#### **1.0 INTRODUCTION**

This Site Management Plan ("SMP") was prepared for the Pawling Engineered Products, Inc. ("Pawling") facility located at 157 Charles Coleman Boulevard in Pawling, New York (the "Site") at the request of the New York State Department of Environmental Conservation ("NYSDEC") in order to proceed with a reclassification of the Site (Site #314002) from a Class 2 Inactive Hazardous Waste Site to a Class 4 Inactive Hazardous Waste Site (Figure 1).

Pawling operated several remedial systems at the Site from March 1992 to March 2009 to address an area of impacted soil and groundwater that resulted from historic releases associated with a waste burning trench at the Site. Following completion of the remedial work, some contamination was left in the subsurface at this Site, which is hereafter referred to as "residual contamination." This SMP was prepared to manage residual contamination at the Site until the Declaration of Covenants and Restrictions (Appendix A) is extinguished and defines Site-specific implementation procedures as required by the Declaration of Covenants and Restrictions.

This Site Management Plan was prepared on behalf of Pawling, in accordance with the requirements in NYSDEC DER-10 Technical Guidance for Site Investigation and Remediation, dated May 2010 and the guidelines provided by NYSDEC. This SMP addresses the means for implementation of Institutional Controls ("ICs") and Engineering Controls ("ECs") that are required by the Declaration of Covenants and Restrictions for the Site.

#### Purpose Purpose

The Site contains contamination left following completion of the remedial action. ECs have been incorporated into the Site remedy to monitor remaining contamination to ensure protection of public health and the environment. A Declaration of Covenants and Restrictions recorded with the Dutchess County Clerk will require compliance with this SMP and all ECs and ICs placed on the Site. The ICs place restrictions on Site use, and mandate operation, maintenance, monitoring and reporting measures for all ECs and ICs. This SMP specifies the methods necessary to ensure compliance with all ECs and ICs required by the Declaration of Covenants and Restrictions for contamination that remains at the site. This SMP has been approved by the NYSDEC, and compliance with this SMP is required by the grantor of the Declaration of Covenants and Restrictions and the grantor's successors and assigns. This SMP may only be revised with the approval of the NYSDEC.

The SMP provides a detailed description of all procedures required to manage residual contamination at the Site following the completion of the Remedial Action. This includes: (1) development, implementation, and management of all Engineering and Institutional Controls; (2) development and implementation of monitoring systems and a Monitoring Plan; (3) submittal of Periodic Review Reports, performance of inspections and certification of results, and demonstration of proper communication of Site information to NYSDEC; and (4) defining criteria for termination of monitoring and reporting obligations. To address these needs, this SMP includes three plans: (1) an Engineering and Institutional Control Plan for implementation and management of EC/ICs; (2) a Monitoring Plan for implementation of Site Monitoring; and (3) a Site Management Reporting Plan for submittal of data, information, recommendations, and certifications to NYSDEC

Site Management activities, reporting, and EC/IC certification will be scheduled on a certification period basis. The certification period will be once every three years. Important notes regarding this SMP are as follows:

- This SMP defines site-specific implementation procedures as required by the Declaration of Covenants and Restrictions.
- At the time this report was prepared, the SMP and all Site documents related to remedial investigation and remedial action are maintained at the NYSDEC Region 3 offices in New Paltz.

### 1.1 Site Description

The "Site" is the Pawling Engineered Products facility located at 157 Charles Coleman Boulevard, Pawling, Dutchess County, New York (Figure 1). As reported in previous Site investigation documents, Pawling Engineered Products has been at this location since 1946 producing rubber products and fabricated plastics. There are three buildings running north to south along the eastern property boundary with parking on the west side of the Site. The Swamp River is located on the far west and north limits of the Site. The area is a mix of commercial and residential properties with railroad tracks and playing fields for the Trinity Pawling School directly to the east of the Site and the Swamp River directly to the west and north (Figure 1).

# 1.2 Site History

The NYSDEC alleged that from on or about June 2, 1987 the discharges of cooling water from the Site to the Swamp River contained several metals and organic solvents. Subsequent investigations related to this allegation identified solvents in the area of a former waste burning trench located at the northern end of the facility's parking lot. This area became the focus of Remedial Investigation ("RI") and Remedial Action ("RA") at the Site. A more complete description of the Site's history, RI findings, and RA are presented in the following documents:

- Groundwater Investigation, September 2, 1988. Groundwater Technology, Inc.
- *Groundwater Investigation and Remedial Design Report,* August 28, 1990. Groundwater Technology, Inc.
- Limited Feasibility Study, December 27, 1990. Groundwater Technology, Inc.
- Remedial System Design, February 26, 1991. Groundwater Technology, Inc.
- *Record of Decision*, March 1992. New York State Department of Environmental Conservation.
- *Groundwater and Soil Remedial System Start-Up and First Quarterly Report,* August 26, 1992. Groundwater Technology, Inc.
- Project Update, December 2004. Pawling Corporation.
- Status Report, April 2003 through March 2004, March 7, 2005. Shaw Environmental.
- Status Report, February 27, 2007. Roux Associates, Inc.
- Summary of Investigation Soil Vapor Intrusion Study, December 3, 2009. Roux Associates, Inc.
- Groundwater Sampling Results, June 28, 2011. Roux Associates, Inc.

Electronic copies of these documents are presented in Appendix B. In addition, at the time this SMP was prepared; all Site documents related to the RI and RA are maintained at the NYSDEC Region 3 offices in New Paltz, New York.

### **1.3 Geological Conditions**

Based on a review of the RI results, the area of the Site near the former waste burning trench contained 4 to 8 feet of fill material (fine sand, stones, and pieces of rubber) overlying stratified alluvium ranging from silt to gravel. Bedrock in the areas of investigation ranged from 4.5 to

18.5 feet below land surface. Groundwater flows north to northwest at a variable depth of approximately 6 feet below land surface (Groundwater Technology, Inc 1988, 1990a, 1991)

#### **1.4 Remedial Investigation Findings**

The following is a summary of the Remedial Investigation Findings.

#### 1.4.1 Air

A soil vapor intrusion investigation was conducted in March 2009 (Roux Associates, 2009). Analytical data suggested that VOC impacted groundwater beneath the Site contributed a de minimus amount of VOCs to soil vapor. As an example, PCE was detected in groundwater in May 2009 at a concentration of 2.6 micrograms per liter (" $\mu$ g/L") and in soil vapor in March 2009 at a concentration of 8.1  $\mu$ g/m<sup>3</sup>. No other VOCs were detected in both groundwater and soil vapor. There were no VOCs in indoor air that exceeded the New York State Department of Health ("NYSDOH") Air Guidance Values.

#### 1.4.2 Soil

The August 28, 1990 Groundwater Investigation and Remedial Design Report collected several soil samples for laboratory analysis (Groundwater Technologies, Inc., 1990b). That report indicates that there were no volatile, semi-volatile, or priority pollutant metals contamination in the soil at the locations sampled. The August 1992 Groundwater and Soil Remedial System Start-up and First Quarterly Report reported that VOCs in soils analyzed ranged from non-detect to 8,284 parts per billion ("ppb") in NVP-1 at the 8-10 foot interval (in the saturated zone)(Groundwater Technologies, Inc., 1992).

#### 1.4.3 Groundwater

Pre-remedial action groundwater samples were collected between 1988 and 1992. These data were reported in the various Site investigation reports listed in Section 1.2 above, and indicate that the major portion of the groundwater plume was situated between GT-7S and RW-1S (Figure 2) where, in 1992, detected concentrations of total VOCs were 299,000 to 526,000  $\mu$ g/L, respectively (Groundwater Technology, Inc., 1992). At that time, the downgradient edge of the plume located at GT-4S and GT-5S had concentrations of total VOCs of 21 and 31  $\mu$ g/L, respectively (Groundwater Technology, Inc., 1992).

#### **1.5 Summary of Remedial Action**

Pawling began remediation at the Site in 1992 and since that time has implemented a very effective and costly program. All remedial work was done with constant oversight, understanding, and direction from the NYSDEC. The groundwater treatment system began operation on March 11, 1992. Initially the system consisted of groundwater extraction wells, a low-profile air stripper followed by liquid phase granular activated carbon, air sparging, soil vapor extraction ("SVE"), and vapor phase granular activated carbon for off-gas treatment (Groundwater Technology, Inc., 1992). More specifically, the groundwater treatment system consisted of the following components:

- One air sparge point (SP-1);
- Five combined air sparge/SVE points (VP-1 through VP-5) plus one existing monitoring well (GT-2/VP-6);
- Two overburden recovery wells (RW-1S and RW-2S);
- One bedrock recovery well (RW-1D);
- Two bedrock monitoring wells (MW-2D1 and MW-2D2);
- Two overburden monitoring wells (GT-6S and GT-7S);
- One nested vapor probe (NVP-1); and
- Several previously installed onsite and offsite, overburden and bedrock monitoring wells.

Since its installation, the remedial system has undergone various changes and improvements. One of the most significant additions was the installation of a dual phase extraction ("DPE") system at monitoring well GT-7S in August of 1995. The DPE system consisted of a high-vacuum blower connected to GT-7S. The high-vacuum blower pulled groundwater into a knockout tank. The groundwater was then pumped from the knockout tank to the existing low profile air stripper for treatment.

The SVE system was permanently shutdown in June 2003 with NYSDEC approval (Shaw Environmental, 2005). The total amount of volatile organic compounds ("VOCs") removed by the SVE system was approximately 215 pounds. In October 2006, the groundwater treatment system stopped pumping from the two overburden recovery wells RW-1S and RW-2S due to

mechanical issues with the air compressor. The total amount of VOCs removed by the groundwater treatment system at that time was approximately 240 pounds. Historical performance monitoring data included in the attachments to this SMP indicate that the groundwater treatment system was very effective in removing the majority of VOCs from the groundwater and groundwater monitoring showed that concentrations of VOCs in the majority of monitoring wells were below the NYSDEC Ambient Water-Quality Standards and Guidance Values ("AWQSGVs").

In June 2007, a pump was installed in RW-1D and began pumping approximately 12 gallons per minute to the existing air stripper for treatment. Approximately 245,000 gallons of groundwater was extracted from RW-1D. By the end of 2007 VOCs had been detected at concentrations above AWQSGVs in only one well at the Site since 2006 (RW-1D).

The groundwater treatment system was shut down in March 2009 and groundwater samples were collected in May, July, and October 2009. Analytical results indicated that the only detection of VOCs above AWQSGVs was found in GT-7S. These concentrations were relatively low and appeared to have reached a steady state, asymptotic level. Concentrations of VOCs in downgradient wells indicated no exceedances of AWQSGVs demonstrating that contaminants are not migrating from the Site and natural attenuation of residual contamination is occurring.

### **1.5.1 Remaining Contamination**

In May 2011, groundwater samples were collected from three monitoring wells, GT-6S, GT-7S, and RW-ID using low flow sampling procedures (Roux Associates, 2011). Each sample was analyzed for the following volatile organic compounds ("VOCs"): toluene; trichloroethene; tetrachloroethene; 1,l,l-trichloroethane; vinyl chloride; cis-1,2-dichloroethene, and trans-1,2-dichloroethene.

Trichloroethene and cis-1,2-dichloroethene were detected in monitoring well GT-7S at concentrations above their respective NYSDEC AWQSGVs. The total concentration of these VOCs was  $32.2 \,\mu$ g/L. Two degradation products, vinyl chloride and cis-1,2-dichloroethene, were detected in monitoring well RW-1D above their respective NYSDEC AWQSGV at a total concentration of 78.1  $\mu$ g/L indicating natural attenuation of residual contamination is occurring.

# **1.5.2 Engineering and Institutional Controls**

Since contaminated groundwater remains beneath the Site, Engineering and Institutional Controls (ECs and ICs) are required to protect human health and the environment. Long-term management of EC/ICs and of residual contamination will be executed under this Site specific SMP.

The Site has one EC as follows:

• Monitored Natural Attenuation.

A series of ICs are required to implement, maintain and monitor this EC. The Declaration of Covenants and Restrictions requires compliance with these ICs. The ICs consist of the following:

- The Grantor and the Grantor's successors must comply with the Declaration of Covenants and Restrictions and with all elements of this SMP.
- Groundwater monitoring must be performed and reported as defined in this SMP (Sections 3.0 and 5.0).
- On-site environmental monitoring devices, including groundwater monitor wells must be protected and replaced as necessary to ensure continued functioning in the manner specified in this SMP.
- ECs may not be discontinued without an amendment or the extinguishment of the Declaration of Covenants and Restrictions for the Site.

The Site has certain ICs in the form of Site restrictions. Adherence to these ICs is required under the Declaration of Covenants and Restrictions. ICs that apply to the Site are:

- Use of groundwater underlying the Site is prohibited without treatment rendering it safe for the intended use.
- Grantor agrees to submit to NYSDEC a written statement that certifies, under penalty of perjury, that: (1) controls employed at the Site are unchanged from the previous certification or that any changes to the controls were approved by the NYSDEC; and, (2) nothing has occurred that impairs the ability of the controls to protect public health and environment or that constitute a violation or failure to comply with the SMP. NYSDEC retains the right to access such Site at any time in order to evaluate the continued maintenance of any and all controls. This certification shall be submitted annually, or an alternate period of time that NYSDEC may allow. This statement must be certified by an expert that the NYSDEC finds acceptable.

The objective of the identified EC/ICs is to:

• Prevent future exposure to contaminated groundwater.

## 2.0 ENGINEERING AND INSTITUTIONAL CONTROL PLAN

Remedial activities completed at the Site were conducted in accordance with the NYSDEC-approved work plans. The remedial goals included attainment of drinking water standards to the extent practicable for onsite groundwater. Since residual contaminated groundwater exists beneath a portion of the Site, EC/ICs are required to protect human health and the environment. This Engineering and Institutional Control Plan describes the procedures for the implementation and management of all EC/ICs at the Site.

The purpose of this Plan is to provide:

- a description of all EC/ICs on the Site;
- the basic operation and intended role of each implemented EC/IC;
- a description of the key components of the ICs created as stated in the Declaration of Covenants and Restrictions;
- a description of the features that should be evaluated during each inspection and compliance certification period;
- a description of plans and procedures to be followed for implementation of EC/ICs; and
- any other provisions necessary to identify or establish methods for implementing the EC/ICs required by the Site remedy, as determined by the NYSDEC.

# 2.1 Engineering Control ("EC") Components

The ECs include: (1) monitoring natural attenuation of groundwater on the Site.

### 2.1.1 Monitored Natural Attenuation

Groundwater monitoring activities to assess natural attenuation will continue, as determined by NYSDOH and NYSDEC, until residual groundwater concentrations are found to be below NYSDEC standards or have become asymptotic over an extended period. Monitoring will continue until permission to discontinue is granted in writing by NYSDEC and NYSDOH. The monitoring activities are outlined in the Monitoring Plan included in Section 3 of this SMP.

### 2.2 Institutional Controls ("ICs") Components

The ICs are required by the NYSDEC to: (1) implement, maintain and monitor ECs; and (2) prevent future exposure to residual contamination by controlling groundwater use.

Adherence to these ICs on the Site is required under the Declaration of Covenants and Restrictions and will be implemented under this SMP. A copy of the Declaration of Covenants and Restrictions is presented as Appendix A.

The following are the ICs for the Site:

- 1. The Grantor and the Grantor's successors must comply with the Declaration of Covenants and Restrictions and with all elements of this SMP.
- 2. Groundwater monitoring must be performed as defined in this SMP (Section 3.0).
- 3. On-site environmental monitoring devices, including groundwater monitor wells must be protected and replaced as necessary to ensure continued functioning in the manner specified in this SMP.
- 4. Data and information pertinent to the ECs must be reported at the frequency and in a manner defined in this SMP (Section 5.0).
- 5. ECs may not be discontinued without an amendment or the extinguishment of the Declaration of Covenants and Restrictions for the Site.
- 6. The following Site Restrictions apply to the Site:
  - Use of groundwater underlying the Site is prohibited without treatment rendering it safe for the intended use.
  - The Site owner will submit to NYSDEC a written statement that certifies, under penalty of perjury, that: (1) controls employed at the Site are unchanged from the previous certification or that any changes to the controls were approved by the NYSDEC; and, (2) nothing has occurred that impairs the ability of the controls to protect public health and environment or that constitute a violation or failure to comply with the SMP. NYSDEC retains the right to access such Site at any time in order to evaluate the continued maintenance of any and all controls. This certification shall be submitted annually, or an alternate period of time that NYSDEC may allow. This statement must be certified by an expert that the NYSDEC finds acceptable.

- 10 -

## 3.0 MONITORING PLAN

The Monitoring Plan describes the measures for evaluating the performance and effectiveness of the implemented ECs in reducing or mitigating contamination at the Site. Monitoring of the performance of the remedy and overall reduction in contamination on-site will be determined by NYSDEC based upon trends in contaminant levels in groundwater in the affected areas and an assessment whether the remedy continues to be effective in achieving remedial goals. Monitoring programs are summarized in the embedded table below and outlined in detail in Section 3.1

Monitoring / Inspection Schedule

Monitoring Program	Frequency *	Matrix	Analysis
Groundwater	Once every Five Quarters	Groundwater	VOCs

\* The frequency of events will be conducted as specified and will be determined by the NYSDEC thereafter.

### 3.1 Engineering Control System Monitoring

### 3.1.1 Monitored Natural Attenuation

Natural attenuation monitoring for groundwater will begin no more than 60 days following approval of this SMP and will be conducted once every five quarters. Groundwater samples will be collected from monitoring wells GT-7S, RW-lD and GT-6S (Figure 2) using low flow purging and sampling procedures. Each sample will be analyzed for the following constituents: toluene; TCE; PCE; 1,1,1-TCA; vinyl chloride; and cis 1,2-dichloroethylene. Following three sampling events, Pawling and the NYSDEC will reevaluate the need for continued groundwater monitoring.

Groundwater monitoring data will be submitted following each sampling event and will be incorporated into the Periodic Review Report as discussed in Section 5.0.

### 3.2 Groundwater Monitoring Well Maintenance

If biofouling or silt accumulation has occurred in the on-site monitoring wells, as determined by significant changes in well production or depth to bottom measurements, the wells will be physically agitated/surged and redeveloped. Additionally, monitoring wells will be

properly decommissioned and replaced in kind, if an event renders the wells unusable. Well decommissioning, for the purpose of replacement, should be reported to NYSDEC prior to performance and in the Periodic Review Report. Well decommissioning without replacement in kind must receive prior approval by NYSDEC. Well abandonment will be performed in accordance with NYSDEC's "Groundwater Monitoring Well Decommissioning Procedures." Monitoring wells that are decommissioned because they have been rendered unusable will be reinstalled in the nearest available location, unless otherwise approved by the NYSDEC and NYSDOH.

#### 3.3 Inspections

Inspections of all systems installed on the Site will be conducted at the frequency specified in SMP Monitoring Plan schedule in Schedule 3.0. A comprehensive Site inspection will be conducted once every three years. Site-wide inspection should also be performed after all severe weather conditions that may affect Engineering Controls or monitoring devices. During these inspections, an inspection form will be completed (Appendix C). The form will compile sufficient information to assess the following:

- compliance with all ICs;
- an evaluation of the condition and continued effectiveness of ECs;
- general Site conditions at the time of the inspection;
- confirm that any Site records are up to date; and
- changes, or needed changes, to the monitoring system.

Inspections will be conducted in accordance with the procedures set forth in the Monitoring Plan of this SMP (Section 3). The reporting requirements are outlined in the Site Management Reporting Plan (Section 5).

If an emergency, such as a natural disaster or an unforeseen failure of any of the ECs occurs, an inspection of the Site will be conducted to verify the effectiveness of the EC/ICs implemented at the Site by a qualified environmental professional as determined by NYSDEC.

## **3.4 Monitoring Reporting Requirements**

Forms and any other information generated during regular monitoring events and inspections will be kept on file. All forms, and other relevant reporting formats used during the monitoring/inspection events, will be (1) subject to approval by the NYSDEC and (2) submitted at the time of the Periodic Review Report, as specified in the Site Management Reporting Plan of the SMP. An Annual Groundwater Report will be prepared for submission, subsequent to each groundwater sampling event and submitted to the NYSDEC within 30 days of the receipt of the laboratory data. The report will include, at a minimum:

- date of event;
- personnel conducting sampling;
- description of the activities performed;
- type of samples collected (e.g., groundwater, outdoor air, etc.);
- copies of all field forms completed (e.g., well sampling logs, chain-of-custody documentation, etc.);
- sampling results in comparison to appropriate standards/criteria;
- a figure illustrating sample type and sampling locations;
- copies of all laboratory data sheets and the required laboratory data deliverables required for all points sampled (also to be submitted electronically in the NYSDEC-identified format);
- a copy of the laboratory certification;
- any observations, conclusions, or recommendations; and
- a determination as to whether plume conditions have changed since the last reporting event.

Data will be reported to the NYSDEC and NYSDOH in electronic format. A summary of the monitoring program deliverables are summarized in the table below.

Task	Frequency	Quarterly Reporting Requirement	Annual Reporting Requirements
Groundwater Monitoring	Once every 5 quarters	No	Every 5 quarters
Site Inspection	Once every 3 years	No	Every 3 years

# Monitoring / Inspection Deliverables

A summary of all monitoring data collected will be reported to NYSDEC once every three years in the Periodic Review Report. Further information on the reporting requirements is outlined in the Site Management Reporting Plan of the SMP.

# 3.5 Notifications

The following information is presented as an Electronic Database in Appendix D in an electronic database format:

- a Site summary;
- the name of the current Site owner and/or the remedial party implementing the SMP for the Site;
- the location of the Site;
- the current status of Site remedial activity;
- a copy of the Declaration of Covenants and Restrictions; and
- a contact name and phone number of a person knowledgeable about the Declaration of Covenants and Restrictions' requirements, in order for NYSDEC to obtain additional information, as necessary.

This information should be: 1) modified as conditions change; (2) revised in Appendix D of this document; and, (3) submitted to NYSDEC in the Site Management Monitoring Report. Should the Declaration of Covenants and Restrictions be modified or terminated, the copy of the revised Declaration of Covenants and Restrictions will also be updated in this manner.

# **3.5.1** Non-Routine Notifications

Non-routine notifications are to be submitted by the property owner(s) to the NYSDEC on an as-needed basis for the following reasons:

• notice within 48 hours of any emergency, such as a fire, flood, or earthquake that reduces or has the potential to reduce the effectiveness of Engineering Controls in place at the

Site, including a summary of action taken and the impact to the environment and the public.

Follow-up status reports on actions taken to respond to any emergency event requiring ongoing responsive action shall be submitted to the NYSDEC within 45 days of the date of the emergency and shall describe and document actions taken to restore the effectiveness of the ECs.

## **3.6** Certification

Site inspections and sampling activities will take place as outlined above. Frequency of inspection is subject to change by NYSDEC. Inspection certification for all ICs and ECs will be submitted to NYSDEC once every three years as part of the Periodic Review Report. A qualified environmental professional, as determined by NYSDEC, will perform inspection and certification. Further information on the certification requirements are outlined in the Site Management Reporting Plan.

# 4.0 OPERATION AND MAINTENANCE PLAN

The Site remedy does not rely on any mechanical systems, such as sub-slab depressurization systems or air sparge/ soil vapor extraction systems to protect public health and the environment. Therefore, the operation and maintenance of such components is not included in this SMP.

# 5.0 SITE MANAGEMENT REPORTING PLAN

All inspections will be conducted at the frequency specified in the schedules provided in Section 3 Monitoring Plan of this SMP. A comprehensive Site-wide inspection will be conducted once every three years. The inspections will determine and document the following:

- compliance with all ICs, including Site usage;
- an evaluation of the condition and continued effectiveness of ECs;
- general Site conditions at the time of the inspection;
- confirm that any Site records are up to date; and
- changes, or needed changes, to the remedial or monitoring system.

If an emergency, such as a natural disaster or an unforeseen failure of any of the ECs occurs, an inspection of the Site will be conducted to verify the effectiveness of the EC/ICs implemented at the Site by a qualified environmental professional as determined by NYSDEC.

In case of an emergency, the Site owner, Pawling Engineered Products, Inc., can be contacted at (800) 431-3456 and the NYSDEC can be contacted at (518) 402-9662.

# 5.1 Reporting

An Annual Groundwater Report will be submitted to NYSDEC approximately two months following each groundwater sampling event (no later than 30 days after the data has been received). Groundwater monitoring reports will be submitted following sample collection and as part of the Periodic Review Report, which will be submitted once every three years. The Periodic Review Report will be prepared in accordance with Section 6 of the NYSDEC DER-10 Technical Guidance for Site Investigation and Remediation requirements. The first Periodic Review Report will be due 18 months from the date of the approval of this SMP. This Site Management Reporting Plan and its requirements are subject to revision by NYSDEC. The Periodic Review Report will include the following:

- identification of all required EC/ICs;
- an evaluation of the EC/IC Plan and the Monitoring Plan for adequacy in meeting remedial goals;
- assessment of the continued effectiveness of all EC/ICs;

- certification of the EC/ICs;
- results of the required periodic Site Inspection;
- all deliverables generated during the reporting period;
- all applicable inspection forms and other records generated for the Site during the reporting period;
- cumulative data summary tables and/or graphical representations of contaminants of concern by media (groundwater) which include a listing of all compounds analyzed along with the applicable standards, with all exceedances highlighted;
- results of all analyses, copies of all laboratory data sheets, and the required laboratory data deliverables required for all points sampled during the calendar year (also to be submitted electronically in the NYSDEC-specified format);
- a Site evaluation, which will address the following:
  - the performance and effectiveness of the remedy;
  - the operation and the effectiveness of all treatment units, etc., including identification of any needed repairs or modifications;
  - any new conclusions or observations regarding Site contamination based on inspections or data generated by the Monitoring Plan for the media being monitored; and
  - recommendations regarding any necessary changes to the remedy and/or Monitoring Plan, including decommissioning of the ECs/ICs.
- a figure showing sampling and well locations, and significant analytical values at sampling locations; and
- comments, conclusions, and recommendations, based on an evaluation of the information included in the report, regarding EC/ICs at the Site.

