas within DUs that pose impacts, and provide DU-specific datasets for use in assessing contaminant fate and transport, conducting the FS, and supporting site response actions. Consistent with team decisions, a minimum of 15 samples will be collected and analyzed for each DU to calculate EPCs for impacted site media. Also consistent with team decisions, DUs are established as geometric exposure areas, either 0.5 acres or 1 acre in size to best reflect the respective CSMs and expected distribution of site impacts. As shown on Figures 17-3 through 17-20, unbiased sampling grids within the DUs will consist of 16 sampling locations for each DU, greater than the 15 point minimum sample size to generate robust and representative EPCs for each of the DUs. Refer to the media-specific text provided in this worksheet for further details on the sampling design for each medium.

17.4 Derivation of Exposure Point Concentrations

EPCs will be calculated for surface and subsurface soil, groundwater, surface water, and sediment. Calculated EPCs will be equal to the 95% UCL on the arithmetic mean concentration or the maximum concentration, whichever is lower (USEPA, 2002c).

The most current version of ProUCL available at the time the risk assessments are started will be used to calculate the ProUCL-recommended 95% UCL. Consistent with the recommendations presented in the ProUCL guidance (USEPA, 2015c) regarding minimum sample size and frequency of detection, UCLs will be calculated where at least 10 samples and at least 6 detects are available. When the minimum sample size and number of detects are not met for a dataset, or if the UCL is greater than the maximum detected concentration, the maximum detected concentration will be used as the EPC.

Soil EPCs will be calculated for each individual DU and may also be calculated on a sitewide or a localized basis, if needed, to evaluate potential human or ecological exposures. Future excavation activities may result in the subsurface soil being brought to the surface and "mixed" with the surface soil. Therefore, total soil (0 to 10 ft bgs) EPCs for human health will be calculated by combining the surface and subsurface soil data sets for each COPC. The total soil EPC will be calculated as a volume-weighted EPC that accounts for the different sampling depths for the surface (0 to 1 ft bgs) and subsurface (1 to 10 ft bgs) horizons. A volume-weighted total soil 95% UCL will be derived by calculating separate surface soil and subsurface soil UCLs within a DU and adjusting them by a factor of 0.1 (10%) and 0.9 (90%), respectively.

For eight DUs, the preliminary screening evaluation (Appendix E) indicated that concentrations in the subsurface horizon were below residential screening levels and BTVs and did not warrant further sampling. Therefore, in those DUs, the un-biased sampling grid will only represent samples from the 0 to 1 ft bgs horizon and an alternate approach for the total soil EPC will be warranted. Based on the CSMs and the initial screening results, it is anticipated that the surface soil will be more contaminated than the sub-surface soil in these DUs. A conservative initial estimate of the total soil exposure for the construction worker and resident will be evaluated assuming that the 0 to

1 ft bgs EPC is representative of total soil. If no unacceptable risks are identified with this evaluation, then no additional evaluation is warranted. If unacceptable risks are identified, additional evaluation will be conducted considering the available Phase I subsurface soil data and the associated uncertainties will be discussed in the HHRA.

Surface water and sediment EPCs may be calculated on an exposure area-basis or may be calculated for a particular stream channel (e.g., primary north-south channel and tributaries) or stream type (e.g., channels with and without wooden revetments).

Groundwater EPCs will be calculated using data collected from the sitewide well network. In general, one round of data will be available from each monitoring well. The exception will be for DU01 which will have two rounds of data available for the determination of EPCs. Groundwater data from each well will be individually evaluated to identify COPCs and each well will be evaluated separately in the HHRA. The team may also elect to calculate EPCs for localized sets of monitoring wells to assess potential AOC-related impacts (e.g., petroleum at Building 203) or on a site-wide basis.

17.5 Surface Soil Sampling

For each DU, the team has established a uniform 0.5 to 1 acre geometric exposure area to encompass impacted surface soil identified through prior investigations and the preliminary screening evaluation. Within each DU boundary, surface soil samples will be collected from an unbiased grid to develop a representative surface soil dataset, which will be suitable for statistical evaluation and calculation of EPCs. The depth of surface soil samples will be 0 to 1 ft bgs, which is consistent with the potential human health and ecological exposure pathways and receptors associated with surface soil (refer to Tables 10-1 through 10-4). The team has identified a minimum of 15 surface soil samples as the appropriate number of unbiased grid samples to be sent for laboratory analysis. This range of samples is expected to generate a robust and representative dataset for each of the DUs. Relative to presenting and implementing the sampling grids, the team is proposing 16 evenly spaced sampling locations for each DU.

Inaccessible areas are expected to occur within selected DUs (refer to Figures 17-3 through 17-20). The sampling grid will be designed to avoid those areas. If unanticipated inaccessible areas are encountered during the Phase III RI field investigation, the specific sampling locations will be adjusted as necessary to ensure collection of the minimum required set of samples.

Analytical parameters for surface soil will vary by DU based on the parameters that exceeded the preliminary screening evaluation (refer to Appendix E), and the CSM for each DU relative to additional parameters that could be present but have not yet been analyzed. Cr^{6+} will be analyzed in 10% of samples analyzed for metals to assess what, if any, fraction of total chromium is present in the more toxic Cr^{6+} form. Additional parameters for surface soil samples will include pH and ORP for samples that will be analyzed for Cr^{6+}, to validate the analytical results relative to field conditions. Refer to Table 10-5 for a summary of data needs for each DU, and refer to the sampling rationale table, Table 17-1, for more specific analytical details relative to the surface soil sampling design.

17.6 Subsurface Soil Sampling

At DUs warranting additional subsurface soil sampling based on the preliminary screening evaluation (Appendix E), the same 0.5 to 1 acre geometric exposure area established for surface soil will be used for the subsurface soil sampling grid. The team's objective is to provide both surface and subsurface soil data from the same exposure area for use in cumulative risk assessment calculations, as well as for total soil (combined surface and subsurface soil) quantification if desired.

At each subsurface soil sampling location, the entire 1 to 10 ft bgs subsurface depth horizon (or 1 to 2 ft bgs in wetland areas) will be composited for laboratory analysis. Per team agreements, depth-discrete subsurface soil sampling is not required; a composite subsurface soil sample is appropriate to assess potential risks from exposure to subsurface soil within that depth horizon (refer to Tables 10-1 through 10-4). Similar to the surface soil sampling design, the team is proposing 16 evenly spaced sampling locations for DUs warranting subsurface soil sampling. This range of samples is expected to generate a robust and representative dataset for each of the DUs.

Also similar to the surface soil sampling design, areas of limited accessibility are expected to occur within selected DUs (refer to Figures 17-3 through 17-20). The sampling grid will be designed to avoid those areas. If unanticipated areas of limited accessibility are encountered during the Phase III RI field investigation (either horizontally or vertically due to steep terrain, boulders or other structural impedances), the specific sampling locations will be adjusted as necessary to ensure collection of the minimum required set of samples, as described in Worksheet #11 (Section 11.5).

Analytical parameters for subsurface soil will vary by DU based on the parameters that exceeded the preliminary screening evaluation (refer to Appendix E), the CSM for DUs warranting subsurface soil sampling relative to additional parameters that could be present but have not yet been analyzed, and data needs for the FS, such as geochemical parameters. Cr^{6+} will be analyzed in 10% of samples analyzed for metals to assess what, if any, fraction of total chromium is present in the more toxic Cr^{6+} form. Additional parameters for subsurface soil samples will include pH and ORP for samples that will be analyzed for Cr^{6+}, to validate the analytical results relative to field conditions.

Additionally, the field data collection requirements at DU01 include analysis of soil permeability to support the evaluation of potential LNAPL response actions. The data collection requirements were developed based on review of guidance documents EM 1110-1-4010 Multi-Phase Extraction (USACE, June 1999) and Evaluating LNAPL Remedial Technologies for Achieving Project Goals (ITRC, December 2009). Three representative core samples (Shelby tubes) of subsurface soils (2 from the silty-sand, perched water bearing soil zone and 1 from a clay unit) will be submitted for laboratory analysis of soil permeability. In the event that an LNAPL response action is part of the selected remedy at DU01, additional testing can be considered during a pre-design investigation (PDI) or pilot-scale treatability study during the post-Decision Document (DD) implementation phase of the CERCLA process. Geotechnical parameters will not require data validation so are not included in the analytical worksheets. Refer to Table 10-5 for a summary of data needs for each DU, and refer to the sampling rationale table, Table 17-1 for more specific analytical details relative to the subsurface soil sampling design.

17.7 Surface Water and Sediment Sampling

The team will collect a representative dataset for surface water and sediment at a sitewide scale, as well as from exposure areas in the vicinity of DUs that could potentially impact downgradient surface water and sediment. The objective of this sampling is to provide a dataset for use in calculating EPCs to quantify potential risks and to assess the nature and extent of potential site impacts within both revetted and non-revetted drainage channels. A sitewide network of sediment and surface water samples will also be collected upstream of the DUs . These locations are within revetted drainage channels, as well as within non-revetted drainage channels. The team will collect approximately 30 samples from sitewide upstream locations (15 from revetted channels and 15 from non-revetted channels), which will be suitable for statistical evaluation and generation of surface water and sediment BTVs. The proposed surface water and sediment sampling locations for the Phase III RI field investigation are shown on Figure 17-1.

For DUs that could potentially impact downgradient surface water and sediment, the team will collect samples within exposure areas along a linear stretch of the nearby drainage channel, with a minimum of 15 samples per exposure area, spanning the upstream, adjacent, and downstream portions of the channel relative to the nearest DU. In several locations (refer to Figure 17-1), upstream surface water and sediment samples will be further upstream of the DU, as part of the sitewide background/reference sampling locations. Similar to all planned surface water and sediment sampling locations, if sufficient water is in the drainage channel during the Phase III RI field investigation, then the team will collect associated surface water samples at that particular sediment sampling location. Otherwise, only sediment will be collected from that location.

Analytical parameters for surface water and sediment will be consistent for sitewide background/reference sampling locations, but may vary by DU based on the parameters that exceeded the preliminary screening evaluation (refer to Appendix E), and the CSM for each DU relative to additional parameters that could be present but have not yet been analyzed. Both total (unfiltered) and dissolved (filtered) samples will be collected for metals (including Cr^{6+} and mercury) at all surface water locations. Filtered surface water samples will also be collected for organic parameters (SVOCs, PAHs, PCBs) at locations where the surface water turbidity is elevated (>10 NTU). Cr^{6+} will be analyzed in 10% of samples analyzed for metals to assess what, if any, fraction of total chromium is present in the more toxic Cr^{6+} form. Additional geochemical parameters will include hardness for surface water and TOC for sediment, to support the ecological risk assessment, and pH and ORP for samples that will be analyzed for Cr^{6+}, to validate the analytical results relative to field conditions. Refer to Table 10-5 for a summary of data needs on a sitewide basis and for each exposure area, and refer to the sampling rationale table, Table 17-2 for more specific analytical details relative to the surface water and sediment sampling design.

17.8 Groundwater Sampling

Existing groundwater monitoring wells were installed at 15 background locations, as well as 6 locations in the vicinity of DU01 (Former Building 203). To achieve project objectives, an expanded network of groundwater monitoring wells will be established to collect groundwater samples on a sitewide scale, as well as on a local scale in the vicinity of DUs that could potentially (or have been demonstrated to) have localized groundwater impacts.

The team will select biased locations in perched groundwater for additional groundwater monitoring wells on a sitewide scale, as well as at a DU-specific scale. This will include sitewide sufficient coverage to quantify perched groundwater flow directions and groundwater conditions across the site. The rationale for the location and construction of each proposed monitoring well is provided on Table 17-3, and the design of the expanded groundwater monitoring well network (existing and proposed wells) is shown on Figure 17-2. The rationale for the analytical sampling protocol at each proposed monitoring well is provided on Table 17-4.

Each new well will be constructed with the appropriate total well depth and screen interval to enable well development and low-flow groundwater sampling per EPA guidelines. Both total (unfiltered) and dissolved (filtered) samples will be collected for SVOCs, PCBs, and metals (including Cr^{6+} and mercury), if collected. It is not appropriate to field-filter samples for VOCs. Fe^{2+} will be analyzed in the field. Refer to Worksheet #14 for groundwater sampling procedures and to the groundwater sampling rationale table, Table 17-4, for more groundwater specific analytical details.

All existing and new groundwater monitoring wells will be sampled, with the exception of the 15 background wells that were previously sampled to generate groundwater BTVs. This includes re-sampling the 6 wells at DU01, Former Building 203 Area, for a second round of groundwater data associated with known petroleum impacts in that area. Groundwater levels will be measured at all existing and new groundwater monitoring wells, including the 15 background wells, to support the groundwater flow evaluation and mapping.

Analytical parameters for groundwater will be consistent for sitewide groundwater monitoring wells, but may vary for wells in the near vicinity of selected DUs based on the parameters that exceeded the preliminary screening evaluation (refer to Appendix E), and the CSM for each DU relative to additional parameters that could be present but have not yet been analyzed. As indicated in the subsurface soil sampling design section, AOCs AST 35/FPH, STB, and MP revealed potential petroleum impacts during grab groundwater sampling. As such, groundwater monitoring wells will be installed in these areas for further field confirmation of the presence or absence of site impacts. Groundwater samples will be analyzed for the same parameters as selected for the petroleum-related DUs (e.g., DU01, Former Building 203 Area).

Additionally, the field data collection requirements at DU01 include analysis of hydraulic conductivity to support potential LNAPL response actions and preliminary remedial technology screening. The data collection requirements were developed based on review of guidance documents EM 1110-1-4010 Multi-Phase Extraction (USACE, June 1999) and Evaluating LNAPL Remedial Technologies for Achieving Project Goals (ITRC, December 2009). Hydraulic conductivity will be calculated using slug testing at five wells within the suspected dissolved-phase plume associated with the LNAPL at DU01.

Cr^{6+} will be analyzed in 10% of samples analyzed for metals to assess what, if any, fraction of total chromium is present in the more toxic Cr^{6+} form. Additional geochemical parameters will include pH and ORP for samples that will be analyzed for Cr^{6+}, to validate the analytical results relative to field conditions. Additionally, a subset of groundwater monitoring wells (approximately 20%) will be selected for analysis of an expanded parameter list to assess the potential for MNA, potential for specific chemical oxidation states, and potential fate and transport properties. These additional parameters will consist of biochemical oxygen demand, total oxygen demand, total organic carbon, Fe^{2+} (field analysis), chlorides, sulfates and sulfides, nitrates and nitrites, alkalinity, methane, ethane, and ethene. Calcium, potassium, and sodium will also be included to support this data need; however, these compounds are already included in the groundwater sampling list of parameters as part of metals analysis. Refer to Table 10-5 for a summary of data needs on a sitewide basis and for each DU, and refer to the sampling rationale table, Table 17-4 for more specific analytical details relative to the groundwater sampling design.

Worksheet #18: Sampling Locations and Methods/SOP Requirements Table

The soil, groundwater, sediment, and surface water sampling locations are presented in Worksheet #17, with associated tables and figures. See Worksheet #19 for additional details on analytical methods and SOPs. See Worksheet #21 for additional details on project sampling procedures including SOPs.

This page intentionally left blank.

Worksheet #19: Analytical SOP Requirements Table

Worksheet #19 is used to provide the project-specific sample containers, preservation, and holding time requirements. Sample containers will be certified pre-cleaned according to EPA protocols. The purity of preservation chemicals will be guaranteed by the manufacturer.

Field sampling personnel will obtain sample containers from vendors who specialize in environmental sampling supplies and will inspect them prior to use. Containers that have not been pre-cleaned according to EPA protocols or do not meet the requirements of Worksheet #19 will not be used and will be discarded. Each sample will be collected into a new, unused container.

Matrix	Analytical Group	Analytical and Preparation Method/SOP Reference	Containers (Number, Size, and Type)	Preservation Requirements (Chemical, Temperature, Light Protected)	Maximum Holding Time (Preparation/ Analysis)

No. of Sample Locations See Worksheet # 18

QC Sample	Frequency/ Number	Method / SOP QC Acceptance Limits	Corrective Action	Person(s) Responsible for Corrective Action	Data Quality Indicator (DQI)	Measurement Performance Criteria
Surrogate Spike	Per sample (including MS/MSD, LCS, and Blanks)	Recovery limits per QSM 5.0. Laboratory statistical limits for surrogates not in QSM 5.0	Reanalyze samples if outside limits. If confirmed, report with a comment. If blank or LCS surrogates are outside limits, reanalyze. If still outside limits evaluate the instrument and spiker unit before proceeding.	ELLE Analyst	Accuracy	Results within acceptance limits
Method blanks	1 per prep batch of up to 20 samples	No analytes detected > 1/2 LOQ or >1/10 the amount measured in any sample	If the MB contains target analytes and the associated samples do not, corrective action is not required. If sample detects are10x the blank value data can be reported. Otherwise reanalyze samples after a clean MB is obtained.	ELLE Analyst	Accuracy/Laboratory Contamination	No analytes detected > 1/2 LOQ or >1/10 the amount measured in any sample

No. of Sample Locations See Worksheet # 18

QC Sample	Frequency/Number	Method / SOP QC Acceptance Limits	Corrective Action	Person(s) Responsible for Corrective Action	Data Quality Indicator (DQI)	Measurement Performance Criteria
Method Blank	1 per prep batch of up to 10 samples	No analytes detected > 1/2 LOQ or >1/10 the amount measured in any sample	Reanalyze blank to confirm detections. If detects confirm, redigest samples that are not ND or not >20x the blank value.	ELLE Analyst	Accuracy/Laboratory Contamination	No analytes detected > 1/2 LOQ or >1/10 the amount measured in any sample
MS/MSD	1 per prep batch of up to 10 samples	Recovery limits per QSM 5.0; RPD ≤20%	Flag outliers	ELLE Analyst	Accuracy/Bias/Precision	Results within acceptance limits
LCS/LCSD	1 per prep batch of up to 10 samples	Recovery limits per QSM 5.0; RPD ≤20%	Analytes in the LCS that fail high and are ND in the samples can be reported. All others are re-digested and reanalyzed.	ELLE Analyst	Accuracy/Bias/Precision	Results within acceptance limits
Duplicate	1 per 10 samples	RPD must be ≤20%	Flag data	ELLE Analyst	Precision	Results within acceptance limits

Worksheet #28.13: QC Samples Table

Matrix Solid
Analytical Group Metals - Hg
Concentration Level Low
Sampling SOP See Worksheet #21
Analytical Method/ SOP Reference 7471A/B
Sampler's Name TBD
Field Sampling Organization AECOM
Analytical Organization Eurofins Lancaster Laboratories Environmental, LLC (ELLE)
No. of Sample Locations See Worksheet # 18

QC Sample	Frequency/Number	Method / SOP QC Acceptance Limits	Corrective Action	Person(s) Responsible for Corrective Action	Data Quality Indicator (DQI)	Measurement Performance Criteria

Worksheet #34, 35, and 36: Data Verification and Validation (Steps IIa and IIb) Process Table

Data Review Input	Description	Responsible for Verification	Step I/IIa/IIb(1)
Verification Chain-of-custody forms Sample Login/Receipt	Review the sample shipment for completeness, integrity, and sign accepting the shipment. All sample labels will be checked against the chain-of-custody form, and any discrepancies will be identified, investigated, and corrected. The samples will be logged in at every storage area and work station required by the designated analyses. Individual analysts will verify the completeness and accuracy of the data recorded on the forms. Verification of sample login/receipt and chain-of-custody forms will be documented on the laboratory sample receipt form.	Laboratory sample custodians and analysts	I
Verification Chain-of-custody forms	Check that the chain-of-custody form was signed/dated by the sampler relinquishing the samples and by the laboratory sample custodian receiving the samples for analyses.	Project Chemist or Data Validators	I
Verification SAP sample tables	Verify that all proposed samples listed in the SAP tables have been collected. Sample completeness will be documented in the data validation report.	Site Supervisor or Designee	I
Verification Sample log sheets and field notes	Verify that information recorded in the log sheets and field notes are accurate and complete. Sample log sheet verification will be documented by dated signature on the last page or page immediately following the review material.	Site Supervisor or Designee	I
Verification Field QC samples	Check that field QC samples, described in Worksheet #12 and listed in Worksheet #18,19,20,30 were collected as required. QC sample completeness will be documented in the data validation report.	Site Supervisor or Designee	I
Verification Analytical data package	All analytical data packages will be verified internally for completeness by the laboratory performing the work. The laboratory project manager (or designee) will sign the case narrative for each data package. All laboratory data package reviews will be documented in the laboratory narratives.	Laboratory Project Manager	I
Verification Analytical data package	Verify the data package for completeness. Missing information will be requested from the laboratory and validation (if performed) will be suspended until missing data is received. Data package completeness will be documented in the data validation report.	Site Supervisor, Project Chemist or Data Validators	I
Verification Electronic data deliverables	Verify the electronic data against the chain-of-custody and hard copy data package for accuracy and completeness before loading into project database. Electronic data deliverable verification will be documented.	Data Manager and/or Data Validators	I
Validation Chain-of-custody	Examine the traceability of the data from time of sample collection until reporting of data. Ensure that the custody and integrity of the samples were maintained from collection to analysis and that custody records are complete and any deviations are recorded. Chain-of-custody verification will be documented in the data validation report.	Project Chemist or Data Validators	IIa

Worksheet #34, 35, and 36: Data Verification and Validation (Steps IIa and IIb) Process Table (Continued)

Data Review Input	Description	Responsible for Verification	Step I/IIa/IIb(1)
Validation Holding Times	Review that the samples were shipped and stored at the required temperature, meeting the requirements listed in Worksheet #18,19,20,30. Ensure that the analyses were performed within the holding times. If holding times were not met, confirm that deviations were documented. Holding time examination will be documented in the data validation report.	Project Chemist or Data Validators	IIa
Validation Sample results for representativeness	Check that the laboratory recorded both the temperature at sample receipt and the pH of the chemically preserved samples (if applicable) to ensure sample integrity was sustained from sample collection to analysis. Representativeness will be documented in the data validation report.	Project Chemist or Data Validators	IIa/IIb
Validation Laboratory data results for accuracy	Ensure that the laboratory QC samples were analyzed and that the measurement performance criteria, listed in Worksheet #28, were met for all field samples and QC analyses. Check that specified field QC samples were collected and analyzed, as listed in Worksheet #12, and that the analytical QC criteria were met. Accuracy will be documented in the data validation report.	Project Chemist or Data Validators	IIa/IIb
Validation Field and laboratory duplicate analyses for precision	Check the field sampling precision by calculating the RPD for field duplicate samples. Check the laboratory precision by reviewing the RPD or percent difference values from laboratory duplicate analyses; MS/MSDs; and LCS/LCS duplicates. Ensure compliance with the precision goals listed in Worksheets #12 and #28. Precision will be documented in the data validation report.	Project Chemist or Data Validators	IIa/IIb
Validation Project action limits	Assess and document the impact on matrix interferences or sample dilutions performed because of the high concentration of one or more contaminant on the other target compounds reported as undetected. Project action limit achievement will be documented in the data validation report.	Project Chemist or Data Validators	IIa/IIb
Validation Data quality assessment report	Summarize deviations from methods, procedures, or contracts. Qualify data results based on method or QC deviation and explain all the data qualifications. Present tabular qualified data and data qualifier codes and summarize data qualification outliers. Determine if the data met the MPC and determine the impact of any deviations on the technical usability of the data. Result qualification will be documented in the in the data validation report.	Project Chemist or Data Validators	IIa/IIb
Validation SAP QC sample documentation	Ensure that all QC samples specified in the SAP were collected and analyzed and that the associated results were within acceptance limits. QC sample documentation will be documented in the data validation report	Project Chemist or Data Validators	IIa/IIb
Validation Analytical data deviations	Determine the impact of any deviation from sampling or analytical methods, and laboratory SOP requirements and matrix interferences effect on the analytical results. Data deviations will be documented in the data validation report.	Project Chemist or Data Validators	IIb

Notes:
1. IIa=compliance with methods, procedures, and contracts [see Table 10, page 117, Uniform Federal Policy for Quality Assurance Project Plans (UFP-QAPP) manual, V.1, March 2005.]
2. IIb=comparison with measurement performance criteria in the SAP [see Table 11, page 118, UFP-QAPP manual, V.1, March 2005]

This page intentionally left blank.

The laboratory will provide SEDD version 5.2 Stage 2a for the project. The SEDD files will comply with the EPA published specifications, be in extensible mark-up language (XML) and be provided on a SDG basis.

The USACE ADR web-based program will be used for this project. AECOM will provide the contract laboratory (Eurofins Laboratories) with a project specific ADR eQAPP for their review. The laboratory will utilize the eQAPP to verify compliance of the laboratory SEDD files prior releasing the SEDD files.

The SEDD file will consist of project and laboratory QC samples. The ADR program will check for format and content compliance. ADR will perform an automated data review of the project samples including but not limited to: holding times: sample temperature upon laboratory receipt; laboratory and field blank contamination; and accuracy and precision of laboratory control samples, MS/MSD, surrogates, field duplicates, and laboratory duplicates. ADR will produce validation outlier reports and assign qualifiers.

This page intentionally left blank.

Worksheet #37: Data Usability Assessment

Summarize the usability assessment process and all procedures, including interim steps and any statistics, equations, and computer algorithms that will be used

AECOM will validate the fixed-laboratory data for all definitive analyses conducted. Validation will be conducted in accordance with the protocols described in Worksheets #34-36. These procedures are consistent with EPA National Data Validation Functional Guidelines. The Project Chemist, in conjunction with the project team, will determine whether the analytical data meet the requirements to support the investigation. The results of laboratory measurements will be compared to the data quality objectives described in Worksheet #11.

Describe the evaluative procedures used to assess overall measurement error associated with the project

A data assessment will be performed in accordance with USEPA guidance QA/G-9R, *Data Quality Assessment, A Reviewer's Guide* (EPA/240/B-06/002) dated February 2006. In accordance with USEPA guidance, a data assessment is intended to provide documentation to clearly demonstrate that the collected data are of the right type, quality, and quantity to meet the objectives of the project. A comprehensive evaluation of how the data meet precision, accuracy, representativeness, comparability, and completeness (PARCC) objectives will also be performed. All soil, sediment, surface water, and groundwater analytical data will be validated in-house and the data packages to be presented in the RI report.

The data usability assessment will reconcile the DQOs of this SAP to the results of the data collection and analytical results, data validation evaluation (as applicable), and field QC results.

Data quality indicators, such as precision, accuracy, completeness, representativeness, and comparability measurements, aid in the evaluation process and are discussed in the following subsections.

<u>Precision</u>

The most commonly used estimates of precision are the RPD for cases in which only two measurements are available and the percent relative standard deviation (%RSD) when three or more measurements are available. The latter is especially useful in normalizing environmental measurements to determine acceptability ranges for precision because it effectively corrects for the wide variability in sample analyte concentration indigenous to samples.

Precision is represented as the RPD between measurement of an analyte in duplicate samples or in duplicate spikes. RPD is defined as follows:

$$RPD = \frac{|C_1 - C_2|}{(C_1 + C_2)/2} \times 100$$

Where:

C1 = First measurement value

C2 = Second measurement value

The %RSD is calculated by the standard deviation of the analytical results of the replicate determinations relative to the average of those results for a given analyte. This method of precision measurement can be expressed by the formula:

$$\%RSD = \sqrt{\frac{\sum_{i=1}^{n} x_i^2 - \left[\sum_{i=1}^{n} x_i\right]^2 / n}{n - 1}} \times 100 / RF$$

Where:

RF = Response factor

N = Number of measurements

Precision control limits for evaluation of sample results are established by the analysis of control samples. The control samples can be method blanks fortified with surrogates (e.g., for organics), or LCS purchased commercially or prepared at the laboratory. The LCS is typically identified as blank spikes (BS) for organic analyses. For multi-analyte methods, the LCS or BS may contain only a representative number of target analytes rather than the full list.

The RPD for duplicate investigative sample analysis provides a tool for evaluating how well the method performed for the respective matrices.

Accuracy/Bias

Accuracy control limits are established by the analysis of control samples, which are water and/or solid/waste matrices. For organic analyses, the LCS may be a surrogate compound in the blank or a select number of target analytes in the BS. The LCS is subjected to all sample preparation steps. When available, a solid LCS may be analyzed to demonstrate control of the analysis for soil. The amount of each analyte recovered in an LCS analysis is recorded and entered into a database to generate statistical control limits. These empirical data are compared with available method reference criteria and available databases to establish control criteria.

The % R for spiked investigative sample analysis (e.g., matrix spike) provides a tool for evaluating how well the method worked for the matrix. These values are used by the USACE to assess a reported result within the context of the project DQOs. For results that are outside control limits provided as requirements in the SAP, corrective action appropriate to the project will be taken and the deviation will be noted in the case narrative accompanying the sample results. The %R is defined as follows:

$$\% R = \frac{(A_T - A_O)}{A_F} \times 100$$

Where:

AT = Total amount recovered in fortified sample

A0 = Amount recovered in unfortified sample

AF = Amount added to sample

Accuracy for some procedures is evaluated as the degree of agreement between a new set of results and a historical database or a table of acceptable criteria for a given parameter. This degree of agreement is measured as %D from the reference value and is primarily used by the laboratory as a means for documenting acceptability of continuing calibration.

The %D is calculated by expressing, as a percentage, the difference between the original value and new value relative to the original value. This method for precision measurement can be expressed by the formula:

$$\% D = \frac{C1 - C2}{C_1} \times 100$$

Where:

C1 = Concentration of analyte in the initial aliquot of the sample.

C2 = Concentration of analyte in replicate.

Completeness

Site-wide completeness goals account for all aspects of sample handling, from collection through data reporting. The level of completeness can be affected by loss or breakage of samples during transport, as well as external problems that prohibit collection of the sample. The following calculation is used for determining the percent complete:

$$\text{Completeness} = \frac{A}{B} \times 100$$

Where:

A = Number of usable data points.

B = Total number of data points collected.

The formula for sampling completeness is:

$$\text{Sampling Completeness} = \frac{\text{Number of locations sampled}}{\text{Number of planned sample locations}} \times 100$$

An example formula for analytical completeness is:

$$\text{VOC Analytical Completeness} = \frac{\text{Number of Usable Data Points}}{\text{Expected Number of Usable Data Points}} \times 100$$

The ability to meet or exceed completeness objectives is dependent on the nature of samples submitted for analysis.

The following table lists the completeness goals for a project. If the completeness goal is not met because of controllable circumstances, then the samples will be recollected and reanalyzed, as necessary, to meet the completeness objective. If the completeness goal is not met because of uncontrollable circumstances, such as inaccessible sample points, matrix interferences, etc., then the deficiency will be evaluated. Note that Project Completeness Goals apply separately to each study area environmental medium.

Project Completeness Goals

Task	Subtask	Completeness Goal
Sampling	Sample Collection	95% (per media)
Field Measurements	Conductivity	100% of collected samples (per media)
	pH/Turbidity/DO	100% of collected samples (per media)
Analytical Measurements	All Laboratory Analyses	95% of collected analytes (per media)
		80% of each target analyte (per media)

Representativeness

Data representativeness for a project is accomplished by implementing approved sampling procedures and analytical methods that are appropriate for the intended data uses, and which are established within this project-specific SAP.

Comparability

Comparability of data sets generated for a project will be obtained through the implementation of standard sampling and analysis procedures, by the use of traceable reference materials for laboratory standards, and by expressing the results in comparable concentration units.

Sensitivity

Sensitivity is the ability of the method or acceptable sensitivity instrument to detect the contaminant of concern and other target compounds at the level of interest. Quantitative MPC need to be determined for acceptable sensitivity to ensure that the quantitation limits can be routinely achieved for each matrix, analytical parameter, and concentration level. The use of standards and instrument calibration will enable the instrument to identify and differentiate between various compounds/analytes of interest and interferences.

Assessment of Data Usability

In addition, data assessment is considered the final step in the data evaluation process and can be performed only on data of known and documented quality. For a project, all data will be assessed for usability, regardless of the data evaluation/validation process implemented. As mentioned previously, data usability goes beyond validation because it evaluates the achievement of the DQOs based on the comparison of the specific WPs with the obtained results. The results of the data usability assessment, and particularly any changes to the DQOs necessitated by the data not meeting usability criteria, will be included in each final data quality assessment report. As noted in Worksheet #15, screening criteria for some analytes is below the LOD; however, if contaminants of concern are present, it is expected that they will be detected at concentrations that will exceed the LOD.

Primarily, the assessment of the usability will follow procedures described in appropriate USEPA guidance documents, particularly *Guidance for Data Usability in Risk Assessment* (Publication No. 9285.7-05FS, September 1992), and will be conducted according to the process outlined below.

Sampling and Analysis Activities Evaluation

The first step of the data usability evaluation will include a review of the sampling and analysis activities in comparison to Site-Wide data quality indicators (DQIs) and study-specific WPs. Specific limitations to the data, i.e., results that are qualified as estimated (J/UJ), or rejected (R), will be determined and documented in the database. The data acquisition and evaluation process consists of a series of procedures that were designed to maximize final data quality.

Assessment of DQIs

The second part of data usability pertains to the assessment of the program-specific DQIs. Each investigator will compare the performance achieved for each data quality criterion against the expected and planned performance. In general, this comparison will follow from the DQIs used to define each DQO. The comparison is the most critical component of the assessment process. Any deviation from planned performance will be documented and evaluated to determine whether corrective action is advisable. Potential corrective actions will range from resampling and/or reanalysis of data, to qualification or exclusion of the data for use in the data interpretation. In the event that corrective action is not possible, the limitations, if any, of the data with regard to achieving the DQOs will be noted.

In conjunction with the DQI achievement review, the investigators will need to make decisions for the use of qualified values, which are a consequence of the formalized evaluation/validation process. Data qualifiers will be applied to individual data results. Data usability decisions will be made based on the assessment of the usability of each of these results for the intended purpose. Evaluation will describe the uncertainty (e.g., bias, imprecision) of the qualified results. Cumulative QC exceedances from the DQIs may require technical judgment to determine the overall effect on the usability of the data. Decisions about usability of qualified data for use in risk assessment will be based on the USEPA document mentioned, which allows for the use of estimated values. Finally, data users may choose to determine final data usability qualifiers as a result of the overall examination and decision process.

Achievement of DQOs

The third step in the data usability process concerns achievement of the DQOs. After the data set has been assessed to be of known quality, data limitations have been documented, and overall result applicability/usability for its intended purpose has been determined, the final data assessment can be initiated by considering the answers to the following questions:

- Are the data adequate to determine the extent to which hazardous substances have migrated or to what extent they are expected to migrate from potential hazardous substance source areas?
- Do the data collected adequately characterize the nature and extent of potential hazardous substance source areas at the site?
- Are the data statistically adequate to allow evaluation on a per chemical and per media basis?
- Do the data collected allow assessment of hydrogeological factors, which may influence contaminant migration/distribution?
- Is the sample set sufficient to develop site-specific removal and disposal treatment methodologies?
- Have sufficient data been collected to evaluate how factors, including physical characteristics of the site and climate and water table fluctuations, affect contaminant fate and transport?
- Have sufficient data been collected to determine the toxicity, environmental fate, and other significant characteristics of each hazardous substance present?
- Has an adequate amount of information been gathered to determine groundwater characteristics and current and potential groundwater uses for locations close to the site?
- Is the data set sufficient to evaluate the potential extent and risk of future releases of hazardous substances, which may remain as residual contamination at the source facility?

The principal investigators, in conjunction with the project team, will formulate solutions if data gaps are found as a result of problems, biases, or trends in the analytical data or if conditions exist that were not anticipated in the development of the DQOs. It is particularly important that each data usability evaluation specifically address any limitations on the use of the data that may result from a failure to achieve the stipulated DQO.

Identify the personnel responsible for performing the usability assessment

Data validation will be coordinated by the AECOM Project Chemist and will be conducted by the AECOM data validation staff. Data usability will be assessed by the AECOM PM with the assistance of the AECOM Project Chemist.

Describe the documentation that will be generated during usability assessment and how usability assessment results will be presented so that they identify trends, relationships (correlations), and anomalies

The documentation generated during data validation will include a memorandum that describes the information reviewed, the results of this review, and a recommendation on data usability and limitations of specific data points. The memorandum provides information on the samples included in the review and the date they were collected, the condition of samples when received at the laboratory and any discrepancies noted during the receiving process, verification of sample preparation and analysis within the method specified holding time, review of associated QC analyses including blanks, LCSs, MSs, and field and/or laboratory duplicates. As a result of this review standard qualifiers are entered into the database so that data users can readily identify any limitations associated with a specific data point.

Table 10-1
Potential Human Health Exposure Pathways and Receptors - Current Scenarios
Camp Hero Remedial Investigation
Montauk, New York

Source	Source Medium	Release Mechanism	Exposure Medium	Exposure Route	On-Site Outdoor Maintenance Worker (Adult) [1]	On-Site Park Employee (Adult) [1]	On-Site Indoor Worker (Adult) [2]	On-Site Recreational User (Child/Adult) [3]	On-Site Trespasser (Youth) [4]
					Human Receptors - Current Scenarios				
Camp Hero AOCs	Surface Soil		Surface Soil (0 to 1 ft)	Ingestion	●	●		●	●
				Dermal	●	●		●	●
		Emission of Particulates and Vapors	Air (Dust & Vapors)	Inhalation	●	●		●	●
	Subsurface Soil (Infiltration/ Percolation from Surface Soil)		Suburface Soil (1 to 10 ft)	Ingestion					
				Dermal					
		Emission of Particulates	Air (Dust)	Inhalation					
		Emission of Vapors	Air (VOCs)	Inhalation					
		Migration of Vapors to Indoor Air	Indoor Air (VOCs)	Inhalation			Q		
		Leaching	Groundwater [5]	Ingestion					
				Dermal					
				Inhalation of VOCs in Shower Air					
				Inhalation of VOCs in Trench					
			Migration of Vapors to Indoor Air (from Groundwater)	Inhalation			●		
	Surface Soil	Erosion/ Runoff	Surface Water [6] (also from Groundwater)	Ingestion					
				Dermal	●	●		●	●
			Sediment [6]	Ingestion	●	●		●	●
				Dermal	●	●		●	●

Notes
● = Potentially complete exposure pathway to be evaluated.
Empty block = Incomplete exposure pathway.
Q = Pathway will be qualitatively evaluated.

1. Park employee (e.g., park police or naturalist) spends 225 days per year traveling to the DUs to check abandoned buildings, fences, or environmental study areas. The outdoor worker spends 40 days/year traveling to various DUs to repair park equipment or perform grounds maintenance. A fraction of exposure will be used to account for time spent at each DU for each worker.
2. Indoor worker is used to address the vapor intrusion exposure pathway only. Scenario will be evaluated where volatiles are present in the subsurface (within 100 feet horizontally and vertically of source area).
3. Recreational user is an adult and child (0 to 6 years) receptor that visits the Camp Hero park for 176 days/year (12 weeks during the winter for 2 days/week and 38 weeks during the rest of the year for 4 days/week). They spend their time walking on trails, picnicking, camping, wading in stream beds, etc. A fraction of exposure is used to account for time spent at each DU from the 176 days/year.
4. Trespasser is a youth (ages 6 through 16 years) that spends 88 days/year in the park climbing fences into restricted areas of a DU where current access is restricted. The trespasser is used to evaluate current land use exposure to soil, surface water and sediment instead of the recreational user at AOCs that have restricted (fenced) areas.
5. Groundwater lies in shallow perched zones and is not suitable for potable water use. If volatiles are identified as groundwater COPCs, then inhalation of vapors in indoor air (vapor intrusion) exposure pathway is addressed for the indoor worker.
6. Streams are intermittent so wading scenario is evaluated for all receptors (no full immersion swimming). Incidental ingestion of sediment is evaluated, assuming hand-to-mouth contact.

Table 10-2
Potential Human Health Exposure Pathways and Receptors - Future Scenarios
Camp Hero Remedial Invetigation
Montauk, New York

				Dermal	●	●		●	●	x	

Notes
Empty block = Incomplete exposure pathway
● = Potentially complete exposure pathway to be evaluated.
X = Pathway will be quantified for informational purposes only to address potential unlimited use/unrestricted exposure (UU/UE).
o = Pathway will be quantified if groundwater contamination is migrating offsite.
Q = Pathway will be qualitatively evaluated.

1. Park employee (e.g., park police or naturalist) spends 225 days per year traveling to the DUs to check abandoned buildings, fences, or environmental study areas. The outdoor worker spends 40 days/year traveling to various DUs to repair park equipment or perform grounds maintenance. A fraction of exposure will be used to account for time spent at each DU for each worker.
2. Indoor worker is used to address the vapor intrusion exposure pathway only; Scenario will be evaluated where volatiles are present in the subsurface (within 100 feet horizontally and vertically of source area).
3. Recreational user is an adult and child (0 to 6 years) receptor that visits the Camp Hero park for 176 days/year (12 weeks during the winter for 2 days/week and 38 weeks during the rest of the year for 4 days/week). They spend their time walking on trails, picnicking, camping, wading in stream beds, etc. A fraction of exposure is used to account for time spent at each DU from the 176 days/year.
4. Trespasser is a youth (ages 6 through 16 years) that spends 88 days/year in the park climbing fences into restricted areas of a DU where current access is restricted. The trespasser is used to evaluate current land use exposure to soil, surface water and sediment instead of the recreational user at AOCs that have restricted (fenced) areas. However, the recreational user is used to evaluate future land use, assuming the fences are removed from the DU.
5. Future excavation activities may result in the subsurface soil being brought to the surface and "mixed" together. Therefore, a total soil data set (0 to 10 feet bgs) will be derived for surface soil and/or subsurface soil COPCs, assuming future land re-development occurs.
6. Residential use is calculated for informational purposes to account for possible UU/UE scenarios. There are currently no plans for future residential use (per Mr. Foley of the Long Island State Parks Region on April 3, 2017) so this exposure scenario is unlikely and highly conservative. Residential exposure to groundwater is evaluated if COPCs are identified; however, an evaluation of the perched groundwater indicates it is not suitable for potable use so this scenario is also unlikely and highly conservative. The vapor intrusion pathway will be addressed if volatiles are identified as groundwater COPCs.
7. Groundwater lies in shallow perched zones and is not suitable for potable water use; therefore, any evaluation of this water as drinking water is provided for informational purposes only to address potential UU/UE. If groundwater COPCs are detected in less than 10 feet bgs, then direct contact with groundwater is evaluated for the construction worker. If a volatile is identified as a groundwater COPC, then inhalation of vapors migrating from groundwater to trench air is evaluated. Offsite residential exposure to groundwater is only evaluated if offsite migration is identified. Given that perched groundwater is not potable, this evaluation is unlikely and highly conservative.
8. Streams are intermittent so wading scenario is evaluated for all receptors (no full immersion swimming). Incidental ingestion of sediment is evaluated, assuming hand-to-mouth contact.

Table 10-3
Potential Ecological Exposure Pathways and Receptors
Camp Hero Remedial Investigation
Montauk, New York

Source	Source Medium	Release Mechanism	Exposure Medium	Exposure Route	Ecological Receptors: Terrestrial Plants (1)	Terrestrial Invertebrates (1)	Aquatic Organisms (2)	Benthic Invertebrates (2)	Terrestrial Insectivorous Wildlife (3)	Terrestrial Herbivorous Wildlife (3)	Semi-Aquatic Insectivorous Wildlife (4)	Semi-Aquatic Herbivorous Wildlife (4)
Camp Hero AOCs	Surface Soil		Surface Soil (0 to 1 ft)	Ingestion/Bio-uptake					●	●		
				Direct Contact	●	●			● (10)	● (10)		
	Surface Soil	Emission of Particulates and Vapors	Air (Dust & Vapors) (5,6)	Inhalation								
	Surface Soil → Infiltration/ Percolation → Subsurface Soil		Subsurface Soil (1 to 10 ft) (7)	Ingestion								
				Direct Contact

	Subsurface Soil	Emission of Vapors	Air (VOCs) (6)	Inhalation								
	Subsurface Soil	Leaching	Groundwater (8)	Ingestion								
				Direct Contact								
	Surface Soil	Erosion/ Runoff	Surface Water (9) (also from Groundwater; exchange with Sediment)	Ingestion/Bio-uptake							(11)	(11)
				Direct Contact			●				● (10)	● (10)
			Sediment (9)	Ingestion/Bio-uptake							X	X
				Direct Contact				●			● (10)	● (10)

Notes
● = Potentially complete exposure pathway to be evaluated
Empty block = Incomplete exposure pathway

1. Soil invertebrates and plants are assumed to take up soil COPECs through the integument and root hairs respectively.
2. Aquatic and benthic organisms may be exposed to constituents in surface water and sediments and take up site-related chemicals by sorption across skin and gills and by ingestion of water or sediment, respectively.
3. Terrestrial wildlife ingest plant parts (i.e., leaves, seeds, roots) and soil invertebrates that may have taken up COPECs from the soil into their body tissues. Soil may also be incidentally ingested during feeding.
4. Semiaquatic wildlife may ingest contaminated benthic organisms and aquatic plants in aquatic sites. Sediment may also be incidentally ingested during feeding.
5. Inhalation of contaminated dust is expected to be insignificant because the site is well vegetated and dust generation is minimal.
6. VOCs may volatilize into soil air spaces from soil and migrate to the soil surface where they may be emitted to the atmosphere, but scientific data to estimate exposure of wildlife is lacking, so the pathway is not evaluated quantitatively. Exposure to VOCs by breathing contaminated air is expected to be insignificant compared to exposure by ingestion pathways.
7. Ecological receptors are not expected to come into contact with subsurface soils; therefore, this exposure pathway is considered incomplete. The majority of bird and mammal exposure comes from ingestion of food (plants and soil invertebrates). The majority of plant and invertebrate chemical exposure is from uptake in surface soil.
8. Ecological receptors are not expected to be exposed to groundwater; therefore, this exposure pathway is considered incomplete.
9. Streams are intermittent and unlikely to support a fish community or associated piscivores. Wildlife receptors may consume aquatic plants and/or invertebrates.
10. Dermal absorption of surface soil, sediment, or surface water contaminants is potentially complete for ecological receptors, but scientific data to estimate exposure of wildlife is lacking, so the pathway is not evaluated quantitatively. Exposure to COPECs by dermal absorption by wildlife is expected to be insignificant compared to exposure by ingestion pathways.
11. Wildlife receptors may drink surface water, but much of their water requirements are met through food ingestion. Drinking is considered an insignificant pathway compared to food intake, so the pathway is not evaluated quantitatively.

Table 10-4
Ecological Assessment and Measurement Endpoints
Camp Hero Remedial Investigation
Montauk, New York

Receptor of Concern	Exposure Pathway	Assessment Endpoint [1]	Testable Hypothesis	Measurement Endpoint	Data Available
Lower trophic level terrestrial species (e.g., earthworms and plants).	Uptake of chemicals in soil.	**AE 1**: Protection and maintenance (survival, growth, and reproduction) of plants and soil invertebrates.	H_0: The concentration of COPECs in surface soil does not exceed a level known to be toxic to plants or soil invertebrates.	Compare concentrations of COPECs in surface soil with soil benchmarks developed to protect growth and reproduction of plant and soil invertebrates.	Site-specific chemical data for surface soil from within DUs.
Terrestrial insectivorous birds (represented by the American robin).	Ingestion of chemicals in soil and accumulated in soil invertebrates.	**AE 2**: Protection and maintenance (survival, growth, and reproduction) of insectivorous birds.	H_0: The ingestion of bioaccumulative COPECs in soil invertebrates and surface soil does not exceed a level known to be toxic to birds.	Comparison of literature-derived chronic NOAEL-based benchmarks to estimated chronic daily intake for representative birds for each COPEC.	Site-specific chemical data for surface soil from within DUs.
Terrestrial herbivorous birds (represented by mourning dove).	Ingestion of chemicals accumulated in plants.	**AE 3**: Protection and maintenance (survival, growth, and reproduction) of herbivorous birds.	H_0: The ingestion of bioaccumulative COPECs in plants does not exceed a level known to be toxic to birds.	Comparison of literature-derived chronic NOAEL-based benchmarks to estimated chronic daily intake for representative birds for each COPEC.	Site-specific chemical data for surface soil from within DUs.
Terrestrial herbivorous mammals (represented by meadow vole).	Ingestion of chemicals in soil and accumulated in plants.	**AE 4**: Protection and maintenance (survival, growth, and reproduction) of herbivorous mammals.	H_0: The ingestion of bioaccumulative COPECs in plants and in surface soil does not exceed a level known to be toxic to mammals.	Comparison of literature-derived chronic NOAEL-based benchmarks to estimated chronic daily intake for representative mammals for each COPEC.	Site-specific chemical data for surface soil from within DUs.
Terrestrial insectivorous mammals (represented by masked shrew).	Ingestion of chemicals in soil and accumulated in soil invertebrates.	**AE 5**: Protection and maintenance (survival, growth, and reproduction) of insectivorous mammals.	H_0: The ingestion of bioaccumulative COPECs in surface soil and soil invertebrates does not exceed a level known to be toxic to mammals.	Comparison of literature-derived chronic NOAEL-based benchmarks to estimated chronic daily intake for representative mammals for each COPEC.	Site-specific chemical data for surface soil from within DUs.
Sediment-dwelling organisms (e.g., benthic invertebrates and amphibian larvae).	Uptake of chemicals from sediment.	**AE 6**: Protection and maintenance of benthic organisms.	H_0: The concentration of COPECs in the sediment does not exceed a level known to be toxic to benthic organisms.	Compare concentrations of COPECs in sediment to sediment threshold effect levels.	Site-specific chemical data for sediment from within or downstream from DUs.
Aquatic organisms (e.g., aquatic invertebrates and amphibian larvae)	Uptake of chemicals from surface water.	**AE 7**: Protection and maintenance of aquatic organisms.	H_0: The concentration of COPECs in surface water does not exceed a level known to be toxic to aquatic organisms.	Compare concentrations of COPECs in surface water to surface water quality criteria for chronic exposure.	Site-specific chemical data for surface water from within or downstream from DUs.
Semiaquatic herbivorous mammals (represented by the meadow vole).	Ingestion of chemicals accumulated in aquatic plants from sediment.	**AE 8**: Protection and maintenance (survival, growth, and reproduction) of semiaquatic herbivorous mammals.	H_0: The ingestion of bioaccumulative COPECs in aquatic plants does not exceed a level known to be toxic to mammals.	Comparison of literature-derived chronic NOAEL-based benchmarks to estimated chronic daily intake for representative mammals for each COPEC.	Site-specific chemical data for sediment from within or downstream of DUs.
Semiaquatic insectivorous bird (represented by the American robin).	Ingestion of chemicals in sediment and accumulated in benthic invertebrates.	**AE 8**: Protection and maintenance (survival, growth, and reproduction) of semiaquatic insectivorous birds.	H_0: The ingestion of bioaccumulative COPECs in sediment and sediment invertebrates does not exceed a level known to be toxic to mammals.	Comparison of literature-derived chronic NOAEL-based benchmarks to estimated chronic daily intake for representative birds for each COPEC.	Site-specific chemical data for surface water from within or downstream of DUs.
Semiaquatic insectivorous mammals (represented by masked shrew).	Ingestion of chemicals in sediment and accumulated in benthic invertebrates.	**AE 10**: Protection and maintenance (survival, growth, and reproduction) of wetland insectivorous mammals.	H_0: The ingestion of bioaccumulative COPECs in sediment and sediment invertebrates does not exceed a level known to be toxic to mammals.	Comparison of literature-derived chronic NOAEL-based benchmarks to estimated chronic daily intake for representative mammals for each COPEC.	Site-specific chemical data for sediment from within or downstream from DUs.

Notes:

1. Assessment endpoints identified for evaluation are based on the parameters used to derive toxicity benchmarks (see Measurement Endpoint column) and are not intended to imply measurement of these parameters in the field.
COPEC - Chemical of Potential Ecological Concern.
DU - Decision Unit.
H_0 = Null Hypothesis.
NOAEL - No Observed Adverse Effect Level.

Site-Wide Groundwater	N/A	N/A	N/A	N/A	-	-	-	-	GW		GW	GW	-	GW	Sitewide well network to assess regional groundwater impacts.
Groundwater Near AST35/FPH, STB, MP	N/A	Former AST-35, Fuel Pump House, Suspected Tank B	N/A	N/A	-	-	-	GW	GW		GW	GW	-	GW	Sitewide network wells in the vicinity of these former AOCs will also be analyzed for petroleum-related compounds in addition to the sitewide parameters based on prior detection in grab water samples and field indicators. Soil samples will be collected from the well installation borings to support the CSM.