The Periodic Review Report will be submitted in electronic format to the Region 3 NYSDEC offices, located in New Paltz, New York, and to the NYSDOH.

# **5.2 Certification of EC/ICs**

A Professional Engineer licensed to practice in New York State will sign and certify in the Periodic Review Report that:

• On-Site EC/ICs are unchanged from the previous certification.

- The EC/ICs remain in place and effective.
- Nothing has occurred that would impair the ability of the controls to protect the public health and environment.
- Access is available to the Site by NYSDEC and NYSDOH to evaluate continued maintenance of the EC/ICs.

# **APPENDIX A**

# **Copy of Declaration of Covenants and Restrictions**

#### DECLARATION OF COVENANTS AND RESTRICTIONS

**THIS COVENANT** is made the  $\underline{6^{\pm}}$  day of December, 2013, by Pawling Engineered Products, Inc., a corporation organized and existing under the laws of the State of Delaware and having an office for the transaction of business at 157 Charles Colman Boulevard, Pawling, New York 12564.

WHEREAS, Pawling Rubber Company Site is the subject of an Order on Consent (dated June 6, 2013), executed by Pawling Engineered Products, Inc. as part of the New York State Department of Environmental Conservation's (the "Department") State Superfund Program, namely that parcel of real property located on 157 Charles Coleman Boulevard in the Town of Pawling, County of Dutchess, State of New York, which is part of lands conveyed by Pawling Corporation to Pawling Engineered Products, Inc. by deed dated June 29, 2011 and recorded in the Dutchess County Clerk's Office on July 6, 2011 in Instrument No. 02-201102950, and being more particularly described in Appendix "A", attached to this declaration and made a part hereof, and hereinafter referred to as "the property"; and

**WHEREAS**, the Department approved a remedy to eliminate or mitigate all significant threats to the environment presented by contamination at the Property and such remedy requires that the Property be subject to restrictive covenants.

**NOW, THEREFORE**, Pawling Engineered Products, Inc., for itself and its successors and/or assigns, covenants that:

First, the Property subject to this Declaration of Covenants and Restrictions is as shown on a map attached to this declaration as Appendix "B" and made a part hereof.

Second, unless prior written approval by the Department or, if the Department shall no longer exist, any New York State agency or agencies subsequently created to protect the environment of the State and the health of the State's citizens, hereinafter referred to as "the Relevant Agency," is first obtained, where contamination remains at the Property subject to the provisions of the Site Management Plan ("SMP"), there shall be no construction, use or occupancy of the Property that results in the disturbance or excavation of the Property which threatens the integrity of any engineering controls or which results in unacceptable human exposure to contaminated soils.

Third, the owner of the Property shall not disturb, remove, or otherwise interfere with the installation, use, operation, and maintenance of engineering controls required for the Remedy, if any, which are described in the SMP, unless in each instance the owner first obtains a written waiver of such prohibition from the Department or Relevant Agency.

Fourth, the owner of the Property shall prohibit the use of the groundwater underlying the Property without treatment rendering it safe for drinking water or industrial purposes, as appropriate, unless the user first obtains permission to do so from the Department or Relevant Agency.

Fifth, the owner of the Property shall provide a periodic certification, prepared and submitted by a professional engineer or environmental professional acceptable to the Department or Relevant Agency, which will certify that any institutional and engineering controls put in place are unchanged from the previous certification, comply with the SMP, and have not been impaired.

Sixth, the owner of the Property shall continue in full force and effect any institutional and engineering controls required for the Remedy and maintain such controls, unless the owner first obtains permission to discontinue such controls from the Department or Relevant Agency, in compliance with the approved SMP, which is incorporated and made enforceable hereto, subject to modifications as approved by the Department or Relevant Agency.

Seventh, this Declaration is and shall be deemed a covenant that shall run with the land and shall be binding upon all future owners of the Property, and shall provide that the owner and its successors and assigns consent to enforcement by the Department or Relevant Agency of the prohibitions and restrictions that the Order on Consent requires to be recorded, and hereby covenant not to contest the authority of the Department or Relevant Agency to seek enforcement.

Eight, any deed of conveyance of the Property, or any portion thereof, shall recite, unless the Department or Relevant Agency has consented to the termination of such covenants and restrictions, that said conveyance is subject to this Declaration of Covenants and Restrictions.

written below.	FREOF, the undersigned	has executed this instrume	ent the day
By: Print Name: Title:	John Rickert Chief Operating Officer	Date: 12-6-13	
STATE OF NEW YORK	) ):ss: )		

On the  $\cancel{brh}$  day of December, in the year 2013, before me, the undersigned, personally appeared JOHN RICKERT, personally known to me or proved to me on the basis of satisfactory evidence to be the individual whose name is subscribed to the within instrument and acknowledged to me that he executed the same in his capacity, and that by his signature on the instrument, the individual, or the person upon behalf of which the individual acted, executed the instrument.

#### 1.0 INTRODUCTION

#### 1.1 Background

Pawling Corporation, a commercial fabricator of plastics and rubber products, operates a facility at 157 Charles Colman Boulevard in the City of Pawling, Dutchess County, New York (Figure 1). The facility is authorized to discharge non-contact cooling water to the Swamp River through a SPDES permit, number NY-000-4616, effective January 1, 1985.

The Department of Environmental Conservation (DEC) alleges that from on or about June 2, 1987 the discharges of the cooling water to the Swamp River contained Copper, Zinc and organic solvents. In addition, the DEC alleges that stormwater runoff from the Pawling property discharged to the ground water via a storm grate and dry well, and beginning on approximately the same date, contained Copper, Lead and Iron in concentrations exceeding State ground water discharge limits.

A consent order, issued by the DEC, Case #3-1489/8712, was received by Pawling Corporation on February 24, 1988 documenting these allegations and requiring that a ground water investigation be performed to identify the extent and source of ground water contamination. Pawling Corporation contracted Groundwater Technology, Inc. to perform the ground water investigation.

Groundwater Technology, Inc. developed a work plan which was approved by the DEC on June 17, 1988. The work plan contained details for a Remedial Investigation/Feasibility Study for the Pawling site. This report presents the results of the Preliminary Assessment and Preliminary Remedial Investigation. Recommendations and proposed work steps for a Comprehensive Remedial Investigation are also included in this report.

## 1.2 Objectives and Overview

The overall objectives of the ground water investigation were:

- to delineate the concentration and extent of metal and solvent contamination in the ground water
- to determine if upgradient sources are contributing to the contamination
- to evaluate the pathways of contaminant migration and,
- to provide the information required for design of a site remediation system.

The specific work scope designed to achieve these objectives consisted of a site inspection and background data review, soil borings and soil sample analysis, installation of ground water monitor wells in both overburden and bedrock, ground water gauging and sampling, and stream water and sediment sampling. The procedures, results, data analysis and conclusions associated with these tasks are detailed in Sections 2 and 3 of this report. Recommendations for the Comprehensive Remedial Investigation are outlined in Section 4.

### 2.0 TECHNICAL WORK SCOPE

The format of this technical work scope closely follows that of the approved work plan. The work steps of the Preliminary Assessment and Preliminary Remedial Investigation are detailed in Sections 2.1 and 2.2. Each section contains information on the specific procedures employed for each task and presents the results obtained. Conclusions derived from these work steps are provided in Section 3.0.

## 2.1 Preliminary Assessment/Site Inspection

The Preliminary Assessment and Site Inspection were performed in order to acquire background and site specific information to be utilized in selecting the boring and monitor well locations. Background geologic data, on-site production well information, past and current plant disposal practices, and a fracture trace analysis were undertaken to aid in the selection of the locations.

# 2.1.1 Background Geology

A review of selected published topographic, geologic and soil maps shows that the Pawling Corporation site lies in the broad Harlem Valley. This valley extends in a north-south direction through eastern Dutchess County, New York (Simmons et al, 1961). The Swamp River and its 100 year flood plain occupy this valley within the site area.

The soils covering the site consist of the Saco soil series occupying the area along the Swamp River, and the Copake soil series situated east of the river (Secor, 1955). The Saco soil is silty clay loam in texture and forms in very poorly drained alluvial material. It occurs along slowly flowing streams on nearly level relief. The soil is subject to frequent flooding. The surficial material at depth consists of stratified sands and gravel composed chiefly of bedrock fragments.

The Copake soil is fine sandy loam in texture and is found along well drained stream terraces. The surficial material at depth is stratified glacial outwash consisting of sand and gravel.

Bedrock in the site area outcrops along the railroad rightof-way south of the Pawling facility buildings. Depth to bedrock across the remainder of the site was estimated from the background literature to be approximately 20 feet.

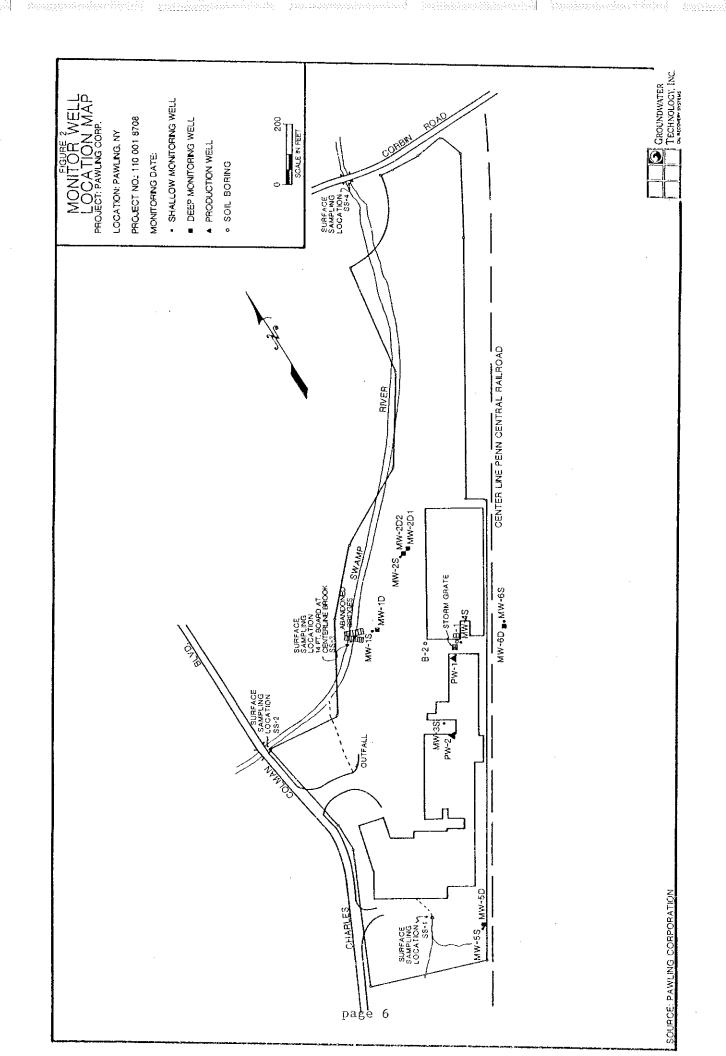

page 5

Fisher et al (1970) have mapped the bedrock as the Stockbridge Marble, Cambrian in age. A thrust fault was also mapped by Fisher et al as being located within the site area, coincident with the Swamp River.

## 2.1.2 Production Well Information

The well log for one of the on-site production wells was located through a US Department of Interior computer search of well records. The log is contained in Appendix A. The log states that bedrock was encountered at 20 feet, and is specified as the Stockbridge limestone. The well construction consists of six-inch diameter steel casing to 20 feet, with open borehole to 145 feet. The well yield was rated at 50 gallons per minute (gpm). Discussions with Pawling Corporation employees indicated that the actual yield of this well is 125 gpm and that the pump is a 7 1/2 hp jet pump set at 55 feet below grade.

Information obtained from Pawling Corporation employees concerning the second production well specified that the total depth is 164 feet and that a 2 hp jet pump is set at 80 feet below grade. They estimated that the yield is 100 gpm. Well construction consists of six-inch steel casing and open borehole. No well log was available.

2.1.3 Environmental Audit

The plant audit delineated the following:

- Plant has SPDES discharge for temperature.
- Plant uses Methyl Ethyl Ketone, Toluene, Naphtha, 1,1,1 Trichloroethane, Trichloroethene, in pase) Tetrachloroethene, Hexane, and Isopropyl Alcohol. (in past)
- Plant used powdered Lead in the past, friendlike, tetractories
- Plant does not use Copper.
- Approximately 75,000 gallons per day of water are being pumped from the production wells.
- The storm grate between the buildings goes to a dry well in the parking lot. The waste storage area is near this grate.
- Present and former sanitary sewer lines run adjacent to the plant along the east side (former, abandoned line is closer to plant).
- Both loading docks have drainage sumps which are pumped via diaphragm pumps to the 001 outfall and the storm grate.
- Drum storage areas are bermed, with drain pipe through berm with valves.

The site visit delineated the following potential contaminant source areas (see Figure 2):

- landfill contains hospital wastes, municipal wastes, cured rubber and machinery
- storm grate/dry well
- solvent burning in trenches
- surface spillage/dumping from hazardous materials handling area and storm runoff

## 2.1.4 Fracture Trace Analysis

1. **1**. 1

ģ

202-226

12

1. 17

12.00

A fracture trace analysis was performed on the bedrock outcrop located south of the facility along the railroad rightof-way. A brunton compass was used to measure selected planar features. Strikes and dips were measured on surfaces which appeared to represent bedding planes, joints, horizontal features, and fractures.

The strikes and dips were plotted on a stereonet to determine the general orientation of the readings. The results indicated the presence of a joint set trending N 8 W vertical, a horizontal surface trending N 70 E 10 S, and a bedding plane trending N 57 E 72 S. Bedding planes were correlated to the mineral banding in the rocks. There was no clustering of the fracture readings, suggesting that there is either more than one fracture set or that the fractures relate to the folding of the rocks. Appendix B contains all of the collected data.

### 2.1.5 Soil Boring and Monitor Well Location

The information obtained from the Preliminary Assessment and Site Inspection was utilized in selecting the boring and monitor well locations. Figure 2 denotes the locations. The rationale for the locations selected is as follows:

- MW-lS and MW-lD were placed downgradient of the dry well
- MW-2S and MW-2D were placed downgradient of the trenching and as far downgradient as access would allow

المجامع والمحافظ والمحافظ والمحافظ والمحافية المحافظ والمحافظ والمحا

Sec. 2202.

2000

0,20

- MW-3 and MW-4 were placed as couplets to the production wells
- MW-5S and MW-5D were placed upgradient of all known site disposal activities
- B-1 was placed near the storm grate, and
- B-2 was placed near the trenching area.

# 2.2 Preliminary Remedial Investigation

The Preliminary Remedial Investigation included seven soil borings, five overburden monitor wells, four bedrock monitor wells, ground water gauging and sampling, and stream sediment and water sampling. The investigation was designed to evaluate the contaminant concentrations present at this site, and to determine the pathways of on-site and off-site migration.

Detailed procedures for each task performed during the Preliminary Investigation are presented in Sections 2.2.1 through 2.2.6. The remaining sections of the Preliminary Remedial Investigation specify decontamination, quality assurance/quality control, and health and safety measures utilized throughout the investigation.

# 2.2.1 Soil Borings

A total of seven soil borings were drilled in the overburden materials in order to determine geologic and chemical characteristics of the soils across the site. The five overburden shallow well locations and two boring locations are shown on Figure 2. The location of each soil boring was approved by the on-site DEC engineer, Shayne Mitchell, prior to drilling.

The soil borings were drilled with Groundwater Technology, Inc.'s Mobile B-47 hollow-stem auger drill rig. The auger size was 4.25 inch I.D. and 7.63 inch O.D. Soil samples were collected with a split-spoon sampler advanced using a 140 pound drive hammer, as per Standard ASTM Method. Soil samples were collected at five-foot intervals or at significant lithologic changes, until bedrock was encountered. A project hydrogeologist supervised all drilling activities.

The upper four to eight feet of unconsolidated material at each location consisted of fill material. The fill material was comprised of dark brown fine sand, stones, and rubber pieces. The underlying materials in MW-1, MW-3, and MW-5 consisted of stratified alluvium. Soil textures ranged from predominantly fine sand and silt in MW-1 to sand and gravel in MW-3 and MW-5. The underlying materials in MW-2, MW-4, B-1, and B-2 were comprised of fine sands. Auger refusal was encountered in each boring; the depth ranged from 4.5 feet in B-2 to 18.5 feet in MW-3S. At the time of drilling, auger refusal was believed to be bedrock. The average depth to the water table encountered during drilling was eight feet. The drilling logs provide the specific information for each borehole (Appendix C).

page 11

During drilling operations, soil samples were collected from each major lithologic unit and sent to a laboratory for grain size analysis. Appendix D contains the grain size distribution curves developed from the standard sieve analyses. The hydraulic conductivities calculated from these curves are shown in Table 1.

#### TABLE 1

## HYDRAULIC CONDUCTIVITY VALUES DERIVED FROM GRAIN-SIZE ANALYSIS

Sam	ple	Hydraulic Conductivity (cm/sec)
MW-2 MW-3 S-2 MW-3 S-3 B-1 S-2 MW-5 S-2	10-12 fee 10-12 fee 10-12 fee 15-17 fee 10-12 fee 10-12 fee 15-17 fee	9.0 x $10^{-4}$ 1.6 x $10^{-3}$ 4.9 x $10^{-3}$ 4.9 x $10^{-3}$ 4.9 x $10^{-3}$ 4.9 x $10^{-3}$

Soil samples obtained from the split-spoon sampler were also field screened with a portable Gas Chromatograph (GC). This instrument detected volatile organic compounds at the part per billion level. The GC extracted a small sample of soil gas from each sample vial. The gas was passed through a chromatographic column and then over a chemical detector. The level of response and the time it took the sample to pass through the column were used to determine relative concentrations and types of compounds. The GC was calibrated for Trans 1,2 Dichloroethylene, 1,1,1 Trichloroethane, Trichloroethene, Tetrachloroethene, and Toluene. The results of the analysis are shown in Table 2. Only the soil samples from MW-2 showed levels above the detection limit [1 part per billion (ppb)]. Sample SS-1, collected from five to seven feet, showed 1.10 ppb of TCE; sample SS-2, collected from 10 to 12 feet, showed 11.78 ppb TCE and 414.69 ppb of Toluene. Some preliminary water sampling results from the GC screening are also shown in Table 2.

Upon retrieval of the spoon sampler device from the borehole at each sampling depth, proper containers were filled with soil for volatile organic and inorganic parameter analysis. These samples were stored on ice. The soil samples that exhibited the highest levels during the field screening were sent to the laboratory for analysis. If no levels were detected, the deepest sample with sufficient volume for sample analysis was sent.

Based upon the above rationale, the following samples were submitted for laboratory analysis: B-1 SS-2, MW-1 SS-2, MW-2 SS-2, MW-3 SS-3, and MW-5 SS-3. An additional soil sample from MW-2 collected at 19.5 feet (MW-2 Core Hole) was also analyzed. A sample from MW-4S was not selected because of its proximity to B-1. Section 2.2.2 discusses the results of the laboratory testing.

The two boreholes not completed as monitor wells (B-1 and B-2) were abandoned by grouting with a cement-bentonite mixture. The cuttings from the boreholes were field screened to determine proper disposal procedures. All the soils, except those from MW-2, recorded less than 1 part per million (ppm) volatiles and were therefore disposed of on-site. The cuttings from MW-2 were containerized and stored on-site for later disposal.

## 2.2.2 Soil Sampling

The selected soil samples were delivered to Camo Laboratories in Poughkeepsie, New York for confirmatory analysis for Purgeable Organics by EPA Method 624, for Base Neutral Extractable Organic analysis by EPA Method 625, and for Priority Pollutant Metals analysis.

The results indicated that no Purgeable Volatiles or Base Neutral compounds were detected in any of the soil samples. This data confirms the non-detectable levels recorded by the field GC for B-1, MW-1, MW-3, and MW-5; however, it contradicts the field GC data for MW-2. The laboratory results report non-detectable levels for MW-2 SS-2, while the field GC reported 414.69 ppb Toluene and 11.78 ppb TCE. The laboratory results of the Priority Pollutant Metals analyses in soils are shown in Table 3. Concentrations of Antimony, Selenium, Silver, and Thallium were all reported as below the detection limits. The complete laboratory report is included in Appendix E.

Baker & Chesnin				
Background Range	2-200	0.03-0.3	5-500	10-300

The metal concentrations in Table 3 represent total metals in the soils. A range of naturally occurring metal concentrations have been reported by Bohn (1979) and Baker and Chesnin (1975). These ranges are also listed in Table 3. All of the on-site soil samples lie within these reported background levels. The soil sample from the upgradient location (MW-5 SS-3) contains levels of most of the metals sampled, at concentrations that are within an order of magnitude of the levels detected in soil samples from other well or boring locations at the site.

The results of the Camo laboratory analysis on the soil samples indicates that there is no Volatile, Semi-Volatile or Priority Pollutant Metal contamination in the soils at the locations sampled.

## 2.2.3 Monitor Well Installation

The objectives of this work scope were to install monitor wells in the aquifer in the overburden material as well as deep monitor wells into the bedrock. The result of this work scope would determine:

- the overburden aquifer flow direction
- the bedrock aquifer flow direction
- the interaction between both aquifers, and
- the extent of contamination, both vertically and horizontally.

# 2.2.3.1 Overburden Wells

Five overburden wells were installed on June 6 through 8, 1988 inside the boreholes drilled by a hollow-stem auger rig at the five selected locations (Figure 2). Each monitor well was constructed of two-inch fiberglass reinforced epoxy (FRP) well screen and casing with flush threaded joints. The well screen was placed from five feet above the water table to the depth of auger refusal. A bentonite seal, one foot in thickness, was placed above the sand pack. A cement-bentonite grout was placed above this bentonite seal. A lockable protective metal casing was installed at the top of MW-1S, the other wells received eight-inch or five-inch flushmounted road boxes. Well construction details are shown on the drilling logs (Appendix C).

# 2.2.3.2 Bedrock Wells

Three bedrock wells were drilled in close proximity to the overburden wells shown in Figure 2. Two monitor well nests (MW-3 and MW-4) utilize the production wells as the bedrock wells (PW-1 and PW-2). The drilling was performed in two phases:

- Coring of the upper 15 feet of rock by Groundwater Technology, Inc.'s Mobile B-47 drill rig
- Air rotary drilling with monitor well completion performed by Goold and Sons Well Drillers.

The coring was performed on June 9, 10, and 14, 1988. Augers were advanced until a good seal into the rock was achieved. A five-foot long N-X core barrel was then utilized to obtain core samples. A Groundwater Technology, Inc. hydrogeologist supervised all coring operations. The core samples were labeled and stored in wooden boxes for subsequent examination.

The results of the coring determined that a boulder layer, ranging in thickness from 5 to 14 feet, is present above the bedrock. The bedrock encountered was a banded and brecciated marble, with fracture zones containing iron staining and silt. The drilling logs in Appendix C denote the depths and abundance of observed fractures.

The Rock Quality Designator (RQD) was determined for each core barrel sample. The RQD represents a modified form of recording core recovery. The equation to calculate RQD is:

# % RQD = 100 x length of core in pieces 4 inches and longer hole length actually drilled

The % RQD for the collected core samples ranged from 0 to 98.1 %. The very low percentages of 0 % in MW-2D and 8.3 % in MW-1D represent a boulder layer. The other percentages indicate a weathered upper bedrock surface which (within 15 feet) becomes fairly competent. The remaining drilling and monitor well installations were performed using an air rotary drill rig. Alan Goold and Sons installed the bedrock wells on June 16, 17, 20, and 21, 1988 under Groundwater Technology, Inc. supervision. The overburden sections of the bedrock wells were drilled using a roller bit inside the same borehole used for the rock coring. Due to a boulder layer above the bedrock, this technique caused the hole to cave; therefore, mud rotary was used in the overburden sections of the boreholes at MW-2D1, MW-2D2, and MW-5D.

The overburden sections of the bedrock wells were completed by driving a six-inch steel casing with an attached drive shoe into competent bedrock. An air rotary bit was used to complete the wells open hole by drilling inside the casing into bedrock. Total depth of the three proposed wells was 150 feet.

Two bedrock wells were installed at the MW-2 well location. A highly fractured zone, from 35 feet to 42 feet, was encountered in MW-2D1, which contained high levels of contamination. A field decision was rendered that this zone might not be connected to underlying fractures; therefore, drilling was ceased and the well completed at only 42 feet. An additional well (MW-2D2) was drilled adjacent to MW-2D1, which was cased through this upper fractured zone and drilled to the proposed completion depth of 150 feet. The geology and fracture determination discerned from the cuttings, drilling water, and rate of drilling are shown in the drilling logs in Appendix C. Various colored marble was encountered at all three locations. MW-2D and MW-5D contained a highly fractured and major water bearing zone at approximately 30 to 42 feet. At the MW-2 location, 5 ppm of volatile organics was measured on the headspace of the drilling waters from this zone with the PID utilized for the ambient air monitoring (see Section 2.2.9). A fracture was encountered at 42 feet in MW-1; however, it was not a major water bearing fracture. At MW-1, the water bearing zones were present at 85 to 145 feet.

The mud used during casing installation was containerized and proper disposal procedures were followed. All drilling waters were placed into polyethylene holding ponds and treated with activated carbon. The waters were discharged to the ground or the sanitary sewer, as directed by the DEC.

2.2.4 Well Development/Elevation and Location Survey

The wells were developed immediately after installation in order to remove fine sediments and other associated drilling materials. The overburden wells were developed by repeated surging and bailing with a bailer. The bedrock wells were developed by air jetting until the water was free of sediment. MW-2S was developed a second time on June 28, 1988 using a water jet. Drilling muds from MW-2D2 had filled the well screen and necessitated the redevelopment.

The development water was retained in polyethylene lined holding ponds and treated using activated carbon. The water was discharged to the ground or the sanitary sewer. The sediment remaining in the polyethylene was containerized for future laboratory analysis. The wells were undisturbed from June 20, 1988 to June 28, 1988 to allow equilibration with the surrounding aquifer.

Following the installation of the monitor wells, top-ofcasing and ground elevations were surveyed to a common benchmark by J.K. Devine, a licensed land surveyor, (see Survey Data, Appendix F).

# 2.2.5 Ground Water Gauging and Sampling

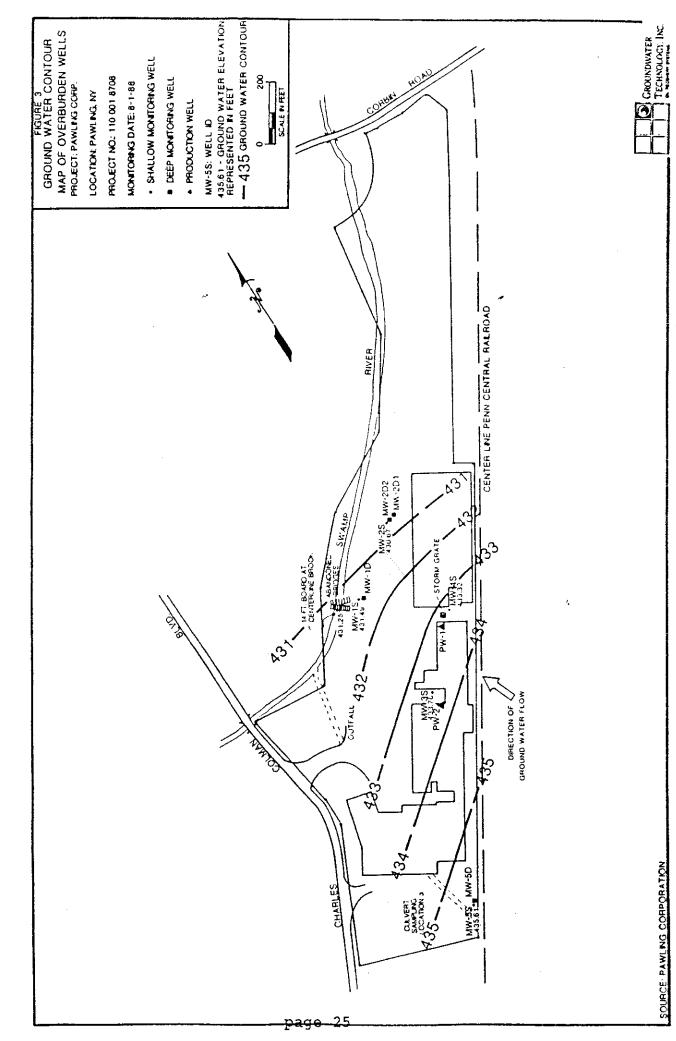

The monitor wells were gauged on June 28 and August 1, 1988 in order to determine the ground water gradient(s). The water level in each well was gauged using an ORS interface probe (see Ground Water Gradient Data, Appendix G). This instrument can detect air/water/product interfaces with an accuracy of  $\pm$  0.01 feet. This probe was also used to determine if a phase-separated immiscible layer was present in each well. Based on the gauging data from August 1, 1988, an immiscible layer was not detected in any of the wells. The gauging data from August 1, 1988 was utilized to produce ground water contour maps for the overburden and bedrock wells (Figures 3 and 4). The June 28 data was not used because of missing water level data. The MW-2S water level for both dates is suspect due to the presence of drilling mud.

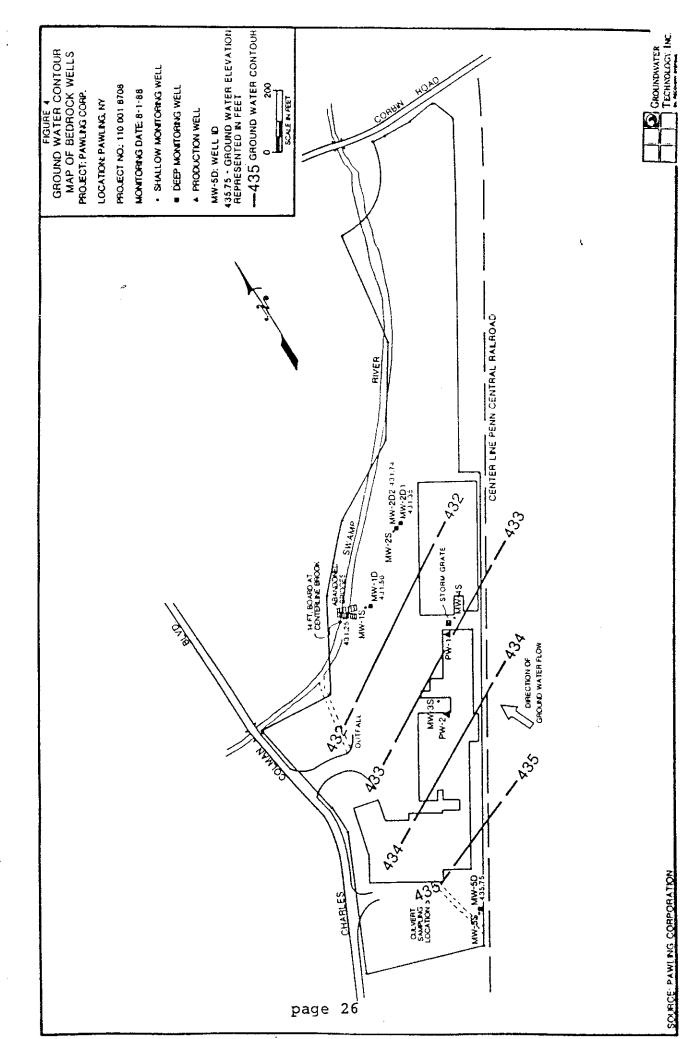

The overburden aquifer portrayed a ground water flow direction to the north-northwest at a 0.6 % gradient. The ground water in the bedrock wells indicated a north-northwest flow direction at a 0.55 % gradient. This data indicates that MW-5S and MW-5D are upgradient of only part of the Pawling site.

1

The observed elevation difference between the overburden and bedrock wells was 0.01 feet at MW-1, 1.07 feet at MW-2, and 0.14 feet at MW-5. The MW-2S elevation may not accurately represent the overburden water level due to the presence of drilling mud. The bedrock wells have slightly higher water level elevations than the overburden wells, indicating the existence of a vertical gradient.

The monitor wells were sampled on June 28 and 29, 1988. Prior to sample collection, three well volumes of water were evacuated from each well. This water was discharged to polyethylene lined holding ponds and treated using activated

e sources a state

14

1.15 (221.13

21. 313 23

carbon. A submersible pump was used to evacuate the water from the bedrock monitor wells and a bailer was used for the evacuation of the overburden wells.

The wells were sampled from least to most contaminated based upon contamination levels observed during drilling. The sampling order for the deep wells was MW-5D, MW-1D, MW-2D2, MW-2D1. The sampling sequence for the overburden wells was MW-5, MW-3, MW-1, MW-4. MW-2 was not sampled due to the inability to remove the drilling mud; however, sampling results were recorded on the field GC.

Samples were collected using decontaminated teflon bailers and clean rope. Decontamination procedures are described in Section 2.2.7. Water samples were poured directly from the bailer into properly prepared laboratory jars, and placed on ice until delivery to the laboratory. Proper chain of custody procedures were employed throughout the sampling.

The two production wells at the Pawling facility were sampled from a sampling port located in the piping on June 30, 1988. These wells were constantly in use during the day, and it was assumed that at least three to five well volumes had been removed prior to sample collection.

Analyses for all samples included Purgeable Organics by EPA Method 624, Base Neutral Extractable Organics by EPA Method 625, and Priority Pollutant Metals. Two samples were collected for metals analysis from the monitor wells: one unfiltered and one filtered. Hydrochloric acid and Nitric acid were used as preservatives in the 624 analysis and the metals analysis, respectively. Camo Laboratories in Poughkeepsie, New York performed all analyses.

The laboratory results indicated that all compounds in the Base Neutral 625 analysis were below detection limits. The ground water sampling results of the volatile organics and metals are summarized in Tables 4 and 5. Appendix H contains full laboratory results.

Six volatile organic compounds were detected in the ground water samples: 1,1 Dichloroethylene (1,1 DCE), Trans 1,2 Dichloroethylene (Trans 1,2 DCE), 1,1,1 Trichloroethane (1,1,1 TCA), Trichloroethene (TCE), Tetrachloroethene (PCE), and Toluene.

Toluene was the volatile compound present at the highest concentration, 3,000 ppb in MW-2Dl and 22,140 ppb in MW-2S (Table 4). Toluene was not detected at any other well location. Trans 1,2 DEC, 1,1,1 TCA, TCE, and PCE were detected at various concentrations in many of the wells, ranging from 2 ppb to 3,517 ppb (Table 4) The production wells contained only these four compounds. Trans 1,2 DCE generally exhibited the highest concentrations of the four compounds. Trans, 1,2 DCE is a breakdown product of TCE and PCE. MW-2D contained the highest level of Trans 1,2 DCE 880 ppb. Only one well, MW-1S, contained 1,1 DCE at 8 ppb. The upgradient overburden well, MW-5S, contained 14 ppb PCE.

The MW-2 location, particularly the overburden well, contained the highest concentrations of total volatiles on the site. PW-2 contains the next highest concentrations. The high pumping rate of this well may be drawing the contamination from the MW-2 area.

The DEC Ground Water Quality Standards and Guidance Values for the detected volatile organics are shown in Table 4. The regulations require that no individual standard or guidance value be exceeded, and that the total of the listed volatiles not exceed 100 ppb. According to these regulations, the water quality in MW-1D is within DEC drinking water limits.

ģ

The metals which were detected above the laboratory detection limits were Arsenic, Copper, Lead, and Zinc. The concentrations of Arsenic, Copper, and Zinc are below the DEC ground water quality standards. The concentrations stated in the regulations are listed in Table 5. The only sample results which exceed the DEC standards are the Lead contents in MW-1D, MW-5S, and PW-1. The concentration in MW-5S (0.11ppm), the upgradient well, is approximately the same concentration as in PW-1 (0.13 ppm). The Lead concentrations may vary due to natural background variations in the Lead mineral content in the overburden materials and bedrock.

## 2.2.6 Surface Water Gauging and Sampling

The interaction of the surface water and ground water at this site was evaluated through surface water gauging and sampling. A staff gauge was placed on the abandoned railroad bridge at the edge of Swamp River to measure the stream water level (Figure 2). The elevation of the top of the gauge was surveyed by Mr. Devine. The stream water level was recorded at the same time that the ground water levels were gauged on June 28 and August 1, 1988. The elevations of the stream were 430.65 and 431.25 feet, respectively. These elevations compare very closely to the overburden and bedrock ground water elevations, suggesting that the Swamp River is an effluent stream receiving ground water discharge from the overburden and bedrock aquifers.

Surface water and sediment samples were collected on June 29, 1988 at four locations: two on upgradient stream channels and two downgradient on the Swamp River. Figure 2 shows the sampling locations. The sampling sequence was SS-1, SS-2, SS-3, and SS-4.

A double ended sampler was utilized to collect a sample from the water column just above the stream bed. After the samples were collected, they were poured directly into properly cleaned laboratory jars. The sediment samples were collected at the same locations as the water samples using a properly decontaminated steel shovel. Samples were placed on ice until delivery to the laboratory. Analyses included

page 31

Purgeable Volatile Organics by EPA Method 624, Base Neutrals Extractable Organics by EPA Method 625, and Priority Pollutant Metals.

The lab results indicate that all the volatile organic and base neutral compounds are at concentrations at or below detectable limits in both the water and sediment samples. The following table summarizes the levels of metals found in the water and sediments from the stream. Full laboratory results are contained in Appendix H.

#### TABLE 6

# PRIORITY POLLUTANT METALS IN SURFACE WATER (in ppm)

	Arsenic	<u>Copper</u>	Lead	<u>Mercury</u>	<u>Zinc</u>
ss-1	0.005	0.01	0.010	حقة ورب	0.01

SS-S4	6.0	9.0	27.0	30.0	0.2	22.0	2.0	87

NOTE: -- = non-detectable levels

3

The surface water sample results show no significant increase in metals concentration from the upstream sampling locations (SS-1 and SS-2) to the downstream location (SS-4). Lead levels increase from SS-1 and SS-2 to SS-3. At SS-3, Lead concentrations exceed DEC Water Quality Standards; however, the concentration becomes non-detectable further downstream (SS-4).

The stream sediment sample results compare fairly closely to the soil sample results; however, no Cadmium was detected in the stream sediment and low levels of Silver were detected. There appears to be no significant increase in concentrations from the upstream locations to the downstream sampling point.

## 2.2.7 Decontamination Procedures

A portable steam generator was used to clean all drilling equipment, such as augers, core barrels and split-spoon samplers, between monitor well locations. The split-spoon sampler was cleaned between samples with a soap and water wash, and a tap water and final distilled water rinse. Decontamination waters were containerized in polyethylene holding ponds and treated with activated carbon.

The teflon bailers and double-ended sampler were cleaned with Liquinox and water and rinsed with distilled water. The bailers used to collect samples for the 624 and 625 analyses were rinsed with acetone and hexane. The bailers used to collect samples for the metals analyses were rinsed with hydrochloric acid. The bailers and sampler were allowed to thoroughly air dry before use. The interface probe was cleaned between gaugings in a similar manner as for the 624/625 analyses.

## 2.2.8 Field QA/QC Program

SL ACTOR

d

SUM 127

020.02

A trip blank was prepared and analyzed as part of the ground water and surface water sampling. Two vials were filled with deionized water at the laboratory. Transportation to the site and return to the lab was completed in an identical manner. The trip blank was analyzed for Purgeable Volatile Organics via EPA 624.

An equipment or field blank was collected the day of water sampling to ensure that the sampler was effectively cleaned. Deionized water was poured through a decontaminated teflon bailer and collected in sample bottles and returned to the lab for analysis.

The analysis completed on the field and trip blank indicate non-detectable levels of cross contamination.

## 2.2.9 Health and Safety

The Health and Safety Plan for this site is enclosed in Appendix I. All OHSA health and safety standards applicable to hazardous site investigations were undertaken at this site to ensure worker safety. A portable Photoionization Detector

(PID) was used to monitor ambient air for the presence of volatile organic compounds in the work area. No levels greater than 1 ppm were recorded in the ambient air in the work area at any time during this investigation. Level D protection was utilized throughout the field investigation.

# 3.0 CONCLUSIONS

The conclusions presented relate to the achievement of the original objectives of this investigation. The following conclusions are based on the work performed during this investigation and may alter with additional data.

### <u>Objective 1</u>

Delineate the concentration and extent of metal and solvent 1 A contamination in the ground water. 3 6 A. S. L. L. TEL PAL 111 10: 1< ∧ ≟ **把**作 1. Conclusions: TCI del 10 151

↓ 2.1 The highest concentrations of dissolved organic solvents were detected in ground water sampled from and the the overburden aquifer at MW-2S. Trans 1,2 DCE, 1,1,1 TCA, and TCE were identified at concentra-To'w 21 tions ranging from 14 to 3,517 ppb. Toluene was also detected at a concentration of 22,140 ppb. 3,000

D(L 88°)

TER TH

A production well (PW-2) exhibited the second highest level of dissolved organic solvents in the ground water. Trans 1,2 DCE, 1,1,1 TCA, TCE and PCE were identified at concentrations ranging from 10 to 52 ppb.

All other ground water samples contained less than 100 ppb of dissolved organic solvents.

- Lead concentrations exceeded DEC Ground Water Quality Standards in three wells - MW-1D, MW-5S, and PW-1. Detected concentrations were 0.035 ppm, 0.11 ppm, and 0.13 ppm. The upgradient well, MW-5S, contained concentrations greater than or approximately equal to the levels recorded in other wells on-site; therefore, the levels of Lead in the ground water at Pawling Corporation do not appear to be the result of contamination produced by site industrial activities. No other Priority Pollutant Metal was detected in the ground water sampled.
- The data collected above indicates that the Pawling Corporation has not contributed to levels of Priority Pollutant Metals in ground water that are in excess of DEC standards.

# <u>Objective 2</u>

Determine if upgradient sources are contributing to the contamination.

# Conclusions:

- The upgradient wells MW-5S and MW-5D are upgradient of only part of the Pawling Corporation site. Additional information is necessary in order to determine if upgradient sources are contributing to the contamination.
- MW-5S exhibited concentrations of Lead and PCE exceeding DEC Ground Water Quality Standards and Guidance Values. These levels may indicate a low level upgradient source contributing to the contamination.

## <u>Objective 3</u>

Evaluate the pathways of migration of contaminant movement.

#### Conclusions:

- Based upon the observed volatile organic concentrations, most contaminated ground water is in the overburden aquifer at MW-2. The soils from the ground suface to a depth of five feet below grade exhibited less than 1.2 ppb volatile organics; therefore, the contamination has either been transported to this location via overburden ground water flow from an upgradient source, or the source was placed on the land surface at or near this location prior to filling when the area was lower in elevation.
- The contamination observed in the bedrock at MW-2D1 is probably due to migration from the overburden soil and/or ground water through the highly fractured upper bedrock surface.
- The contamination in MW-2D2 is probably also due to migration through bedrock fractures. Downward migration was probably enhanced by the greater density of the chlorinated solvents.
- Delineation of contaminant migration routes to the production wells needs to be further investigated.
- The Swamp River does not appear to play a role in contaminant migration within the area sampled during this investigation.
- Off-site migration routes are not fully known.

**Objective** 4

Provide information required for design of a site remediation system.

## Conclusions:

- Geologic data concerning lithology, stratigraphy, permeability, and ground water gradients have been obtained.
- A better delineation of on-site and off-site contaminant migration is required before a complete remediation system can be designed.

# 4.0 COMPREHENSIVE REMEDIAL INVESTIGATION

#### 4.1 Introduction

The results of the Preliminary Remedial Investigation indicate the need for further delineation of potential upgradient sources. Groundwater Technology, Inc. proposes that an additional upgradient monitor well couplet be drilled east of the Pawling facility. The exact location will be approved by the DEC prior to drilling. An extensive Comprehensive Remedial Investigation and Feasibility Study will be submitted if the ground water sampling results indicate that the solvent contamination originates on the Pawling property.

The work scope detailed in Section 4.2 consists of installation of an overburden and bedrock monitor well and ground water gauging and sampling. Information concerning decontamination, health and safety, project staff, and project schedule are also provided.

#### 4.2 Technical Work Scope

### 4.2.1 Overburden Monitor Well Installation

An overburden monitor well will be installed east (upgradient) of the Pawling site in order to determine the ground water quality in the upper aquifer. An air rotary drill rig using a roller bit and temporary casing will be utilized for the well installation. This method will allow one drill rig to be employed for both the overburden and bedrock drilling.

The overburden monitor well will be constructed of two-inch fiberglass reinforced epoxy (FRP) well screen and casing with flush threaded joints. FRP construction ensures that low levels of organic compounds will not desorb out or adsorb onto the well screen and material. This assures the collection of representative samples of the ground water in the formation surrounding the well. Use of FRP well material has been EPA-approved.

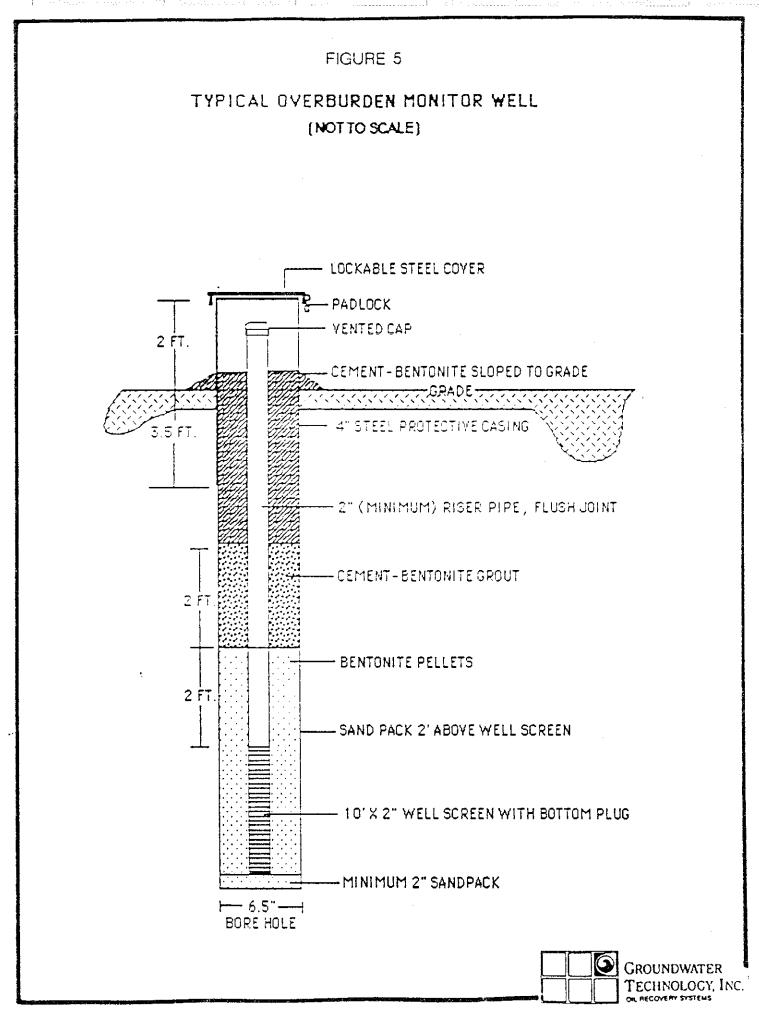

The well screen will extend from five feet above the water table to the top of bedrock, site conditions permitting. A bentonite seal, two-feet in thickness, will be emplaced at the top of the sand pack. A cement-bentonite grout, tremied in place, will be used above the bentonite seal. A lockable, protective metal casing will be installed at the top of the well. Figure 5 shows the construction of a typical overburden monitor well.

### 4.2.2 Bedrock Well Installation

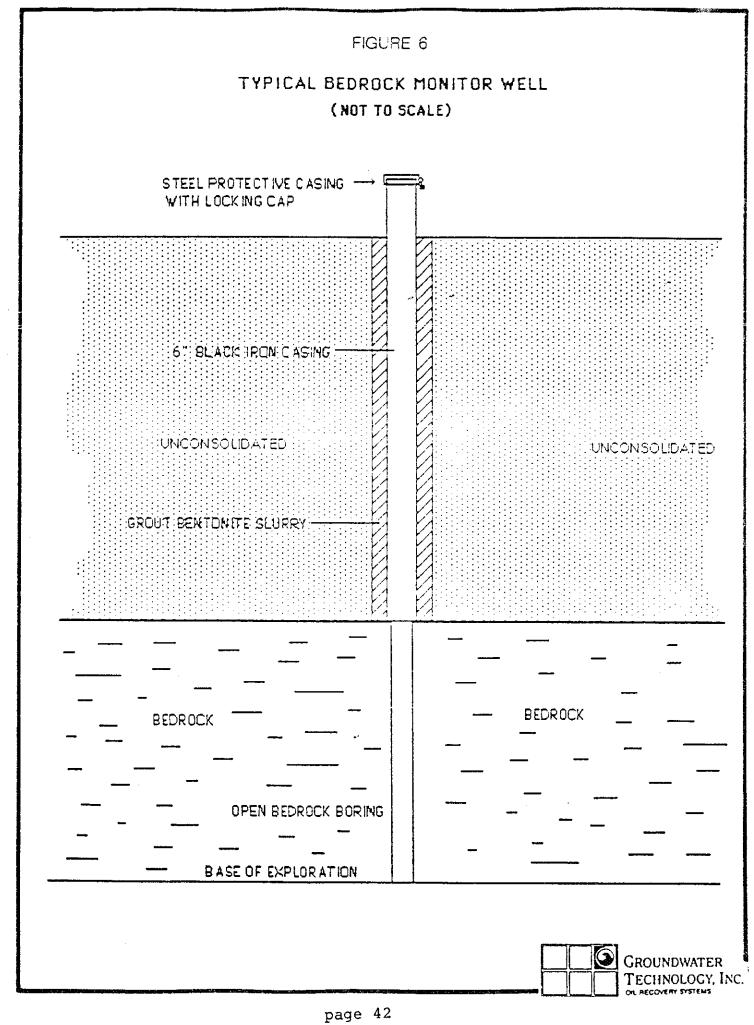

The purpose of the bedrock well will be to denote water quality in the bedrock upgradient of the site. It will also determine whether vertical migration of contaminants exists between the overburden and bedrock aquifers. One bedrock well will be drilled east of the site in close proximity to the overburden monitor well.

An air rotary drill rig will be utilized to install the bedrock well. A six-inch steel casing will be tremie grouted in place from the top of the bedrock to the ground surface. Drilling will proceed inside of this casing to a depth of approximately 150 feet below grade. The well will be completed as open hole.

Figure 6 shows the typical construction to be employed. The project hydrogeologist will supervise all monitor well installations. All well construction specifications will be included on the drilling log.

### 4.2.3 Well Development/Elevation and Location Survey

1

The well development will be performed immediately after well installation. Water levels will be measured before and after development in order to estimate permeability from recovery time.

The overburden well will be developed by repeated surging and bailing with a surface sampler. The bedrock well will be developed by air jetting. These methods will remove any fine sediments from the formation immediately adjacent to the well screen and annulus of the rock hole. Water samples will therefore be free of sediments and other associated drilling materials.

Purged waters will be collected and treated through activated carbon. Wells will be left undisturbed for at least one week after development to allow time for the wells to equilibrate with the surrounding aquifer.

Following the installation of the monitor wells, top-ofcasing elevations will be surveyed to a common benchmark by a licensed land surveyor. Locations of monitor wells will also be denoted during this survey.