Notes:
VOCs - Specific parameters from TCL based on preliminary screening evaluation results, plus NYSDEC STARs list
SVOCs - Selected TCL SVOCs based on preliminary screening evaluation, plus NYSDEC STARs list (includes full TCL PAHs plus NYSDEC STARs list)
Metals - Full TAL metals
GeoChem - Specific geochemical parameters to further evaluate the speciation of metals (such as hexavalent chromium) and to support the FS
GeoTech - Specific subsurface physical characteristic data to evaluate potential LNAPL response actions
MNA - Monitored natural attenuation parameters to support the FS

DU05-S016	DP	Surface Soil	10'	0-1'		DU05-S016-00-01				X				To collect an unbiased grid of surface soil samples from the 0-1 foot horizon, to generate representative surface soil EPCs, and to quantify potential human health and ecological risks.
DU06														
DU06-S001	DP	Subsurface Soil	10'	1-10'	X	DU06-S001-01-10		X		X				To collect an unbiased grid of subsurface soil samples from the 1-10 foot horizon, to generate representative subsurface soil EPCs, and to quantify potential human health risks.
DU06-S001	DP	Surface Soil	10'	0-1'	X	DU06-S001-00-01		X		X	X	X		To collect an unbiased grid of surface soil samples from the 0-1 foot horizon, to generate representative surface soil EPCs, and to quantify potential human health and ecological risks. Cr6+ will be analyzed in 10% of samples analyzed for TAL metals, with pH and ORP to validate results relative to field conditions.
DU06-S002	DP	Subsurface Soil	10'	1-10'	X	DU06-S002-01-10		X		X				To collect an unbiased grid of subsurface soil samples from the 1-10 foot horizon, to generate representative subsurface soil EPCs, and to quantify potential human health risks.
DU06-S002	DP	Surface Soil	10'	0-1'	X	DU06-S002-00-01		X		X				To collect an unbiased grid of surface soil samples from the 0-1 foot horizon, to generate representative surface soil EPCs, and to quantify potential human health and ecological risks.

Notes:
Subsurface soil sample depths may be modified in the field based on actual field conditions (i.e., field screening, soil types, depth to water)
__-__ represents depth below ground surface to top and bottom of sample interval
Investigation Method: HA = hand auger, DP = Direct Push Soil Boring, SN = Sonic Soil Boring
Cr^{6+} will be analyzed in 10% of samples analyzed for TAL metals, along with pH and ORP to validate the analytical results relative to field conditions
VOCs - Specific parameters from TCL based on preliminary screening evaluation results, plus NYSDEC STARs list
SVOCs - Selected TCL SVOCs based on preliminary screening evaluation, plus NYSDEC STARs list (includes full TCL PAHs plus NYSDEC STARs list)
PCBs - Polychlorinated biphenyls
Metals - Full TAL metals
GeoChem - Specific geochemical parameters to further evaluate the speciation of metals (such as hexavalent chromium) and to support the FS
GeoTech - Specific subsurface physical characteristic data to evaluate potential LNAPL response actions
ORP - Oxidation-Reduction Potential

Notes:
Subsurface soil sample depths may be modified in the field based on actual field conditions (i.e., field screening, soil types, depth to water)
__-__ represents depth below ground surface to top and bottom of sample interval
Investigation Method: HA = hand auger, DP = Direct Push Soil Boring, SN = Sonic Soil Boring
Cr^{6+} will be analyzed in 10% of samples analyzed for TAL metals, along with pH and ORP to validate the analytical results relative to field conditions
VOCs - Specific parameters from TCL based on preliminary screening evaluation results, plus NYSDEC STARs list
SVOCs - Selected TCL SVOCs based on preliminary screening evaluation, plus NYSDEC STARs list (includes full TCL PAHs plus NYSDEC STARs list)
PCBs - Polychlorinated biphenyls
Metals - Full TAL metals
GeoChem - Specific geochemical parameters to further evaluate the speciation of metals (such as hexavalent chromium) and to support the FS
GeoTech - Specific subsurface physical characteristic data to evaluate potential LNAPL response actions
ORP - Oxidation-Reduction Potential

DU15-S016	DP	Surface Soil	10'	0-1'	X	DU15-S016-00-01			X	X				To collect an unbiased grid of surface soil samples from the 0-1 foot horizon, to generate representative surface soil EPCs, and to quantify potential human health and ecological risks.

Notes:
Subsurface soil sample depths may be modified in the field based on actual field conditions (i.e., field screening, soil types, depth to water)
__-__ represents depth below ground surface to top and bottom of sample interval
Investigation Method: HA = hand auger, DP = Direct Push Soil Boring, SN = Sonic Soil Boring
Cr^{6+} will be analyzed in 10% of samples analyzed for TAL metals, along with pH and ORP to validate the analytical results relative to field conditions
VOCs - Specific parameters from TCL based on preliminary screening evaluation results, plus NYSDEC STARs list
SVOCs - Selected TCL SVOCs based on preliminary screening evaluation, plus NYSDEC STARs list (includes full TCL PAHs plus NYSDEC STARs list)
PCBs - Polychlorinated biphenyls
Metals - Full TAL metals
GeoChem - Specific geochemical parameters to further evaluate the speciation of metals (such as hexavalent chromium) and to support the FS
GeoTech - Specific subsurface physical characteristic data to evaluate potential LNAPL response actions
ORP - Oxidation-Reduction Potential

DU18-S012	HA	Surface Soil	N/A	0-1'		DU18-S012-00-01				X				To collect an unbiased grid of surface soil samples from the 0-1 foot horizon, to generate representative surface soil EPCs, and to quantify potential human health and ecological risks.
DU18-S013	HA	Surface Soil	N/A	0-1'		DU18-S013-00-01				X				To collect an unbiased grid of surface soil samples from the 0-1 foot horizon, to generate representative surface soil EPCs, and to quantify potential human health and ecological risks.
DU18-S014	HA	Surface Soil	N/A	0-1'		DU18-S014-00-01				X				To collect an unbiased grid of surface soil samples from the 0-1 foot horizon, to generate representative surface soil EPCs, and to quantify potential human health and ecological risks.
DU18-S015	HA	Surface Soil	N/A	0-1'		DU18-S015-00-01				X				To collect an unbiased grid of surface soil samples from the 0-1 foot horizon, to generate representative surface soil EPCs, and to quantify potential human health and ecological risks.
DU18-S016	HA	Surface Soil	N/A	0-1'		DU18-S016-00-01				X				To collect an unbiased grid of surface soil samples from the 0-1 foot horizon, to generate representative surface soil EPCs, and to quantify potential human health and ecological risks.

Notes:
Subsurface soil sample depths may be modified in the field based on actual field conditions (i.e., field screening, soil types, depth to water)
__-__ represents depth below ground surface to top and bottom of sample interva
Investigation Method: HA = hand auger, DP = Direct Push Soil Boring, SN = Sonic Soil Boring
Cr^{6+} will be analyzed in 10% of samples analyzed for TAL metals, along with pH and ORP to validate the analytical results relative to field conditions

VOCs - Specific parameters from TCL based on preliminary screening evaluation results, plus NYSDEC STARs list
SVOCs - Selected TCL SVOCs based on preliminary screening evaluation, plus NYSDEC STARs list (includes full TCL PAHs plus NYSDEC STARs list)
PCBs - Polychlorinated biphenyls
Metals - Full TAL metals
GeoChem - Specific geochemical parameters to further evaluate the speciation of metals (such as hexavalent chromium) and to support the FS
GeoTech - Specific subsurface physical characteristic data to evaluate potential LNAPL response actions
ORP - Oxidation-Reduction Potential

CH-SWSD041	SW	Surface Water	N/A	X	CH-SWSD041-SW01	X		X				X	Near DU07	To collect a representative set of surface water and sediment samples for exposure areas potentially impacted by DU source areas to refine the CSM and calculate EPCs for human health and ecological risk assessments.
CH-SWSD042	SD	Sediment	0-0.5'		CH-SWSD042-SD01	X		X			X		Near DU07	To collect a representative set of surface water and sediment samples for exposure areas potentially impacted by DU source areas to refine the CSM and calculate EPCs for human health and ecological risk assessments.
CH-SWSD042	SW	Surface Water	N/A	X	CH-SWSD042-SW01	X		X				X	Near DU07	To collect a representative set of surface water and sediment samples for exposure areas potentially impacted by DU source areas to refine the CSM and calculate EPCs for human health and ecological risk assessments.
CH-SWSD043	SD	Sediment	0-0.5'		CH-SWSD043-SD01	X		X			X		Near DU07	To collect a representative set of surface water and sediment samples for exposure areas potentially impacted by DU source areas to refine the CSM and calculate EPCs for human health and ecological risk assessments.
CH-SWSD043	SW	Surface Water	N/A	X	CH-SWSD043-SW01	X		X				X	Near DU07	To collect a representative set of surface water and sediment samples for exposure areas potentially impacted by DU source areas to refine the CSM and calculate EPCs for human health and ecological risk assessments.

Notes:
All surface water samples will be evaluated for hardness; all sediment samples will be evaluated for TOC.
Cr^{6+} will be analyzed in 10% of samples analyzed for TAL metals, along with pH and ORP to validate the analytical results relative to field conditions.
Total (unfiltered) and dissolved (field-filtered) surace water samples will be collected for metals.
SW - Surface Water
SD - Sediment
VOCs - Specific parameters from TCL based on preliminary screening evaluation results, plus NYSDEC STARs list
SVOCs - Selected TCL SVOCs based on preliminary screening evaluation, plus NYSDEC STARs list (includes full TCL PAHs plus NYSDEC STARs list)
PCBs - Polychlorinated biphenyls
Metals - Full TAL metals, including mercury
GeoChem - Specific geochemical parameters to further evaluate the speciation of metals (such as Cr6+) and to support the FS
DO - Dissolved Oxygen
ORP - Oxidation-Reduction Potential
TOC - Total Organic Carbon

CH-SWSD082	SW	Surface Water	N/A	X	CH-SWSD082-SW01	X		X				X	Near DU13, DU14	To collect a representative set of surface water and sediment samples for exposure areas potentially impacted by DU source areas to refine the CSM and calculate EPCs for human health and ecological risk assessments.
CH-SWSD083	SD	Sediment	0-0.5'		CH-SWSD083-SD01	X		X			X		Near DU13, DU14	To collect a representative set of surface water and sediment samples for exposure areas potentially impacted by DU source areas to refine the CSM and calculate EPCs for human health and ecological risk assessments.
CH-SWSD083	SW	Surface Water	N/A	X	CH-SWSD083-SW01	X		X				X	Near DU13, DU14	To collect a representative set of surface water and sediment samples for exposure areas potentially impacted by DU source areas to refine the CSM and calculate EPCs for human health and ecological risk assessments.
CH-SWSD084	SD	Sediment	0-0.5'		CH-SWSD084-SD01	X		X			X		Near DU13, DU14	To collect a representative set of surface water and sediment samples for exposure areas potentially impacted by DU source areas to refine the CSM and calculate EPCs for human health and ecological risk assessments.
CH-SWSD084	SW	Surface Water	N/A	X	CH-SWSD084-SW01	X		X				X	Near DU13, DU14	To collect a representative set of surface water and sediment samples for exposure areas potentially impacted by DU source areas to refine the CSM and calculate EPCs for human health and ecological risk assessments.
CH-SWSD085	SD	Sediment	0-0.5'		CH-SWSD085-SD01	X		X			X		Near DU13, DU14	To collect a representative set of surface water and sediment samples for exposure areas potentially impacted by DU source areas to refine the CSM and calculate EPCs for human health and ecological risk assessments.
CH-SWSD085	SW	Surface Water	N/A	X	CH-SWSD085-SW01	X		X				X	Near DU13, DU14	To collect a representative set of surface water and sediment samples for exposure areas potentially impacted by DU source areas to refine the CSM and calculate EPCs for human health and ecological risk assessments.
CH-SWSD086	SD	Sediment	0-0.5'		CH-SWSD086-SD01	X		X			X		Near DU13, DU14	To collect a representative set of surface water and sediment samples for exposure areas potentially impacted by DU source areas to refine the CSM and calculate EPCs for human health and ecological risk assessments.
CH-SWSD086	SW	Surface Water	N/A	X	CH-SWSD086-SW01	X		X				X	Near DU13, DU14	To collect a representative set of surface water and sediment samples for exposure areas potentially impacted by DU source areas to refine the CSM and calculate EPCs for human health and ecological risk assessments.
CH-SWSD087	SD	Sediment	0-0.5'		CH-SWSD087-SD01	X		X			X		Near DU13, DU14	To collect a representative set of surface water and sediment samples for exposure areas potentially impacted by DU source areas to refine the CSM and calculate EPCs for human health and ecological risk assessments.
CH-SWSD087	SW	Surface Water	N/A	X	CH-SWSD087-SW01	X		X				X	Near DU13, DU14	To collect a representative set of surface water and sediment samples for exposure areas potentially impacted by DU source areas to refine the CSM and calculate EPCs for human health and ecological risk assessments.

Notes:
All surface water samples will be evaluated for hardness; all sediment samples will be evaluated for TOC.
Cr^{6+} will be analyzed in 10% of samples analyzed for TAL metals, along with pH and ORP to validate the analytical results relative to field conditions.
Total (unfiltered) and dissolved (field-filtered) surace water samples will be collected for metals.
SW - Surface Water
SD - Sediment
VOCs - Specific parameters from TCL based on preliminary screening evaluation results, plus NYSDEC STARs list
SVOCs - Selected TCL SVOCs based on preliminary screening evaluation, plus NYSDEC STARs list (includes full TCL PAHs plus NYSDEC STARs list)
PCBs - Polychlorinated biphenyls
Metals - Full TAL metals, including mercury
GeoChem - Specific geochemical parameters to further evaluate the speciation of metals (such as Cr6+) and to support the FS
DO - Dissolved Oxygen
ORP - Oxidation-Reduction Potential
TOC - Total Organic Carbon

CH-SWSD118	SD	Sediment	0-0.5'		CH-SWSD118-SD01	X		X			X		Near DU01, DU02, DU03	To collect a representative set of surface water and sediment samples for exposure areas potentially impacted by DU source areas to refine the CSM and calculate EPCs for human health and ecological risk assessments.
CH-SWSD118	SW	Surface Water	N/A	X	CH-SWSD118-SW01	X		X				X	Near DU01, DU02, DU03	To collect a representative set of surface water and sediment samples for exposure areas potentially impacted by DU source areas to refine the CSM and calculate EPCs for human health and ecological risk assessments.
CH-SWSD119	SD	Sediment	0-0.5'		CH-SWSD119-SD01	X		X			X		Near DU01, DU02, DU03	To collect a representative set of surface water and sediment samples for exposure areas potentially impacted by DU source areas to refine the CSM and calculate EPCs for human health and ecological risk assessments.
CH-SWSD119	SW	Surface Water	N/A	X	CH-SWSD119-SW01	X		X				X	Near DU01, DU02, DU03	To collect a representative set of surface water and sediment samples for exposure areas potentially impacted by DU source areas to refine the CSM and calculate EPCs for human health and ecological risk assessments.
CH-SWSD120	SD	Sediment	0-0.5'		CH-SWSD120-SD01	X		X	X	X	X		Near DU01, DU02, DU03	To collect a representative set of surface water and sediment samples for exposure areas potentially impacted by DU source areas to refine the CSM and calculate EPCs for human health and ecological risk assessments. Cr6+ will be analyzed in 10% of samples analyzed for TAL metals, with pH and ORP to validate results relative to field conditions.
CH-SWSD120	SW	Surface Water	N/A	X	CH-SWSD120-SW01	X		X	X			X	Near DU01, DU02, DU03	To collect a representative set of surface water and sediment samples for exposure areas potentially impacted by DU source areas to refine the CSM and calculate EPCs for human health and ecological risk assessments. Cr6+ will be analyzed in 10% of samples analyzed for TAL metals, with pH and ORP to validate results relative to field conditions.

Notes:
All surface water samples will be evaluated for hardness; all sediment samples will be evaluated for TOC.
Cr^{6+} will be analyzed in 10% of samples analyzed for TAL metals, along with pH and ORP to validate the analytical results relative to field conditions.
Total (unfiltered) and dissolved (field-filtered) surace water samples will be collected for metals.
SW - Surface Water
SD - Sediment
VOCs - Specific parameters from TCL based on preliminary screening evaluation results, plus NYSDEC STARs list
SVOCs - Selected TCL SVOCs based on preliminary screening evaluation, plus NYSDEC STARs list (includes full TCL PAHs plus NYSDEC STARs list)
PCBs - Polychlorinated biphenyls
Metals - Full TAL metals, including mercury
GeoChem - Specific geochemical parameters to further evaluate the speciation of metals (such as Cr6+) and to support the FS
DO - Dissolved Oxygen
ORP - Oxidation-Reduction Potential
TOC - Total Organic Carbon

Notes:
All surface water samples will be evaluated for hardness; all sediment samples will be evaluated for TOC.
Cr^{6+} will be analyzed in 10% of samples analyzed for TAL metals, along with pH and ORP to validate the analytical results relative to field conditions.
Total (unfiltered) and dissolved (field-filtered) surace water samples will be collected for metals.
SW - Surface Water
SD - Sediment
VOCs - Specific parameters from TCL based on preliminary screening evaluation results, plus NYSDEC STARs list
SVOCs - Selected TCL SVOCs based on preliminary screening evaluation, plus NYSDEC STARs list (includes full TCL PAHs plus NYSDEC STARs list)
PCBs - Polychlorinated biphenyls
Metals - Full TAL metals, including mercury
GeoChem - Specific geochemical parameters to further evaluate the speciation of metals (such as Cr^{6+}) and to support the FS
DO - Dissolved Oxygen
ORP - Oxidation-Reduction Potential
TOC - Total Organic Carbon

CH-MW034	DU13	Low-Flow	Groundwater	Mid-screen	X			X		CH-MW034-02		X		X			To assess groundwater conditions sitewide and in the vicinity of DU13.
CH-MW035	DU13	Low-Flow	Groundwater	Mid-screen	X			X		CH-MW035-02		X		X			To assess groundwater conditions sitewide and in the vicinity of DU13.
CH-MW036	DU08	Low-Flow	Groundwater	Mid-screen	X			X	X	CH-MW036-02		X		X		X	To assess groundwater conditions sitewide and in the vicinity of DU08.
CH-MW037	DU08	Low-Flow	Groundwater	Mid-screen	X			X		CH-MW037-02		X		X			To assess groundwater conditions sitewide and in the vicinity of DU08.
CH-MW038	DU07	Low-Flow	Groundwater	Mid-screen	X			X		CH-MW038-02		X		X			To assess groundwater conditions sitewide and in the vicinity of DU07.
CH-MW039	DU07	Low-Flow	Groundwater	Mid-screen	X			X		CH-MW039-02		X		X			To assess groundwater conditions sitewide and in the vicinity of DU07.
CH-MW040	DU15	Low-Flow	Groundwater	Mid-screen	X			X		CH-MW040-02		X	X	X			To assess groundwater conditions sitewide and in the vicinity of DU15. PCBs were previously detected in a grab groundwater sample from a temporary monitoring well.
CH-MW041	DU06	Low-Flow	Groundwater	Mid-screen	X			X		CH-MW041-02		X		X			To assess groundwater conditions sitewide and in the vicinity of DU06.
CH-MW042	DU06	Low-Flow	Groundwater	Mid-screen	X			X		CH-MW042-02		X		X	X		To assess groundwater conditions sitewide and in the vicinity of DU06. Cr6+ will be analyzed in 10% of samples analyzed for TAL metals.
CH-MW043	MP	Low-Flow	Groundwater	Mid-screen	X			X	X	CH-MW043-02	X	X		X		X	To assess groundwater in the vicinity of observed potential petroleum impacts near the Motor Pool hydraulic lift.MNA parameters will be collected to assess the potential for MNA, specific chemical oxidation states, and fate and transport properties.

Notes:
Total (unfiltered) and dissolved (field-filtered) samples will be collected for SVOCs, PCBs, Metals, Cr^{6+}, and Fe^{3+}. Filtered samples are not appropriate for VOCs.
MNA parameters will be analyzed in 10% of groundwater samples. MNA parameters consist of biochemical oxygen demand, total oxygen demand, total organic carbon, ferrous iron (field analysis), chlorides, sulfates and sulfides, nitrates and nitrites, alkalinity, methane, ethane, and ethene.
Cr^{6+} will be analyzed in 10% of samples analyzed for TAL metals, along with pH and ORP to validate the analytical results relative to field conditions.

VOCs - Specific parameters from TCL based on preliminary screening evaluation results, plus NYSDEC STARs list
SVOCs - Selected TCL SVOCs based on preliminary screening evaluation, plus NYSDEC STARs list (includes full TCL PAHs plus NYSDEC STARs list)
Metals - Full TAL metals, including mercury
MNA - Monitored natural attenuation parameters to support the FS
LNAPL - Light Non-aqueous Phase Liquid
ORP - Oxidation-Reduction Potential
SpCond - Specific Conductivity
DO - Dissolved Oxygen
Turb - Turbidity

EXECUTIVE SUMMARY

Camp Hero is a formerly used defense site (FUDS) undergoing a Remedial Investigation and Feasibility Study (RI/FS) under the Comprehensive Environmental Restoration, Compensation, and Liability Act (CERCLA).

Camp Hero State Park is located on the eastern tip of the south fork of Long Island, New York, approximately 5 miles east of the Village of Montauk. The former Camp Hero was established in early 1942 as a Coastal Defense Installation and the facility changed ownership within the military multiple times over the course of the following decades. Between 1974 and 1984, site lands were transferred to State, Local, and other Federal agencies, and the facility was permanently closed in 1982. The area is now used as Camp Hero State Park and is owned by the New York State Parks Commission.

Former Department of Defense (DoD) activities at Camp Hero may have resulted in contaminated material or an environmental release from these materials at certain Areas of Concern (AOCs). Forty-seven AOCs were identified as part of the RI. The AOCs include former waste disposal areas, former coal storage areas, abandoned drum locations, possible and former underground storage tanks, and a Motor Pool building, among others.

The primary objectives of the background soil study are to: 1) provide soil background threshold values (BTVs) for screening metal and polycyclic aromatic hydrocarbon (PAH) concentrations, and 2) provide background soil data sets for statistical background means comparisons, where needed, for the baseline human health risk assessment (HHRA) and Screening-Level Ecological Risk Assessment (SLERA). Soil BTVs are used to distinguish metal and PAH concentrations within decision units or exposure areas considered in the HHRA or the SLERA from naturally occurring or anthropogenic background conditions. Decision units or exposure areas with chemical concentrations that are above risk-based screening criteria and BTVs and are statistically above the background mean using hypothesis testing are carried forward for further evaluation in the CERCLA process.

U.S. Environmental Protection Agency (USEPA) ProUCL 5.1 statistical software and PAleontological STatistics (PAST) 3.13 data analysis software were used to conduct the statistical analysis of the background soil data. The analysis included summary statistics, goodness-of-fit testing, permutation testing, outlier testing, and finally BTV calculations. Table ES-1 summarizes the BTVs selected for the soil medium.

1.0 INTRODUCTION

Camp Hero is a formerly used defense site (FUDS) undergoing a Remedial Investigation and Feasibility Study (RI/FS) under the Comprehensive Environmental Restoration, Compensation, and Liability Act (CERCLA). A total of 47 areas of concern (AOCs) have been identified during previous investigations, which included Phase I and II RI field investigations. This RI/FS program for Camp Hero is being conducted by AECOM in coordination with the United States Army Corps of Engineers (USACE), New England and New York Districts, as well as the Environmental and Munitions (EM) Center of Expertise (CX).

Camp Hero State Park is located on the eastern tip of the south fork of Long Island, New York, approximately 5 miles east of the Village of Montauk. The former Camp Hero was established in early 1942 as a Coastal Defense Installation and the facility changed ownership within the military multiple times over the course of the following decades. Between 1974 and 1984, site lands were transferred to State, Local, and other Federal agencies, and the facility was permanently closed in 1982. The area is now used as Camp Hero State Park and is owned by the New York State Parks Commission.

Former Department of Defense (DoD) activities at Camp Hero may have resulted in contaminated material or an environmental release from these materials at certain Areas of Concern (AOCs). Forty-seven AOCs were identified as part of the RI. The AOCs include former waste disposal areas, former coal storage areas, abandoned drum locations, possible and former underground storage tanks, and a Motor Pool building, among others.

The purpose of conducting the background study and deriving background threshold values (BTVs) is to help identify what AOCs require further evaluation in the Comprehensive Environmental Restoration, Compensation, and Liability Act (CERCLA) Remedial Investigation (RI), Feasibility Study, Proposed Plan, and Decision Document process for Camp Hero.

1.1 Background Soil Study Scope and Objectives

The primary objectives of the background soil study are to: 1) provide soil BTVs for screening metal and polycyclic aromatic hydrocarbon (PAH) concentrations, and 2) provide background soil data sets for statistical background means comparisons, where needed, for the baseline human health risk assessment (HHRA) and Screening-Level Ecological Risk Assessment (SLERA).

1.2 Background Soil Study Organization

This Background Soil Study is organized into the following sections:

- Section 1: Introduction – Describes the purpose of the study, including its scope and objectives.
- Section 2: Data Handling and Evaluation – Describes the soil background data set and how it was used to derive BTVs. This section includes summary statistics, limit of quantitation (LOQ) screening results, outlier testing, and permutation testing.
- Section 3: Development of Background Threshold Values (BTVs) – Describe how the BTVs were derived based on goodness-of-fit (GOF) distribution testing and how non-detects were handled. A brief discussion of the BTV results is also included.

All figures and tables referenced in the text are provided in Attachment B and Attachment D, respectively.

The following attachments are included in this background soil study:

- Attachment A contains the references for the background soil study.
- Attachment B contains the figures showing the background sampling locations.
- Attachment C contains the background data sample results, including the low molecular weight (LMW) PAH, high molecular weight (HMW) PAH, and benzo(a)pyrene (BaP) toxicity equivalence (TEQ) sample results.
- Attachment D contains the background data summary tables.
- Attachment E contains the ProUCL BTV output files.

2.0 DATA HANDLING AND EVALUATION

This section describes the background soil data set and how it was handled to effectively generate soil BTVs.

2.1 Background Soil Data Set

A total of 62 background soil samples (30 surface and 32 subsurface) were collected as part of the Phase I investigation conducted in May and June 2016. The Phase I investigation activities are documented in the Phase I Field Investigation Report (AECOM-Tidewater JV, 2016), which provides the laboratory analytical data reports from the Phase I investigation.

Figures 1 through 5 provided in Attachment B display the locations of the background soil samples. The samples were collected from four different locations (BG-01 through BG-04) representing two different soil types, Whitman Sandy loam (WSL; outwash deposits of stratified sand and gravel) and Montauk loam (ML; glaciofluvial deposits of stratified sand and gravel in forms of kames). These two soil types represent the soil types where most of the Camp Hero RI AOCs are located, excluding urban soil complexes, which are not representative of background conditions (AECOM-Tidewater JV, 2016).

A total of 16 soil borings were advanced for background sampling: 8 borings in the WSL (4 borings at 2 locations) and 8 were located in the ML (4 borings at 2 locations). One surface soil sample was collected from 0 to 1 foot from each boring. Fourteen additional surface soil samples were collected between the four background locations and spaced at a minimum of 25 feet (ft) apart. For subsurface soil, the borings were advanced to 10 ft below ground surface (bgs) or the depth of the perched aquifer, whichever was encountered first. Two subsurface soil samples were collected per boring: 4 to 5 ft bgs and 9 to 10 ft bgs or 1 to 2 ft above the depth to ground water, whichever was encountered first (AECOM-Tidewater JV, 2016).

In summary, the sample sizes for the background soil samples are as follows:

- n = 15 for surface soil in Montauk Loam (at locations BG-02, BG-04)
- n = 15 for surface soil in Whitman Sandy Loam (at locations BG-01, BG-03)
- n = 16 for subsurface soil in Montauk Loam (at locations BG-02, BG-04)
- n = 16 for subsurface soil in Whitman Sandy Loam (at locations BG-01, BG-03)

Attachment C presents the background soil sample results.

2.2 Data Evaluation and Handling

Background samples were analyzed using United States Environmental Protection Agency (USEPA) method SW6010C (metals) and 8270D in SIM mode (PAHs). All validated, qualified data were considered usable for the BTV derivation with the exception of unusable or rejected ("R" qualified) samples. However, no rejected data were identified in the background data sets.

The limit of quantitation (LOQ) is the lowest concentration of a substance that produces a quantitative result within specified limits of precision and bias. The LOQ is typically larger than the limit of detection (LOD; but may be equal to the LOD, depending upon the acceptance limits for precision and bias); therefore, the following is true:

$$\text{Method Detection Limit (MDL)} < \text{LOD} \leq \text{LOQ}$$

Quantitative results can only be achieved at or above the LOQ. Measurements between the MDL and the LOQ assure the presence of the analyte with confidence, but their numeric values are estimates ("J" qualified).

No "B" qualified results (blank contamination) were identified in the background soil data set. However, "J" qualified results (estimated values) were identified and were carried forward as detect results. Where applicable, the average of the field and duplicate samples were used to represent the sample. Tables 1 and 2 (provided in Attachment D) present the summary statistics for surface and subsurface soil. The USEPA's ProUCL 5.1 statistical software was used to generate the summary statistics (USEPA, 2015).

USACE and AECOM discussed the consideration of uncensored analytical data (USACE, 2016), specifically for the analytical results of metals. Uncensored data can be useful to minimize information loss for non-detected analytical results. For the dataset generated for this background evaluation, uncensored analytical data were not available; however, the majority of analytical results, particularly the metals, were detected values.

The analytical results provided by the laboratory were compared to the MDL and LOQ to assess potential distortion of deriving the BTVs. Tables 3 and 4 (provided in Attachment D) present the MDL and LOQ summary for metals and PAHs, respectively. The ML and WSL soil types were kept separate for the metals, but not for the PAHs (USACE, 2016), at this stage for the purpose of exploratory data analysis (EDA).

As previously indicated, most of the metals were detected at 100% or close to 100%, so the use of MDLs, LODs, LOQs, and/or uncensored data was not needed. For selenium and silver where the sample results were mostly non-detects (NDs), the LOD or LOQ was used as the BTV (see Section 3.2).

Cadmium was the only metal with non-detect results where the team needed to consider the MDL, LOD, and/or LOQ rather than the uncensored result. Cadmium was detected at a frequency of 25% to 69% in the four data sets. However, three out of four of these data sets were reported 100% below LOQ, and therefore, the need of numerical values for NDs for statistical evaluation was not required. The surface soil WSL data set for cadmium data had only 2 detected results above LOQ. Since the combined surface soil data set is mostly non-detects, the LOQ is selected as the BTV (see Section 3.2).

In all cases (i.e., for both metals and PAHs), the Kaplan-Meier (KM) method or the regression on order statistics (ROS) method was used in subsequent BTV calculations, when the data set contained non-detect values (see Section 3.2).

2.3 Polycyclic Aromatic Hydrocarbon (PAH) Summation Concentrations

LMW PAH and HMW PAH concentrations were derived for each sample to support the BTV calculations and future SLERA background analysis. PAHs constitute a class of organic substances that are made up of carbon and hydrogen atoms grouped into at least two condensed aromatic ring structures. The LMW PAHs are composed of fewer than four rings and HMW PAHs are composed of four or more rings. The bioavailability of PAHs in soil is influenced by organic carbon quality and quantity, aging and weather, microbial action, methylation/hydroxylation, adsorption/desorption hysteresis, and ultra-violet light interaction (Fairbrother, 2005). USEPA has grouped the PAHs into LMW and HMW categories as a means to address the differences in physical/chemical properties of individual PAAHs which influence toxicity and environmental fate (USEPA, 2007). Table 5 presents the LMW and HMW PAHs categories and the molecular weight of each individual PAH.

To derive the LMW and HMW PAH concentrations, the PAHs were broken into the aforementioned categories for each sample result and the concentrations were summed. For data sets with NDs, the MDL was applied and the concentrations were summed using the KM method (Helsel, 2009). Thus, each sample had a representative LMW and HMW PAH concentration value.

BaP TEQ concentrations were derived for each sample to support the BTV calculations and future HHRA background analysis. Carcinogenic PAHs exhibit similar toxicological properties, but they differ in the degree of toxicity. Toxicity equivalence factors (TEFs) were applied to adjust the measured concentration of the carcinogenic PAHs in relation to BaP which is the most toxic. Table 6 presents the carcinogenic PAHs and their corresponding TEFs (USEPA, 1993 and 2016). The individual carcinogenic PAH concentrations were multiplied by the TEF, then the TEF-multiplied concentrations were summed for each sample. When one or more of the carcinogenic PAHs were NDs, similar to LMW and HMW PAHs, the MDL was applied and the TEF-multiplied concentrations were summed using the KM method (Helsel, 2009).

The PAH summation results are provided in Attachment C.

2.4 Outlier Testing

Including potentially erroneous outliers in a background data set tends to generate distorted and inflated estimates of the BTV. USEPA's ProUCL 5.1 statistical software could be used to conduct outlier testing. The Dixon's outlier test was used for sample sizes that were less than 25. The Rosner's test was used for data sets greater than or equal to 25.

Both outlier tests identified extreme values that were much smaller than the rest of the data set (lower tail) and much higher than the rest of the data set (upper tail). Both outlier tests were performed at 5% significance level for identifying an outlier in this background evaluation. A limitation of the outlier testing was that the tests assumed that the data without the outlier were normally distributed, which was not always the case.

Although the statistical outlier tests were useful to identify extreme values; however, outliers were excluded only if a physical justification was also evident, such as gross QC failures for the laboratory analysis, samples collected at the wrong spatial coordinates, or transcription errors, etc. The project team did not identify any issues or errors for all the soil background data collected, and therefore, no statistical outliers or extreme values were excluded in the subsequent BTV calculation.

2.5 Permutation Testing

The objective of the permutation testing was to compare the mean concentrations of each metal for ML and WSL soil types at the surface and subsurface and determine if the means were statistically similar to each other. Another round of permutation testing was also conducted to compare the mean concentrations of the surface and subsurface soil data sets for the metals. Tables 7, 8, and 9 summarize the permutation testing results.

If the mean concentrations were determined to be similar, then the ML and WSL data sets were combined for that particular metal at the specified depth (surface or subsurface). If the mean concentrations were significantly different, then the soil types should be analyzed separately for that particular metal at the specified depth. If the mean concentrations of metals were determined to be similar between the surface and subsurface soil, then the two soil depths may be combined to strengthen the derivation of the BTV.

The USEPA's ProUCL 5.1 statistical software was initially run to calculate summary statistics and perform Goodness of Fit Tests (GOF) for each metal of each soil type at each depth level (Singh and Maichle, 2015). This resulted in the analysis of 22 metals for the following subset groups:

- ML Surface Soil
- WSL Surface Soil

- ML Subsurface Soil
- WSL Subsurface Soil
- Surface Soil and Subsurface Soil

The PAST 3.13 data analysis software was used to: (1) perform test for equal variance, and (2) compare means of ML and WSL surface/subsurface using either the Student's t-test or the permutation test (Monte Carlo, n = 9,999), based on the conditions specified below (Hammer et al., 2001):

- If both soil data sets were normally or approximately normally distributed:
  - Equal variance was tested using the F-test. If the variances were equal, then the Student's t-test was used to test if both mean concentrations were statistically similar.
  - In cases where the F-test rejected the null hypothesis (H0), equal variance was also tested using the non-parametric, Monte Carlo test. Results of the Student's t-test and Monte Carlo permutation test were both reported for the mean comparison.
- If the GOF results for both soil data sets were different, then only the Monte Carlo permutation test was used to compare variance and mean concentrations.
- The H0 stated that the two data sets were taken from populations with equal mean. When $p < 0.05$, the H0 is rejected.
- Outliers were included in all data sets. ND data were censored at the full detection limit.

2.5.1 Surface Metals

For surface metals, equal variance was confirmed for all normally distributed data (10/22 metals). Additionally, the Monte Carlo test confirmed equal variance for all other metals which were not normally distributed (8/22 metals), except antimony and cobalt.

Testing for equal means determined that only arsenic, iron, and manganese rejected the H0 (explained below under Soil Type Analysis).

Both selenium and silver were not tested for GOF, equal variance, or equal means because they had NDs greater than 85% and reliable statistics could not be determined.

2.5.2 Subsurface Metals

For subsurface metals, equal variance was confirmed for half of the normally distributed data set (2/22 metals). Arsenic and chromium were determined to be normally distributed by GOF, but both the F-test and Monte Carlo test rejected the equal variance null hypothesis. Additionally, the Monte Carlo test confirmed equal variance in half of the other metals which were tested (8/22).

Testing for equal means determined that only calcium rejected the H0 (explained below under Soil Type Analysis).

Both selenium and silver were not tested for GOF, equal variance, or equal means because they had NDs equal to 100% and reliable statistics could not be determined.

2.5.3 Discussion of Soil Type Analysis

The Montauk and Whitman soil series occurred in similar geographic locations but varied greatly in drainage and slope, with slightly varied composition in the amounts of granite, gneiss, and schist. The United States Department of Agriculture (USDA) described the Montauk series as well drained soils formed in lodgment or flow till derived primarily from granitic materials with lesser amounts of gneiss and schist (USDA, 2015). The Whitman soil series consisted of very poorly drained soils formed in lodgment till containing granite, gneiss, and schist.

Up to 4 feet in depth, Whitman soil contained masses of iron accumulation (USDA, 2016). ML surface soils within the site had higher mean concentrations of iron than WSL surface soils. The availability of iron in the Whitman series may be restricted due to the accumulation of these masses. The lack of these masses at depth may explain why mean concentrations in subsurface soils were considered equal.

Manganese availability in soil was strongly influenced by pH and the presence of iron in soils. The Montauk series was extremely acidic at the surface with pH decreasing in the subsurface, while the Whitman series was moderately acidic throughout. The relationship with how pH (ML) and iron accumulation (WSL) varied with depth could explain this difference seen at the surface.

The availability of arsenic in soils may be influenced by similar processes and variations with depth, but the presence of arsenic in the environment was largely determined by industrial activities involving lead and copper (ATSDR, 2007). Additionally, inorganic arsenic was used as a pesticide. Without further information about land use practices influencing each area, the higher presence of arsenic in ML soil may not be explained by only soil type.

Calcium was the only metal which had statistically different mean concentrations at subsurface depths. As mentioned previously, ML soils were significantly more acidic than WSL at all depths. ML soil was most acidic at the surface and pH increased with depth. ML soils had significantly more calcium than in the subsurface. This is most likely attributed to surface calcium leaching throughout the profile due to low surface pH and accumulating in the subsurface at higher mean concentrations. This same behavior would not be expected with WSL which had a consistent and higher pH (relative to ML) with depth.

Outliers were included in this evaluation. No outliers were detected for arsenic, iron, or manganese at the surface. However, calcium had upper statistical outliers for both surface and subsurface ML soil (1700 and 2500 mg/kg, respectively) and only subsurface soil for WSL (960 mg/kg). The inclusion of these outliers may have influenced equal means testing, but given the difference in nature of ML and WSL soils with regards to pH and depth, these outliers may be indicative of the differences due to soil type.

Based on the results of testing for equal variance and mean, the ML and WSL results for arsenic, iron and manganese in surface soil, and calcium in subsurface soil should be evaluated separately in deriving the BTVs.

2.5.4 Soil Depth Analysis

Although surface and subsurface soils are generally evaluated separately in the risk assessment, there may be desire to combine data from surface and subsurface soils to derive the BTVs with a larger, more robust data set, when there were no significant differences between different soil depths. As such, the same aforementioned comparison approach was performed for metals between the surface and subsurface data sets. With the exception for arsenic, calcium, iron, and manganese, where either surface or subsurface was determined to be different between soil types, all other metals were compared using the data sets with combined soil types.

Table 9 presents the comparison summary of soil depths. The following metals were determined to have similar mean concentrations between surface and subsurface soils, and thus a combined depth BTV may be considered: aluminum, arsenic, beryllium, calcium, chromium, copper, iron, nickel, selenium, silver, vanadium, and zinc.

3.0 DEVELOPMENT OF BACKGROUND THRESHOLD VALUES (BTVs)

3.1 Overview of BTV Calculation

For each established background data set described above, the upper tolerance limit (UTL) was derived, which is representative of the upper bound of the data distribution. The assessed UTL95-95 represents the 95% confidence level of the 95% percentile of the background population. The UTL95-95 is a value that represents the upper limit of a tolerance interval such that 95% of the observations from the background population will be less than or equal to that upper-limit value with a confidence coefficient (CC) of 95%. The UTL95-95 is designed to simultaneously provide coverage for 95% of all potential observations (current and future) from the background population with a CC of 95%. The use of UTL95-95 is preferred to upper prediction limit (UPL95) when the number of future comparisons is large or unknown.

From an exceedance perspective, a UTL95-95 is the value that will be exceeded less than 5% of the time by all values potentially coming from the background population, with a CC of 95%. This is true for each chemical analyte. A parametric UTL95-95 takes into account the variability of current and future observations. When the dataset does not follow a discernible distribution, a non-parametric UTL represented by a higher-order statistic (for example, the largest value or the second largest value) will be used as an estimate of BTV. Results derived using the ProUCL software (USEPA 2015) were used to determine UTL95-95 BTVs (see Attachment E). If a dataset follows no discernible distribution, ProUCL determines the order statistic for a non-parametric UTL95-95 based on the sample size. This means that the order statistic to use is not fixed a-priori in ProUCL. The technical details, including the mathematical equation for determining the parametric and non-parametric UTLs, are described in Section 3.4 of the ProUCL Technical Guide (Singh and Singh, 2013). For data sets with non-detects, the technical details are described in Section 5.3.3 of the same document.

3.2 BTV Selection Process

For each established background data set, the normality of the data was first checked using the goodness-of-fit test in the ProUCL software. Based on the ProUCL guidelines, the Shapiro-Wilk W test was used for a sample size of 50 or less and the Lillifors test was used for a sample size greater than 50. If the data fit a normal distribution, the parametric (normal) method was used to derive the associated BTVs.

If the data did not fit a normal distribution, a possible fit to a gamma or lognormal distribution was evaluated. If the data fit a gamma distribution, the parametric (gamma) method was used to derive the BTVs. Otherwise, if the data fit a lognormal distribution, the parametric (lognormal) method was used to derive the BTVs. If the data did not fit any of the three aforementioned parametric distributions, the non-parametric method was used to derive the associated BTVs.

For each established data set containing one or more non-detects, the Kaplan-Meier (KM) method or the regression on order statistics (ROS) method was used to derive the associated BTVs. When a data set entirely consisted of non-detects, the Limit of Detection (LOD) was used as a non-statistical BTV. If a data set entirely or mostly consisted of non-detects and J-qualified results less than the Limit of Quantitation (LOQ), the LOQ was used as a non-statistical BTV.

3.3 Discussion of BTV Results

Tables 10 (surface soil), 11 (subsurface soil), and 12 (combined depths for selected metals) summarize the results of BTV calculation. The goodness-of-fit test results, along with the selected UTL95-95 and UTL calculation methods are presented. The UPL95 is also presented for reference and informational purposes only. Table 13 presents a condensed summary of UTL95-95 results for surface soil, subsurface soil, and combined depths side-by-side. Attachment E presents the statistical outputs from the ProUCL software.

Selenium and silver were entirely or mostly non-detects, and cadmium and thallium (surface only) were entirely or mostly below LOQ. In these cases, the LOD or the LOQ will be used as the non-statistical BTV. All other metals were detected 100% or close to 100% and followed a parametric distribution (normal, gamma, or lognormal). Thus, the background metal data sets were considered to be relatively robust and likely belonged to a single population without extreme values.

For the data sets of surface PAHs, the percentage of non-detects varied from 10% to 90%, and therefore, the KM method or the ROS method was used to calculate UTL95-95. Acenaphthylene and dibenz(a,h)anthracene were not detected over 90% of the surface data set, and thus, the LOQ will be used as the non-statistical BTV. All subsurface PAHs were not detected over 90% of the data set or consisted of 100% non-detects, and therefore, the LOD or the LOQ will be used as the non-statistical BTV.

Total BaP TEQ (mg/kg)				
BaP TEQ	--	0.493	0.00296	--

Notes:

All units in milligrams per kilogram (mg/kg)

BTV = Background Threshold Value

N/A = Not Applicable

ML = Montauk Loam

WSL = Whitman Sandy Loam

UTL = Upper Tolerance Limit

[1] ML and WSL soil types combined based on results of permutation tests, unless otherwise noted

[2] EPA's ProUCL software (Version 5.1) was used to calculate BTVs for each analyte

[3] Subsurface soil BTVs and combined soil BTVs were not calculated for PAHs due to the high number of NDs in the subsurface soil data set.

Table 1

Notes:
All units are in milligrams per kilogram (mg/kg)
If the dataset contains nondetects, summary statistics are censored at the MDL and are estimated by the Kaplan-Meier (KM) method.
If duplicates exist, 1. if the duplicate pair was both detect or both non-detect, the average of the duplicate results was used as a single data point; 2. if the duplicate pair contained a detect and non-detect, the maximum detect was used.
-- = no value; ft = feet; MDL = method detection limit; ND = non-detect; PAH = polycyclic aromatic hydrocarbon; Std = standard.

Data Qualifier	Explanation
J	The analyte was positively identified; the associated numerical value is an estimated quantity with an unknown bias.
J+	The result is an estimated quantity, but the result may be biased high.
J-	The result is an estimated quantity, but the result may be biased low.
UJ	The analyte was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the actual limit of quantitation necessary to accurately and precisely measure the analyte in the sample.
U	The result has been evaluated to be undetected at the reporting limit or at the reported concentration; result is considered to be a false positive.

Notes:
All units are in milligrams per kilogram (mg/kg)
If the dataset contains nondetects, summary statistics are censored at the MDL and are estimated by the Kaplan-Meier (KM) method.
If duplicates exist, 1. if the duplicate pair was both detect or both non-detect, the average of the duplicate results was used as a single data point; 2. if the duplicate pair contained a detect and non-detect, the maximum detect was used.
-- = no value; ft = feet; MDL = method detection limit; ND = non-detect; PAH = polycyclic aromatic hydrocarbon; Std = standard.

Data Qualifier	Explanation
J	The analyte was positively identified; the associated numerical value is an estimated quantity with an unknown bias.
J+	The result is an estimated quantity, but the result may be biased high.
J-	The result is an estimated quantity, but the result may be biased low.
UJ	The analyte was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the actual limit of quantitation necessary to accurately and precisely measure the analyte in the sample.
U	The result has been evaluated to be undetected at the reporting limit or at the reported concentration; result is considered to be a false positive.

95% Chebyshev UPL	44249	99% Percentile	30380
95% USL	31000		

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

Nonparametric Distribution Free Background Statistics

Data appear to follow a Discernible Distribution at 5% Significance Level

Nonparametric Upper Limits for BTVs(no distinction made between detects and nondetects)

Order of Statistic, r	32	95% UTL with95% Coverage	0.63
Approx, f used to compute achieved CC	1.684	Approximate Actual Confidence Coefficient achieved by UTL	0.806
Approximate Sample Size needed to achieve specified CC	59	95% UPL	0.441
95% USL	0.63	95% KM Chebyshev UPL	0.657

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

95% Chebyshev UPL	53928	99% Percentile	37380
95% USL	38000		

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

95% Chebyshev UPL	350.6	99% Percentile	285.9
95% USL	320		

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

95% USL	22000		

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

MLE Sd (bias corrected)	0.381	95% Percentile of Chisquare (2kstar)	4.569

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Minimum	0.01	Mean	0.289

Nonparametric Distribution Free Background Statistics

Data do not follow a Discernible Distribution (0.05)

Nonparametric Upper Limits for BTVs(no distinction made between detects and nondetects)

Order of Statistic, r	30	95% UTL with95% Coverage	4.9
Approx, f used to compute achieved CC	1.579	Approximate Actual Confidence Coefficient achieved by UTL	0.785
Approximate Sample Size needed to achieve specified CC	59	95% UPL	2.37
95% USL	4.9	95% KM Chebyshev UPL	4.099

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

95% Chebyshev UPL	33571	99% Percentile	20000
95% USL	20000		

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.

Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

90% Chebyshev UPL	15.7	95% Percentile	12
95% Chebyshev UPL	19.91	99% Percentile	13.42
95% USL	14		

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Nonparametric Distribution Free Background Statistics

Data appear to follow a Discernible Distribution at 5% Significance Level

Nonparametric Upper Limits for BTVs(no distinction made between detects and nondetects)

Order of Statistic, r	30	95% UTL with95% Coverage	0.016
Approx, f used to compute achieved CC	1.579	Approximate Actual Confidence Coefficient achieved by UTL	0.785
Approximate Sample Size needed to achieve specified CC	59	95% UPL	0.0119
95% USL	0.016	95% KM Chebyshev UPL	0.01

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

Nonparametric Distribution Free Background Statistics

Data appear to follow a Discernible Distribution at 5% Significance Level

Nonparametric Upper Limits for BTVs(no distinction made between detects and nondetects)

Order of Statistic, r	30	95% UTL with95% Coverage	0.065
Approx, f used to compute achieved CC	1.579	Approximate Actual Confidence Coefficient achieved by UTL	0.785
Approximate Sample Size needed to achieve specified CC	59	95% UPL	0.0606
95% USL	0.065	95% KM Chebyshev UPL	0.0749

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

Nonparametric Distribution Free Background Statistics

ProUCL Output - Background Threshold Values (with NDs)
(version 5.1.002)

Data appear to follow a Discernible Distribution at 5% Significance Level

Nonparametric Upper Limits for BTVs(no distinction made between detects and nondetects)

Order of Statistic, r	30	95% UTL with95% Coverage	0.3
Approx, f used to compute achieved CC	1.579	Approximate Actual Confidence Coefficient achieved by UTL	0.785
Approximate Sample Size needed to achieve specified CC	59	95% UPL	0.273
95% USL	0.3	95% KM Chebyshev UPL	0.346

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

Nonparametric Distribution Free Background Statistics

Data appear to follow a Discernible Distribution at 5% Significance Level

Nonparametric Upper Limits for BTVs(no distinction made between detects and nondetects)

Order of Statistic, r	30	95% UTL with95% Coverage	0.2
Approx, f used to compute achieved CC	1.579	Approximate Actual Confidence Coefficient achieved by UTL	0.785
Approximate Sample Size needed to achieve specified CC	59	95% UPL	0.2
95% USL	0.2	95% KM Chebyshev UPL	0.25

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

Nonparametric Distribution Free Background Statistics

Data appear to follow a Discernible Distribution at 5% Significance Level

Nonparametric Upper Limits for BTVs(no distinction made between detects and nondetects)

Order of Statistic, r	30	95% UTL with95% Coverage	0.36
Approx, f used to compute achieved CC	1.579	Approximate Actual Confidence Coefficient achieved by UTL	0.785
Approximate Sample Size needed to achieve specified CC	59	95% UPL	0.217

95% USL	0.36	95% KM Chebyshev UPL	0.313

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

Nonparametric Distribution Free Background Statistics

Data appear to follow a Discernible Distribution at 5% Significance Level

Nonparametric Upper Limits for BTVs(no distinction made between detects and nondetects)

Order of Statistic, r	30	95% UTL with95% Coverage	0.43
Approx, f used to compute achieved CC	1.579	Approximate Actual Confidence Coefficient achieved by UTL	0.785
Approximate Sample Size needed to achieve specified CC	59	95% UPL	0.419
95% USL	0.43	95% KM Chebyshev UPL	0.527

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

(version 5.1.002)

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Minimum	0.01	Mean	0.203

Nonparametric Distribution Free Background Statistics

Data appear to follow a Discernible Distribution at 5% Significance Level

Nonparametric Upper Limits for BTVs(no distinction made between detects and nondetects)

Order of Statistic, r	61	95% UTL with95% Coverage	0.63
Approx, f used to compute achieved CC	1.605	Approximate Actual Confidence Coefficient achieved by UTL	0.823
Approximate Sample Size needed to achieve specified CC	93	95% UPL	0.334
95% USL	4.9	95% KM Chebyshev UPL	2.884

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

95% UPL	20.4	90% Percentile	12
90% Chebyshev UPL	21.97	95% Percentile	16.85
95% Chebyshev UPL	28.61	99% Percentile	23.78
95% USL	25		

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Nonparametric Distribution Free Background Statistics

Data appear to follow a Discernible Distribution at 5% Significance Level

Nonparametric Upper Limits for BTVs(no distinction made between detects and nondetects)

Order of Statistic, r	32	95% UTL with95% Coverage	0.00517
Approx, f used to compute achieved CC	1.684	Approximate Actual Confidence Coefficient achieved by UTL	0.806
Approximate Sample Size needed to achieve specified CC	59	95% UPL	0.00344
95% USL	0.00517	95% KM Chebyshev UPL	0.00455

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Approximate Sample Size needed to achieve specified CC	59	95% UPL	0.416
95% USL	0.642	95% KM Chebyshev UPL	0.576

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

EXECUTIVE SUMMARY

Camp Hero is a formerly used defense site (FUDS) undergoing a Remedial Investigation and Feasibility Study (RI/FS) under the Comprehensive Environmental Restoration, Compensation, and Liability Act (CERCLA).