### 4.2.4 Ground Water Gauging and Sampling

Following the completion of the monitor well installation program, Groundwater Technology, Inc. will gauge each monitor well using an ORS interface probe. From this data, the ground water gradient will be determined. This information will be compared to previous gauging events in order to verify ground water movement at the site.

The two newly installed upgradient wells will be sampled subsequent to gauging. Prior to sample collection, three to five well casing volumes of water will be evacuated from each well. A bailer will be used for the evacuation of the overburden well and a submersible pump will be used in the bedrock well. Evacuated water will be collected and treated in a similar manner as the development waters.

Samples will be collected using a decontaminated teflon bailer and rope. Water samples will be poured directly from the bailer into properly prepared laboratory jars, and placed on ice until delivery to the laboratory. Proper chain of custody procedures will be employed throughout the sampling. The sample will be analyzed for Purgeable Organics by EPA Method 624.

## 4.2.5 Decontamination Procedures

A portable steam generator will be used to clean all drilling equipment, drill rods, bit and casing between monitor wells. Decontamination waters will be containerized and treated through activated carbon prior to disposal.

The teflon bailer will be cleaned with Liquinox and water and rinsed with distilled water, acetone and hexane. The bailer will be allowed to thoroughly air dry before use. The interface probe will be cleaned in a similar manner between gaugings.

If protective clothing is deemed necessary for worker safety, the discarded clothing will be stored in DOT approved drums for later disposal.

#### 4.2.6 Field QA/QC Program

A trip blank will be prepared and analyzed as part of the ground water sampling. Volatile organic bottles will be filled with deionized water at the laboratory. Transportation to the site and return to the lab will be in an identical manner as the other sample containers. The trip blank will be subjected to the same analysis as the ground water.

### 4.2.7 Health and Safety

Groundwater Technology, Inc. has prepared a health and safety plan for the Pawling site which is enclosed in Appendix I. All OHSA health and safety standards applicable to hazardous waste site investigations will be undertaken at this site to ensure worker safety. A portable Photoionization Detector (PID) will be used to monitor ambient air for the presence of volatile organic compounds in the work area. The PID levels associated with the different levels of personal protective gear are specified in the site health and safety plan.

#### 4.2.8 Summary Report

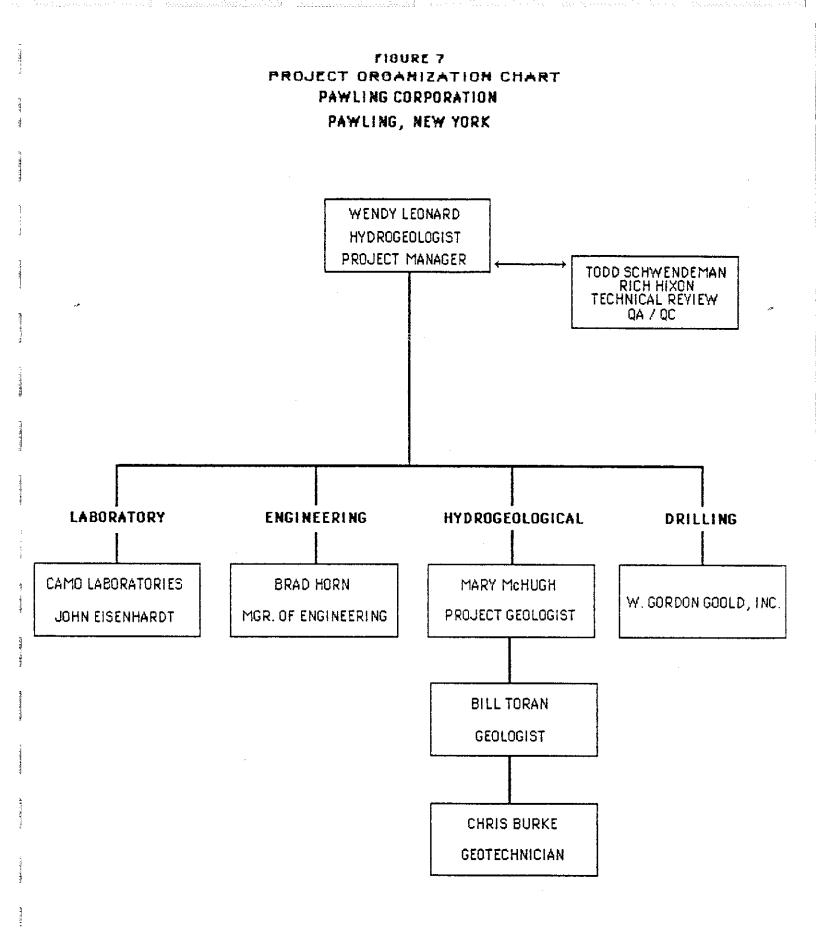

A report detailing work steps and results will be prepared upon the completion of the laboratory analyses. Conclusions will be presented evaluating the contribution of upgradient sources to the solvent contamination.

#### 4.3 Project Organization

The project organizational chart is shown in Figure 7. Groundwater Technology Inc. personnel will perform all hydrogeological and engineering work.

#### 4.4 Schedule

The proposed schedule of work is shown in Figure 8.

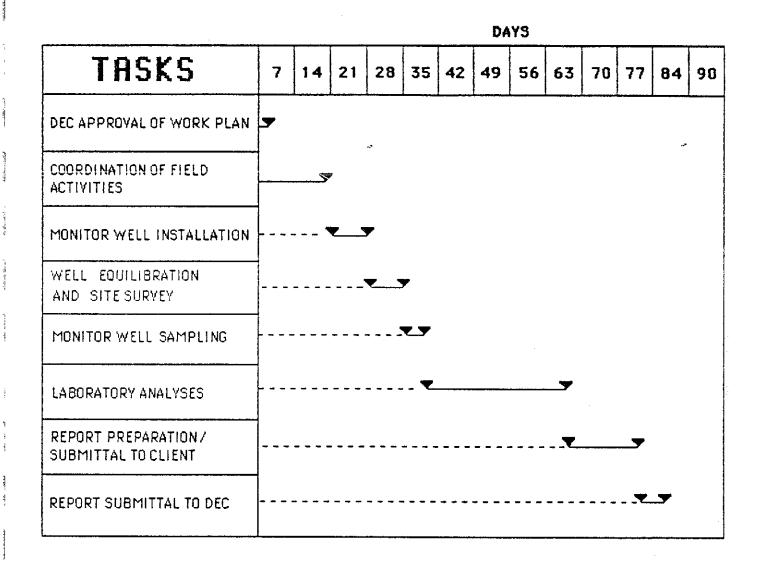

,

- MW-3 and MW-4 were placed as couplets to the production wells
- MW-5S and MW-5D were placed upgradient of all known site disposal activities
- B-1 was placed near the storm grate, and
- B-2 was placed near the trenching area.

# 2.2 Preliminary Remedial Investigation

The Preliminary Remedial Investigation included seven soil borings, five overburden monitor wells, four bedrock monitor wells, ground water gauging and sampling, and stream sediment and water sampling. The investigation was designed to evaluate the contaminant concentrations present at this site, and to determine the pathways of on-site and off-site migration.

Detailed procedures for each task performed during the Preliminary Investigation are presented in Sections 2.2.1 through 2.2.6. The remaining sections of the Preliminary Remedial Investigation specify decontamination, quality assurance/quality control, and health and safety measures utilized throughout the investigation.

#### 2.2.1 Soil Borings

A total of seven soil borings were drilled in the overburden materials in order to determine geologic and chemical characteristics of the soils across the site. The five overburden shallow well locations and two boring locations are shown on Figure 2. The location of each soil boring was approved by the on-site DEC engineer, Shayne Mitchell, prior to drilling.

The soil borings were drilled with Groundwater Technology, Inc.'s Mobile B-47 hollow-stem auger drill rig. The auger size was 4.25 inch I.D. and 7.63 inch O.D. Soil samples were collected with a split-spoon sampler advanced using a 140 pound drive hammer, as per Standard ASTM Method. Soil samples were collected at five-foot intervals or at significant lithologic changes, until bedrock was encountered. A project hydrogeologist supervised all drilling activities.

The upper four to eight feet of unconsolidated material at each location consisted of fill material. The fill material was comprised of dark brown fine sand, stones, and rubber pieces. The underlying materials in MW-1, MW-3, and MW-5 consisted of stratified alluvium. Soil textures ranged from predominantly fine sand and silt in MW-1 to sand and gravel in MW-3 and MW-5. The underlying materials in MW-2, MW-4, B-1, and B-2 were comprised of fine sands. Auger refusal was encountered in each boring; the depth ranged from 4.5 feet in B-2 to 18.5 feet in MW-3S. At the time of drilling, auger refusal was believed to be bedrock. The average depth to the water table encountered during drilling was eight feet. The drilling logs provide the specific information for each borehole (Appendix C). During drilling operations, soil samples were collected from each major lithologic unit and sent to a laboratory for grain size analysis. Appendix D contains the grain size distribution curves developed from the standard sieve analyses. The hydraulic conductivities calculated from these curves are shown in Table 1.

#### TABLE 1

### HYDRAULIC CONDUCTIVITY VALUES DERIVED FROM GRAIN-SIZE ANALYSIS

Soil samples obtained from the split-spoon sampler were also field screened with a portable Gas Chromatograph (GC). This instrument detected volatile organic compounds at the part per billion level. The GC extracted a small sample of soil gas from each sample vial. The gas was passed through a chromatographic column and then over a chemical detector. The level of response and the time it took the sample to pass through the column were used to determine relative concentrations and types of compounds. The GC was calibrated for Trans 1,2 Dichloroethylene, 1,1,1 Trichloroethane, Trichloroethene, Tetrachloroethene, and Toluene. The results of the analysis are shown in Table 2. Only the soil samples from MW-2 showed levels above the detection limit [1 part per billion (ppb)]. Sample SS-1, collected from five to seven feet, showed 1.10 ppb of TCE; sample SS-2, collected from 10 to 12 feet, showed 11.78 ppb TCE and 414.69 ppb of Toluene. Some preliminary water sampling results from the GC screening are also shown in Table 2.

Upon retrieval of the spoon sampler device from the borehole at each sampling depth, proper containers were filled with soil for volatile organic and inorganic parameter analysis. These samples were stored on ice. The soil samples that exhibited the highest levels during the field screening were sent to the laboratory for analysis. If no levels were detected, the deepest sample with sufficient volume for sample analysis was sent.

Based upon the above rationale, the following samples were submitted for laboratory analysis: B-l SS-2, MW-l SS-2, MW-2 SS-2, MW-3 SS-3, and MW-5 SS-3. An additional soil sample from MW-2 collected at 19.5 feet (MW-2 Core Hole) was also analyzed. A sample from MW-4S was not selected because of its proximity to B-1. Section 2.2.2 discusses the results of the laboratory testing.

The two boreholes not completed as monitor wells (B-1 and B-2) were abandoned by grouting with a cement-bentonite mixture. The cuttings from the boreholes were field screened to determine proper disposal procedures. All the soils, except those from MW-2, recorded less than 1 part per million (ppm) volatiles and were therefore disposed of on-site. The cuttings from MW-2 were containerized and stored on-site for later disposal.

2.2.2 Soil Sampling

The selected soil samples were delivered to Camo Laboratories in Poughkeepsie, New York for confirmatory analysis for Purgeable Organics by EPA Method 624, for Base Neutral Extractable Organic analysis by EPA Method 625, and for Priority Pollutant Metals analysis.

The results indicated that no Purgeable Volatiles or Base Neutral compounds were detected in any of the soil samples. This data confirms the non-detectable levels recorded by the field GC for B-1, MW-1, MW-3, and MW-5; however, it contradicts the field GC data for MW-2. The laboratory results report non-detectable levels for MW-2 SS-2, while the field GC reported 414.69 ppb Toluene and 11.78 ppb TCE. The laboratory results of the Priority Pollutant Metals analyses in soils are shown in Table 3. Concentrations of Antimony, Selenium, Silver, and Thallium were all reported as below the detection limits. The complete laboratory report is included in Appendix E.

Background Range	2-200	0.03-0.3	5-500	10-300

The metal concentrations in Table 3 represent total metals in the soils. A range of naturally occurring metal concentrations have been reported by Bohn (1979) and Baker and Chesnin (1975). These ranges are also listed in Table 3. All of the on-site soil samples lie within these reported background levels. The soil sample from the upgradient location (MW-5 SS-3) contains levels of most of the metals sampled, at concentrations that are within an order of magnitude of the levels detected in soil samples from other well or boring locations at the site.

The results of the Camo laboratory analysis on the soil samples indicates that there is no Volatile, Semi-Volatile or Priority Pollutant Metal contamination in the soils at the locations sampled.

# 2.2.3 Monitor Well Installation

The objectives of this work scope were to install monitor wells in the aquifer in the overburden material as well as deep monitor wells into the bedrock. The result of this work scope would determine:

- the overburden aquifer flow direction
- the bedrock aquifer flow direction
- the interaction between both aquifers, and
- the extent of contamination, both vertically and horizontally.

# 2.2.3.1 Overburden Wells

Five overburden wells were installed on June 6 through 8, 1988 inside the boreholes drilled by a hollow-stem auger rig at the five selected locations (Figure 2). Each monitor well was constructed of two-inch fiberglass reinforced epoxy (FRP) well screen and casing with flush threaded joints. The well screen was placed from five feet above the water table to the depth of auger refusal. A bentonite seal, one foot in thickness, was placed above the sand pack. A cement-bentonite grout was placed above this bentonite seal. A lockable protective metal casing was installed at the top of MW-IS, the other wells received eight-inch or five-inch flushmounted road boxes. Well construction details are shown on the drilling logs (Appendix C).

### 2.2.3.2 Bedrock Wells

Three bedrock wells were drilled in close proximity to the overburden wells shown in Figure 2. Two monitor well nests (MW-3 and MW-4) utilize the production wells as the bedrock wells (PW-1 and PW-2). The drilling was performed in two phases:

- Coring of the upper 15 feet of rock by Groundwater Technology, Inc.'s Mobile B-47 drill rig
- Air rotary drilling with monitor well completion performed by Goold and Sons Well Drillers.

The coring was performed on June 9, 10, and 14, 1988. Augers were advanced until a good seal into the rock was achieved. A five-foot long N-X core barrel was then utilized to obtain core samples. A Groundwater Technology, Inc. hydrogeologist supervised all coring operations. The core samples were labeled and stored in wooden boxes for subsequent examination.

The results of the coring determined that a boulder layer, ranging in thickness from 5 to 14 feet, is present above the bedrock. The bedrock encountered was a banded and brecciated marble, with fracture zones containing iron staining and silt. The drilling logs in Appendix C denote the depths and abundance of observed fractures.

The Rock Quality Designator (RQD) was determined for each core barrel sample. The RQD represents a modified form of recording core recovery. The equation to calculate RQD is:

# % RQD = 100 x length of core in pieces 4 inches and longer hole length actually drilled

The % RQD for the collected core samples ranged from 0 to 98.1 %. The very low percentages of 0 % in MW-2D and 8.3 % in MW-1D represent a boulder layer. The other percentages indicate a weathered upper bedrock surface which (within 15 feet) becomes fairly competent. The remaining drilling and monitor well installations were performed using an air rotary drill rig. Alan Goold and Sons installed the bedrock wells on June 16, 17, 20, and 21, 1988 under Groundwater Technology, Inc. supervision. The overburden sections of the bedrock wells were drilled using a roller bit inside the same borehole used for the rock coring. Due to a boulder layer above the bedrock, this technique caused the hole to cave; therefore, mud rotary was used in the overburden sections of the boreholes at MW-2D1, MW-2D2, and MW-5D.

The overburden sections of the bedrock wells were completed by driving a six-inch steel casing with an attached drive shoe into competent bedrock. An air rotary bit was used to complete the wells open hole by drilling inside the casing into bedrock. Total depth of the three proposed wells was 150 feet.

Two bedrock wells were installed at the MW-2 well location. A highly fractured zone, from 35 feet to 42 feet, was encountered in MW-2D1, which contained high levels of contamination. A field decision was rendered that this zone might not be connected to underlying fractures; therefore, drilling was ceased and the well completed at only 42 feet. An additional well (MW-2D2) was drilled adjacent to MW-2D1, which was cased through this upper fractured zone and drilled to the proposed completion depth of 150 feet. The geology and fracture determination discerned from the cuttings, drilling water, and rate of drilling are shown in the drilling logs in Appendix C. Various colored marble was encountered at all three locations. MW-2D and MW-5D contained a highly fractured and major water bearing zone at approximately 30 to 42 feet. At the MW-2 location, 5 ppm of volatile organics was measured on the headspace of the drilling waters from this zone with the PID utilized for the ambient air monitoring (see Section 2.2.9). A fracture was encountered at 42 feet in MW-1; however, it was not a major water bearing fracture. At MW-1, the water bearing zones were present at 85 to 145 feet.

The mud used during casing installation was containerized and proper disposal procedures were followed. All drilling waters were placed into polyethylene holding ponds and treated with activated carbon. The waters were discharged to the ground or the sanitary sewer, as directed by the DEC.

2.2.4 Well Development/Elevation and Location Survey

The wells were developed immediately after installation in order to remove fine sediments and other associated drilling materials. The overburden wells were developed by repeated surging and bailing with a bailer. The bedrock wells were developed by air jetting until the water was free of sediment. MW-2S was developed a second time on June 28, 1988 using a water jet. Drilling muds from MW-2D2 had filled the well screen and necessitated the redevelopment.

The development water was retained in polyethylene lined holding ponds and treated using activated carbon. The water was discharged to the ground or the sanitary sewer. The sediment remaining in the polyethylene was containerized for future laboratory analysis. The wells were undisturbed from June 20, 1988 to June 28, 1988 to allow equilibration with the surrounding aquifer.

Following the installation of the monitor wells, top-ofcasing and ground elevations were surveyed to a common benchmark by J.K. Devine, a licensed land surveyor, (see Survey Data, Appendix F).

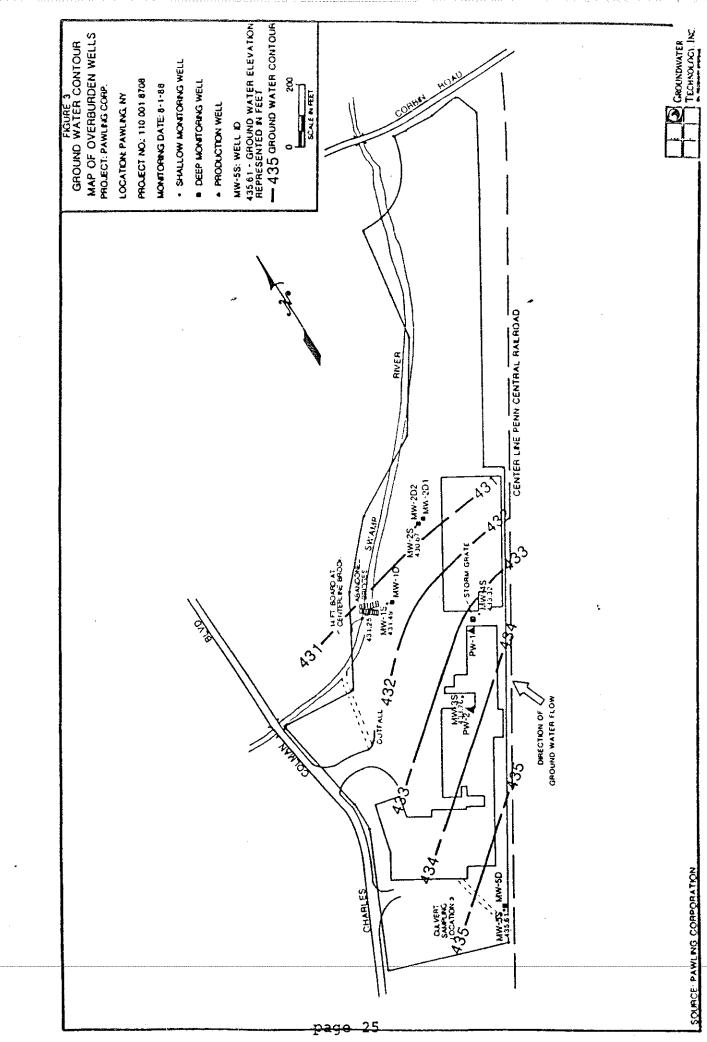

#### 2.2.5 Ground Water Gauging and Sampling

The monitor wells were gauged on June 28 and August 1, 1988 in order to determine the ground water gradient(s). The water level in each well was gauged using an ORS interface probe (see Ground Water Gradient Data, Appendix G). This instrument can detect air/water/product interfaces with an accuracy of  $\pm$  0.01 feet. This probe was also used to determine if a phase-separated immiscible layer was present in each well. Based on the gauging data from August 1, 1988, an immiscible layer was not detected in any of the wells. The gauging data from August 1, 1988 was utilized to produce ground water contour maps for the overburden and bedrock wells (Figures 3 and 4). The June 28 data was not used because of missing water level data. The MW-2S water level for both dates is suspect due to the presence of drilling mud.

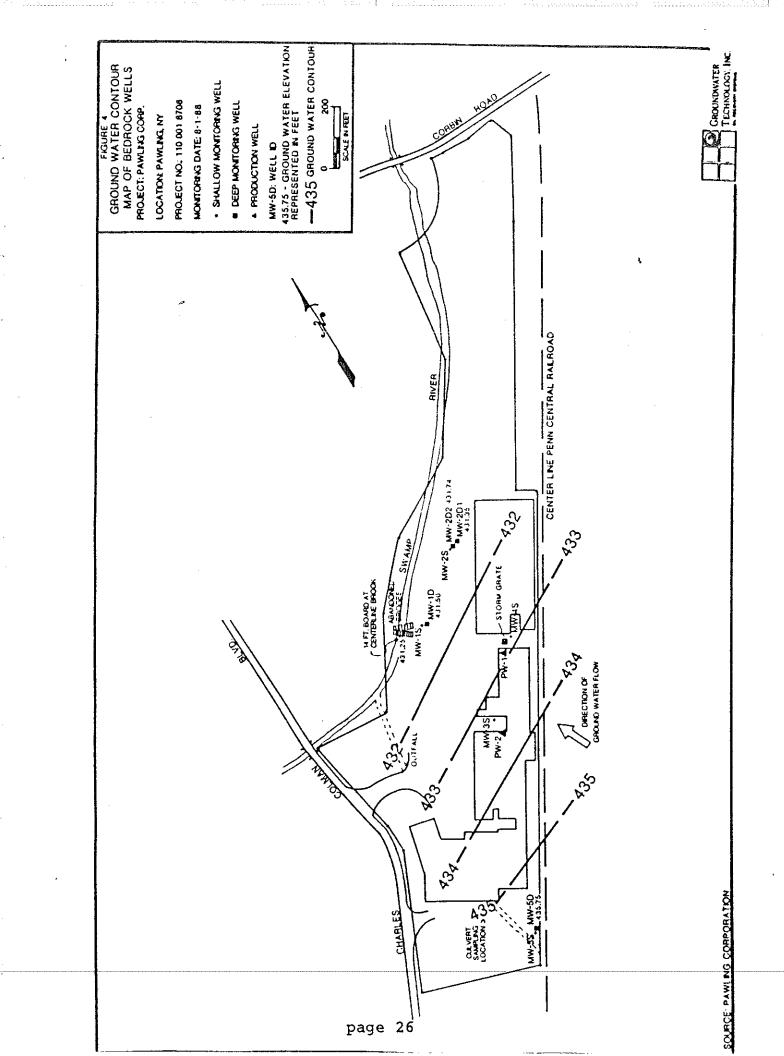

The overburden aquifer portrayed a ground water flow direction to the north-northwest at a 0.6 % gradient. The ground water in the bedrock wells indicated a north-northwest flow direction at a 0.55 % gradient. This data indicates that MW-5S and MW-5D are upgradient of only part of the Pawling site.

The observed elevation difference between the overburden and bedrock wells was 0.01 feet at MW-1, 1.07 feet at MW-2, and 0.14 feet at MW-5. The MW-2S elevation may not accurately represent the overburden water level due to the presence of drilling mud. The bedrock wells have slightly higher water level elevations than the overburden wells, indicating the existence of a vertical gradient.

The monitor wells were sampled on June 28 and 29, 1988. Prior to sample collection, three well volumes of water were evacuated from each well. This water was discharged to polyethylene lined holding ponds and treated using activated

. :

carbon. A submersible pump was used to evacuate the water from the bedrock monitor wells and a bailer was used for the evacuation of the overburden wells.

김 가 네...

The wells were sampled from least to most contaminated based upon contamination levels observed during drilling. The sampling order for the deep wells was MW-5D, MW-1D, MW-2D2, MW-2D1. The sampling sequence for the overburden wells was MW-5, MW-3, MW-1, MW-4. MW-2 was not sampled due to the inability to remove the drilling mud; however, sampling results were recorded on the field GC.

Samples were collected using decontaminated teflon bailers and clean rope. Decontamination procedures are described in Section 2.2.7. Water samples were poured directly from the bailer into properly prepared laboratory jars, and placed on ice until delivery to the laboratory. Proper chain of custody procedures were employed throughout the sampling.

The two production wells at the Pawling facility were sampled from a sampling port located in the piping on June 30, 1988. These wells were constantly in use during the day, and it was assumed that at least three to five well volumes had been removed prior to sample collection.

Analyses for all samples included Purgeable Organics by EPA Method 624, Base Neutral Extractable Organics by EPA Method 625, and Priority Pollutant Metals. Two samples were collected for metals analysis from the monitor wells: one

#### page 27

unfiltered and one filtered. Hydrochloric acid and Nitric acid were used as preservatives in the 624 analysis and the metals analysis, respectively. Camo Laboratories in Poughkeepsie, New York performed all analyses.

The laboratory results indicated that all compounds in the Base Neutral 625 analysis were below detection limits. The ground water sampling results of the volatile organics and metals are summarized in Tables 4 and 5. Appendix H contains full laboratory results.