Camp Hero State Park is located on the eastern tip of the south fork of Long Island, New York, approximately 5 miles east of the Village of Montauk. The former Camp Hero was established in early 1942 as a Coastal Defense Installation and the facility changed ownership within the military multiple times over the course of the following decades. Between 1974 and 1984, site lands were transferred to State, Local, and other Federal agencies, and the facility was permanently closed in 1982. The area is now used as Camp Hero State Park and is owned by the New York State Parks Commission.

Former Department of Defense (DoD) activities at Camp Hero may have resulted in contaminated material or an environmental release from these materials at certain Areas of Concern (AOCs). Forty-seven AOCs were identified as part of the RI. The AOCs include former waste disposal areas, former coal storage areas, abandoned drum locations, possible and former underground storage tanks, and a Motor Pool building, among others.

The primary objectives of the background groundwater study are to: 1) provide groundwater background threshold values (BTVs) for screening metal aconcentrations, and 2) provide background groundwater data sets for statistical background means comparisons, where needed, for the baseline human health risk assessment (HHRA). Groundwater BTVs are used to distinguish metal concentrations within decision units or exposure areas considered in the HHRA from naturally occurring or anthropogenic background conditions. Decision units or exposure areas with chemical concentrations that are above risk-based screening criteria and BTVs and/or are statistically above the background mean using hypothesis testing are carried forward for further evaluation in the CERCLA process.

U.S. Environmental Protection Agency (USEPA) ProUCL 5.1 statistical software and PAleontological STatistics (PAST) 3.13 data analysis software were used to conduct the statistical analysis of the background groundwater data. The analysis included summary statistics, goodness-of-fit testing, permutation testing, outlier testing, and finally BTV calculations. Table ES-1 summarizes the BTVs selected for the groundwater medium.

1.0 INTRODUCTION

Camp Hero is a formerly used defense site (FUDS) undergoing a Remedial Investigation and Feasibility Study (RI/FS) under the Comprehensive Environmental Restoration, Compensation, and Liability Act (CERCLA). A total of 47 areas of concern (AOCs) have been identified during previous investigations, which included Phase I and II RI field investigations. This RI/FS program for Camp Hero is being conducted by AECOM in coordination with the United States Army Corps of Engineers (USACE), New England and New York Districts, as well as the Environmental and Munitions (EM) Center of Expertise (CX).

Camp Hero State Park is located on the eastern tip of the south fork of Long Island, New York, approximately 5 miles east of the Village of Montauk. The former Camp Hero was established in early 1942 as a Coastal Defense Installation and the facility changed ownership within the military multiple times over the course of the following decades. Between 1974 and 1984, site lands were transferred to State, Local, and other Federal agencies, and the facility was permanently closed in 1982. The area is now used as Camp Hero State Park and is owned by the New York State Parks Commission.

Former Department of Defense (DoD) activities at Camp Hero may have resulted in contaminated material or an environmental release from these materials at certain Areas of Concern (AOCs). Forty-seven AOCs were identified as part of the RI. The AOCs include former waste disposal areas, former coal storage areas, abandoned drum locations, possible and former underground storage tanks, and a Motor Pool building, among others. The primary objective of the Phase II RI field investigation was to install 15 background monitoring wells to collect background groundwater data and to investigate the extent of light non-aqueous phase liquid (LNAPL) and related constituents in soil and groundwater at the former Building 203 AOC; the investigation results are documented in the Camp Hero Phase II Field Investigation Report (AECOM-Tidewater JV, 2017).

The purpose of conducting the background groundwater study and deriving background threshold values (BTVs) is to help identify what AOCs require further evaluation in the Comprehensive Environmental Restoration, Compensation, and Liability Act (CERCLA) Remedial Investigation (RI), Feasibility Study, Proposed Plan, and Decision Document process for Camp Hero.

1.1 Background Groundwater Study Scope and Objectives

The primary objectives of the background groundwater study are to: 1) provide groundwater BTVs for screening metal concentrations, and 2) provide background groundwater data sets for statistical background means comparisons, where needed, for the baseline human health risk assessment (HHRA).

1.2 Background Groundwater Study Organization

This Background Groundwater Study is organized into the following sections:

- Section 1: Introduction – Describes the purpose of the study, including its scope and objectives.
- Section 2: Data Handling and Evaluation – Describes the groundwater background data set and how it was used to derive BTVs. This section includes summary statistics, limit of quantitation (LOQ) screening results, outlier evaluation, and permutation testing.
- Section 3: Development of Background Threshold Values (BTVs) – Describe how the BTVs were derived based on goodness-of-fit (GOF) distribution testing and how non-detects were handled. A brief discussion of the BTV results is also included.

All figures and tables referenced in the text are provided in Attachment B and Attachment C of the report, respectively.

The following attachments are included in this background groundwater study:

- Attachment A contains the references for the background groundwater study.
- Attachment B contains the background sampling location figure.
- Attachment C contains the background data sample results.
- Attachment D contains the background data summary tables.
- Attachment E contains the ProUCL BTV output files.

2.0 DATA HANDLING AND EVALUATION

This section describes the background groundwater data set and how it was handled to effectively generate groundwater BTVs.

2.1 Background Groundwater Data Set

A total of 14 background groundwater samples (six wells from the east basin and eight wells from the west basin) were collected in December 2016. These two groundwater basins represent the groundwater types where most of the Camp Hero RI AOCs are located. The depth of the background wells, as well as the methods of field sampling and handling, are documented in the Camp Hero Phase II Field Investigation Report (AECOM-Tidewater JV, 2017). Figure 1 provided in Attachment B displays the locations of the background groundwater wells.

Dry perched groundwater conditions were generally not encountered during the December 2016 sampling event, and sufficient groundwater was produced for sampling; therefore, a second round of sampling (scheduled for Spring of 2017) was not required.

In summary, the sample sizes for the background groundwater samples are as follows:

- n = 6 for groundwater in the east basin (at locations CH-MW005, CH-MW006, CH-MW007, CH-MW009, CH-MW010, and CH-MW012)
- n = 8 for groundwater in the west basin (at locations CH-MW001, CH-MW002, CH-MW003, CH-MW004, CH-MW011, CH-MW013, CH-MW014, and CH-MW015)

Attachment C presents the background groundwater sample results.

2.2 Data Evaluation and Handling

Background samples were analyzed using United States Environmental Protection Agency (USEPA) method SW6020A (all other metals), SW7470A (mercury), and E218.6 (chromium VI), for both dissolved and total fractions. All validated, qualified data were considered usable for the BTV derivation, and there were no unusable or rejected ("R" qualified) samples.

The limit of quantitation (LOQ) is the lowest concentration of a substance that produces a quantitative result within specified limits of precision and bias. The LOQ is typically larger than the limit of detection (LOD; but may be equal to the LOD, depending upon the acceptance limits for precision and bias); therefore, the following is true:

$$\text{Method Detection Limit (MDL)} < \text{LOD} \leq \text{LOQ}$$

Quantitative results can only be achieved at or above the LOQ. Measurements between the MDL and the LOQ assure the presence of the analyte with confidence, but their numeric values are estimates ("J" qualified).

No "B" qualified results (blank contamination) were identified in the background groundwater data set. However, "J" qualified results (estimated values) were identified and were carried forward as detect results. Where applicable, the average of the field and duplicate samples were used to represent the sample.

During statistical evaluation, monitoring well CH-MW011 was deemed to be an outlier. The fall of 2016 was a notably dry season with low-precipitation, leading to drought conditions and decreased perched groundwater availability at some background well locations. Insufficient groundwater was present at CH-MW011 to fully develop the newly-installed well or to complete sampling via low-flow methodology. Instead, the well was developed to the extent possible by removing a few gallons of water over multiple development cycles and a grab-groundwater sample was collected. The minimal development and the grab sampling technique likely did not produce a sample representative of aquifer conditions.Statistical results are presented for both the background data sets with and without the outlier; however, the set of results without the outlier is recommended to be used, and the set of results for all locations (including the outlier) is for reference purposes only.

After excluding CH-MW011, there was no indication that there were other outliers through the graphical displays, and the project team did not identify any issues or errors for all the other groundwater background data collected, and therefore, no other statistical outliers or extreme values were excluded in the subsequent BTV calculation.

Tables 1 and 2 (provided in Attachment D) present the summary statistics for background groundwater concentrations, without and with the outlier, respectively. The USEPA's ProUCL 5.1 statistical software was used to generate the summary statistics (USEPA, 2015).

USACE and AECOM discussed the consideration of uncensored analytical data (USACE, 2016). Uncensored data can be useful to minimize information loss for non-detected analytical results. For the dataset generated for this background evaluation, uncensored analytical data were not available; however, the majority of analytical results were detected values. The groundwater analytical results provided by the laboratory were compared to the MDL and LOQ to assess potential impact of deriving the BTVs. Table 3 presents the MDL and LOQ censoring summary for all metals, for both dissolved and total fractions, and without and with the outlier.

The majority of the metals were detected at 100% or close to 100%, or not detected above the LOQ at all, so the use of uncensored data was not needed. For 27 fraction-analytes (of the without outlier set) where all sample results were non-detects (NDs) or below LOQ, the LOD or the LOQ was used as the BTV (i.e., uncensored data were not needed).

The only metals with non-detect results where the team needed to consider the MDL, LOD, and/or LOQ rather than the uncensored result were (total and dissolved) aluminum, chromium (VI), iron, and nickel, which were detected 31% to 85% in the eight data sets.

In all cases, the Kaplan-Meier (KM) method or the regression on order statistics (ROS) method was used in subsequent BTV calculation, when the data set contained non-detect values (see Section 3.2).

2.3 Permutation Testing

The objective of the permutation testing was to compare the mean concentrations of each metal collected from the east basin and the west basin, and determine if the means were statistically similar to each other. Table 4 summarizes the permutation testing results.

If the mean concentrations were determined to be similar, then the east and west basin data sets were combined to strengthen the derivation of the BTV. If the mean concentrations were significantly different, then the east and west basins should be analyzed separately for that particular metal.

The USEPA's ProUCL 5.1 statistical software was initially run to calculate summary statistics and perform goodness-of-fit test (GOF) for each metal from each basin (Singh and Maichle, 2015). This resulted in the analysis of 50 fraction-metals.

The PAST 3.13 data analysis software was used to compare means of east and west basins using either the Student's *t*-test or the permutation test (Monte Carlo, n = 9,999), based on the conditions specified below (Hammer et al., 2001):

- If both groundwater data sets were normally distributed:
  - Equal variance was tested using the *F*-test. If the variances were equal, then the Student's *t*-test was used to test if both mean concentrations were statistically similar.
  - In cases where the variances were not equal, the unequal variance version of the Student's *t*-test was used to test if both mean concentrations were statistically similar.
  - Results of the Student's *t*-test and Monte Carlo permutation test were both reported for the mean comparison.

- If one or both of the GOF results for the two groundwater data sets were not normally distributed, then only the Monte Carlo permutation test was used to compare mean concentrations.

- The H_0 stated that the two data sets were taken from populations with equal means. When $p < 0.05$, the H_0 is rejected.

- Both versions of the data set, without and with the outlier CH-MW011, were tested. ND data were censored at the full detection limit.

2.3.1 Discussion of Comparison Between East and West Basins

Using the GOF test, dissolved magnesium, dissolved nickel, dissolved vanadium, total cobalt, total magnesium, and total nickel were found to be normally distributed in both the east and west basins, for the without outlier CH-MW011 data set. In addition, dissolved and total magnesium were found to be normally distributed for the all locations data set. Thus, the mean comparisons for these analytes were based on the Student's *t*-test. For all other analytes where there were detected results, the permutation test was used to compare the means.

Only 1 out 50 fraction-analytes showed significant differences between the east basin and the west basin, for the without outlier CH-MW011 set, and this fraction-analyte was dissolved aluminum. (Note: Total aluminum showed no significant differences.) The *p*-value of the test was very marginal (0.0421) for a 5% significance level. It should be noted that if the *t*-Test or the Wilcoxon Rank Sum Test (a common test for median) were to be used, the conclusion would have been that the east basin and the west basin were not significant different at 5% significance level. In light of this, it is recommended to combine the east and west basins for all fraction-analytes, and thus, resulting a combined background sample size of 13 (without the outlier CH-MW011).

Although ND data were substituted by detection limit, which may create some uncertainties or reliability issues of the permutation test, graphical displays, such as box-and-whisker plots, were also used to visually inspect the differences between the east and west basins. These plots did not indicate there were evidences of significant or systematic differences between the east and west basins. As an additional line of evidence, the Wilcoxon Rank Sum Test also indicated that there were no significant differences for all 50 fraction-analytes. It should be noted that all detection limits reported for ND data were always below any detected results, and the detection limit did not vary sample-by-sample for almost all cases.

The statistical comparison of the perched groundwater from the east and west basins, which demonstrated similar populations, is consistent with the depositional setting of the two basins, which were formed under the same geologic conditions. The deposits which comprise the upper soil found in both basins are end products of the advance and retreat of several glaciers. Most of the material carried from the glacier was sand and well-rounded gravel, which was redeposited as stratified sand and gravel glacial till deposits. Upon further retreat of the ice, the till and parts of the outwash and morainic deposits were covered by water or wind-deposited silt, clay, and fine sand to varying depths, resulting in lenses and beds of silt and clay. The perched groundwater evaluated for the Camp Hero RI, including the background perched groundwater, was obtained from the same perched water bearing zone within the lenses and beds of silt and clay deposited across Camp Hero (United States Geological Survey [USGS] 1960).

3.0 DEVELOPMENT OF BACKGROUND THRESHOLD VALUES (BTVs)

3.1 Overview of BTV Calculation

For each established background data set described above, the upper tolerance limit (UTL) was derived, which is representative of the upper bound of the data distribution. The assessed UTL95-95 represents the 95% confidence level of the 95% percentile of the background population. The UTL95-95 is a value that represents the upper limit of a tolerance interval such that 95% of the observations from the background population will be less than or equal to that upper-limit value with a confidence coefficient (CC) of 95%. The UTL95-95 is designed to simultaneously provide coverage for 95% of all potential observations (current and future) from the background population with a CC of 95%. The use of UTL95-95 is preferred to upper prediction limit (UPL95) when the number of future comparisons is large or unknown.

From an exceedance perspective, a UTL95-95 is the value that will be exceeded less than 5% of the time by all values potentially coming from the background population, with a CC of 95%. This is true for each chemical analyte. A parametric UTL95-95 takes into account the variability of current and future observations. When the data set does not follow a discernible distribution, a non-parametric UTL represented by a higher-order statistic (for example, the largest value or the second largest value) will be used as an estimate of BTV. Results derived using the ProUCL software (USEPA 2015) were used to determine UTL95-95 BTVs (see Attachment E). If a data set follows no discernible distribution, ProUCL determines the order statistic for a non-parametric UTL95-95 based on the sample size. This means that the order statistic to use is not fixed *a-priori* in ProUCL. The technical details, including the mathematical equation for determining the parametric and non-parametric UTLs, are described in Section 3.4 of the ProUCL Technical Guide (Singh and Singh, 2013). For data sets with non-detects, the technical details are described in Section 5.3.3 of the same document.

3.2 BTV Selection Process

For each established background data set, the normality of the data was first checked using the goodness-of-fit test in the ProUCL software. Based on the ProUCL guidelines, the Shapiro-Wilk W test was used for a sample size of 50 or less and the Lillifors test was used for a sample size greater than 50. If the data fit a normal distribution, the parametric (normal) method was used to derive the associated BTVs.

If the data did not fit a normal distribution, a possible fit to a gamma or lognormal distribution was evaluated. If the data fit a gamma distribution, the parametric (gamma) method was used to derive the BTVs. Otherwise, if the data fit a lognormal distribution, the parametric (lognormal) method was used to derive the BTVs. However, specific caution was employed when using lognormal-based UTL, and if such UTL was deemed to be unreliable or unstable, the non-parametric UTL was used instead. If the data did not fit any of the three aforementioned parametric distributions, the non-parametric method was used to derive the associated BTVs.

For each established data set containing one or more non-detects, the Kaplan-Meier (KM) method or the regression on order statistics (ROS) method was used to derive the associated BTVs. When a data set entirely consisted of non-detects, the Limit of Detection (LOD) was used as a non-statistical BTV. If a data set entirely or mostly consisted of non-detects and J-qualified results less than the Limit of Quantitation (LOQ), the LOQ was used as a non-statistical BTV.

3.3 Discussion of BTV Results

Table 5 (without the outlier CH-MW011) and Table 6 (all locations) summarize the results of the BTV calculations. The goodness-of-fit test results, along with the selected UTL95-95 and UTL calculation methods are presented. The UPL95 is also presented for reference and informational purposes only. Table 7 presents a condensed summary of UTL95-95 results for the recommended BTV set without the outlier CH-MW011. Attachment E presents the statistical outputs from the ProUCL software.

Thirteen fraction-analytes were entirely non-detects, and 14 fraction-analytes were entirely below LOQ (but have some "J" qualified detected results). In these cases, the LOD or the LOQ will be used as the non-statistical BTV. The majority of the other fraction-analytes were detected 100% or close to 100% and followed a parametric distribution (mostly normal or gamma). Thus, the background groundwater metal data sets were considered to be relatively robust and likely belonged to a single population without extreme values.

Notes

All groundwater analytical results are reported in ug/L.

If duplicates exist: (1) if the duplicate pair was both detects or both non-detects, the average of the duplicate results was used as a single data point; (2) if the duplicate pair contained a detect and a non-detect, the detected value was used.

If the dataset contains nondetects, summary statistics are estimated by the Kaplan-Meier (KM) method.

Summary statistics calculations are censored at the method detection limit (MDL).

Acronyms

% = percent
-- = no data
max = maximum
MDL = method detection limit
min = minimum
Std Dev = standard deviation
ug/l = microgram per liter

Table 5
BTV Summary Table for Groundwater (Without Outlier CH-MW11)
Camp Hero Remedial Investigation
Montauk, New York

Analyte	n	Percent NDs	Percent Total Results < LOQ	Max Detect	Goodness-of-Fit Test Results (5% Significance Level)	Background Threshold Value (BTV)			
						Upper Tolerance Limit (UTL)	Upper Prediction Limit (UPL)	UTL Method	UPL Method

Notes
All groundwater analytical results are reported in ug/L.
If duplicates exist: (1) if the duplicate pair was both detects or both non-detects, the average of the duplicate results was used as a single data point; (2) if the duplicate pair contained a detect and a non-detect, the detected value was used.
If the dataset contains nondetects, summary statistics and BTVs are estimated by the Kaplan-Meier (KM) or robust regression on order statistics (ROS) method.
BTV calculations are censored at the method detection limit (MDL), as the laboratory had reported detected results ("J") down to the MDL level. Although there may be uncertainties censoring at MDL, the statistical calculations are benefited by maintaining the proper rank-order and using the lowest censoring limit (Helsel 2005).
Goodness-of-Fit Test at 5% significance level is used to test for distributional assumption.
The distributional assumption from Goodness-of-Fit Test and the detection rate are used to select the appropriate BTV calculation method.

Acronyms
% = percent
-- = no data
BTV = background threshold value
LOD = level of detection
LOQ = level of quantitation
max = maximum
n = sample size
ND = non-detect
No. = number
ug/l = microgram per liter
UPL = upper prediction limit
UTL = upper tolerance limit

Table 6
BTV Summary Table for Groundwater (All Locations)
Camp Hero Remedial Investigation
Montauk, New York

Analyte	n	Percent NDs	Percent Total Results < LOQ	Max Detect	Goodness-of-Fit Test Results (5% Significance Level)	Background Threshold Value (BTV)			
						Upper Tolerance Limit (UTL)	Upper Prediction Limit (UPL)	UTL Method	UPL Method

Notes
All groundwater analytical results are reported in ug/L.
If duplicates exist: (1) if the duplicate pair was both detects or both non-detects, the average of the duplicate results was used as a single data point; (2) if the duplicate pair contained a detect and a non-detect, the detected value was used.
If the dataset contains nondetects, summary statistics and BTVs are estimated by the Kaplan-Meier (KM) or robust regression on order statistics (ROS) method.
BTV calculations are censored at the method detection limit (MDL), as the laboratory had reported detected results (“J”) down to the MDL level. Although there may be uncertainties censoring at MDL, the statistical calculations are benefited by maintaining the proper rank-order and using the lowest censoring limit (Helsel 2005).
Goodness-of-Fit Test at 5% significance level is used to test for distributional assumption.
The distributional assumption from Goodness-of-Fit Test and the detection rate are used to select the appropriate BTV calculation method.

Acronyms
% = percent
-- = no data
BTV = background threshold value
LOD = level of detection
LOQ = level of quantitation
max = maximum
n = sample size
ND = non-detect
No. = number
ug/l = microgram per liter
UPL = upper prediction limit
UTL = upper tolerance limit

Gamma GOF Tests on Detected Observations Only

A-D Test Statistic	0.2	**Anderson-Darling GOF Test**
5% A-D Critical Value	0.663	Detected data appear Gamma Distributed at 5% Significance Level
K-S Test Statistic	0.182	**Kolmogorov-Smirnov GOF**
5% K-S Critical Value	0.4	Detected data appear Gamma Distributed at 5% Significance Level

Detected data appear Gamma Distributed at 5% Significance Level

Gamma Statistics on Detected Data Only

k hat (MLE)	1.422	k star (bias corrected MLE)	0.522
Theta hat (MLE)	106.3	Theta star (bias corrected MLE)	289.5
nu hat (MLE)	11.38	nu star (bias corrected)	4.178
MLE Mean (bias corrected)	151.2		
MLE Sd (bias corrected)	209.2	95% Percentile of Chisquare (2kstar)	3.951

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Nonparametric Distribution Free Background Statistics

Data appear to follow a Discernible Distribution at 5% Significance Level

Nonparametric Upper Limits for BTVs(no distinction made between detects and nondetects)

Order of Statistic, r	13	95% UTL with95% Coverage	338
Approx, f used to compute achieved CC	0.684	Approximate Actual Confidence Coefficient achieved by UTL	0.487
Approximate Sample Size needed to achieve specified CC	59	95% UPL	338
95% USL	338	95% KM Chebyshev UPL	463.6

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

Nonparametric Distribution Free Background Statistics

Data appear to follow a Discernible Distribution at 5% Significance Level

Nonparametric Upper Limits for BTVs(no distinction made between detects and nondetects)

Order of Statistic, r	14	95% UTL with95% Coverage	20500
Approx, f used to compute achieved CC	0.737	Approximate Actual Confidence Coefficient achieved by UTL	0.512
Approximate Sample Size needed to achieve specified CC	59	95% UPL	20500
95% USL	20500	95% KM Chebyshev UPL	25323

ProUCL Output - UTL/UPL
(version 5.1.002)

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

Nonparametric Distribution Free Background Statistics

Data appear to follow a Discernible Distribution at 5% Significance Level

Nonparametric Upper Limits for BTVs(no distinction made between detects and nondetects)

Order of Statistic, r	14	95% UTL with95% Coverage	7.8
Approx, f used to compute achieved CC	0.737	Approximate Actual Confidence Coefficient achieved by UTL	0.512
Approximate Sample Size needed to achieve specified CC	59	95% UPL	7.8
95% USL	7.8	95% KM Chebyshev UPL	9.473

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

Nonparametric Distribution Free Background Statistics

Data do not follow a Discernible Distribution (0.05)

Nonparametric Upper Limits for BTVs(no distinction made between detects and nondetects)

Order of Statistic, r	13	95% UTL with95% Coverage	0.13
Approx, f used to compute achieved CC	0.684	Approximate Actual Confidence Coefficient achieved by UTL	0.487
Approximate Sample Size needed to achieve specified CC	59	95% UPL	0.13
95% USL	0.13	95% KM Chebyshev UPL	0.136

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.

Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers

and consists of observations collected from clean unimpacted locations.

The use of USL tends to provide a balance between false positives and false negatives provided the data

represents a background data set and when many onsite observations need to be compared with the BTV.

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

ProUCL Output - UTL/UPL
(version 5.1.002)

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

95% Chebyshev UPL	35869	99% Percentile	20116
95% USL	20500		

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

ProUCL Output - UTL/UPL

Nonparametric Distribution Free Background Statistics

Data appear to follow a Discernible Distribution at 5% Significance Level

Nonparametric Upper Limits for BTVs(no distinction made between detects and nondetects)

Order of Statistic, r	13	95% UTL with95% Coverage	3.7
Approx, f used to compute achieved CC	0.684	Approximate Actual Confidence Coefficient achieved by UTL	0.487
Approximate Sample Size needed to achieve specified CC	59	95% UPL	3.7
95% USL	3.7	95% KM Chebyshev UPL	4.68

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

Nonparametric Distribution Free Background Statistics

Data appear to follow a Discernible Distribution at 5% Significance Level

Nonparametric Upper Limits for BTVs(no distinction made between detects and nondetects)

Order of Statistic, r	13	95% UTL with95% Coverage	3.7
Approx, f used to compute achieved CC	0.684	Approximate Actual Confidence Coefficient achieved by UTL	0.487
Approximate Sample Size needed to achieve specified CC	59	95% UPL	3.7
95% USL	3.7	95% KM Chebyshev UPL	4.646

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

Nonparametric Distribution Free Background Statistics

Data appear to follow a Discernible Distribution at 5% Significance Level

Nonparametric Upper Limits for BTVs(no distinction made between detects and nondetects)

Order of Statistic, r	13	95% UTL with95% Coverage	0.555
Approx, f used to compute achieved CC	0.684	Approximate Actual Confidence Coefficient achieved by UTL	0.487
Approximate Sample Size needed to achieve specified CC	59	95% UPL	0.555
95% USL	0.555	95% KM Chebyshev UPL	0.904

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

95% Chebyshev UPL	11.41	99% Percentile	6.14
95% USL	6.2		

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Nonparametric Distribution Free Background Statistics

Data appear to follow a Discernible Distribution at 5% Significance Level

Nonparametric Upper Limits for BTVs(no distinction made between detects and nondetects)

Order of Statistic, r	13	95% UTL with95% Coverage	2.4
Approx, f used to compute achieved CC	0.684	Approximate Actual Confidence Coefficient achieved by UTL	0.487
Approximate Sample Size needed to achieve specified CC	59	95% UPL	2.4
95% USL	2.4	95% KM Chebyshev UPL	3.029

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

Nonparametric Distribution Free Background Statistics

Data appear to follow a Discernible Distribution at 5% Significance Level

Nonparametric Upper Limits for BTVs(no distinction made between detects and nondetects)

Order of Statistic, r	13	95% UTL with95% Coverage	33100
Approx, f used to compute achieved CC	0.684	Approximate Actual Confidence Coefficient achieved by UTL	0.487
Approximate Sample Size needed to achieve specified CC	59	95% UPL	33100
95% USL	33100	95% KM Chebyshev UPL	42422

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

Nonparametric Distribution Free Background Statistics

ProUCL Output - UTL/UPL
(version 5.1.002)

Data appear to follow a Discernible Distribution at 5% Significance Level

Nonparametric Upper Limits for BTVs(no distinction made between detects and nondetects)

Order of Statistic, r	14	95% UTL with95% Coverage	30000
Approx, f used to compute achieved CC	0.737	Approximate Actual Confidence Coefficient achieved by UTL	0.512
Approximate Sample Size needed to achieve specified CC	59	95% UPL	30000
95% USL	30000	95% KM Chebyshev UPL	43369

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

95% Chebyshev UPL	20168	99% Percentile	12326
95% USL	12700		

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

95% Chebyshev UPL	2387	99% Percentile	1275
95% USL	1300		

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Nonparametric Distribution Free Background Statistics

Data appear to follow a Discernible Distribution at 5% Significance Level

Nonparametric Upper Limits for BTVs(no distinction made between detects and nondetects)

Order of Statistic, r	13	95% UTL with95% Coverage	4.7
Approx, f used to compute achieved CC	0.684	Approximate Actual Confidence Coefficient achieved by UTL	0.487
Approximate Sample Size needed to achieve specified CC	59	95% UPL	4.7
95% USL	4.7	95% KM Chebyshev UPL	8.384

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

95% Chebyshev UPL	6941	99% Percentile	4333
95% USL	4440		

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Approx, f used to compute achieved CC	0.684	Approximate Actual Confidence Coefficient achieved by UTL	0.487
Approximate Sample Size needed to achieve specified CC	59	95% UPL	4.5
95% USL	4.5	95% KM Chebyshev UPL	5.881

ProUCL Output - UTL/UPL
(version 5.1.002)

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

Gamma ROS Statistics using Imputed Non-Detects

GROS may not be used when data set has > 50% NDs with many tied observations at multiple DLs

GROS may not be used when kstar of detects is small such as <1.0, especially when the sample size is small (e.g., <15-20)

For such situations, GROS method may yield incorrect values of UCLs and BTVs

This is especially true when the sample size is small.

For gamma distributed detected data, BTVs and UCLs may be computed using gamma distribution on KM estimates

Nonparametric Distribution Free Background Statistics

Data appear to follow a Discernible Distribution at 5% Significance Level

Nonparametric Upper Limits for BTVs(no distinction made between detects and nondetects)

Order of Statistic, r	13	95% UTL with95% Coverage	8
Approx, f used to compute achieved CC	0.684	Approximate Actual Confidence Coefficient achieved by UTL	0.487
Approximate Sample Size needed to achieve specified CC	59	95% UPL	8
95% USL	8	95% KM Chebyshev UPL	10.33

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

Nonparametric Distribution Free Background Statistics

Data appear to follow a Discernible Distribution at 5% Significance Level

Nonparametric Upper Limits for BTVs(no distinction made between detects and nondetects)

Order of Statistic, r	14	95% UTL with95% Coverage	42.4
Approx, f used to compute achieved CC	0.737	Approximate Actual Confidence Coefficient achieved by UTL	0.512
Approximate Sample Size needed to achieve specified CC	59	95% UPL	42.4
95% USL	42.4	95% KM Chebyshev UPL	52.69

Note: The use of USL tends to yield a conservative estimate of BTV, especially when the sample size starts exceeding 20.
Therefore, one may use USL to estimate a BTV only when the data set represents a background data set free of outliers
and consists of observations collected from clean unimpacted locations.
The use of USL tends to provide a balance between false positives and false negatives provided the data
represents a background data set and when many onsite observations need to be compared with the BTV.

June 01st, 2016

Mark MacEwan, P.E.
Senior Program Director, AECOM
3101 Wilson Boulevard, Suite 900
Arlington, VA 22201
D 703.682.9092; mark.macewan@aecom.com.

Mr. MacEwan:

According to the Scope of Work (SOW) pertaining to supporting the overarching former Camp Hero Remedial Investigation (RI) Work Plan (WP) and other planning documents, AECOM intends to check the sites for indicators of residual utilities or unique subsurface features still in place. As part of the contract, subsurface soil samples and/or groundwater samples are required to be acquired near subsurface pollution source features (e.g., underground storage tanks [USTs], above ground storage tanks [ASTs], fuel pump houses [FPHs], waste dumps) without damaging or puncturing military installation infrastructure. Therefore, prior to the sampling activities, Digital Geophysical Mapping (DGM) surveys were planned as a proactive supplement to narrow down the search areas for specific installation infrastructure of interest for subsequent sampling activities. This process will supplement the local public utilities 1-call services as part of utility mark-outs as those only cover active utilities emplaced by the local government. As part of the DGM survey, the following areas were required for assessment of residual installation infrastructure features within the confines of pre-defined search areas at the Camp Hero facility:

- Tank A – Building 0020 – Fire Department, suspected former UST location(s)
- Tank B – Building 0022 – Kitchen/Office, suspected former UST location(s)
- Tank C – Building 0002 – Barracks, suspected former UST location(s)
- Tank D – Building 104R – Commissary, suspected former UST location(s)
- Tank E – Building 3001 – AT&T/Lilco, suspected former UST location(s)
- Tank F – Building FPH – suspected former UST location(s), hazardous materials
- Tank G – Building FPH – suspected former UST location(s),
- Tank 35 - Building FPH – large AST as part of the pump house(s)
- Vaults – Batteries 0216 – unknown use, potential storage or vaults
- Waste Area – Building 0113 – Plotting Room, potential storage or waste dump site

The intent of the geophysical surveys at each of the above sites is to: (a) verify the outline of a tank (if still exists), (b) identify the extent of residual subsurface features, and (c) examine the general vicinity to support the safe subsurface sampling within close proximity to key features.

1.0 FIELD SURVEY NOTES

The field survey methods consisted of a combination of electromagnetic (EM) Digital Geophysical Mapping (DGM) and magnetic (MAG) Analog Geophysical Mapping (AGM) metal detection surveys, at 5-ft increments, within the bounds of passable areas within the bounds of each pre-marked survey area. The DGM was completed using the Geonics EM61-MK2 in relatively open areas while AGM, using a Schonstedt GA-72cd, was reserved for vegetated areas not maneuverable using DGM methods. After each set of sweeps and/or analyses, interpreted locations were relocated, marked, and annotated as to whether a surface feature coincides. As a footnote, the survey techniques will only verify the rough dimensions of a subsurface metal object, not necessarily verify the object is the tank unless inferences can be made because the expected location of the tank matches the outlined location of the tank. Regardless, the objects identified are large enough and should be avoided during sampling or any subsurface investigation activities. The field survey logbook notes in **Attachment A** catalogues file names, field procedures, and surface features pertinent to the process of interpretation of subsurface metal detection data. The expected locations of the tank(s) along with proposed sampling locations, as excerpted from the WP, are provided in **Attachment B** for reference. Lastly, a summary of field surveys with preliminary interpretations specific to each area are as follows. For reference to the text below, the final interpretation maps are provided in **Attachment C**.

1.1 *Tank A – Building 0020*

The findings are shown in **Figure 1** (i.e. a side-by-side representation of the full-sized map Figures B-1, C-1) and summarized by the following:

- Inferred utility junctions, documented culvert end-points, and confirmed fence-line / building infrastructures are identified on the geophysics map
- UST identified in the Figure B-1 could not be identified in C-1 due to the interference from the fence-line observed on surface, which implies the tank was removed as a tank-sized object was not detected elsewhere on survey data
- No unique features were identified which should require new sampling locations
- Utilities should be avoided during subsurface sampling activities

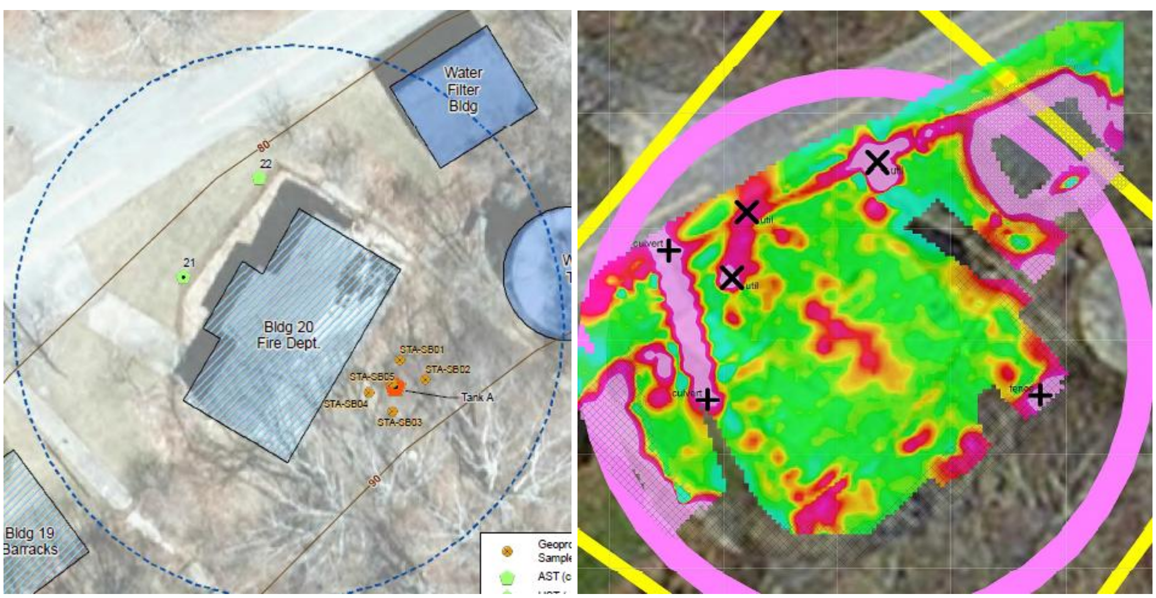

Figure 1. Side-by-Side Representation of Tank A – Building 0020

1.2 *Tank B – Building 0022*

The findings are shown in **Figure 2** (i.e. a side-by-side representation of the full-sized map Figures B-2, C-2) and summarized by the following:

- Inferred utility connections, documented manhole, speed-bump, and well, along with confirmed building infrastructure are identified on the geophysics map
- UST identified in the Figure B-2 appears to be identified in C-2, either in the form of a full-sized tank or the remnant infrastructure associated with the tank
- No unique features were identified which should require new sampling locations
- Utilities should be avoided during subsurface sampling activities

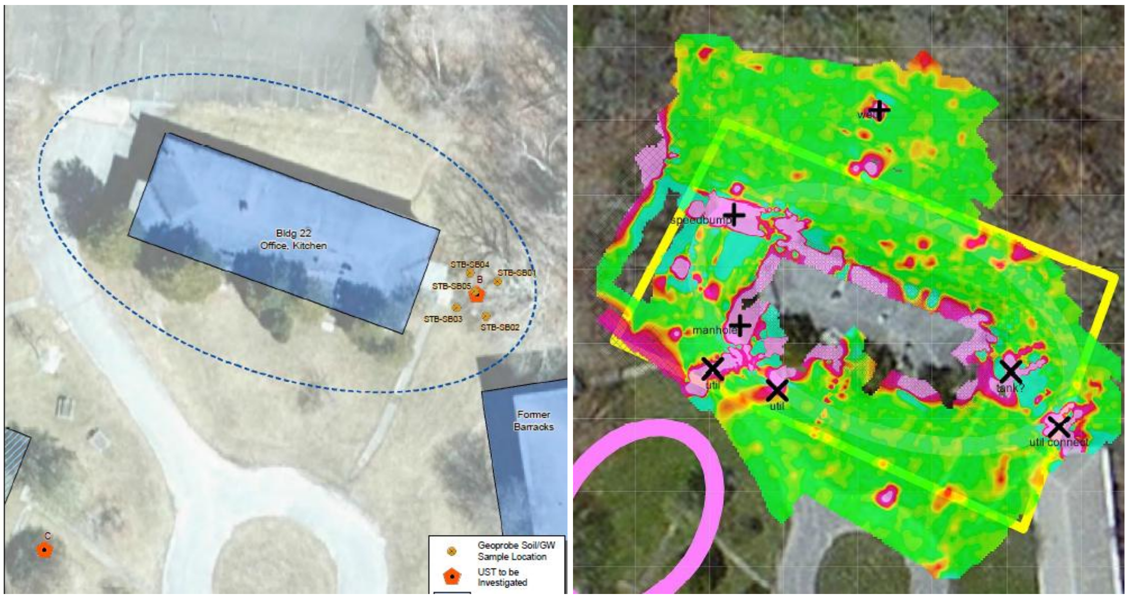

Figure 2. Side-by-Side Representation of Tank B – Building 0022

1.3 *Tank C – Building 0002*

The findings are shown in **Figure 3** (i.e. a side-by-side representation of the full-sized map Figures B-3, C-3) and summarized by the following:

- Inferred utility connections along with debris from former building infrastructure are identified on the geophysics map
- UST identified in the Figure B-3 appears to be identified in C-3, either in the form of a full-sized tank or the remnant infrastructure associated with the tank
- No unique features were identified which should require new sampling locations
- Former building infrastructure and utilities should be avoided during subsurface sampling activities as investigating theses area could damage equipment, along with potentially destroying infrastructure or harming personnel

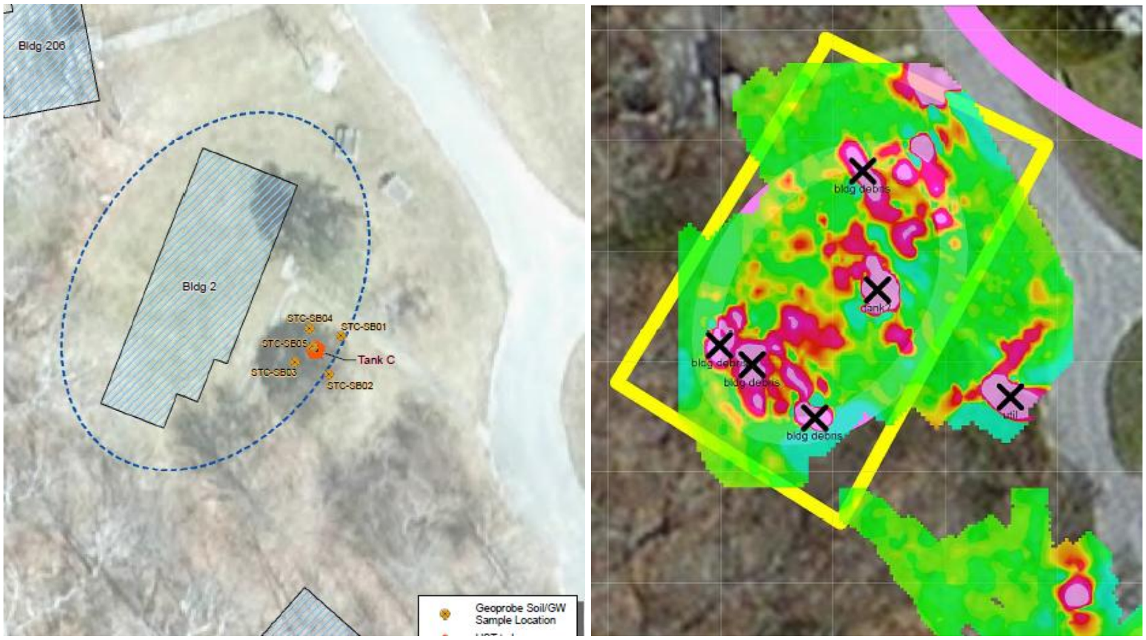

Figure 3. Side-by-Side Representation of Tank C – Building 0002

1.4 *Tank D – Building 104R*

The findings are shown in **Figure 4** (i.e. a side-by-side representation of the full-sized map Figures B-4, C-4) and summarized by the following:

- Inferred abundance of utility connections along with former building and concrete pad infrastructure are identified on the geophysics map
- UST identified in the Figure B-4 could not be identified in C-4, which implies the tank was removed and the tank was not detected elsewhere on survey data
- No unique features were identified which should require new sampling locations
- Former building infrastructure and utilities should be avoided during subsurface sampling activities as investigating theses area could damage equipment, along with potentially destroying infrastructure or harming personnel

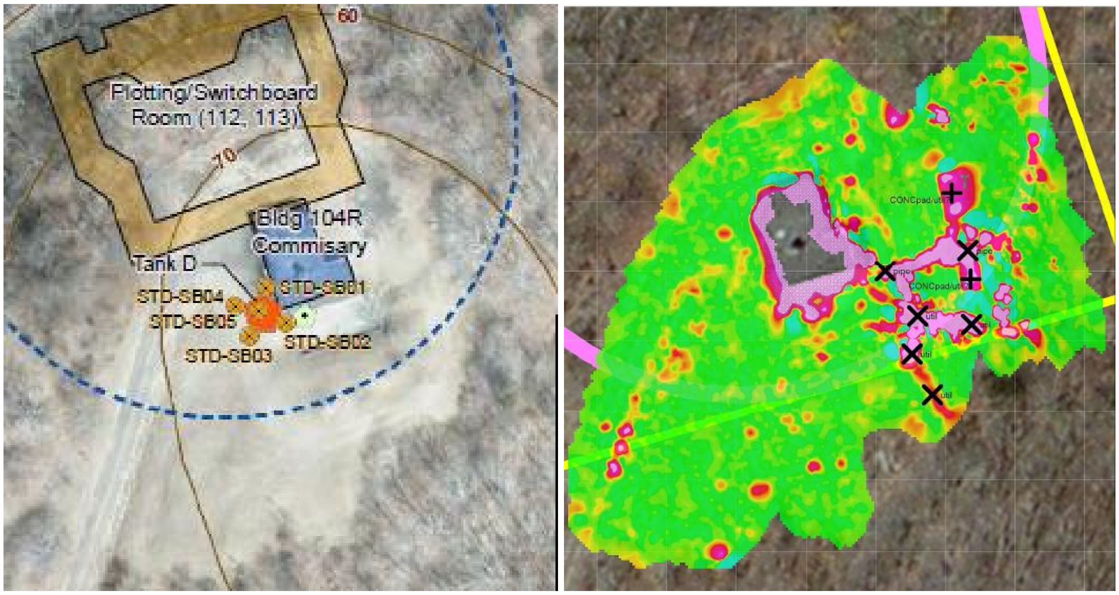

Figure 4. Side-by-Side Representation of Tank D – Building 104R

1.5 *Tank E – Building 3001*

The findings are shown in **Figure 5** (i.e. a side-by-side representation of the full-sized map Figures B-5, C-5) and summarized by the following:

- Confirmed building and fence-line interference, along with verified manholes and telephone pole surface features are identified on the geophysics map
- UST identified in the Figure B-5 could not be identified in C-5 due to the interference from the building, cars, and other metal debris observed on surface
- No unique features were identified which should require new sampling locations
- Current utilities should be avoided if subsurface sampling activities are conducted

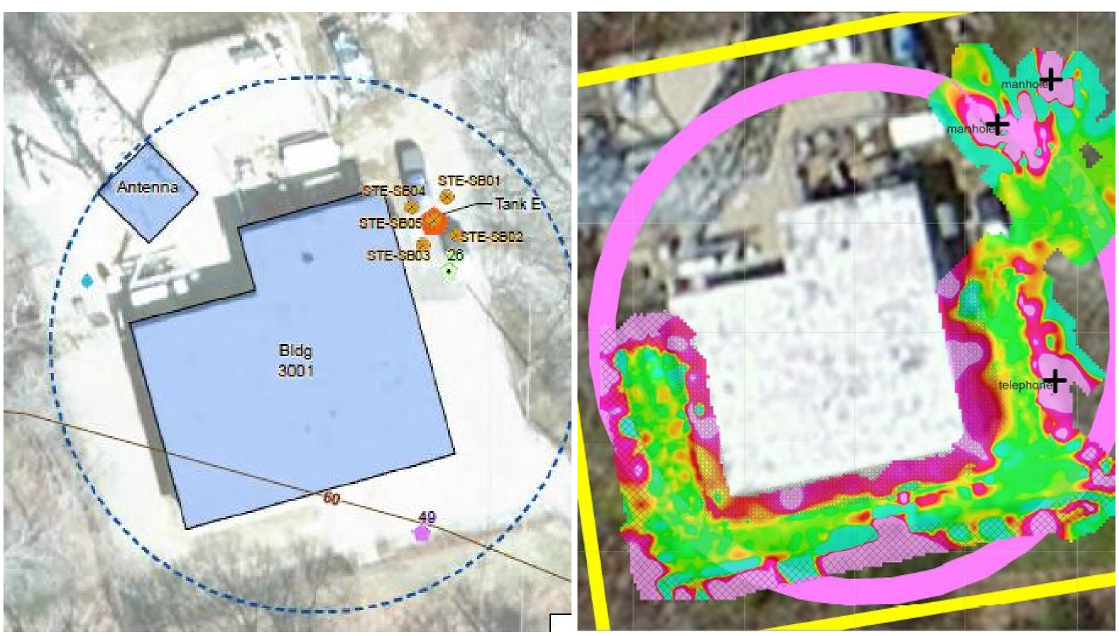

Figure 5. Side-by-Side Representation of Tank E – Building 3001

1.6 *Tank F and Tank G – Pump Houses*

The findings are shown in **Figure 6** (i.e. a side-by-side representation of the full-sized map Figures B-6, B-7, C-6) and summarized by the following:

- Due to dense vegetation and terrain, these area were assessed using AGM and no interferences (e.g., buildings, fences) are identified on the geophysics map
- USTs identified in the Figure B-6/B-7 could not be identified in C-6 due to the fact that a metallic item large enough to represent a UST could not be found and, as such, the USTs are implied to not reside within the bounded areas
- No unique features were identified which should require new sampling locations
- Current features should be avoided if subsurface sampling activities are conducted

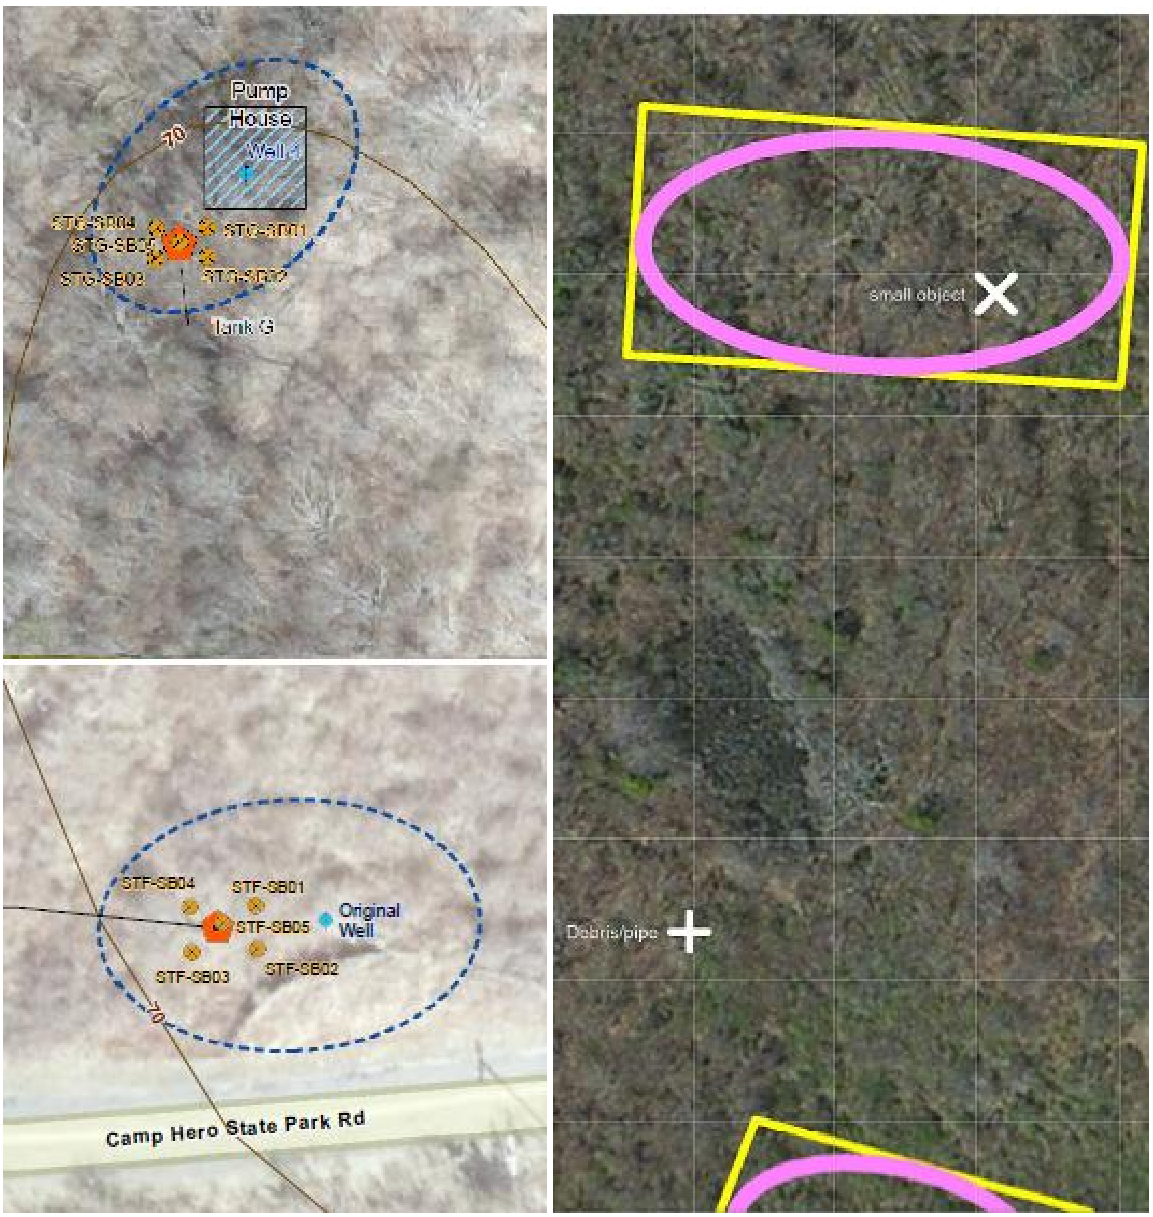

Figure 6. Side-by-Side Representation of Tank F and Tank G – Pump Houses

1.7 *Tank 35 – Fuel Pump House*

The findings are shown in **Figure 7** (i.e. a side-by-side representation of the full-sized map Figures B-8 and C-7) and summarized by the following:

- Confirmed building and fence-line interference, along with fuel piping and fuel pipeline surface features are identified on the geophysics map
- ASTs identified in the Figure B-8 could not be identified in C-7 due to the fact that a structure was an above ground tank and formerly located in a reinforced (with metal rebar) building
- Area west of the building with lots of subsurface anomalies, likely associated with the former fuel pump house infrastructure, should be avoided
- No unique features were identified which should require new sampling locations
- Current features should be avoided if subsurface sampling activities are conducted

Figure 7. Side-by-Side Representation of Tank 35 – Fuel Pump House

1.8 *Storage or Vaults – Battery 216*

The findings are shown in **Figure 8** (i.e. a side-by-side representation of the full-sized map Figures B-9 and C-8) and summarized by the following:

- Confirmed infrastructure interference, as identified on the geophysics map
- USTs identified in the Figure B-9 could not be identified in C-8, likely due to the fact the structures are closed and no longer residing as indicated in DGM data
- Not very many responses of significant size to be considered vaults or storage facilities, mostly debris or infrastructure identified
- No unique features were identified which should require new sampling locations
- Current features should be avoided if subsurface sampling activities are conducted

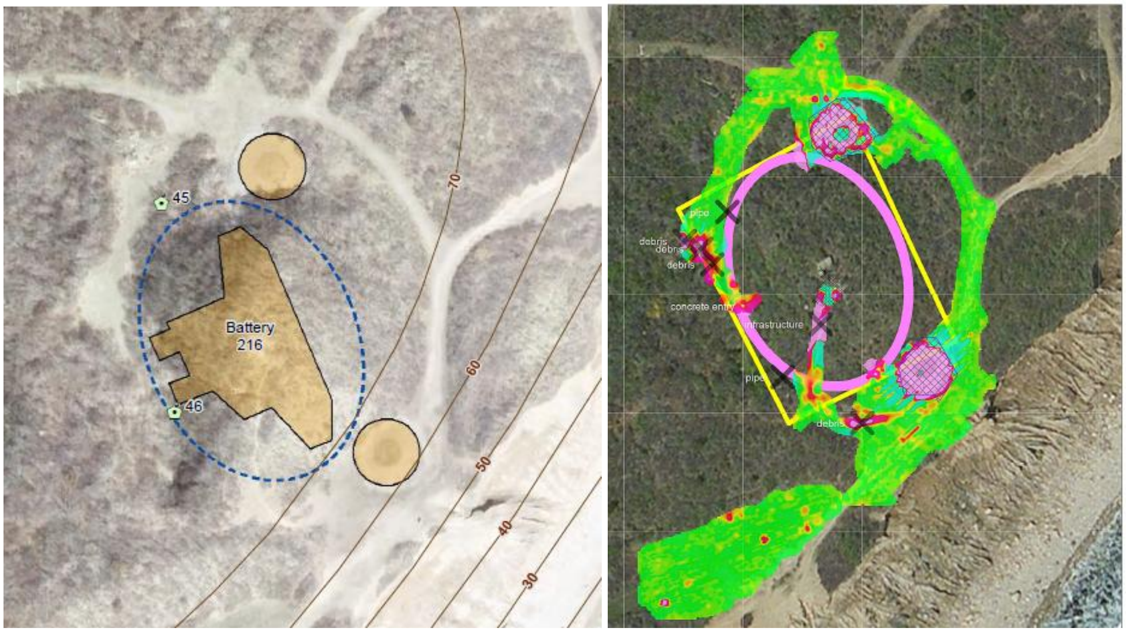

Figure 8. Side-by-Side Representation of Storage or Vaults – Battery 216

1.9 *Waste Area – Building 0113*

The findings are shown in **Figure 9** (i.e. a side-by-side representation of the full-sized map Figures B-10 and C-9) and summarized by the following:

- Two objects and corners of waste area, as identified on the geophysics map
- UST identified in the Figure B-10 could not be identified in C-9, likely due to the fact the structures are closed and no longer residing as indicated in DGM data
- Only one area identified as waste area, remainder of site anomalies too isolated
- No unique features were identified which should require new sampling locations
- Current features should be avoided if subsurface sampling activities are conducted

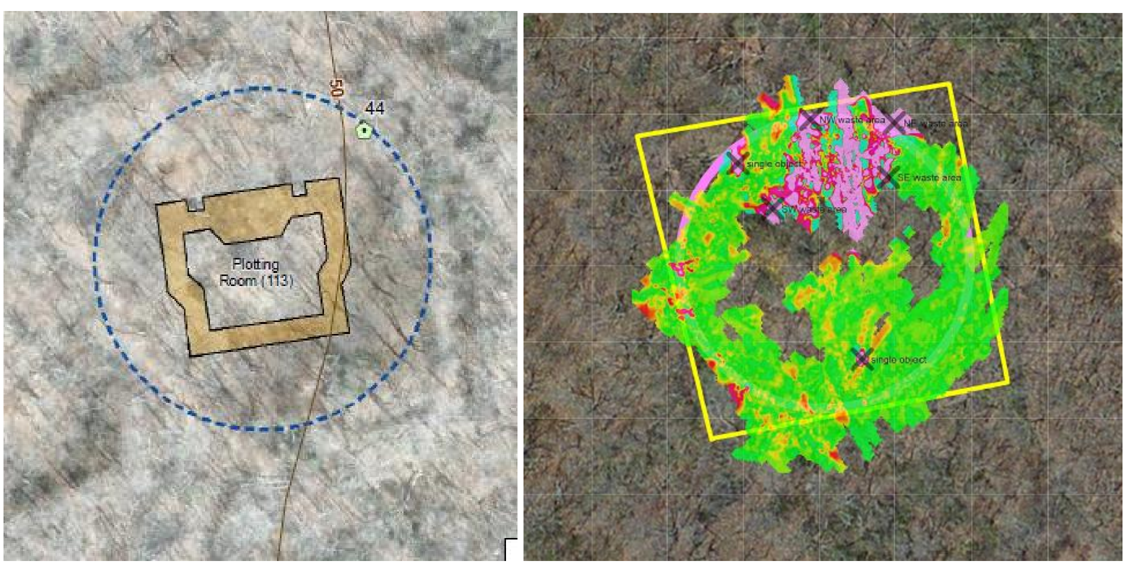

Figure 9. Side-by-Side Representation of Waste Area – Building 113

2.0 APPLICATION SUMMARY OF SURVEY RESULTS

After introducing the side-by-side maps in the previous section, the following is an over-arching summary for the application of the geophysical survey results during sampling activities:

1. Avoid investigating over top of any areas marked-out as infrastructure related (e.g., utilities, buildings, debris) or fuel related (e.g., pipelines, USTs, ASTs);
2. Tank A (Building 0020), Tank D (Building 104R), Tank E (Building 3001), Tank F, Tank G, and Storage Vault (Battery 216) areas *may consider avoiding sampling* as no indications of USTs or other fuel storage within the areas assessed by geophysics;
3. Tank 35 (Building FPH) areas *should consider modifying sampling* as no direct indications of USTs or other significant fuel storage facilities were clearly outlined, but currently standing infrastructure (e.g., building, fencing) and debris were identified to avoid, within the areas assessed by geophysics which overlapped areas expected to contain storage thus requiring careful avoidance;
4. Tank B (Building 0022), Tank C (Building 0002), and Waste Area (Building 113) *should consider maintaining similar sampling patterns* as indications of USTs, UST framework, waste area, and debris were indentified within the areas assessed by geophysics which overlapped areas expected to contain these remnant features; and
5. As a footnote, portions of the Storage Vault (Battery 216) were avoided due to the special plant and vegetation species identified by the AECOM specialist.

The data review results are predicated on sampling in areas deemed necessary while circumventing drilling activities around objects identified within the geophysical survey maps. Anomaly avoidance procedures should be strictly adhered to during sampling activities.

3.0 CONCLUSIONS

In conclusion, areas have been recommended to be separated into three simple categories:

1. Discontinue further sampling due to lack of indications;
2. Modify sampling strategy due to desired sampling locations deemed areas to avoid; and
3. Maintain sampling strategy due to indications of expected remnant features.

If you have any questions or require additional information, please contact the undersigned at your convenience.

LOGBOOK ENTRIES FROM FIELD GEOPHYSICS TEAM

This page intentionally left blank.

May 17, 2016 Camp Hero

Weather: Partly Cloudy with a chance of rain in the late afternoon. High 65°F Low 48°

Crew: Eric Celebrezze (AECOM)
Matt Emmert (URS)

07:00 - Site Safety Brief / Meet with COR & Veg Crew.

07:30 - Setup base station and assemble EM-61.

08:20 - Starting to warm up EM-61 coils. Equipment shake-out.

08:50 - Setup latency test strip.

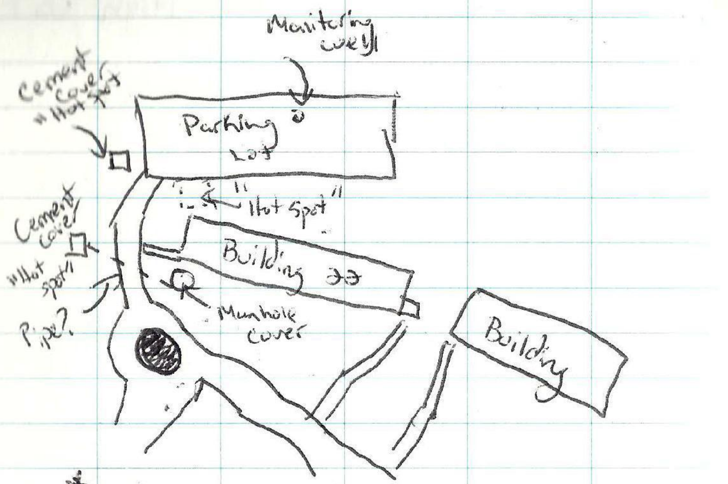
08:52 - Conducting a latency test.
File: 0517lat
Battery: 12.30V

09:08 - Arrive at Bldg 22 for DGM survey.

09:15 - Starting survey
File: 0517BLD22
Battery: 12.30V

10:30 - Finished DGM survey. Three to four hotspots existed that we could audibly hear and at least 1 pipe run was heard while conducting the survey. See map/sketch

May 17, 2Ø16 — Camp Here

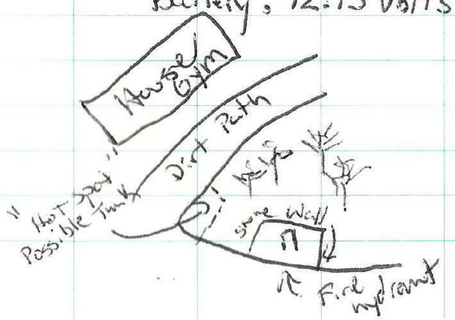


* Note Not to scale

1Ø:55 - Starting DGM survey of the area were building 2 on the map was located. Trees are in the area, survey will be a bit choppy in coverage to avoid obsticles

File: Ø517 BlG2

Battery: 12.15 Volts



*Note Not to Scale

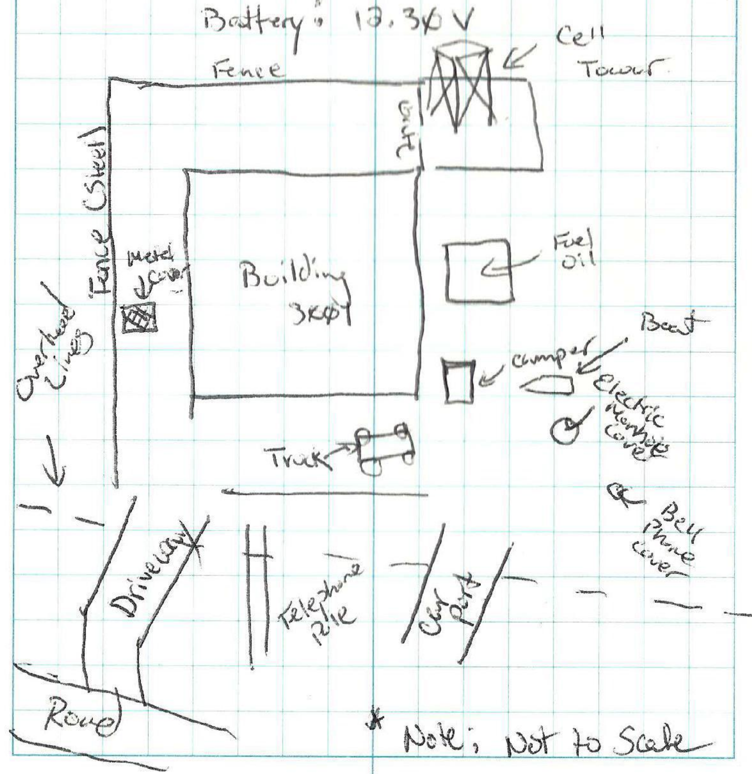
May 17, 2Ø16 — Camp Here

12:5Ø - Arrive at Bldg 3ØØ1 were there is a radio tower in the back corner. Switching the batteries in the EM-61. There is also pockets of cultural debris on the property. A steel fence surrounds the compound.

1255 - Starting DGM survey.

File: Ø517 cop

Battery: 12.3Ø V



* Note: Not to Scale

May 17, 2016 Camp Hero

14:30 - At the fuel pump house to check out veg clearance. Talked to Nicole and suggested a few more clearance locations for option DGM survey results.

14:55 - At the base station conducting a pm latency test.

File: 0517latp

Battery: 12.30 volts

15:00 - Breaking down GPS base station and EM-61 equipment.

15:30 - Left site to process data

END OF REPORT

5/17/16

5/17/16

May 18, 2016 Camp Hero

Weather: Partly Cloudy with a 10% chance of rain. High of 61°F and a low of 47°F. Low UV index.

Crew: Eric Celebrezze (AECOM)

Matt Emmert (URS)

07:15 - Site Safety Meeting

08:00 - Started to setup GPS base station

08:25 - Warming up EM-61 for AM latency tests.

08:40 - Starting AM latency test

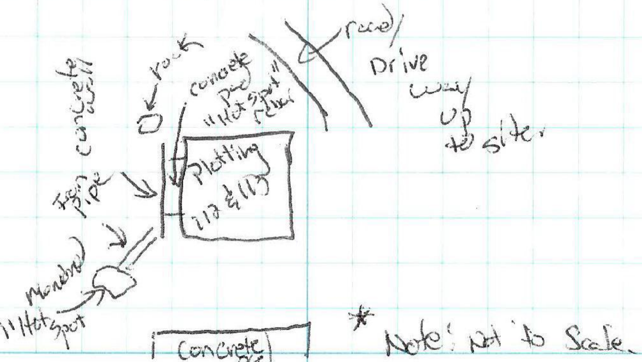
File: 0518latam

Battery: 12.45V

08:52 - At Plotter 112 & 113 for DGM survey.

File: 0518.Plot 112

Battery: 12.45 Volts



* Note: Not to Scale.

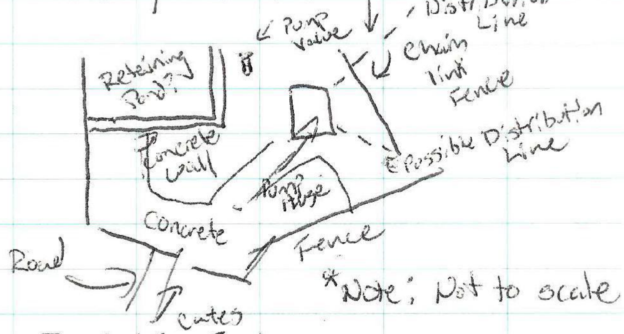
May 18, 2016 Camp Hero

11:50 - Walked Plotting Room 113 to check for veg removed of site. Marked off areas that need to be removed more.

12:10 - Meet with Nicole to explain what veg removal team needs to do in order to conduct DGM survey.

13:15 - At the fuel pump house to begin DGM survey.

File: 0518Fuel
Battery: 12.50V



*Note: Not to scale

File: 0518Fuela
Battery: 12.50V

This file was created due to GPS turning off sometime during the DGM survey.

14:52 - At building 2 site to fill in more DGM survey.

File: 0518Bld2
Battery: 12.30V

May 18, 2016 Camp Hero

16:04 - Starting closing (pm) latency test.

File: 0518latpm
Battery: 12.15V

16:06 - Starting breakdown of equipment.

16:30 - Leaving site to process/download data.

END OF REPORT

5/18/16

5/18/16

May 19, 2Ø16 Camp Hero

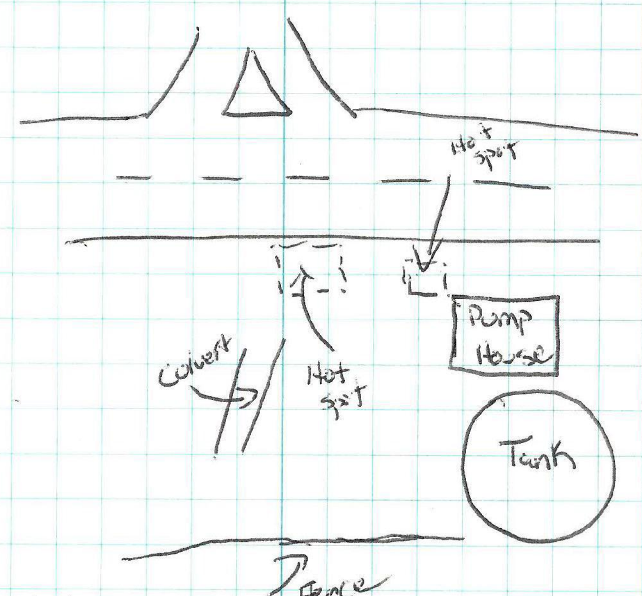
Weather: Cloudy with early AM rain. High of 61°F. Low of 47°F. Low UV index.

Crew: Eric Celebrezze (AECOM)
Matt Emmert (URS)

Ø7:ØØ - On site for site safety meeting.
Ø7:3Ø - Setup the GPS base station and start EM-61 startup.
Ø8:ØØ - Warming up coils for about 15 minutes for AM latency test.
Ø8:15 - Morning latency test
File: Ø519 latam
Battery: 12.6ØV
Ø8:25 - At Plotting 113 doing site walk before starting survey.
Ø8:35 - Starting DGM survey
File: Ø519 Plot 113a
Battery: 12.6ØV
1Ø:1Ø - Finished First Section of Plotting 113 Called Brian about previous days data. Only Bldg 2 additional has been processed.
1Ø:3Ø - Used GPS to determine the area provided to be DGM Plotting 113 is not correct. Plot 113 is now located using the centroid point.

May 19, 2Ø16 Camp Hero

1Ø:3Ø - Veg removal crew was called to come to area and remove veg around the Bunker of 113. Top of bunker will be mag/flag. for anomalies.
11:4Ø - At Fire house to conduct DGM survey to locate tanks.
File: Ø519 Fire
Battery: 12.3ØV



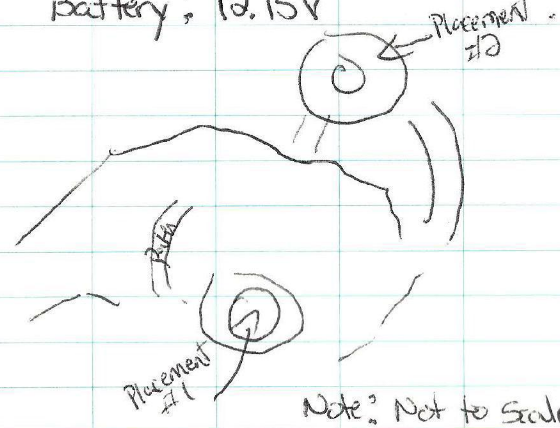
* Note: Not to Scale.

May 19, 2016 Camp Hero

13:00 At Battery 216 for DGM survey.

File: 0519 216

Battery: 12.15V



Note: Not to Scale

14:40 - Stopping DGM survey at Battery 216 to meet Nicole at Plotting 213 AOC to check on veg clearance.

15:15 - Going to conduct a DGM survey on an outer and inner boundry of where the EM-61 can collect data at Plotting Room 113.

File: 0519 Plot 113 ~~Room~~

Battery: 12.00V

15:45 - Conducting PM latency test

File: 0519 latpm

Battery: 12.00V

May 19, 2016 Camp Hero

16:00 - Breaking down GPS base station and packaging up all equipment.

16:30 - Heading out / off-site to download and preprocess todays data.

May 2Ø, 2Ø16 Camp Hero

Weather: Cloudy with a High of 60°F and a low of 47°F. Low UV Index today. Turning to Mostly Sunny.

Crew: Eric Celebrezze (AECOM)
Matt Emmert (URS)

Ø7:ØØ - Site Safety Meeting

Ø7:3Ø - Setting up GPS base station and assemble EM-61 MK2.

Ø7:45 - Started warming up EM-61 coils for morning latency test.

Ø7:55 - Starting morning latency.
File: Ø52Ø latam
Battery: 12.6Ø V

Ø8:ØØ - Heading to Plotting Room 113 to finish DGM survey in that area. Tree cover will be a concern for data collection and we will increase overlap and break into small pieces to achieve maximum coverage.

Ø8:Ø5 - Starting Plotting Room 113
File: Ø52Ø Plot 113
Battery: 12.60V

11:15 - At Battery 216 to finish up DGM survey started yesterday
File: Ø52Ø Bat 216
Battery: 12.60V

May 2Ø, 2Ø16 Camp Hero

12:Ø2 - Finishing another front section of Battery 216.
File: Ø52Ø Bat 216a
Battery: 12.45 V

12:35 - All areas open to DGM survey have been collected at Battery 216.

12:45 - At the base station / latency test strip to close out DGM survey.
File: Ø52Ø latpm
Battery: 12.45 V

13:ØØ Started Analog geophysical survey of Battery 113.

16:ØØ - Started to break down gps base station.

May 20, 2016 Camp Hero

16:30 - Off-site to download and pre process data.

END OF REPORT

EWC 5/20/16

[signature] 5/20/16

Weather: High of 67°F and low of 51°F. Partly Sunny with a low UV index. 17% Chance of Rain in the afternoon.

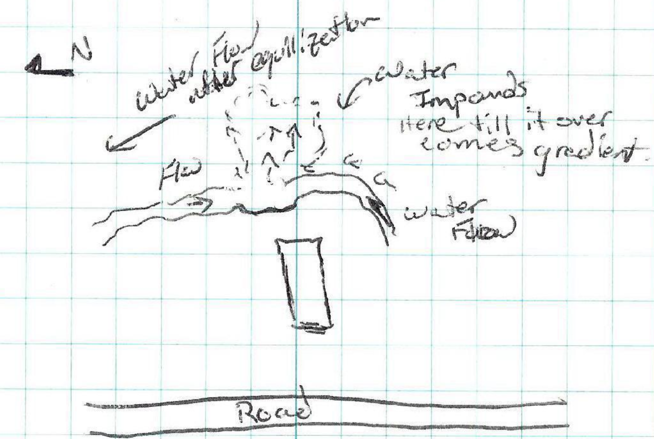
Crew: Eric Celebrezze (AECOM)
Matt Emmert (URS)
Nicole Schulman (URS)

07:00 - Morning Site Safety Meeting.

07:15 - Setup GPS base station

07:30 - GPS is initialized and ready for relocates.

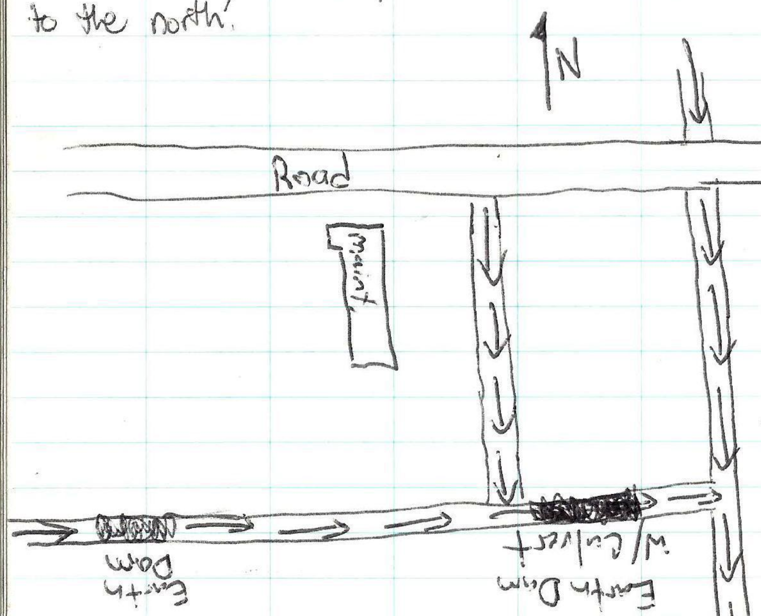
07:40 - Went to GPS culvert/stream sediment however could not get a GPS lock in the stream to take an accurate measurement.



* Note: Not to scale.

May 23, 2016 Camp Hero

08:50 - The general flow of the stream is to the north past behind the maintence building. However, directly behind the building is a slight elevation that heeds to the south. Under storm conditions it is safe to assume the water impounds inbetween these two areas. A lack of plant life supports this assumption of water impoundment. It is also probable that once the gradient has been overcome by the impounded water flow resumes to the north.