Six volatile organic compounds were detected in the ground water samples: 1,1 Dichloroethylene (1,1 DCE), Trans 1,2 Dichloroethylene (Trans 1,2 DCE), 1,1,1 Trichloroethane (1,1,1 TCA), Trichloroethene (TCE), Tetrachloroethene (PCE), and Toluene.

Toluene was the volatile compound present at the highest concentration, 3,000 ppb in MW-2Dl and 22,140 ppb in MW-2S (Table 4). Toluene was not detected at any other well location. Trans 1,2 DEC, 1,1,1 TCA, TCE, and PCE were detected at various concentrations in many of the wells, ranging from 2 ppb to 3,517 ppb (Table 4) The production wells contained only these four compounds. Trans 1,2 DCE generally exhibited the highest concentrations of the four compounds. Trans, 1,2 DCE is a breakdown product of TCE and PCE. MW-2D contained the highest level of Trans 1,2 DCE 880 ppb. Only one well, MW-1S, contained 1,1 DCE at 8 ppb. The

upgradient overburden well, MW-5S, contained 14 ppb PCE.

page 28

The MW-2 location, particularly the overburden well, contained the highest concentrations of total volatiles on the site. PW-2 contains the next highest concentrations. The high pumping rate of this well may be drawing the contamination from the MW-2 area.

The DEC Ground Water Quality Standards and Guidance Values for the detected volatile organics are shown in Table 4. The regulations require that no individual standard or guidance value be exceeded, and that the total of the listed volatiles not exceed 100 ppb. According to these regulations, the water quality in MW-ID is within DEC drinking water limits.

The metals which were detected above the laboratory detection limits were Arsenic, Copper, Lead, and Zinc. The concentrations of Arsenic, Copper, and Zinc are below the DEC ground water quality standards. The concentrations stated in the regulations are listed in Table 5. The only sample results which exceed the DEC standards are the Lead contents in MW-1D, MW-5S, and PW-1. The concentration in MW-5S (0.11ppm), the upgradient well, is approximately the same concentration as in PW-1 (0.13 ppm). The Lead concentrations may vary due to natural background variations in the Lead mineral content in the overburden materials and bedrock.

#### 2.2.6 Surface Water Gauging and Sampling

The interaction of the surface water and ground water at this site was evaluated through surface water gauging and sampling. A staff gauge was placed on the abandoned railroad bridge at the edge of Swamp River to measure the stream water level (Figure 2). The elevation of the top of the gauge was surveyed by Mr. Devine. The stream water level was recorded at the same time that the ground water levels were gauged on June 28 and August 1, 1988. The elevations of the stream were 430.65 and 431.25 feet, respectively. These elevations compare very closely to the overburden and bedrock ground water elevations, suggesting that the Swamp River is an effluent stream receiving ground water discharge from the overburden and bedrock aquifers.

Surface water and sediment samples were collected on June 29, 1988 at four locations: two on upgradient stream channels and two downgradient on the Swamp River. Figure 2 shows the sampling locations. The sampling sequence was SS-1, SS-2, SS-3, and SS-4.

A double ended sampler was utilized to collect a sample from the water column just above the stream bed. After the samples were collected, they were poured directly into properly cleaned laboratory jars. The sediment samples were collected at the same locations as the water samples using a properly decontaminated steel shovel. Samples were placed on ice

until delivery to the laboratory. Analyses included

#### page 31

Purgeable Volatile Organics by EPA Method 624, Base Neutrals Extractable Organics by EPA Method 625, and Priority Pollutant Metals.

The lab results indicate that all the volatile organic and base neutral compounds are at concentrations at or below detectable limits in both the water and sediment samples. The following table summarizes the levels of metals found in the water and sediments from the stream. Full laboratory results are contained in Appendix H.

#### TABLE 6

# PRIORITY POLLUTANT METALS IN SURFACE WATER (in ppm)

ss-1	0.005	0.01	0.010		0.01
ss~2		0.02	0.013	0.0002	0.01
SS <b>-3</b>		0.02	0.033		0.01
SS-4		0.02			

#### TABLE 7

# PRIORITY POLLUTANT METALS IN STREAM SEDIMENT (in ppm)

	<u>Arsenic</u>	<u>Chromium</u>	<u>Copper</u>	<u>Lead</u>	<u>Mercury</u>	<u>Nickel</u>	<u>Silver</u>	<u>Zinc</u>
ss-s1 ss-s2	6.0 7.9	5.0 7.0	25.0 18.0	40.0		13.0 17.0	1.0	106 103
ss-s3	10.7	7.0	27.0	30.0		18.0	2.0	124
SS-S4	6.0	9.0	27.0	30.0	0.2	22.0	2.0	87

NOTE: -- = non-detectable levels

The surface water sample results show no significant increase in metals concentration from the upstream sampling locations (SS-1 and SS-2) to the downstream location (SS-4). Lead levels increase from SS-1 and SS-2 to SS-3. At SS-3, Lead concentrations exceed DEC Water Quality Standards; however, the concentration becomes non-detectable further downstream (SS-4).

The stream sediment sample results compare fairly closely to the soil sample results; however, no Cadmium was detected in the stream sediment and low levels of Silver were detected. There appears to be no significant increase in concentrations from the upstream locations to the downstream sampling point.

#### 2.2.7 Decontamination Procedures

A portable steam generator was used to clean all drilling equipment, such as augers, core barrels and split-spoon samplers, between monitor well locations. The split-spoon sampler was cleaned between samples with a soap and water wash, and a tap water and final distilled water rinse. Decontamination waters were containerized in polyethylene holding ponds and treated with activated carbon.

The teflon bailers and double-ended sampler were cleaned with Liquinox and water and rinsed with distilled water. The bailers used to collect samples for the 624 and 625 analyses were rinsed with acetone and hexane. The bailers used to collect samples for the metals analyses were rinsed with

#### page 33

hydrochloric acid. The bailers and sampler were allowed to thoroughly air dry before use. The interface probe was cleaned between gaugings in a similar manner as for the 624/625 analyses.

#### 2.2.8 Field QA/QC Program

A trip blank was prepared and analyzed as part of the ground water and surface water sampling. Two vials were filled with deionized water at the laboratory. Transportation to the site and return to the lab was completed in an identical manner. The trip blank was analyzed for Purgeable Volatile Organics via EPA 624.

An equipment or field blank was collected the day of water sampling to ensure that the sampler was effectively cleaned. Deionized water was poured through a decontaminated teflon bailer and collected in sample bottles and returned to the lab for analysis.

The analysis completed on the field and trip blank indicate non-detectable levels of cross contamination.

#### 2.2.9 Health and Safety

The Health and Safety Plan for this site is enclosed in Appendix I. All OHSA health and safety standards applicable to hazardous site investigations were undertaken at this site to ensure worker safety. A portable Photoionization Detector (PID) was used to monitor ambient air for the presence of volatile organic compounds in the work area. No levels greater than 1 ppm were recorded in the ambient air in the work area at any time during this investigation. Level D protection was utilized throughout the field investigation.

#### 3.0 CONCLUSIONS

The conclusions presented relate to the achievement of the original objectives of this investigation. The following conclusions are based on the work performed during this investigation and may alter with additional data.

#### <u>Objective 1</u>

Delineate the concentration and extent of metal and solventcontamination in the ground water. $\widehat{p} \cdot M \cdot 2$  $\widehat{p} \cdot M \cdot 2$ DEL ESA $\widehat{p} \cdot M \cdot 2$  $\widehat{p} \cdot M \cdot 2$  $\widehat{p} \cdot M \cdot 2$ Conclusions: $\widehat{T} \cdot C - 44$  $\widehat{T} \cdot C - 44$ 

- The highest concentrations of dissolved organic solvents were detected in ground water sampled from the overburden aquifer at MW-2S. Trans 1,2 DCE, 1,1,1 TCA, and TCE were identified at concentrations ranging from 14 to 3,517 ppb. Toluene was also detected at a concentration of 22,140 ppb. 3,000
- A production well (PW-2) exhibited the second highest level of dissolved organic solvents in the ground water. Trans 1,2 DCE, 1,1,1 TCA, TCE and PCE were identified at concentrations ranging from 10 to 52 ppb.

 All other ground water samples contained less than 100 ppb of dissolved organic solvents.

- Lead concentrations exceeded DEC Ground Water Quality Standards in three wells - MW-1D, MW-5S, and PW-1. Detected concentrations were 0.035 ppm, 0.11 ppm, and 0.13 ppm. The upgradient well, MW-5S, contained concentrations greater than or approximately equal to the levels recorded in other wells on-site; therefore, the levels of Lead in the ground water at Pawling Corporation do not appear to be the result of contamination produced by site industrial activities. No other Priority Pollutant Metal was detected in the ground water sampled.
- The data collected above indicates that the Pawling Corporation has not contributed to levels of Priority Pollutant Metals in ground water that are in excess of DEC standards.

#### <u>Objective 2</u>

Determine if upgradient sources are contributing to the contamination.

#### Conclusions:

- The upgradient wells MW-5S and MW-5D are upgradient of only part of the Pawling Corporation site. Additional information is necessary in order to determine if upgradient sources are contributing to the contamination.
- MW-5S exhibited concentrations of Lead and PCE exceeding DEC Ground Water Quality Standards and Guidance Values. These levels may indicate a low level upgradient source contributing to the contamination.

#### <u>Objective 3</u>

Evaluate the pathways of migration of contaminant movement.

#### Conclusions:

1.

- Based upon the observed volatile organic concentrations, most contaminated ground water is in the overburden aquifer at MW-2. The soils from the ground suface to a depth of five feet below grade exhibited less than 1.2 ppb volatile organics; therefore, the contamination has either been transported to this location via overburden ground water flow from an upgradient source, or the source was placed on the land surface at or near this location prior to filling when the area was lower in elevation.
- The contamination observed in the bedrock at MW-2Dl is probably due to migration from the overburden soil and/or ground water through the highly fractured upper bedrock surface.
- The contamination in MW-2D2 is probably also due to migration through bedrock fractures. Downward migration was probably enhanced by the greater density of the chlorinated solvents.
- Delineation of contaminant migration routes to the production wells needs to be further investigated.
- The Swamp River does not appear to play a role in contaminant migration within the area sampled during this investigation.
- Off-site migration routes are not fully known.

#### <u>Objective 4</u>

Provide information required for design of a site remediation system.

#### Conclusions:

- Geologic data concerning lithology, stratigraphy, permeability, and ground water gradients have been obtained.
- A better delineation of on-site and off-site contaminant migration is required before a complete remediation system can be designed.

#### 4.0 COMPREHENSIVE REMEDIAL INVESTIGATION

#### 4.1 Introduction

The results of the Preliminary Remedial Investigation indicate the need for further delineation of potential upgradient sources. Groundwater Technology, Inc. proposes that an additional upgradient monitor well couplet be drilled east of the Pawling facility. The exact location will be approved by the DEC prior to drilling. An extensive Comprehensive Remedial Investigation and Feasibility Study will be submitted if the ground water sampling results indicate that the solvent contamination originates on the Pawling property.

The work scope detailed in Section 4.2 consists of installation of an overburden and bedrock monitor well and ground water gauging and sampling. Information concerning decontamination, health and safety, project staff, and project schedule are also provided.

#### 4.2 Technical Work Scope

4.2.1 Overburden Monitor Well Installation

An overburden monitor well will be installed east (upgradient) of the Pawling site in order to determine the ground water quality in the upper aquifer. An air rotary drill rig using a roller bit and temporary casing will be utilized for the well installation. This method will allow one drill rig to be employed for both the overburden and bedrock drilling.

The overburden monitor well will be constructed of two-inch fiberglass reinforced epoxy (FRP) well screen and casing with flush threaded joints. FRP construction ensures that low levels of organic compounds will not desorb out or adsorb onto the well screen and material. This assures the collection of representative samples of the ground water in the formation surrounding the well. Use of FRP well material has been EPA-approved.

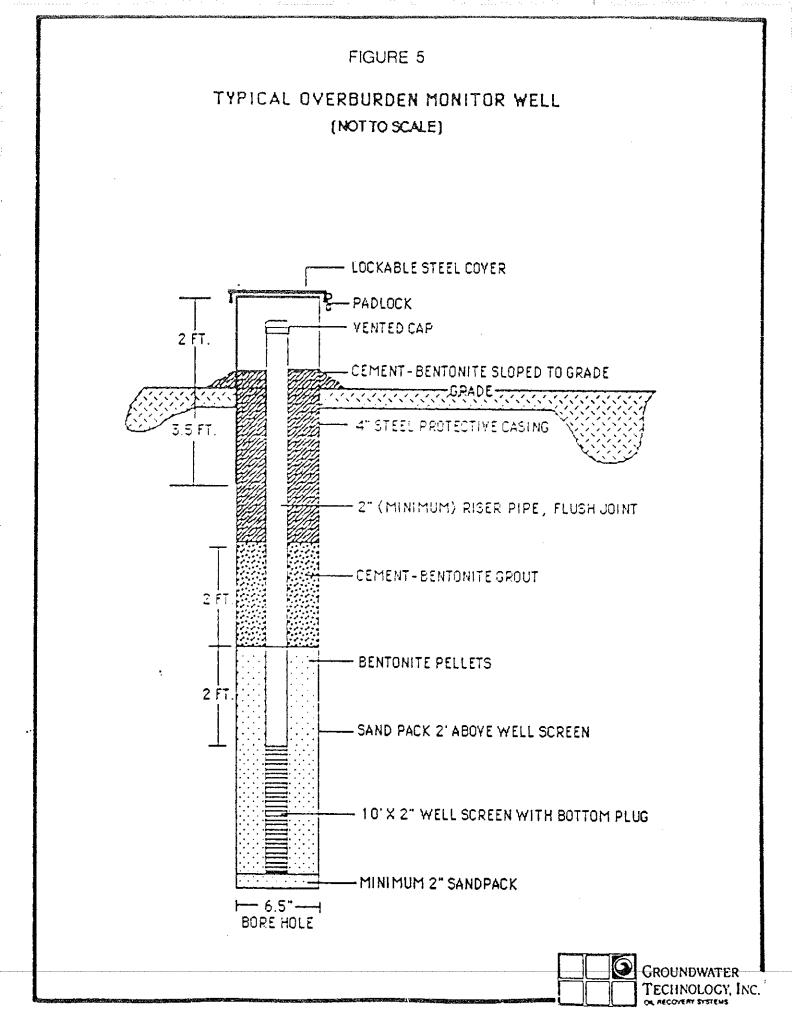

The well screen will extend from five feet above the water table to the top of bedrock, site conditions permitting. A bentonite seal, two-feet in thickness, will be emplaced at the top of the sand pack. A cement-bentonite grout, tremied in place, will be used above the bentonite seal. A lockable, protective metal casing will be installed at the top of the well. Figure 5 shows the construction of a typical overburden monitor well.

4.2.2 Bedrock Well Installation

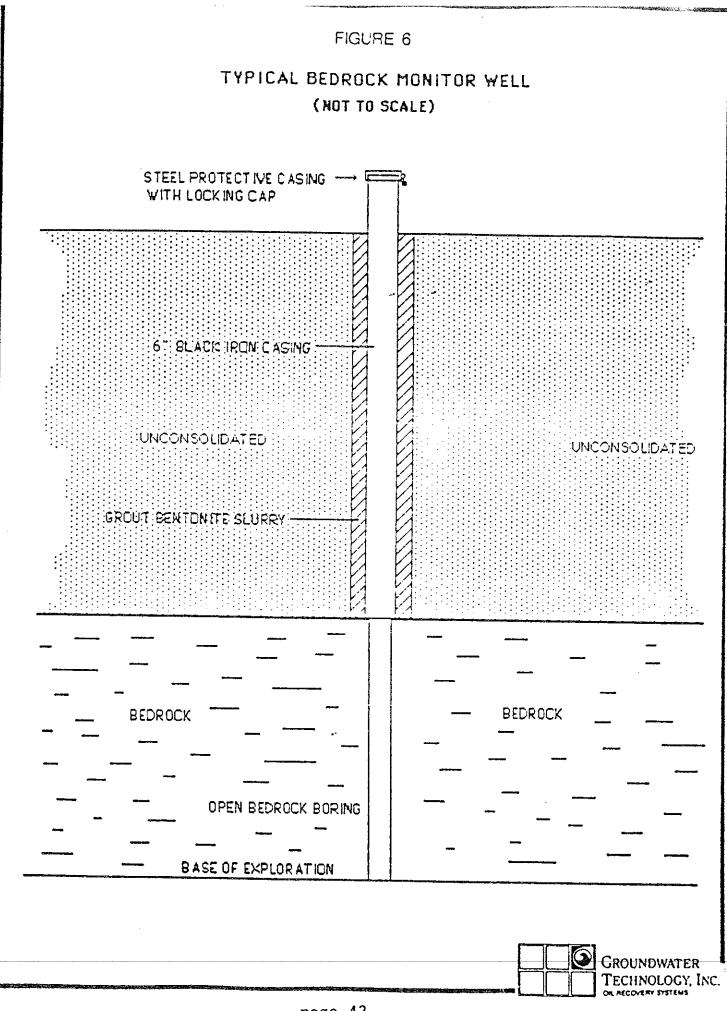

The purpose of the bedrock well will be to denote water quality in the bedrock upgradient of the site. It will also determine whether vertical migration of contaminants exists between the overburden and bedrock aquifers. One bedrock well will be drilled east of the site in close proximity to the overburden monitor well.

An air rotary drill rig will be utilized to install the bedrock well. A six-inch steel casing will be tremie grouted in place from the top of the bedrock to the ground surface. Drilling will proceed inside of this casing to a depth of approximately 150 feet below grade. The well will be completed as open hole.

Figure 6 shows the typical construction to be employed. The project hydrogeologist will supervise all monitor well installations. All well construction specifications will be included on the drilling log.

page 41

page 42

#### 4.2.3 Well Development/Elevation and Location Survey

The well development will be performed immediately after well installation. Water levels will be measured before and after development in order to estimate permeability from recovery time.

The overburden well will be developed by repeated surging and bailing with a surface sampler. The bedrock well will be developed by air jetting. These methods will remove any fine sediments from the formation immediately adjacent to the well screen and annulus of the rock hole. Water samples will therefore be free of sediments and other associated drilling materials.

Purged waters will be collected and treated through activated carbon. Wells will be left undisturbed for at least one week after development to allow time for the wells to equilibrate with the surrounding aquifer.

Following the installation of the monitor wells, top-ofcasing elevations will be surveyed to a common benchmark by a licensed land surveyor. Locations of monitor wells will also be denoted during this survey.

#### 4.2.4 Ground Water Gauging and Sampling

Following the completion of the monitor well installation program, Groundwater Technology, Inc. will gauge each monitor well using an ORS interface probe. From this data, the ground water gradient will be determined. This information will be compared to previous gauging events in order to verify ground water movement at the site.

The two newly installed upgradient wells will be sampled subsequent to gauging. Prior to sample collection, three to five well casing volumes of water will be evacuated from each well. A bailer will be used for the evacuation of the overburden well and a submersible pump will be used in the bedrock well. Evacuated water will be collected and treated in a similar manner as the development waters.

Samples will be collected using a decontaminated teflon bailer and rope. Water samples will be poured directly from the bailer into properly prepared laboratory jars, and placed on ice until delivery to the laboratory. Proper chain of custody procedures will be employed throughout the sampling. The sample will be analyzed for Purgeable Organics by EPA Method 624.

#### 4.2.5 Decontamination Procedures

A portable steam generator will be used to clean all drilling equipment, drill rods, bit and casing between monitor wells. Decontamination waters will be containerized and treated through activated carbon prior to disposal.

The teflon bailer will be cleaned with Liquinox and water and rinsed with distilled water, acetone and hexane. The bailer will be allowed to thoroughly air dry before use. The interface probe will be cleaned in a similar manner between gaugings.

If protective clothing is deemed necessary for worker safety, the discarded clothing will be stored in DOT approved drums for later disposal.

#### 4.2.6 Field QA/QC Program

A trip blank will be prepared and analyzed as part of the ground water sampling. Volatile organic bottles will be filled with deionized water at the laboratory. Transportation to the site and return to the lab will be in an identical manner as the other sample containers. The trip blank will be subjected to the same analysis as the ground water.

#### 4.2.7 Health and Safety

Groundwater Technology, Inc. has prepared a health and safety plan for the Pawling site which is enclosed in Appendix I. All OHSA health and safety standards applicable to hazardous waste site investigations will be undertaken at this site to ensure worker safety. A portable Photoionization Detector (PID) will be used to monitor ambient air for the presence of volatile organic compounds in the work area. The PID levels associated with the different levels of personal protective gear are specified in the site health and safety plan.

#### 4.2.8 Summary Report

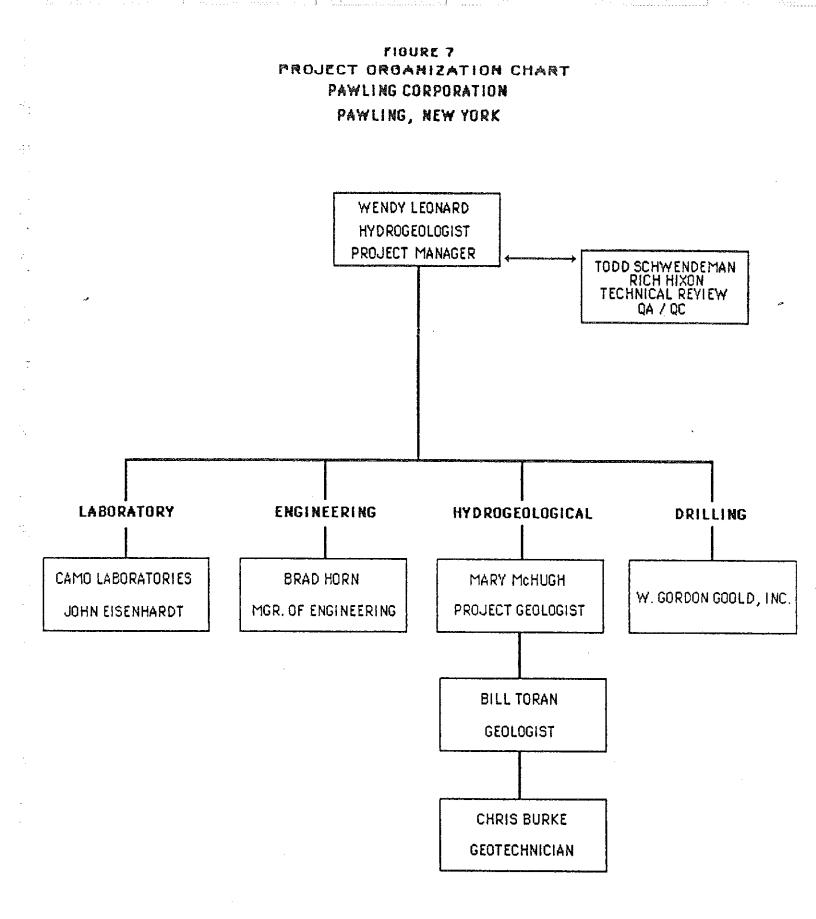

A report detailing work steps and results will be prepared upon the completion of the laboratory analyses. Conclusions will be presented evaluating the contribution of upgradient sources to the solvent contamination.

#### 4.3 Project Organization

The project organizational chart is shown in Figure 7. Groundwater Technology Inc. personnel will perform all hydrogeological and engineering work.

#### 4.4 Schedule

The proposed schedule of work is shown in Figure 8.

# TABLE OF CONTENTS

# 1.0 INTRODUCTION

#### 1.1 Purpose and General Approach

This limited scope feasibility study presents an evaluation of remediation alternatives to aid in selecting a remedial system design to treat soil and groundwater impacted by organic waste solvents at the Pawling Corporation facility in Pawling, New York. The study has been prepared to assist Pawling Corporation in choosing an appropriate remedial action to treat soil and groundwater impacted by volatile organic compounds (VOCs) near a former waste-burning trench located at the northern end of the facility's parking lot. Although Pawling Corporation is not presently under formal consent order or state RI/FS proceedings, the limited feasibility study has been requested by the New York State Department of Environmental Conservation (NYS DEC), Region 3, as part of ongoing NYS DEC oversight of the project.

This study has been conducted following the procedures for performing feasibility studies as outlined in the U.S. Environmental Protection Agency's (EPA) "Guidance for Conducting Remedial Investigations and Feasibility Studies under CERCLA", EPA/540/G-89/004 (October, 1988). The analysis and conclusions presented herein are based on data collected between August, 1987 and August, 1990. A brief history of previous investigations performed at the site, a description of the geologic and hydrogeologic conditions at the site and the distribution of contaminants within the soil and groundwater are described in this introduction. Section 2.0 presents a review of existing soil and groundwater standards or anticipated cleanup levels based on state and federal standards and requirements. Section 3.0 screens various treatment technologies for remediation of soil and groundwater and the merits of each technology based on cost, implementability and effectiveness. Section 4 discusses treatability testing.

Finally, Section 5.0 describes two remedial alternatives based on a detailed evaluation of preferred treatment technologies that are cost effective, easily implementable, limit the migration of contaminants, and are proven technologies that will provide the best overall protection of human health and the environment.

# 1.2 Site History

The Pawling site (New York I.D.No. 314002, EPA I.D.No. NYD001354349) is located at 157 Charles Colman Boulevard (formerly Maple Boulevard), Pawling, Dutchess County, New York (Figure 1, Site Location Map). The Pawling Corporation has been at this location since 1946 producing rubber products and fabricated plastics. The property is located adjacent to a wetlands area along the Swamp River. As part of daily plant operation, the facility is authorized to discharge non-contact cooling water to the Swamp River through a SPDES permit, number NY-000-4616, effective January 1, 1985. The NYS DEC alleges that from on or about June 2, 1987 the discharges of the cooling water to the Swamp River contained copper, zinc and organic solvents. In addition, the NYS DEC alleges that stormwater runoff from the Pawling property discharged to the groundwater via a storm grate and dry well, and beginning on approximately the same date, contained copper, lead and iron in concentrations exceeding New York State Groundwater discharge limits.

A consent order, issued by the NYS DEC (Case #3-1489/8712), was received by Pawling Corporation on February 24, 1988 documenting these allegations and requiring that a groundwater investigation be performed to identify the extent and source of groundwater contamination.

Subsequent investigation of the site began with a Phase I investigation completed by Gibbs & Hill, Inc., in June, 1988. The Phase I study provided a review of historical site usage, existing site conditions based on a site walkover and interviews with Pawling Corporation personnel, and the geology of the site based on a review of published data.

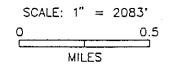

Concurrent with the Phase Linvestigation, Pawling Corporation contracted Groundwater Technology, Inc. to perform a groundwater investigation. To date, Groundwater Technology has completed the ground water investigations listed below.

- Groundwater Investigation, Pawling Corporation, Pawling, New York, September 2, 1988.
- Amended Groundwater Investigation, Pawling Corporation, Pawling, New York, February 1, 1989.
- Draft Phase II Groundwater Investigation, Pawling Corporation, Pawling, New York, September, 1990.
- Letter report on installation and sampling of monitoring wells, December, 1990.

FIGURE 1 SITE LOCATION MAP PAWLING CORPORATION PAWLING, NY

. . .

The overall objectives of the groundwater investigations were:

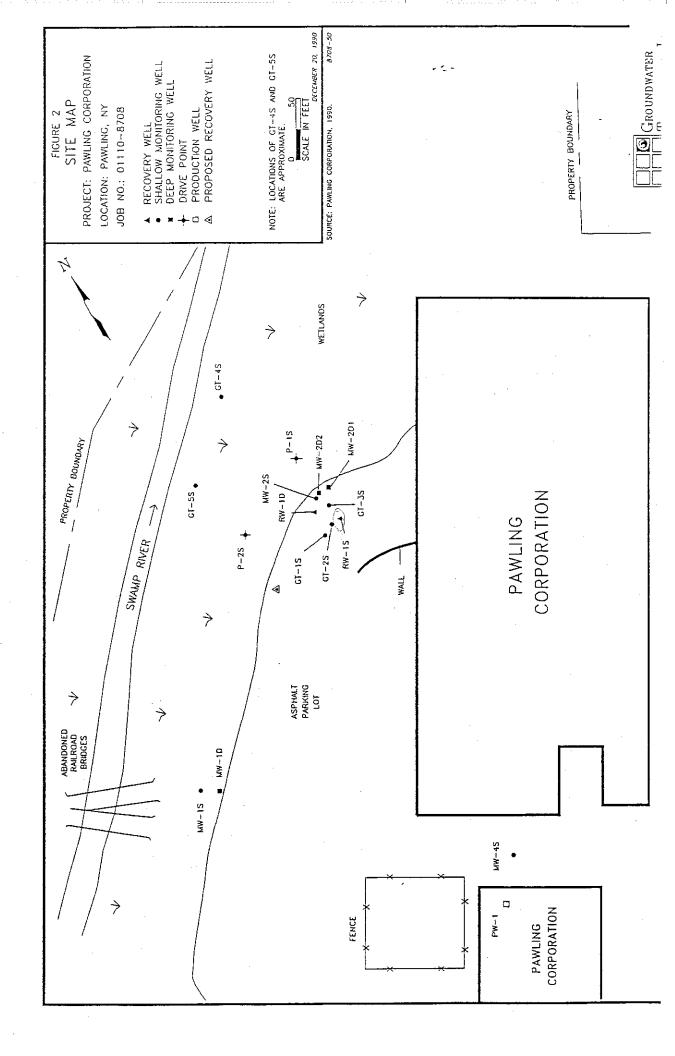

- to delineate the concentration and extent of metal and solvent contamination in the groundwater,
- to evaluate the pathways of contaminant migration, and
- to provide the information required for design of a site remediation system.

The overall work scope designed to achieve these objectives consisted of a site inspection, aerial photo review, background data review, soil borings and soil sample analysis, a soil gas survey, installation of groundwater monitoring wells in both overburden and bedrock, groundwater gauging and sampling, overburden and bedrock pumping tests, and stream water and sediment sampling. The locations of monitoring wells installed during the investigations are shown on the Site Map (Figure 2). The results of these investigations identified an area of groundwater containing dissolved concentrations of VOCs (vicinity of well RW-1S) near a former waste-solvent burning trench located at the northern end of the facility's parking lot.

Based on the discovery of the dissolved VOCs on site, Groundwater Technology began design of a remedial system in August of 1990. On October 29, 1990, the NYS DEC, Region 3, instituted a schedule for the remedial project which included deadlines for submittal of a limited feasibility study. This report summarizes the results of a limited feasibility study and describes two remedial alternatives applicable to the site.

## 1.3 Site Geology/Hydrogeology

The analysis of well logs from the monitoring well installations in the area of detected VOCs (northern edge of parking lot) reveals that the stratigraphy of overburden deposits below 3 to 4 feet of fill consists predominantly of silt and fine sand above a thin (2-4 feet) layer of sand and gravel and discontinuous till. Bedrock in the site area outcrops along the railroad located south of the Pawling Corporation buildings. A ridge of shallow bedrock (less than 10 feet below ground surface) extends between wells MW-1S and MW-4S. In the vicinity of RW-1S, the bedrock was encountered at depths ranging from 15 to 20 feet, and is highly fractured from the bedrock surface to a depth of approximately 42 feet below grade.

Rock fragments retrieved during drilling consisted of grey sandstone above yellow and grey limestone. Fisher et al (1970) have mapped the bedrock as the Stockbridge Limestone, Cambrian in age.

Depth to groundwater in the vicinity of RW-1S is approximately seven feet below grade and varies in response to seasonal fluctuations. The comparison of water levels in the nearby well couplet MW-1D and MW-1S, (and wells MW-5D and MW-5S, MW-6D and MW-6S) revealed that the bedrock wells show slightly higher water elevations than the overburden wells indicating the existence of an upward vertical gradient between the bedrock and overburden aquifers.

The wells drilled into top of the bedrock (MW-2D<sub>1</sub> and RW-1D, both drilled 22 feet into bedrock) showed slightly lower water levels than the deep bedrock well, MW-2D<sub>2</sub>, indicating the existence of an upward vertical gradient also within the bedrock aquifer.

Both the overburden and the bedrock aquifers showed generally similar directions of groundwater flow. The groundwater flow in the overburden aquifer is to the north-northwest at a 0.8% average gradient. The groundwater levels in the bedrock wells also indicate a north-northwest flow direction at a uniform 0.8 % gradient.

Based on overburden and bedrock pumping tests, groundwater flow appears to be partitioned into three hydrogeologic units: the overburden fill and glacial deposits, the upper 22 feet of highly fractured bedrock, and a lower deep bedrock unit. Groundwater gauging data indicate that groundwater discharges to the Swamp River.

#### 1.4 Distribution of Contaminants

#### 1.4.1 Adsorbed-phase

Soil sampling performed at the site confirms the presence of vapor-phase and adsorbed-phase VOCs. The results of a soil gas survey and field screening of unsaturated soil samples from soil borings showed the presence of elevated VOC soil gas concentrations in the suspected source area near RW-1S (Sample locations and depths are discussed in detail in the Phase II Groundwater Investigation and Remedial Design Report, December 1990).

The results of the soil gas survey showed elevated concentrations of 1-1-1 Trichloroethane (1,1,1-TCA) [4,400 parts per million by volume (ppmv)] at several locations near the source area with lower levels of Trichloroethylene (TCE) (270ppmv) and Tetrachloroethylene (PCE) (2.0 ppmv). Field screening of soil samples from soil borings installed for monitoring wells GT-1S, GT-2S and GT-3S also showed the presence of chlorinated hydrocarbon concentrations ranging from 83 parts per million (ppm) (GT-3S) to 921.4 ppm (GT-2S). Toluene was also detected at a concentration of 630 ppm in a sample collected from a depth of 4-6 feet at well GT-2S.

The presence of adsorbed-phase contamination below the water table is indicated by comparison of field GC screening of soil samples with dissolved-phase VOC concentrations. Based on calculations of theoretical headspace concentrations for specific compounds using Henry's Law Constant, the levels of toluene and TCE from the portable GC analysis of soil samples are higher than calculated levels that would result solely from the volatilization of dissolved toluene and TCE in groundwater. Therefore, the elevated levels of toluene and TCE detected in the saturated soil samples are attributed to toluene and TCE that is adsorbed into the soils.

# 1.4.2 Dissolved-phase

Dissolved concentrations of VOCs in the groundwater in both the overburden and bedrock aquifers has been documented for the site. Groundwater in the source area contains high levels of VOCs of which toluene and TCE are the most predominant compounds. The dissolved-phase concentrations of VOCs are summarized on Table 1. As shown on this table, toluene was detected at a concentration of 170,000 parts per billion (ppb) in well RW-1S with lower concentrations of vinyl chloride, chloroethane, 1,1-dichloroethene (1,1-DCE), Trans-1,2-dichloroethylene (Trans-1,2-DCE), 1,1,1-TCA, TCE, 1,1,2-trichloroethane (1,1,2-TCA), (PCE), toluene and ethylbenzene. Comparison of analytical data from the overburden wells (designated by a suffix S) and bedrock wells (suffix D) shows that the contaminant plume appears to be concentrated in the overburden aquifer with VOC concentrations an order of magnitude lower in the upper bedrock aquifer.

The groundwater pH of both the overburden and bedrock aquifers is slightly acidic to slightly alkaline (6.9-7.3) which is typical for limestone bedrock terrain. The results of the other inorganic water quality analyses indicated elevated levels of iron (2-4 mg/l), manganese (50-60 mg/l), hardness (600-700 mg/l, as  $CaCO_3$ ) and turbidity (40-50 mg/l).

# 1.4.3 Separate-phase

No separate-phase materials have been detected at this site.

# 2.0 DEVELOPMENT OF APPLICABLE OR RELEVANT AND APPROPRIATE REQUIREMENTS

The screening of remedial alternatives has included evaluation of each alternative to meet known or anticipated Applicable or Relevant and Appropriate Requirements (ARARs) for each impacted media (soil and groundwater) or potentially impacted media (air) on site. The ARARs have been developed based on a review of applicable state and federal regulatory standards or clean up levels for soil and groundwater. This review evaluated compliance with both chemical-specific ARARs, [eg., maximum contaminant levels (MCL)], location-specific ARARs, (eg. preservation of wetlands) and action-specific ARARs [eg. Resource Conservation and Recovery Act (RCRA) minimum technology standards]. State and federal regulations and standards reviewed included:

- Safe Drinking Water Act (SWDA)
- New York State Department of Health (NYSDOH) drinking water standards
- Clean Water Act (CWA)
- NY\$DEC Water Quality Regulations
- Toxicity Characteristic Leaching Procedure (TCLP) regulatory levels
- New York State Air Guide 1 limits
- New York State Pollution Discharge Elimination System (SPDES) limits.

This discussion of ARARs is a preliminary evaluation of potential clean up limits. Final clean up standards will involve negotiation with the NYS DEC.

# 2.1 ARARs for Soil

The potential ARARs for VOCs detected in soil on site are shown on Table 2. As shown, the only known soil standards relate to concentrations specified by TCLP extract regulatory levels. One of the goals of the selected remedial alternative will be to reduce soil contamination to below TCLP levels and prevent leaching of adsorbed-phase contamination into the groundwater. In addition, the

handling, transport and disposal of any excavated contaminated soils as a result of remedial actions will conform to RCRA standards, New York State Department of Transportation (NYS DOT) and EPA land disposal restriction regulations.

# 2.2 ARARs for Groundwater

The expected ARARs for contaminants detected in groundwater on site are listed in Table 3. Groundwater or drinking water standards may potentially represent clean up levels for contaminated groundwater. In addition to the potential clean up levels presented in Table 3, the NYS DEC will also require discharge limits of treated groundwater to the Swamp River through SPDES permitting (Table 4).

# 2.3 ARARs for Air

The NYS DEC, Region 3 Air Engineer, Steven Botsford, has indicated that off-gas concentrations of contaminants resulting from the selected remedial design must be below levels listed in Air Guide 1. Preliminary modeling results to determine off-gas concentrations from various remedial technologies indicate that several compounds will exceed Air Guide 1 levels. The selected remedial alternative will be augmented with off-gas treatment to ensure that off-gas concentrations are below Air Guide 1 limits (Table 5).

# 3.1 Introduction

The purpose of this section is to present the analyses that have been performed in order to:

- Develop remedial action objectives specifying contaminants and media of interest appropriate for the site,
- Develop general response actions for each medium requiring evaluation,
- Identify remedial technologies potentially applicable to each general response action,
- Evaluate technologies and eliminate inapplicable technologies based on effectiveness, implementability, and/or relative costs.

#### 3.2 Development of Remedial Action Objectives

Remedial action objectives consist of medium-specific goals for protecting human health and the environment utilizing the determined ARARs. The goals specify the contaminants of concern, the potential exposure routes and potential environmental receptors.

For the Pawling site the three mediums requiring remedial activities are groundwater, soil, and air. VOCs are presently located in the groundwater and soil but may be transferred to the air by potential remedial activities.

The remedial action human health objectives are to prevent human ingestion and/or inhalation of VOCs above MCLs. The environmental protection objectives are to prevent the migration of existing contamination to unaffected areas and to remove contamination from existing impacted zones. Table 6," Remedial Action Objectives, General Response Actions, and Process Options", presents the individual objectives in relation to the impacted medium.

#### 3.3 Development of General Response Actions

Appropriate general response actions for remediation of groundwater, soil and air at the Pawling site have been identified in Table 6. These general response actions are described in the following paragraphs.

TABLE 6 - REMEDIAL ACTION OBJECTIVES, GENERAL RESPONSE ACTIONS, AND PROCESS OPTIONS

# 3.3.1 General Response Actions for Groundwater

2

The following general response actions are considered potentially appropriate for groundwater at the Pawling site.

- No Action: No action is included as a baseline general response against which other actions can be measured.
- Institutional Actions: Institutional Actions, such as fencing or deed restrictions, could potentially be feasible to limit access to the contaminated areas and monitor groundwater contamination characteristics over time.
- Containment: Containment of contaminated groundwater is potentially feasible.
- Collection: Collection of groundwater via recovery wells and/or trenches is potentially feasible, and would require treatment and disposal of the extracted water.
- Treatment: Treatment of groundwater is feasible, and would require extraction followed by above ground treatment.
- Discharge: On-site discharge is feasible, and would require extraction and effective treatment.
  - In situ Treatment: In situ treatment of groundwater is potentially feasible. This would involve treatment of the groundwater in place and would require some groundwater extraction.

### 3.3.2 General Response Actions for Soil

The following general response actions are considered potentially appropriate for soils at the Pawling site:

- No Action: No action is included as a baseline general response against which other actions can be measured.
- Institutional Actions: Institutional Actions could potentially be feasible to limit access to the contaminated areas and monitor soil contamination characteristics over time.
- Containment Actions: Containment actions could potentially be feasible to limit the contamination migration.
- Excavation Actions: Excavation actions could be potentially feasible. This would involve removing the contaminated soil, treatment and disposal of soil either on or off of the site.

In situ Actions: In situ actions could be potentially feasible. These actions would remove or destroy contamination from the soil without removal of the soil.

#### 3.3.3. General Response Actions for Air

The following general response actions are considered potentially appropriate for air at the Pawling

site:

- No Action: No action is included as a baseline general response against which other actions can be measured.
- Treatment: Treatment of air off-gas from remedial technologies is feasible.

# 3.4 Identification of Potential Remedial Technology Types and Processes

Technology types and associated processes that are potentially applicable for the Pawling site have been identified in Tables 7, 8, and 9, and an "Initial Screening of Technologies - Groundwater, Soil and Air." Each of these technologies will be evaluated according to technical implementablity only.

Three technical factors eliminated some remedial technologies and processes based on implementability of the potential remedial technologies and processes. These were:

- Chemical Characteristics The chemical composition of the detected VOCs includes many chlorinated solvents. These solvents have unique characteristics that eliminate some remedial technologies and processes.
- Fractured Bedrock The Pawling site geology consists of a multiple aquifer system, one of which is fractured bedrock. The fractured bedrock presents a technical barrier to implementing some of the remedial technologies and processes.
- Wetlands Destruction The Pawling site is located on the edge of a wetlands. This
  is a barrier to the remedial technologies that would require the destruction of the
  wetlands.

Tables 7, 8 and 9 detail this initial screening based on technical implementability.

# <u>3.5 Evaluation of Remedial Technologies and Processes Based</u> on Effectiveness, Implementability, and/or Relative Costs

#### 3.5.1 Introduction

The remedial action technologies and associated process options (presented in Tables 7, 8, and 9) that are not eliminated from the screening process by the previous criterion (technical implementability) are to be further evaluated. The remaining remedial actions and processes were evaluated based on three criteria, as applicable to the site conditions:

- Effectiveness
- Implementability
- Relative Cost.

<u>Effectiveness</u>: The process options are evaluated on their effectiveness relative to other processes considering 1) their ability to achieve the remedial action objectives, 2) how proven and reliable the process is with respect to contaminants of concern.

Many of the process options within the treatment technology groups are new and in developmental stages. These processes have been evaluated based on vendor information, limited laboratory and full scale tests. On site process options which would provide significant reduction in toxicity, mobility and volume were given special consideration.

<u>Implementability:</u> Implementability encompasses the technical and institutional feasibility of implementing a process option. The technical feasibility will be used to eliminate certain process options that are ineffective and clearly not applicable to the site conditions. The deciding factors for this issue are:

- Difficulty in constructing and operating the process option.
- Potentially adverse health and environmental impact created during implementation.
- Potential material handling difficulties.
- Adverse effects of the chemicals and other materials used by the processes.

<u>Cost:</u> Cost plays a limited role at this stage of the screening process. Process options that are an order of magnitude or greater in unitized cost were screened out if the option did not offer any greater effectiveness, or reliability and provided no greater health or environmental protection. The cost comparison is generally limited to process options, under a particular technology type. Costs are only discussed where they affect the screening process.

The screening of the various technologies and options by media are presented in the following sections.

### 3.5.2 Remedial Technology Screening For Soil

Technically implementable remedial technologies and associated processes for contaminated soil (saturated and unsaturated) are evaluated in the following sections based on the specified criteria. Table 10, "Evaluation of Technologies and Process Options - Soil" summarizes the evaluations.

No Action: The no action process has been retained to act as a baseline from which to analyze the other remedial processes. The no action response is not acceptable because it does not meet any of the remedial action goals.

Institutional Action: Deed Restrictions, involves annotating the property deed to alert prospective purchasers to the conditions of the property. This option does not directly address the contaminants found on-site. This option would limit future exposure by restricting property use.

Effectiveness: This option effectively minimizes the potential direct contact exposure . scenario.

Implementability: This option could be implemented with nominal legal actions.

Relative Cost: This option would have very low costs.

Conclusion: This option is not feasible because it will not reduce the contamination.

 Institutional Action: Fencing involves enclosing all contaminated areas of the site by a chain link fence.

Effectiveness: This option effectively minimizes the potential direct contact exposure scenario.

Implementability: This option could be implemented with common fence construction practice and wetlands permits.

Relative Cost: This option would have very low costs.

Conclusion: This option is not feasible because it will not reduce the contamination.

SOIL GENERAL RESPONSE ACTIONS	No Action		Institutional Actions			Containment	Actions		la dita-freed moot			

 Institutional Action: Monitoring. Monitoring of soil conditions would involve periodic sampling of the subsurface to document any contaminant migration or change.

Effectiveness: This option does nothing to effectively minimize the potential contact with contamination.

Implementability: This option could be implemented with common sampling practices and wetlands permits.

Relative Cost: This option would have very low costs.

Conclusion: This option by itself is not feasible because it will not reduce the contamination or associated risks. It may be included with another remedial process.

Insitu-treatment: Vapor Extraction. Utilizes a network of soil vapor extraction points to draw air from the unsaturated soils. The vapor extraction blower draws air from the unsaturated soils inducing a vacuum in the soil pore spaces. This vacuum will draw VOCs adsorbed on the soil into the pore spaces and out of the extraction point.

Effectiveness: This option will effectively reduce the volume of contamination in the unsaturated soils and prevent any additional migration of VOCs in the unsaturated soils.

Implementability: This option could be implemented with common construction techniques.

Relative Cost: This option would have moderate capital costs and low operation and maintenance costs.

Conclusion: This technology is retained for further consideration.

Insitu-treatment: Air Sparging/ Vapor Extraction. Air sparging consists of a network of sparge points placed with screened intervals below the groundwater table. Compressed air is introduced to the groundwater through the sparge points. The air rises to the top of the groundwater table collecting VOCs from the saturated soils. The VOC laden air is then collected by use of a vapor extraction system as described above.

Effectiveness: Air Sparging has been shown effective for the removal of VOCs from saturated soils.

Implementability: Air Sparging can be implemented using common drilling and construction techniques. Care must be taken to operate the air sparging system with the vapor extraction system and groundwater control system to prevent the migration of contaminants due to the air sparging.

Relative Cost: Air sparging can be implemented with moderate to low capital costs and maintained with low operation and maintenance costs.

Conclusion: This technology is retained for further consideration.

Surfactant Flushing. This option involves construction of injection and extraction wells.
 Surfactants are injected at the upgradient side of the contaminant plume and extracted at the downgradient side. Chemical surfactants strip the soil of the contaminants and allow it to be collected in the downgradient extraction wells.

Effectiveness: This option could be effective for the treatment of saturated soils.

Implementability: This option could be implemented using common well drilling and construction practices.

Relative Cost: This option has low capital costs but requires high operation and maintenance costs due to the chemical addition.

Conclusion: This technology is eliminated due to the existence of more economical technologies with the same effectiveness.

 Steam Injection. Steam injection involves a network of steam injection points and a source of high pressure steam. Steam is put into the soils to volatilize the contaminants.

Effectiveness: This option could be effective for the treatment of soils.

Implementability: This option could be implemented using common well drilling and construction practices.

Relative Cost: This option has moderate capital costs but requires high operation and maintenance costs due to the steam production.

Conclusion: This technology is eliminated due to the existence of more economical

technologies with the same effectiveness.

Thermal Radio Frequency Heating. Involves placement of electrodes along the surface of the contaminated area at the Pawling site. These electrodes when activated would heat the subsurface by means of radio frequency emissions. This increase in soil temperature would then drive the VOCs from the soil into the pore spaces and to the surface.

Effectiveness: This option is not a proven technology and has only been observed in test conditions.

Implementability: This option could be implemented using common construction practices.

Relative Cost: This option has moderate capital costs but requires moderate operation and maintenance costs due to the needed electricity.

Conclusion: This technology is eliminated due to it unproven effectiveness and reliability.

#### 3.5.3 Technology Screening for Groundwater

Technically implementable remedial technologies and associated processes for contaminated groundwater are evaluated in the following sections based on the three specified criteria. Table 11, "Evaluation of Technologies and Process Options - Groundwater" summarizes the evaluations.

No Action. No action has been retained to act as a baseline from which to analyze the other remedial processes. The no action response is not acceptable because it does not meet any of the remedial action goals.

Collection Implementing Overburden Wells: Consists of constructing recovery wells in the overburden aquifer zone for the removal of contaminated concentrated groundwater. This action will directly address the most concentrated contamination on the site and eliminate the possibility of pulling contamination into the bedrock aquifer. This option would reduce contamination by direct removal of groundwater.

Effectiveness: This option effectively controls overburden groundwater and removes contaminated groundwater.

TABLE 11 - EVALUATION OF TECHNOLOGIES AND PROCESS OPTIONS - GROUNDWATER

<b>GENERAL RESPONSE</b>	REMEDIAL	PROCESS			
ACTIONS	TECHNOLOGY	OPTIONS	EFFECTIVENESS	IMPLEMENTABILITY	COST
	Groundwater extraction	Overburden wells	Effective for contaminant capture.		Moderate capital.
					very low O&M.
		Air stripping	Effective for removal of contaminants from	Easily implemented.	Moderate capital,
Collection Treatment	Physical treatment		water stream.		low O&M.

		•	water stream.		high O&M.
	Biological	Bioreactor	Effective for destruction of some of the	Requires secondary treatment of water	Moderate capital,
			contaminants in the water stream.	prior to discharge.	moderate O&M.
	In situ treatment	Air sparging	Effective for removal of contaminants.	Easily implemented. Needs air collection	Moderate capital,
				system and groundwater control.	low O&M.
	On-site discharge	Local river	Effective and reliable discharge method.	SPDES permit required.	Low capital,
			:		very low O&M.

Implementability: The construction of recovery well in the overburden aquifer can be accomplished with conventional drilling techniques. Pumps to remove the water from the well can also be implemented using conventional pumps and practices modified for the specific contaminants.

Cost: The relative cost for implementing and maintaining the wells is minimal.

Conclusion: This technology is retained for further consideration.

Treatment of Groundwater Using Air Stripping: Air stripping is an effective means of removing VOCs from water. Air stripping is a mass transfer process in which volatile constituents in water are transferred to the gas phase (air). Air stripping is frequently accomplished by either a packed tower or air diffuser set up.

The packed tower consists of a tower filled with a packing and attached to an air blower at the base of the tower. The contaminated stream enters the top of the tower as the air enters the bottom. The counter current flow strips the VOCs from the water and exhausts them through the top of the tower.

Diffused air type of strippers operate by passing air from a blower through diffusers that are placed in a contaminated water stream. The air bubbling through the stream strips the VOCs from the water and exhausts them through the top of the stripper. Both air stripping technologies operate on the same properties with much the same efficiencies. The differences remain in the size and configuration of the units physical components.

Effectiveness: Air stripping is a well documented and effective technology to remove VOCs from water streams. Air stripping is applicable for all the contaminants at the Pawling site.

Implementability: Air stripping can be implemented using any number of vendors and common construction techniques.

Relative Cost: Air stripping can be implemented with moderate capital costs and maintained with low maintenance costs.

Conclusion: This technology is retained for further consideration.