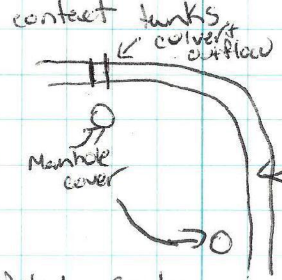


*Note: Not to Scale

May 23, 2016 Camp Hero

09:50 - GPS Well near Battery 113. Found pipe coming out of the ground well concrete debris around it.

10:30 - GPS Two (2) wells near the chlorine contact tanks.



*Note: Not to Scale.

12:00 - Start Analog Survey of Battery 216. Marked out 3 additional locations of possible tanks.

13:00 - Conducting survey of AGP4. Found a pipe and what used to be a manhole that has eroded away.

14:00 - Nicole Schulman off site.

15:02 - Removing V4 off list as it is concrete/rebar.

15:29 - B3 is Manhole cover Removing from list.

15:39 - E3 is Manhole cover Removing from list. E1 is telephone pole with wires. Removed.

May 23, 2016 Camp Hro.

16:37 - A6 was fence and removed from list

16:45 - Breaking down GPS base station and packing away equipment.

GPS Points from survey

EXECUTIVE SUMMARY

Camp Hero is a formerly used defense site (FUDS) undergoing a Remedial Investigation and Feasibility Study (RI/FS) under the Comprehensive Environmental Restoration, Compensation, and Liability Act (CERCLA). A total of 47 areas of concern (AOCs) have been identified during previous investigations, which included Phase I and II RI field investigations. This preliminary screening evaluation was completed for the available RI dataset to (1) determine which AOCs require further assessment as part of the Phase III RI field investigation and (2) refine the list of parameters for sample collection during the Phase III RI field investigation with the intent of completing the RI phase of the CERCLA process.

This document summarizes the existing dataset used in the evaluation, establishes the selection of the preliminary screening values, including site-specific background threshold values (BTVs), and summarizes the results of the evaluation. To complete the preliminary screening evaluation, the maximum detected concentration for each analyte in surface and subsurface soil was compared to the most conservative applicable screening criteria and the site-specific BTVs. If no analytes at an AOC exceeded the screening criteria or BTVs, the AOC was identified for no further action (NFA) under the CERCLA process. If however, any analyte exceeded the screening criteria and also the BTVs, then that AOC was identified as requiring further assessment. In some cases, AOCs were also recommended for further assessment if field observations or measurements indicated evidence of a potential release.

Of the 47 AOCs identified at Camp Hero, NFA is warranted for 25 AOCs, and further assessment is recommended for 21 AOCs as part of the Phase III RI field investigation. The 47th AOC (Waste Disposal System or WSD) is comprised of 14 segments across the Camp Hero site. Of these segments, 8 warrant NFA, and 6 warrant further assessment.

This page intentionally left blank.

1.0 INTRODUCTION AND SITE BACKGROUND

Camp Hero is a formerly used defense site (FUDS) undergoing a Remedial Investigation and Feasibility Study (RI/FS) under the Comprehensive Environmental Restoration, Compensation, and Liability Act (CERCLA). A total of 47 areas of concern (AOCs) have been identified during previous investigations, which included Phase I and II RI field investigations. This RI/FS program for Camp Hero is being conducted by AECOM in coordination with the United States Army Corps of Engineers (USACE), New England and New York Districts, as well as the Environmental and Munitions (EM) Center of Expertise (CX).

1.1 Preliminary Screening Evaluation Scope and Objectives

The primary objectives of the Camp Hero RI are to determine the nature and extent of potential releases and impacts in site media from former military operations, and to subsequently quantify whether there are unacceptable risks posed to human health or ecological receptors. This preliminary screening evaluation was completed for the available RI dataset to (1) determine which AOCs require further assessment as part of the Phase III RI field investigation and (2) refine the list of parameters for sample collection during the Phase III RI field investigation with the intent of completing the RI phase of the CERCLA process.

1.2 Site Location and History

Camp Hero State Park is located on the eastern tip of the south fork of Long Island, New York, approximately 5 miles east of the Village of Montauk. The park consists of 469 acres and is bound by Montauk Highway (Route 27) to the north, the Atlantic Ocean to the south, Montauk Point State Park to the east, and Camp Hero State Park's undeveloped sanctuary area to the west. The landscape includes wooded areas, freshwater wetlands, and seaside bluffs.

The park was initially established in early 1942 as a Coastal Defense Installation. Military development included a series of underground bunkers, gun batteries, barracks, mess halls, hospital facilities, a motor repair shop, a recreation facility, sentry boxes, water supply and sewage facilities, and a radar tower. The military operations continued after 1952, when the park was renamed the Montauk Air Force Station, and generally ended in 1980 when remaining military personnel were transferred off-base and the park was subsequently conveyed to New York State as "Camp Hero State Park" in 1984. In 2015 and 2016, a total of 47 potential AOCs were identified by the USACE for environmental investigation via the CERCLA process.

1.3 Compilation of the Dataset

A historical records review conducted as part of the Camp Hero RI identified 47 AOCs requiring environmental investigation. The AOCs included former waste disposal areas, former coal storage areas, abandoned drum locations, possible and former USTs, and a Motor Pool building, among others. The existing dataset for the preliminary screening was collected over two sampling events at Camp Hero:

- ***Phase I Investigation (AECOM-Tidewater JV 2016).*** The primary objective of the Phase I investigation was to determine the presence or absence of contamination at the 47 Camp Hero AOCs. Phase I activities included collection of discrete, biased surface and subsurface soil samples for use in the preliminary screening evaluation and grab groundwater samples for use in refining the groundwater conceptual site model (CSM).

- ***Phase II Investigation (AECOM-Tidewater JV 2017).*** Phase II activities at the former Building 203 AOC included surface soil sample collection on discrete, unbiased grids within two sample units (SUs) to support the EPC calculation; discrete biased subsurface soil sampling within two SUs for use in preliminary screening; and groundwater sample collection from six newly-installed permanent monitoring wells to support the groundwater CSM.

Figure 1 provides the layout of Camp Hero, with the locations of surface and subsurface soil samples collected during the Phase I and II RI field investigations. These sampling locations provided the datasets for this preliminary screening evaluation. Surface soil samples were collected from 0 to 1 foot (ft) below ground surface (bgs) and subsurface soil samples were collected from 1 to 10 ft bgs.

2.0 SELECTION OF PRELIMINARY SCREENING VALUES

For the available Phase I and II RI field investigation datasets, the maximum detected concentration for each analyte in surface and subsurface soil was compared to the most conservative applicable screening criteria and the site-specific background threshold values (BTVs). If no analytes at an AOC exceeded the screening criteria or BTVs, the AOC was identified for no further action (NFA) under the CERCLA process. If however, any analyte exceeded the screening criteria and also the BTVs, then that AOC was identified as requiring further assessment. In some cases, AOCs were also recommended for further assessment if field observations or measurements indicated evidence of a potential release.

2.1 Selection of Human Health Screening Criteria for Soil

Preliminary human health screening values for surface and subsurface soil for all AOCs were based on the most conservative (lowest values) from the following sets of human health criteria:

- USEPA Regional Screening Levels for Residential Soil with a Target Hazard Quotient (THQ) of 0.1 (USEPA 2016), with updated PAH RSLs calculated from recently-released updated benzo[a]pyrene toxicity values (USEPA 2017).
- 6 NYCRR Part 375-1 Remedial Program Residential Soil Cleanup Objectives (SCOs), Table 6.8(b) (NYCRR 2015).

Additionally, preliminary screening for AOCs with potential petroleum impacts also included the following additional sets of New York State criteria:

- NYSDEC CP-51 Soil Cleanup Guidance Supplemental Residential SCOs, Table 1 (NYSDEC 2010a).
- NYSDEC CP-51 Soil Cleanup Guidance Soil Cleanup Levels (SCLs) for Gasoline and Fuel Oil, Tables 2 and 3 (NYSDEC 2010a).

2.2 Selection of Ecological Screening Criteria for Soil

Preliminary ecological screening values for surface soil for all AOCs were selected using a hierarchic approach using the following sets of ecological criteria. These values consider potential risks to invertebrates and plants, as well as birds and mammals (wildlife) as ecological receptors. The priority for these sets of criteria is based on industry standards associated with the toxicity data, supporting documentation, and frequency of updates. Note that subsurface soil was not compared to ecological criteria because subsurface soil is not considered commonly accessible for the representative receptors being evaluated.

For lower trophic level receptors (soil invertebrates and terrestrial plants):

1. USEPA Ecological Soil Screening Levels (Eco-SSLs) for plants and soil invertebrates derived according to Guidance for Developing Ecological Soil Screening Levels (USEPA 2005), including interim documents developed from 2006 through 2008.

2. Oak Ridge National Laboratory (ORNL) Toxicological Benchmarks for Screening Contaminants of Potential Concern for Effects on Terrestrial Plants (Efroymson et al. 1997a).

3. ORNL Toxicological Benchmarks for Screening Contaminants of Potential Concern for Effects on Soil and litter Invertebrates and Heterotrophic Process (Efroymson et al. 1997b).

4. USEPA Region 4 Supplemental Guidance to Ecological Risk Assessment (USEPA 2015).

5. Los Alamos National Laboratory (LANL) Ecorisk Database, Release 3.3 (LANL 2015).

For higher trophic level receptors (birds and mammals):

1. The lower of the USEPA Eco-SSLs for birds and mammals derived according to USEPA guidance (USEPA 2005).

2. The lowest of the wildlife-based soil Preliminary Remediation Goals (PRGs) presented in ORNL's Preliminary Remediation Goals for Ecological Endpoints (Efroymson et al. 1997c).

3. The lower of the soil screening values for birds and mammals presented in USEPA Region 4 Supplemental Guidance to Ecological Risk Assessment (USEPA 2015).

4. The lowest of the wildlife-based soil screening values for birds and mammals presented in the LANL Ecorisk Database (LANL 2015).

Additionally, preliminary screening for AOCs with potential petroleum impacts also included the following additional sets of New York State criteria:

- NYSDEC CP-51 Soil Cleanup Guidance Supplemental Residential SCOs, Table 1 (NYSDEC 2010a).

- NYSDEC CP-51 Soil Cleanup Guidance Soil Cleanup Levels (SCLs) for Gasoline and Fuel Oil, Tables 2 and 3 (NYSDEC 2010a).

2.3 Development of Site-Specific Background Threshold Values

A site-specific background study was completed at Camp Hero to calculate BTVs for surface soil and subsurface soil, which are applied as part of this preliminary screening evaluation. BTVs were also calculated for metals in groundwater. The soil BTVs were calculated for PAHs and TAL metals based on the generally ubiquitous nature of those parameter groups and the relatively frequent finding that they are not exclusively related to CERCLA releases. The derivation and results of BTVs are provided separately. BTVs will also be calculated for surface water and sediment after completion of the Phase III RI field investigation, which will include the collection of background/reference surface water and sediment samples.

The primary objective of the surface and subsurface soil background study was to provide BTVs for comparison to site-specific sampling results collected during prior field investigations. Permutation testing was conducted to 1) compare the mean of two soil type data sets, Whitman Sandy Loam (WSL) and Montauk Loam (ML) and 2) compare the mean of surface and subsurface soil data sets.

If the mean concentrations for the ML and WSL soil types were determined to be similar, then the ML and WSL data sets were combined for that particular metal at the specified depth (surface or subsurface), resulting in one BTV. However, if the mean concentrations were significantly different, then the soil types were analyzed separately for that particular metal, resulting in two BTVs. Similarly, if mean concentrations between surface and subsurface data for a chemical were determined to be similar, a BTV was calculated based on the combined depth data set.

For four metals (arsenic, calcium, iron, and manganese), the soil types were statistically different for at least one depth horizon. In these cases, the lower of the soil type BTVs was conservatively selected for comparison to the existing soil dataset for identifying analytes and AOCs warranting further assessment. For several metals (aluminum, arsenic, beryllium, calcium, chromium, copper, iron, nickel, selenium, silver, vanadium, and zinc), the permutation testing results identified no significant differences between surface and subsurface different soil depths. In these cases, a combined soil depth BTV was derived and used for screening both surface and subsurface data.

In cases, where the permutation testing identified significant differences with the sampling depths, separate surface and subsurface soil BTVs were derived. If more than one BTV was available per each soil depth, the lowest surface soil BTV was selected to evaluate the surface data and the lowest subsurface BTV was used to evaluate the sub-surface data. The BTVs for surface, subsurface soil, and groundwater, and forthcoming BTVs for surface water and sediment will collectively be used in the human health and ecological risk assessments and may be used to assist the team in making risk-based decisions after the risk assessments are completed.

U.S. Environmental Protection Agency (USEPA) ProUCL 5.1 statistical software and PAleontological STatistics (PAST) 3.13 data analysis software were used to conduct the statistical analysis of the background soil data. The analysis included summary statistics, goodness-of-fit testing, permutation testing, outlier testing, and finally BTV calculations. Refer to the background study report for further details.

2.4 Calculation of the Selected Screening Values

To select screening values for this preliminary screening evaluation, the criteria sources identified for human health and ecological receptors (refer to Section 2.1 and 2.2) were compared to select the most conservative (lowest) value for each parameter. Tables 2 and 3 present the comparison for surface soil, and Tables 4 and 5 present the comparison for subsurface soil.

3.0 ADDITIONAL CONSIDERATIONS

In addition to the analytical screening process described in Section 2.0, additional considerations in evaluating AOCs for further assessment included the results of geophysical or magnetometer surveys (provided separately), an evaluation of AOCs under the context of CERCLA, an evaluation of the types of analytes in exceedance at each of the AOCs, and field observations.

3.1 Geophysical and Magnetometer Surveys

Geophysical or magnetometer surveys were completed at 15 AOCs during the Phase I investigations. At 10 AOCs, results indicated that no underground anomalies were present and no samples were warranted. At 2 AOCs, geophysical surveys indicated tank-sized subsurface anomalies, but small "test holes" verified that no tanks were present at these locations and no evidence of a release was observed (petroleum odor or staining). At 1 AOC, geophysical surveys indicated tank-sized subsurface anomalies and evidence of petroleum was observed in a small "test hole" (petroleum odor and elevated PID readings). Soil and grab-groundwater samples were collected at this AOC. Additionally, extensive visual and magnetometer surveys were conducted at 2 AOCs to locate boilers noted by Cashin (1998) at areas H-7 and H-8, but the boilers could not be located. Refer to Section 4.1 for further details.

3.2 CERCLA Context

A total of 2 AOCs and 1 additional area observed during the Phase I field investigation were identified as exhibiting potential impacts that would not be categorized as a CERCLA release, and thus, are being addressed outside the context of CERCLA. Refer to Section 4.1 for further details.

3.3 Types of Analytes

Through this preliminary screening evaluation, there was 1 AOC with no exceedances other than calcium. Calcium is not considered in either the human health or ecological risk assessments, and is considered an essential nutrient. Thus, NFA is warranted for this AOC. Refer to Section 4.1 for further details.

3.4 Field Observations

Field observations during prior investigations were also considered in evaluating AOCs for further assessment. At 4 AOCs, surface and subsurface soil samples collected in vicinity of identified buried debris exhibited no analytes exceeding screening values or BTVs; however, field observations indicated potential groundwater impacts. During temporary well-point grab sampling of groundwater, the field team reported evidence of a petroleum sheen or odor. Based on this observation, further assessment is warranted at these AOCs. Refer to Section 4.2 for further details.

This page intentionally left blank.

4.0 RESULTS OF THE PRELIMINARY SCREENING EVALUATION

The maximum detected concentration for each analyte in surface and subsurface soil was compared to the most conservative applicable screening criteria and the site-specific BTVs. If no analytes at an AOC exceeded the screening criteria or BTVs, the AOC was identified for NFA under the CERCLA process. If however, any analyte exceeded the screening criteria and also the BTVs, then that AOC was identified as requiring further assessment. In some cases, AOCs were also recommended for further assessment if field observations or measurements indicated evidence of a potential release.

Tables 6 through 9 present the results of the preliminary screening evaluation, and Figure 2 provides the sitewide view of the results. On Figure 2, sampling locations are shown in red if they exhibited at least one analyte in exceedance of this evaluation. The remaining sampling locations (without any analytes in exceedance) are shown in black. Table 10 presents a summary of the results for the Camp Hero AOCs, including which AOCs warrant NFA and which will proceed to the Phase III investigation for further assessment.

4.1 AOCs Warranting No Further Assessment

A total of 25 AOCs, plus 8 of 14 segments of the WDS AOC, warrant NFA based on the results of this preliminary screening evaluation, results of the geophysical surveys, or an evaluation of potential CERCLA releases, as summarized in Table 10.

Based on this preliminary screening evaluation of site data, NFA is warranted for Building 201, Building 2010 (UST 30), Building F100C (UST 34), Drum Site (H-22), Engineering Field Office, Open Pits (H-17), Open Pits (H-21), Plotting Room 113, and 8 segments of the WDS (segments -SB04 and -SB05 Septic Tank, -SB10 Box, -SB11 Cesspool, -SB12 Manhole, -SB14 to -SB17 Cesspools, -SB18 to -SB19, and -SB21/-SB22 Septic Tank/Drain Field). No compounds were exceeding preliminary screening values or BTVs in surface or subsurface soil at these AOCs.

Based on the presence of only calcium in excess of screening criteria, NFA is warranted for one component of the WDS (segment -SB20). As previously indicated, calcium is not considered in either the human health or ecological risk assessments and is considered an essential nutrient.

Based on the results of the geophysical surveys, NFA is warranted at AOCs Battery 216, AGC Sites 1 – 4 (including the Camp Hero State Park Bluffs), Building 20 (Suspected Tank A), Building 104R (Suspected Tank D), Building 3001 (Suspected Tank E), Pump House (Suspected Tank F), and Pump House (Suspected Tank G). No underground anomalies were identified during geophysical and magnetometer surveys and no sampling was conducted.

Based on “test holes” conducted during the Phase I investigation, NFA is warranted at AOCs Building 2 (Suspected Tank C) Building 109 (Suspected Tank H). Geophysical surveys at these AOCs indicated tank-sized subsurface anomalies, but small "test holes" verified that no tanks were present at these locations and no evidence of a release was observed (petroleum odor or staining).

Based on results of a magnetometer survey, AOCs H-7 and H-8 Boilers warrant NFA. An extensive visual and magnetometer survey was conducted to locate the boilers noted by Cashin (1998) at areas H-7 and H-8, but the boilers could not be located. Additionally, based on building access restrictions, the AOC Battery 112 also warrants NFA. Entrances to AOC Battery 112 were sealed for safety purposes; building access is not available.

Based on an evaluation of potential CERCLA releases, NFA "under CERCLA" is required for Battery 113, Building 107, and Building 10. PCBs were detected in either wipe or concrete chip samples at Battery 113 and Building 107, and an AST containing weathered fuel was identified in Battery 113. Additionally, paint and jet hydraulic oil cans were identified in Building 10 during the Phase I investigation, which were likely left by military activities at the site. Building 10 was not included as an AOC in the RI WP, but the existing materials were inventoried during the Phase I field effort at the request of the USACE. While no further assessment is deemed necessary as part of Phase III efforts for Battery 113, Building 107, and Building 10, a response action will be recommended to address the aforementioned findings in these areas.

4.2 AOCs Warranting Further Assessment

A total of 21 AOCs, plus 6 segments of the WDS AOC, warrant further assessment as part of the Phase III investigation based on the results of this preliminary screening evaluation. These AOCs either had constituents in surface or subsurface soil exceeding preliminary screening values and BTVs, or field evidence of a potential release, including petroleum odor or sheen on groundwater from temporary wells. Specifically, further assessment is warranted at AST35 [AST-35 (H-13)], FPH (FPH for AST-35), and STB (Suspected Tank B) AOCs based on the field observation of petroleum sheen or odor during grab-groundwater sampling from temporary well-points during the Phase I field investigation. These AOCs warrant further assessment to verify whether petroleum impacts are present.

4.3 Preliminary Screening Evaluation Summary

An overall summary of this preliminary screening evaluation is presented in Table 10. In summary, of the 47 AOCs identified at Camp Hero, NFA is warranted for 25 AOCs, and further assessment is recommended for 21 AOCs as part of the Phase III investigation. The 47th AOC, the WDS, is comprised of 14 segments across the Camp Hero site. Of these segments, 8 warrant NFA, and 6 warrant further assessment. The Phase III sampling approach, including specific analytes and media needing further evaluation, will be established in the Camp Hero Phase III SAP.

Table 1
Selection of Ecological Screening Criteria
Camp Hero Remedial Investigation
Montauk, New York

Notes:
All units are in milligrams per kilogram (mg/kg).
PAH - Polycyclic Aromatic Hydrocarbon.
PCB - Polychlorinated Biphenyl.
SVOC - Semivolatile Organic Compound.
VOC - Volatile Organic Compound.
USEPA - United States Environmental Protection Agency.

1. USEPA 2005. Guidance for Developing Ecological Soil Screening Levels. Office of Emergency and Remedial Response Washington D.C., November 2003, Revised February 2005. Includes interim documents 2006 through 2008. Lower of bird and mammal values selected for wildlife.
2. Efroymson et al. 1997. Toxicological Benchmarks for Screening Contaminants of Potential Concern for Effects on Terrestrial Plants. 1997 Revision, Oak Ridge National Laboratory Oak Ridge, TN, ES/ER/TM-85/R3.
3. Efroymson et al. 1997. Toxicological Benchmarks for Screening Contaminants of Potential Concern for Effects on Soil and litter Invertebrates and Hetertropyic Process: Revision 1997, Oak Ridge National Laboratory Oak Ridge, TN, ES/ER/TM-126/R2.
4 - USEPA Region 4. 2015. Supplemental Guidance to RAGS: Region 4 Bulletins, Ecological Risk Assessment.
http://www.epa.gov/sites/production/files/2015-09/documents/r4_era_guidance_document_draft_final_8-25-2015.pdf. Soil screening values presented in Table 3.
Lower of bird and mammal values selected for wildlife.
5 - Efroymson et al. 1997. Preliminary Remediation Goals for Ecological Endpoints, Oak Ridge National Laboratory Oak Ridge, TN, ES/ER/TM-162/R2. Lowest available bird or mammal value selected for wildlife.
6 - LANL 2015. Ecorisk Database, Release 3.3. Los Alamos National Laboratory (LANL). September 2015. Lowest available bird or mammal value selected for wildlife.
7. 3,4-dichlorophenol used as a surrogate.
8. 3-chlorophenol used as a surrogate.
9. Value is for trivalent chromium (lower of available values for trivalent and hexavalent chromium).
10. Value is for methylmercury.
11. Selected ecological criteria is the lowest of the selected values for plants, invertebrates, and wildlife.

This page intentionally left blank.

Notes:
All units are in milligrams per kilogram (mg/kg).
BTV - Background Threshold Value.
NYCRR - New York Codes, Rules, and Regulations.
PAH - Polycyclic Aromatic Hydrocarbon.
PCB - Polychlorinated Biphenyl.
RSL - Regional Screening Level.
SCO - Soil Cleanup Objective.
THQ - Target Hazard Quotient.
USEPA - United States Environmental Protection Agency.
1. See Table 1 for ecological screening criteria selection.
2. USEPA Regional Screening Levels for Residential Soil with a Target Hazard Quotient (THQ) of 0.1 (USEPA 2016), with updated PAH RSLs calculated from recently-released updated benzo[a]pyrene toxicity values (USEPA 2017).
3. New York Codes, Rules, and Regulations (NYCRR) Chapter 6, Part 375-1 Remedial Program Residential Soil Cleanup Objectives (SCOs), Table 6.8(b) (NYCRR 2015).
4. Details on the development of the soil BTVs are presented in Appendix C of the Phase III Remedial Investigation Sampling and Analysis Plan.
5. Selected criteria is the higher of the Minimum of Agency Criteria and the BTV.

Notes:
All units are in milligrams per kilogram (mg/kg).
< - Result not detected above laboratory reporting limit.
FD - Field duplicate.
ft - feet.
J - Estimated value.
J- - The chemical was positively identified; however, the associated numerical value is a low estimated concentration.
J+ - The chemical was positively identified; however, the associated numerical value is a high estimated concentration.
N - Normal sample.
NE - Not Established.
PAH - Polycyclic Aromatic Hydrocarbon.
PCB - Polychlorinated Biphenyl.
SVOC - Semivolatile Organic Compound.
R - Rejected.
U - Not detected.
UJ - The analyte was not detected; and the reporting limit is approximate.
VOC - Volatile Organic Compound.
1. See Table 2 for selected surface soil criteria without petroleum criteria.
Surface Criteria exceedances are highlighted and bolded

Notes:
All units are in milligrams per kilogram (mg/kg).
< - Result not detected above laboratory reporting limit.
FD - Field duplicate.
ft - feet.
J - Estimated value.
J- - The chemical was positively identified; however, the associated numerical value is a low estimated concentration.
J+ - The chemical was positively identified; however, the associated numerical value is a high estimated concentration.
N - Normal sample.
NE - Not Established.
PAH - Polycyclic Aromatic Hydrocarbon.
PCB - Polychlorinated Biphenyl.
SVOC - Semivolatile Organic Compound.
R - Rejected.
U - Not detected.
UJ - The analyte was not detected; and the reporting limit is approximate.
VOC - Volatile Organic Compound.

Styrene	1.2							< 0.12 UJ	< 0.082 UJ		< 0.00051 U				
tert-Butylbenzene	100														
Tetrachloroethene	0.06							< 0.12 U	< 0.082 U		< 0.00051 U				

Notes:
All units are in milligrams per kilogram (mg/kg).
< - Result not detected above laboratory reporting limit.
FD - Field duplicate.
ft - feet.
J - Estimated value.
J- - The chemical was positively identified; however, the associated numerical value is a low estimated concentration.
J+ - The chemical was positively identified; however, the associated numerical value is a high estimated concentration.
N - Normal sample.
NE - Not Established.
PAH - Polycyclic Aromatic Hydrocarbon.
PCB - Polychlorinated Biphenyl.
SVOC - Semivolatile Organic Compound.
R - Rejected.
U - Not detected.
UJ - The analyte was not detected; and the reporting limit is approximate.
VOC - Volatile Organic Compound.
1. See Table 2 for selected surface soil criteria without petroleum criteria.
Surface Criteria exceedances are highlighted and bolded