Treatment of Groundwater Using Carbon Adsorption. The process of adsorption onto carbon involves contacting a water waste stream with carbon, usually by flow through packed bed reactors. The carbon selectively adsorbs VOCs by a molecular attraction phenomenon between the VOC molecules and internal pores of carbon granules. Adsorption depends on strength of molecular attraction between adsorbent and adsorbate, molecular weight, surface area, and contact time. Once the micro pore surfaces are saturated with VOCs, the carbon must be either replaced with virgin carbon or removed for thermal regeneration.

Effectiveness: Carbon adsorption is a well documented and effective technology for the removal of VOCs from groundwater. Carbon adsorption is applicable for all the contaminants at the Pawling site.

Implementability: This process can be implemented on-site using available vendors and common construction practices. Spent carbon can be either disposed of in an incinerator facility or regenerated and reused.

Relative Cost: The capital costs involved with carbon adsorption are moderate but maintenance and disposal costs are much higher than other technically feasible processes.

Conclusion: This technology will not be retained for further consideration based on its high maintenance and disposal costs.

Treatment of Groundwater Using a Bioreactor: The bioreactor process uses a microbial population to metabolize organic constituents in a waste stream by means of a passing the waste stream over a fixed film of cultured microorganisms. The bioreactor unit consists of a a honeycomb-like structure (the medium) sealed inside an engineered enclosure. Bacteria growing on the medium adsorb biodegradable organic contaminants from the water and convert them to inert substances such as carbon dioxide and water. An air blower attached to the base of the unit supplies oxygen to the microbial population and nutrients are added to enhance the bacterial growth.

Effectiveness: Bioreactors are an effective technology on non-chlorinated compounds such as toluene.

Implementability: This technology can be implemented using bioreactor vendors and common construction technologies. Due to the bacterial populations sensitivity the reactor requires a lengthy start up time (6 weeks) and regular monitoring to insure the proper biological environment (temperature, pH, dissolved oxygen and nutrients).

Relative Cost: The reactor can be implemented with moderate capital costs and operated with moderate maintenance costs.

Conclusion: This technology is retained for further consideration.

Insitu Treatment of Groundwater Using Air Sparging: Air sparging consists of a network of sparge points placed with screened intervals below the groundwater table. Compressed air is introduced to the groundwater through the sparge points. The air rises to the top of the groundwater table collecting VOCs from the groundwater. The VOC laden air is either allowed to naturally leave the unsaturated soils or is collected by a soil venting system.

Effectiveness: Air Sparging has been shown effective for the removal of VOCs from groundwater.

Implementability: Air Sparging can be implemented using common drilling and construction techniques. Care must be taken to operate the air sparging system with a soil vapor collection system and ground water control system to prevent the migration of contaminants due to the air sparging.

Relative Cost: Air sparging can be implemented with moderate to low capital costs and maintained with low operation and maintenance costs.

Conclusion: This technology is retained for further consideration.

 On-Site Discharge to Local River: Involves piping effluent waters from the treatment system to a local river.

Effectiveness: This is an effective option to discharge the treated groundwater generated at the site.

Implementability: This option can be implemented using common construction techniques. Special care must be taken and permits obtained when the discharge piping crosses a wetlands area.

Relative Cost: This discharge option could be implemented with relatively very low costs.

Conclusion: This technology is retained for further consideration.

# 3.5.4 Summary of Technology Screening

The results of the remedial technology screening determined that the following technologies are applicable for the Pawling site and will be considered in selecting remedial alternatives:

Soil

- Monitoring
- Vapor Extraction
- Air Sparging/Vapor Extraction

# Groundwater

- Groundwater collection by Pumping Overburden Wells
- Groundwater Treatment using Air Stripping
- Groundwater Treatment Using a Bioreactor
- Insitu Treatment of Groundwater Using Air Sparging
- On-site Discharge to Local River

<u>Air</u>

Carbon Adsorption with On-site regeneration.

Treatability studies were conducted on several of the feasible technologies in order to establish the design and operating parameters for optimization of the technology performance. The following testing was performed:

- Pump testing of both the overburden and upper bedrock aquifers to determine the optimum pumping rates and hydraulic capture zones, and
- Pilot testing of groundwater treatment using air stripping.

Results of these tests are contained in the "Phase II Groundwater Investigation and Remedial Design Report, December 31, 1990.

# **1.0 INTRODUCTION**

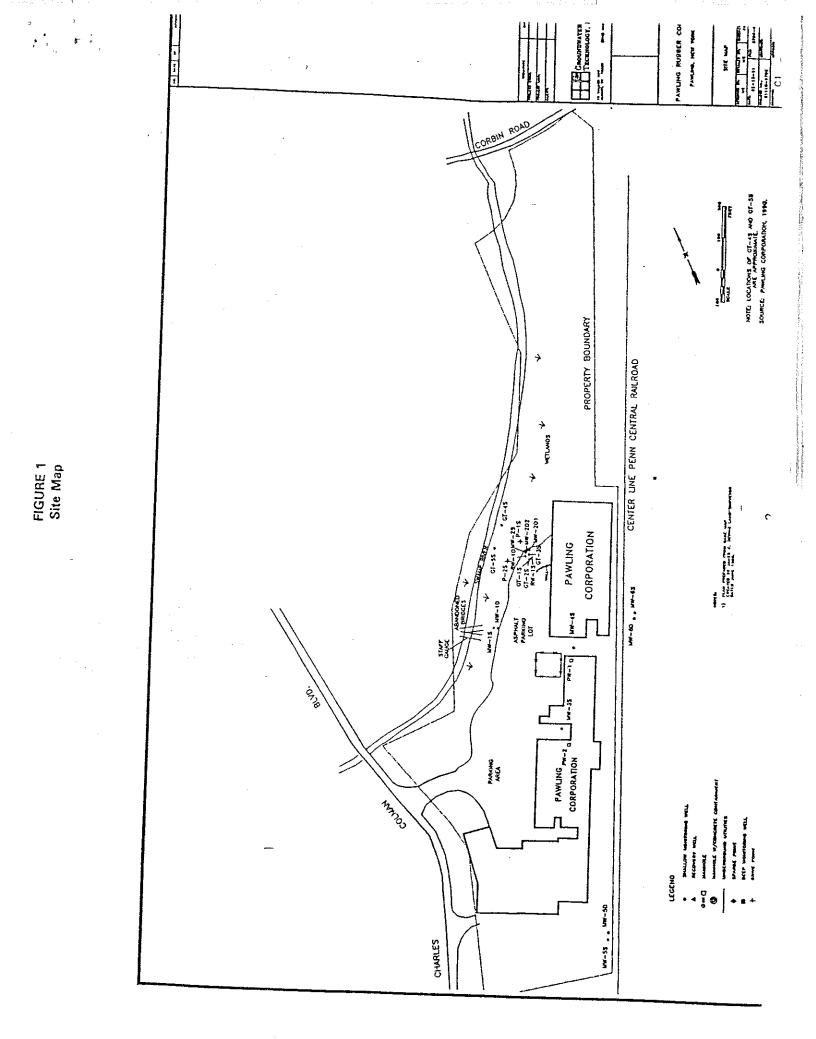

Groundwater Technology, Inc. (Groundwater Technology) was contracted by Pawling Corporation to design and install a remedial system for the facility located in Pawling, New York. (Figure 1, Site Map). Background information and results of prior groundwater investigations are contained in the January 3, 1991 "Groundwater Investigation and Pre-Remedial Design Report, Pawling Corporation". The remedial system for this site was selected by means of a limited Feasibility Study submitted to the New York State Department of Environmental Conservation (NYS DEC) on December 31, 1990. The limited Feasibility Study outlined the decision process to arrive at the preferred remedial alternative. The accepted remedial option was option #1, which included the following remedial technologies:

- Groundwater Extraction from Overburden Recovery Wells,
- Air Stripping,
- Carbon Adsorption,
- Air Sparging,
- Soil Venting, and
- Remedial System Off-Gas Treatment with Solvent Recovery.

All of the above technologies will be integrated to provide a comprehensive remediation strategy for the Pawling site. Each technology, its associated equipment and its configuration in the overall remedial design are given in the following sections.

1

ł

dec.

# 2.0 GROUNDWATER RECOVERY SYSTEM

#### 2.1 Recovery Wells

Two additional overburden recovery wells (RW-2S and RW-3S) will be installed on the northern edge of the Pawling Corporation parking lot, as shown on Figure 2, Remedial System Site Layout. The recovery wells will be constructed of 6-inch stainless steel well screen (0.020-inch slotted) and casing. The wells will be screened from 3 feet below grade to the top of bedrock, approximately 20 feet below grade. A silica sand pack will be placed in the annulus between the well screen and the borehole. A bentonite seal will be placed above the sand pack. Following installation, the wells will be finished with a traffic approved road box. Soil sample descriptions and well construction details will be recorded on well logs prepared by the field geologist.

#### 2.2 Pumps

A multiple well pneumatic pumping system will be deployed to recover groundwater from the three recovery wells on site. The system is powered and controlled by compressed air, and has the following components:

- Air-operated ejector vessels
- Bellows liquid level control
- Pneumatic control panel
- In line flow meters.

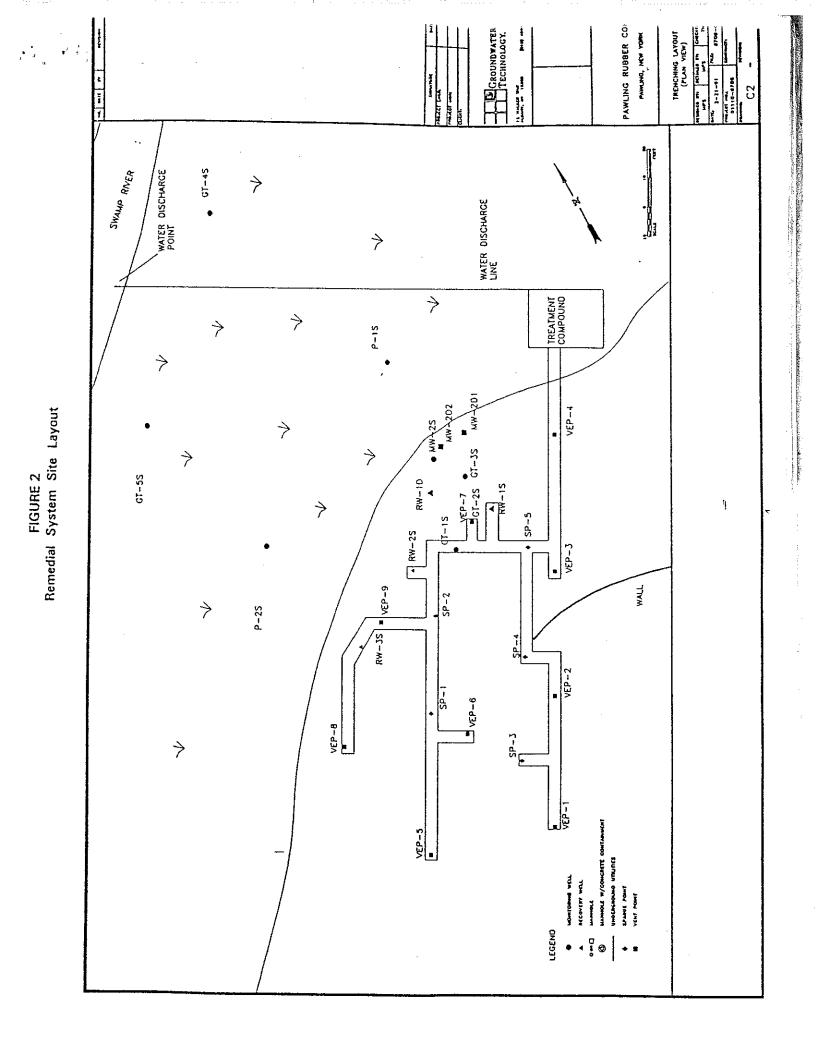

The system is designed to recover approximately 3 gallons per minute (gpm) from each of the three recovery wells for a total system flow of approximately 9 gpm. The system will use 11 cubic feet of air a minute (cfm) at a pressure of 25 pounds per square inch (psi).

Air-operated ejector vessels: Each well will contain an ejector vessel. The ejector vessel is a cylindrical hollow pressure vessel with two inlet and one discharge check valves. The ejector vessel is constructed of carbon steel and the valves are constructed of 304 stainless steel. The ejector is located in the well at the desired depth of drawdown by use of a winch.

The ejector has two operating cycles, fill and discharge. The fill cycle occurs without any pressure on the vessel. This allows the vessel to gravity fill. When the vessel is full the vessel is pressurized by the air line and the water in the vessel is forced up through the discharge check valve into the discharge line. At the end of the discharge cycle the vessel is allowed to depressurize, vent and fill again. Flow rates from the vessel are controlled by adjusting the fill and discharge cycle times.

Bellows liquid level control (BBLC): Each well will contain one BBLC at the well head. The BBLC controls the ejector pumping rate by restricting the high pressure air supply from the control panel. A bubbler line indicates the column of water that is above the ejector vessel by sensing backpressure that is created as water accumulates over the ejector. The bubbler line is mounted approximately 3/8 inches above the intake for the ejector. If the bubbler line senses sufficient amount of water above the ejector (approx. 10 inches) it allows the pump to function at full capacity. At water levels less than 10 inches above the ejector intake the BBLC partially or completely restricts the high pressure discharge air to the pump. A gauge on the face of the BBLC indicates the water level above the intake in inches of water. The BBLC will be mounted level to the wall of the recovery well road box.

Pneumatic control panel: A pneumatic control panel that will regulate the three recovery well ejectors will be mounted inside the equipment compound. The panel has a single air supply hose that supplies

compressed air from the air compressor and air dryer which are described further in Setton 4.2. The control panel will regulate the air pressure to the wells and signal the wells for the proper fill and empty cycles. Complete pump specifications are included in Appendix A, Ejector Pump Specifications.

In line flow meters: 1/2 inch Mastermeter water flow meters will be installed inside the equipment compound. The meters will accurately measure the flow rate from each well and totalize the overall volume of extracted groundwater.

The piping layout is shown in Figure 3, Groundwater Extraction and Sparge System Piping and Instruction Diagram.

#### 2.3 Trenching and Piping:

All lines will be installed in trenches at least 3.5 feet below grade. All lines installed in the trenches will be bedded on 6-inches of clean coarse sand prior to backfilling. A 6-inch lift of sand will also be installed above the pipes (Figure 4, Trench Construction Detail). The trench will be backfilled and tamped in 1-foot lifts to grade with native soils. In locations where the trenches are located in roadways or parking lots the top 6-inches of fill will be a compacted crusher run base provided for repaving. Repaving will be conducted during the summer by Pawling Corporation. The 1 1/2-inch Nitrile PVC blend pump discharge lines will be wrapped with explosion proof heat tape and insulation wherever they are buried less than 3.5 feet below grade to protect them from freezing during winter months. Figure 2, Remedial System Site Layout shows the anticipated layout of the trenches on the site.

All lines that will transport impacted water from the well to the treatment compound will be pressure tested prior to being buried. The pressure test will be performed by sealing off the line, installing a pressure gauge in the line and injecting compressed air to 10 psi. The air pressure in the line will be monitored for any changes and the line and all associated fittings will be visually inspected for any leaks. The pressure test will be maintained for a duration of 2 hours.

#### 2.4 Well Completion:

Each recovery well head will be enclosed in a traffic rated steel 2 foot square road box concreted into place. The road box lid will be bolted closed and have gaskets to seal it from water intrusion. Each road box will house the pump, bellows liquid level controller, water flow adjustment valve, and an explosion proof junction box required for heat taping water lines. The floor of the roadbox will be filled with gravel to drain any moisture that may enter the road box.

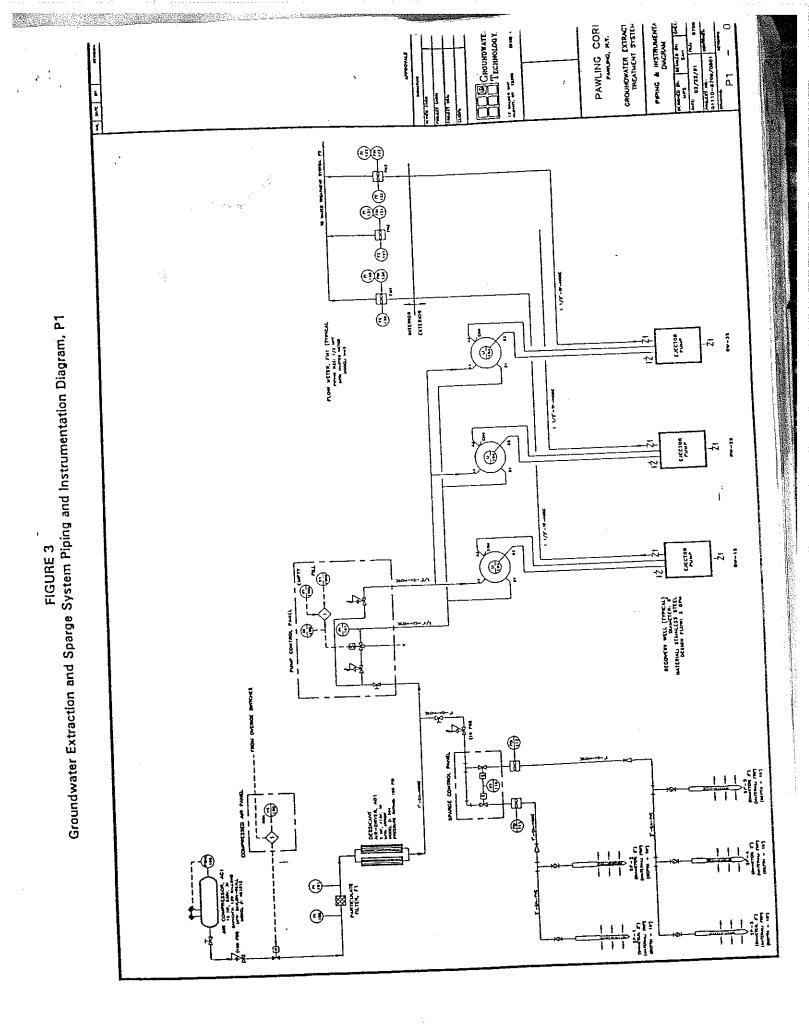

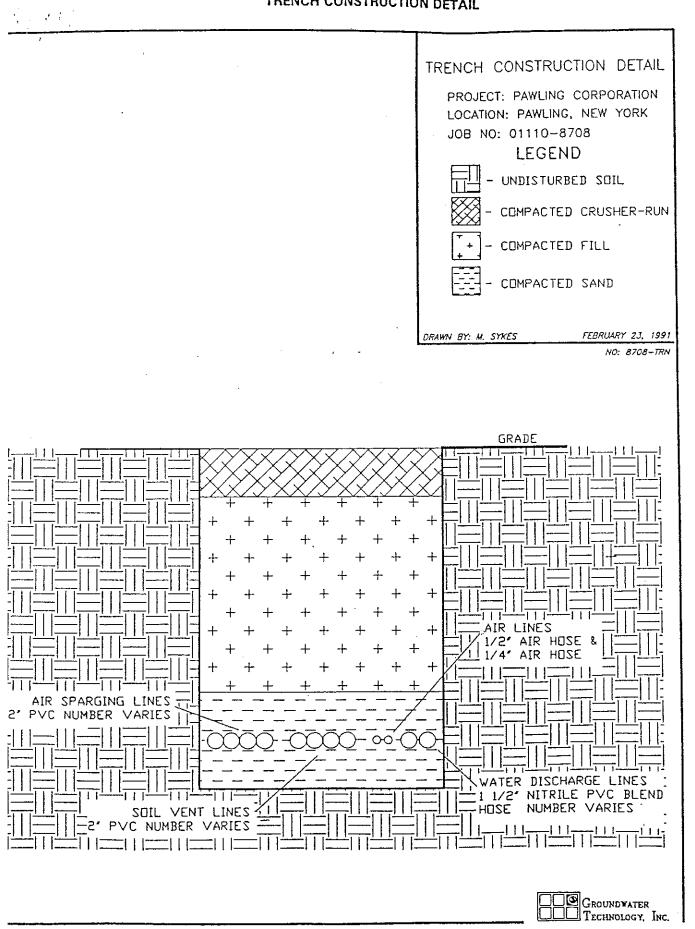

FIGURE 4 TRENCH CONSTRUCTION DETAIL

t

# 3.0 GROUNDWATER TREATMENT SYSTEM

#### 3.1 Air Stripper:

An air stripper will be used to remove volatile organic compounds (VOCs) from the water stream. The air stripper is designed to treat a flowrate of 10 gpm at the anticipated contaminant levels. Increase flow rates can be treated by adding an additional 2 Hp blower.

The following contaminant levels in groundwater (from the pump test conducted in June, 1990) have been used for the air stripper design basis:

- Toluens 170,000 ppb
- TCE 57,000 ppb
- ✓PCE 460 ppb
- Vinyl Chloride 4,800 ppb
- 1,2 DCE 37,000 ppb

The air stripper is a 12 stage diffused air bubble aeration system. The manufacturer is Lowry Engineering. The specified model for the groundwater treatment system is model # 12-2-454. This model is designed to remove 99% of the contaminants in the water stream. The stripper has 2 - 1.5Hp, 230 volt, explosion proof, regenerative blowers that are designed to introduce 140 cfm each of air into the water stream. The bubble action of the introduced air strips the VOCs from the water and transports them out of the air stripper to the off-gas treatment.

The unit is constructed of a high density polyethylene, stainless steel anchor bolts and teflon aerators. There are 12 aerators (1 for each stage). Each stage is separated by a polyethylene baffle that prevents any short circuiting of the system. The unit inlet is 1.5 inches in diameter and is equipped with an instantaneous flow gauge that will indicate the influent liquid flow rate. The unit has a water outlet of 3.0 inches and 2 air outlets of 3.0 inches each. All inlets and outlets are equipped with National Pipe Threads (NPT).

The unit's overall dimensions are 84.25 inches long x 28.25 inches wide x 32.5 inches high. The stripper lid can be removed and all aerators can be easily removed to provide cleaning and maintenance of the unit. Complete air stripper specifications are included with Appendix B, Air Stripper Specifications.

The air stripper will be mounted on a wooden platform approximately 30 inches high to allow water to gravity drain from the air stripper to the transfer sump. The two air blowers will be mounted below the air stripper. Explosion proof pressure flow switches will be used to shut down the remedial system when the backpressure on the blowers reaches a predetermined pressure (approx. 48 inches of water pressure). This will prevent overheating and excessive maintenance for the blowers, and the discharge of untreated groundwater.

#### 3.2 Transfer Pump:

Water from the air stripper will be piped to a 210 gallon transfer equalization tank. The transfer tank will be constructed of high density polyethylene and will be equipped with an air tight lid, a vent to the atmosphere, and the appropriate fittings to mount the transfer pump probes. The water sump will allow for equalized pumping through the carbon polishing system.

Water will be pumped via 1 Hp, 230 volt alternating current (VAC), explosion proof single impeller pump from the water sump though one sediment filter and 2 liquid phase granular activated carbon (GAC) units in series. The units will serve as a tertiary treatment prior to discharge. The pump will be activated by a 1 inch diameter float probe placed in the water sump after the air stripper; an additional high float will shut down the remedial system if there is a failure with the transfer pump. Complete pump specifications are included in Appendix C, Transfer Pump Specifications.

#### 3.3 Sediment Filters:

A sediment filter and housing will be installed after the transfer pump to remove any sediment or iron particles that would be in the water stream after the air stripping system. The unit will be constructed of carbon steel and pressure rated to 250 psi. The filter housing will contain one pleated paper cartridge 44-inches high and 6-inches in diameter. The cartridge will be rated to remove particles greater than 5 microns and capable of entrapping up to 16 lbs of sediment prior to change out. A pressure gauge located on the top of the filter housing will indicate the need for cartridge change outs. At the present time it is expected that one change out per month will be needed. Complete specifications for the sediment filter and housing are included in Appendix D, Sediment Filter Specifications.

いた は最近的な感染なれない。 たいのう

ţ

The sediment filter and housing will keep the carbon polishing units from clogging with particulates and will increase the useful life of the carbon units.

#### 3.4 Carbon Polishing Units:

Two liquid phase GAC units will be installed after the sediment filter. Discharge from the air stripper will be piped through both units as a treatment backup to insure a water discharge within the acceptable discharge limits. Any residual VOCs remaining in the water stream after the air stripper will be adsorbed by the carbon. Each of the units will contain 225 lbs of liquid phase GAC in a steel drum enclosure. The units will be equipped with pressure gauges before, between and after the units to monitor the need for a change out. Each of the units will operate with pressures up to 10 psi. Pressures greater than 5 psi are not expected due to the sediment filter upstream of the GAC units. Sampling between the two units will indicate the time of breakthrough of the carbon unit without discharging water exceeding the permitted limits.

#### 3.5 Discharge Piping:

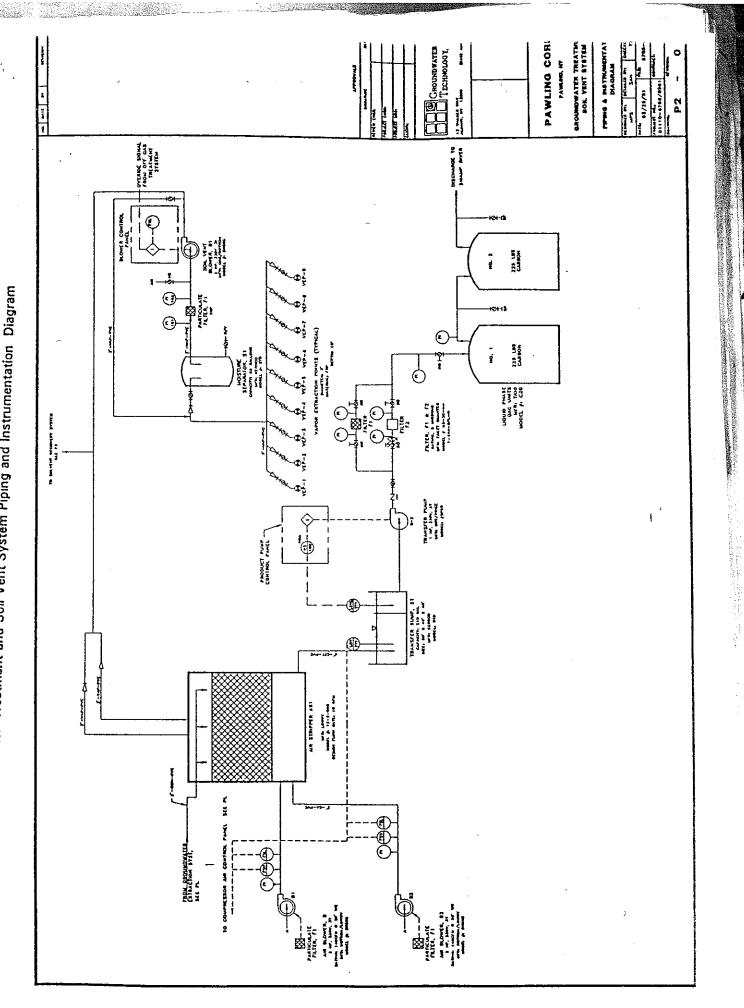

Effluent from the carbon polishing system will discharge to the Swamp River approximately 150 feet north of the equipment compound. The discharge pipe will be constructed of 2 inch carbon steel pipe. The pipe will be mounted on concrete pedestals spaced approximately 12 feet apart. These pedestals will carry the discharge pipe to the Swamp River and minimize any impact to the wetlands area that surrounds the discharge point. Discharge water may be recycled for steam generation and plant processees.

The discharge line will be externally insulated and heat taped to prevent freezing of the line during the winter months. The heat tape will be controlled from a plug assembly located inside the treatment compound. The treatment system piping is shown on Figure 5, Groundwater Treatment and Soil Vent System Piping and Instrumentation Diagram. Final disign of the discharge piping will be based upon final approval of the wetlands permit.

Groundwater Treatment and Soil Vent System Piping and Instrumentation Diagram FIGURE 5

17.4 ×

**.** ',

# 4.0 AIR SPARGING SYSTEM

#### 4.1 Sparge Points:

Sparge points will be installed throughout the impacted area of the site in order to enhance volatilization of the VOCs from the groundwater and soils below the groundwater table. The air will be bubbled into the groundwater from the sparge points. The injected air will act as a stripping device removing VOCs from the impacted water. This injected air will also be used to provide an oxygen source for the microbial population associated with the impacted water. This will help to speed the natural biodegradation process. Each point will deliver 3 - 5 cfm of air to the water table. The sparge points will be constructed of 2 inch fiberglass reinforced plastic (FRP) well riser with 1 foot of FRP well screen on the bottom of the point (Figure 3, Groundwater Extraction and Sparge System Piping and Instrumentation Diagram). The points will be installed using a hollow stem auger drill rig. The bottom of the sparge point will be placed approximately 6 feet below the surface of the groundwater.

An electronic timer and solenoid will allow intermittent airflow to the impacted area. The timer will be programmable to allow for varied air flow intervals. Field conditions will set the time durations and intervals.

It is anticipated at this time that 5 sparge points will be installed. Each of the sparge points will be individually valved and controlled by a pressure regulator located in the treatment compound. A field soil vent radius of influence test will be performed prior to installation to insure the effective areas of influence.

#### 4.2 Air Compressor:

A 15 Horsepower (Hp), 230 VAC, electric air compressor capable of producing 52 cfm compressed air at 100 psi will be installed to operate the pumping, sparging and off-gas treatment systems. The air compressor will be equipped with a fan cooled aftercooler that cools the compressed air and condenses some of the water vapor in the compressed air. This condensate will be removed by a water separator. The compressor will be mounted on a 200 gallon compressed air storage tank to allow for the steady operation of the compressor and keep storage of air for any peak operation needs. Complete air compressor specifications are included in Appendix E, Air Compressor Specifications.

Desiccant Air Dryer: A desiccant air dryer and filters will be installed after the air compressor to remove moisture, residual oil and particles from the air stream. This air dryer conditions the operating air to provide more efficient operation with lower operating maintenance.

#### 4.3 Piping:

Compressed air will be piped via 2 inch schedule 80 PVC pipe to the sparge points. All lines will be installed in a trenches at least 3.5 feet below grade. All lines installed in the trenches will be bedded on 6-inches of clean coarse sand prior to backfilling. A 6-inch lift of sand will also be installed above the pipes (Figure 4, Trench Construction Detail). The trench will be backfilled and tamped in 1-foot lifts to grade with native soils. In locations where the trenches are located in roadways or parking lots the top 6-inches of fill will be a compacted crusher run base provided for repaying.

# 5.0 SOIL VENT SYSTEM

#### 5.1 Vapor Extraction Points:

It is anticipated that 9 Vapor Extraction Points (VEPs) will be installed in the impacted zone of the site (Figure 2, Remedial System Site Layout). The VEPs will be constructed of FRP well screen from 10 feet below grade to a depth of approximately 3 feet below grade. Actual well screen depths will vary upon VOC concentrations detected in soils during drilling. The VEPs will extract existing VOCs from the soil and any additional VOCs that are produced from sparging activities.

2. S. ......

ł

The actual number, spacing and location of VEPs will be determined after a field radius of influence (ROI) test. The ROI test is performed by attaching a soil vent blower to an existing monitoring well that is properly screened above the water table. This simulates the same conditions that occur when the soil vent system is attached to a series of VEPs (wells screened in the vadose zone to remove vapors). During the ROI field test stainless steel vapor probes are placed at several different distances (3, 10, 15, 25, and 30 feet) away from the VEP at a depth of approximately 5 feet below grade. These probes will be used to monitor the conditions existing in the subsurface under the vacuum extracting conditions.

Vacuum measurements are recorded at each of the stainless steel probes while the vacuum blower is extracting vapors from the VEP. These vacuum measurements recorded over a series of different vacuum blower extraction rates will determine exactly what vacuum rate will influence what area around the VEP.

#### 5.2 Piping:

Each VEP will be piped via 2 inch, schedule 40, PVC piping to a 4-inch, schedule 40, PVC header pipe located in the treatment compound. Each VEP will be individually controlled by a ball valve located near the header pipe.

All lines will be installed in trenches at least 3.5 feet below grade. All lines installed in the trenches will be bedded on 6-inches of clean coarse sand prior to backfilling. A 6-inch lift of sand will also be installed above the pipes (Figure 4, Trench Construction Detail). The trench will be backfilled and tamped in 1-foot lifts to grade with native soils. In locations where the trenches are located in roadways or parking lots the top 6-inches of fill will be a compacted crusher run base provided for repaying.

#### 5.3 Moisture Reduction Tank:

A 55 gallon moisture reduction tank will be installed in line after the soil vent header pipe and before the soil vent blower to reduce the moisture in the vapor stream. The tank allows water vapor to condensate in the tank and collect in the bottom. A manually operated drain valve will be at the bottom of the tank to remove the collected moisture during routine maintenance visits.

#### 5.4 Soil Vent Blower:

At the present time it is expected that a 2 Hp, 230 volt regenerative soil vent blower will be installed to extract up to 120 cfm of vapor from the impacted soils via the soil vent network. The blower will be capable of producing a vacuum on the system of up to -60 inches of water column (approx. 2.2 psi). The soil vent blower size may change depending on the results of the field (ROI) test.

The soil vent blower will be rated for Class 1, Division 1, Group D, hazardous locations with explosion proof motor starter and power cord assembly. The blower is equipped with a particulate filter to remove any sand or dirt particulate that may be present in the vapor stream before it reaches the blower. Two vacuum gauges mounted on the blower inlet pipes before and after the particulate filter indicate the vacuum in the line and the need for the filter to be cleaned. Complete specifications for the soil vent blower are included in Appendix F, Soil Vent Blower Specifications.

The soil vent blower will be equipped with an override system that will automatically shut down the soil vent system in the event that the off-gas treatment system becomes inoperable.

Martin Real Property in Control

ł

## 6.0 OFF-GAS TREATMENT

#### 6.1 System Description:

An automatic solvent recovery system will be installed to remove VOCs from the two remedial air streams created by the remedial system (air stripper and soil vent). The solvent recovery unit is completely automatic and will effectively remove 95% of all VOCs from the air effluent. The VOCs will then be condensed to liquid form and collected. After collecting sufficient quantities, according to the manufacturer, the solvents can then be properly transported and disposed. The solvent recovery system uses vapor phase GAC adsorption to collect the solvents from the effluent stream, and steam stripping of the GAC to collect the captured solvent. The solvent recovery has two operating cycles:

- Adsorption
- Desorption

Two GAC vessels in the system allow adsorption of VOCs from the air stream on a continuous basis. One carbon vessel will be in the adsorption cycle while the other vessel is being desorbed. The solvent recovery system is a packaged system that will be skid mounted on two steel skids for ease of installation. The system will be equipped with a control panel that will automatically operate all the functions of the recovery system and shut down the system in case of any malfunction. A schematic diagram of the off-gas treatment system is shown on Figure 6, Off-Gas Treatment System Piping and Instrumentation Diagram. Complete specifications for the off-gas treatment system are included in Appendix G, Off-Gas Treatment "Solvent Recovery System" Specifications.

#### 6.2 Adsorption Cycle:

ł

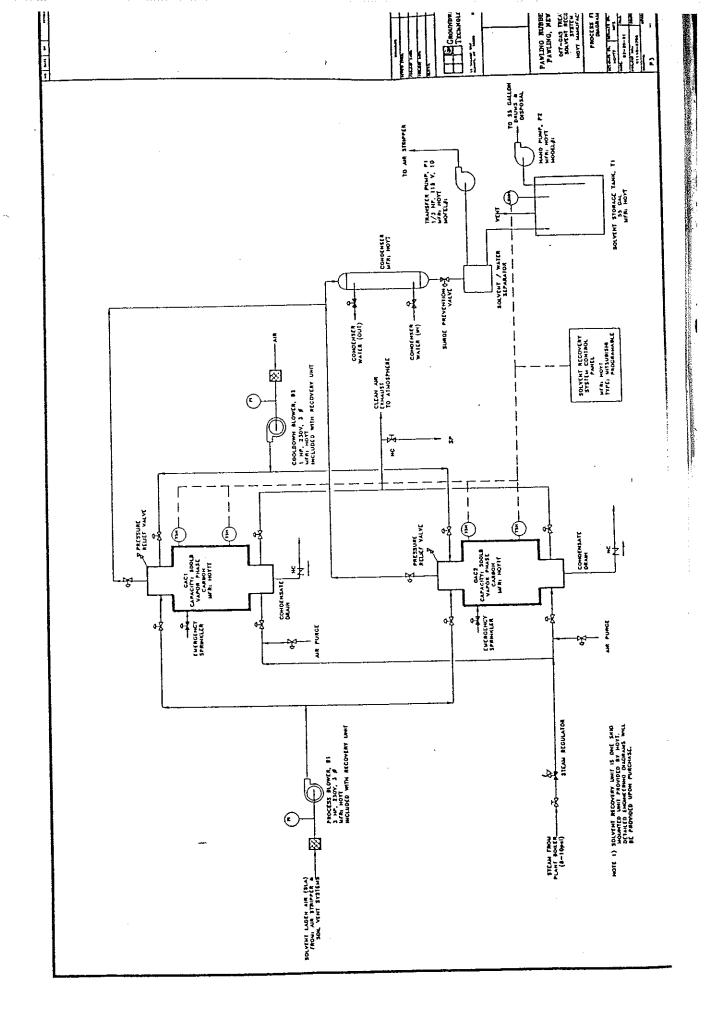

During the adsorption cycle, solvent laden air (SLA) from the air stripper and the soil vent system is blown through one 500 lb GAC adsorption unit via a 3 HP, 230 volt electric process blower rated for Class I, Division 1, Group D, hazardous locations. The blower pushes the SLA across the GAC in the absorber tank allowing the GAC to adsorb the VOCs present in the air stream. Treated air leaves the bottom of the adsorption tank through an exhaust damper into the exhaust piping and out the exhaust stack. A valved port will be provided on the effluent line inside the treatment compound for sampling purposes. The carbon bed collects the VOCs and at a predetermined time the flow of SLA is automatically switched to the other 500 lb carbon vessel.

#### 6.3 Desorption Cycle:

Once a carbon vessel is loaded with the VOCs and the timer has directed the SLA to the alternate carbon vessel the desorption cycle begins. Low pressure steam (8-10 psi) generated in the boiler to constructed in the treatment compound flows back up through the carbon bed. The steam collects the VOCs from the carbon bed and carries them through a piping network to a condenser. The steam condenser allows the steam/solvent mixture to become a water/solvent mixture. This water/solvent mixture is piped to a separator tank that will separate the water and solvent. Water from the separator will be pumped back to the air stripper inlet to be re-treated. Solvent from the separator will be stored in two 55 gallon drums until it is ready to be packaged and transported out of the treatment area. The collected solvent will be transported to a permitted incineration facility.

A purge stream of approximately 2 cfm of dry compressed air flows across the bed after the steam has stripped the carbon bed. This will force any remaining VOCs to the condenser and begin the cooldown process of the carbon bed. After the purge, a 1 HP blower blows ambient air across the carbon bed finishing the cooling process.

FIGURE 6 Off-Gas Treatment System Piping and Instrumentation Diagram

#### 7.0 OVERALL SYSTEM CONTROLS AND OVERRIDES

#### 7.1 Groundwater Pumping and Treatment System:

The groundwater pumping and treatment system will be controlled from 4 separate control panels:

- Pump control panel,
- Air stripper control panel,
- Solvent recovery control panel, and
- Sparge system control panel.

These four panels will be located in the control room of the treatment compound. The panels will monitor several operating parameters and interrupt operations if an alarm condition is detected in the operating parameters. These controls are to be installed to provide the best insurance for proper treatment and safety of operation of the remedial systems.

Alarm conditions that will stop the groundwater pumping are:

- Iow pressure in the air stripper blowers,
- high pressure in the air stripper blowers,
- soil vent system shut down,
- abnormally high water level in the transfer sump, and
- any shut down period in the solvent recovery system.

÷

If any of these conditions exist the air supply to the groundwater pumps would be stopped and water would no longer be pumped from the wells. This control system is to insure that groundwater will not be pumped if the treatment system is inadequate. A light will be installed in an obvious location on the treatment building to insure the rapid detection of such conditions. A manual start up of the groundwater pumping and treatment system would be required after correcting the alarm condition.

#### 7.2 Air Sparging and Soil Venting Systems:

The air sparging system will be controlled via the air stripper control panel. The air sparging compressed air line is connected to the pump compressed air line. This control system will shut down the sparging system whenever the pumping system is not operating. This is important because air sparging needs to be performed with hydraulic control of the groundwater at the site.

The soil vent system will be controlled via the off-gas treatment control panel. The soil vent system will shut down only when the off-gas treatment system has an alarm condition. This will insure the treatment of vapors from the soil vent system.

If the soil vent system is inoperable, the sparge system and pumping system would shut down via the sparge system control panel. This will insure that vapors produced from the sparge system will not be created if the soil vent system in not prepared to collect them.

# 7.3 Off-Gas Treatment System:

The off-gas treatment system will be equipped with a control panel that will monitor the operations of the system and shut down the solvent recovery, groundwater pumping, air sparging, and soil venting systems in the event of an alarm situation. These alarm situations are:

- abnormally high solvent level in the storage tank,
- abnormally high water level in the condensate water tank,
- abnormally high temperature in the carbon bed, and
- any improper valve condition.

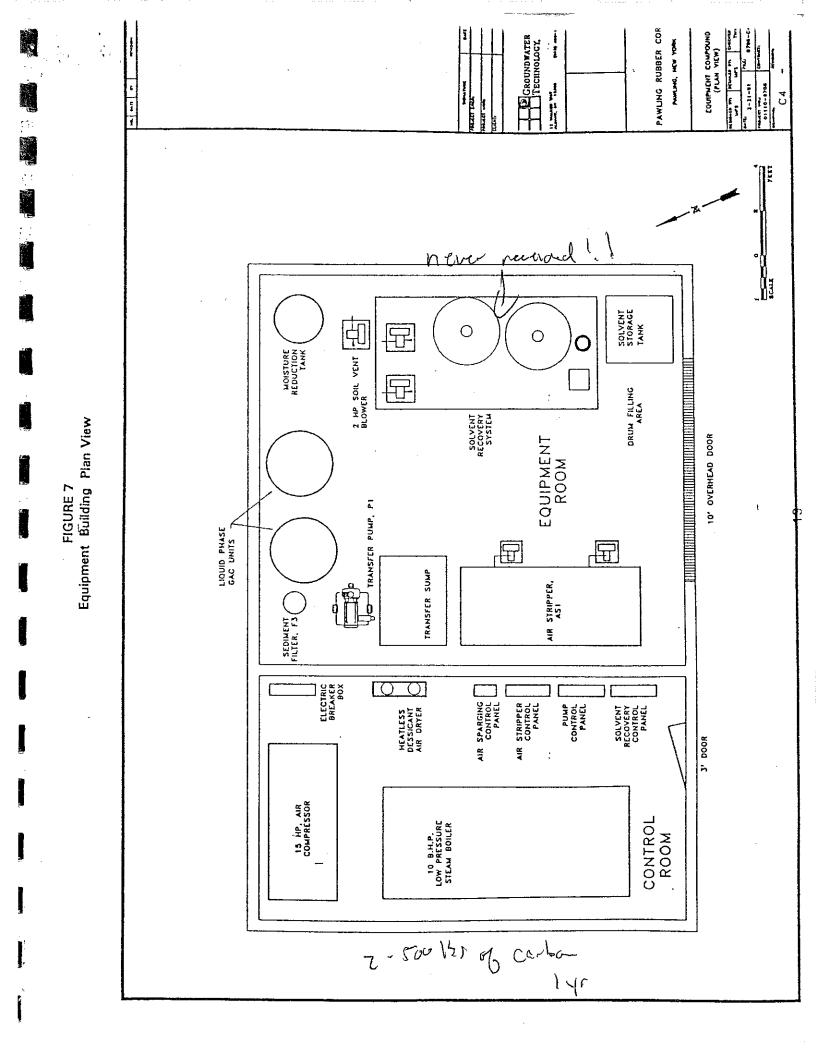

In the event of an alarm condition the control panel will shut down the remediation systems, and contact Groundwater Technology and/or Pawling Corporation via a remote monitoring phone line and a computer modem. This control panel will then specify the specific alarm condition via a computer print out and an alarm light on the panel. This specification of the particular alarm condition will allow for the most efficient correction of the condition.

In the event of an abnormally high temperature in the carbon bed or the remote possibility of a fire in the carbon bed the controller will automatically shut down the remedial systems and open an emergency water valve flooding the carbon bed with water. This water will be released through a condensate drain at the bottom of the carbon bed and be stored in a tank until the problem is assessed and corrected. The controller will notify Groundwater Technology and/or Pawling Corporation of this condition via the phone line and modem.

#### 7.4 Treatment Compound:

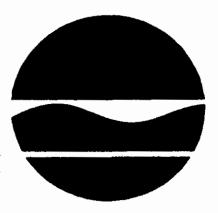

ł

A 20 foot x 30 foot treatment compound will be constructed on site to house all the remedial equipment and its associated controls (Figure 7, Equipment Building Plan View). The compound will be constructed to protect the equipment from adverse weather conditions and vandalism. The building will be divided into two operating rooms, an equipment room and a control room (Figure 8, Hazardous Class Locations). The two rooms will be separated by a 6 inch wall with 3/4 inch fire code sheet rock. The overall building construction will be determined at a later date and included with this report as an addendum when it has been approved by the local building inspector.

# PAWLING RUBBER SITE NUMBER: 314002 PAWLING, NY, DUTCHESS COUNTY

# New York State Superfund Record of Decision

March 1992

NEW YORK STATE DEPARTMENT OF ENVIRONMENTAL CONSERVATION 50 Wolf Road, Albany, New York 12233 THOMAS C. JORLING, Commissioner

#### DECLARATION FOR THE RECORD OF DECISION

Site Name and Location Pawling Rubber 157 Charles Colman Boulevard Pawling, NY 12564 Site Code: 314002 Funding Source: Responsible Party

#### Statement of Purpose

This document describes the remedial alternatives considered for the inactive hazardous waste disposal site at Pawling Rubber, Site Code 314002, and identifies the New York State Department of Environmental Conservation's (NYSDEC) preferred remedial alternative developed in accordance with the New York State Environmental Conservation Law (NYSECL), and consistent with the Comprehensive Environmental Response, Compensation, and Liability Act of 1980 (CERCLA), 42 USC Section 9601, et., seq. as amended by the Superfund Amendments and Reauthorization Act of 1986 (SARA). Exhibit A identifies the documents that comprise the Administrative Record for the site. The documents in the Administrative Record are the basis for the Record of Decision.

#### Assessment of the Site

Actual or threatened releases of hazardous substances from this site, if not addressed by implementing the response action described in this Record of Decision (ROD), present a current or potential threat to public health welfare, and the environment.

#### Statement of Basis

This decision is based upon the Administrative Record for the Pawling Rubber site and the comments received from the public. A copy of the Record is available for public review and/or copying at the following locations:

NYSDEC, Region 3 21 South Putt Corners Road New Paltz, NY 12561

Pawling Village Hall 9 Memorial Avenue Pawling, NY 12564

Pawling Free Library 11 Broad Street Pawling, NY 12564

#### Description of the Remedy

This operable unit is the first of two planned for the site. The first operable unit addresses the source of the contamination by treating the contaminated soil and groundwater in the unconsolidated overburden. The function of this operable unit is to remediate the contamination source and to prevent additional off-site migration. The second operable unit will involve continued study and possible remediation of the bedrock aquifer. The proposed remedy for the Pawling Rubber site consists of the following:

- Overburden groundwater extraction through pumping from recovery wells;
- Groundwater treatment by air stripping and granular activated carbon adsorption polish;
- \* Treatment of contaminated soils in the saturated and unsaturated zones by air sparging and soil ventilation;
- Off-gas treatment by solvent recovery (on-site carbon regeneration);
- ★ Off-site destruction of waste solvent by incineration.

#### Declaration

The selected remedy is protective of human health and the environment complies with Federal and New York State requirements that are legally applicable, or relevant and appropriate requirements (ARARs) to the remedial action. This remedy utilizes permanent solutions, alternative treatment and resource recovery technologies to the maximum extent practicable for this site.

24-92

# **RECORD OF DECISION**

#### Pawling Rubber; Pawling, Dutchess County, Site Number 3-14-002

#### I. PROBLEM STATEMENT

A series of investigations discovered high levels of tetrachloroethene (PCE), trichloroethene (TCE) and toluene in the area of a landfill on the site. Vinyl chloride at 4,800 ppb (parts per billion), trans 1,2 dichloroethene at 20,000 ppb, TCE at 41,000 ppb, PCE at 42 ppb and toluene 170,000 ppb, were detected in the 1990 groundwater investigation. No significant levels were detected in the soil. The soil gas survey conducted in 1990 showed TCE at 270 ppm (parts per million), PCE at 2 ppm, and toluene at 110 ppm. The compounds detected on site are mostly volatile organic compounds (VOCs), which volatilize quickly when exposed to the atmosphere. The site is on a plateau of bedrock, and adjacent to the site is a New York State (NYS) Regulated Wetland which contains the Swamp River. There is no evidence of extensive off-site migration of contamination. The Corbin Road municipal supply well, which is only used under drought conditions, is ¼ mile from the site, and is not presently affected by the site.

#### **II. GOALS FOR THE REMEDIAL ACTIONS**

The goals for the remedial action are to:

- 1. Eliminate the source of contamination, and the prevent of off-site migration of the contamination. The source is the high concentration plume in the groundwater.
- 2. Restore groundwater quality at the site to meet NYS standards within a period of five years from commencement of remedial action.

Groundwater monitoring wells will be sampled to determine the effectiveness of the remedial action. After the first year of the remedial action, the monitoring wells data will be evaluated. If the results of the evaluation suggest that the clean-up goal will not be obtained, the remedial action will be modified accordingly.

The New York State Groundwater Standards for the contaminants of concern:

vinyl chloride	2 ppb	
tetrachloroethene (PCE)	5 ppb	
trichloroethene (TCE)	5 ppb	
1,2 dichloroethene	5 ppb	
toluene	5 ppb	

3. Remediation of contaminated soil.

The levels of contamination detected in the soil are below clean-up action goals,

therefore no soil clean-up goals is required. The air sparging system recommended as one of the remedial actions will strip the contaminants in the saturated zone and unsaturated zones.

The soil clean-up goals for the site have been determined to be the following:

vinyl chloride	0.15 ppm
trichloroethene (TCE)	1.0 ppm
1,2 dichloroethene	0.5 ppm
toluene	1.5 ppm

#### **III. SITE LOCATION AND DESCRIPTION**

The site is located at latitude 41° 34' 07" and longitude 73° 35' 53", on USGS map Pawling, NY quadrangle (Figure 1). The plant site is ten acres and the size of the contamination area is approximately  $\frac{1}{2}$  acre (Figure 2). The site is on plateau and the low lying area to the North and West is a regulated wetland and the Swamp River. The grade difference between the wetland and site is approximately 10 feet.

The site is owned and operated by the Pawling Corporation. The site address is: 157 Charles Colman Boulevard, Pawling, NY 12564.

The New York State Department of Environmental Conservation Inactive Hazardous Waste Site Registry description is located in Exhibit B.

#### IV. SITE HISTORY

The Pawling Corp. formerly the Pawling Rubber Company is a rubber and plastic manufacturer. The site was placed on the New York State Inactive Hazardous Waste Disposal Site Registry in 1983 as a class 2a. A class 2a site is defined as a temporary classification assigned to sites that have inadequate and/or insufficient data for inclusion in any of the other classifications.

During the 1960's to the early 1970's some of the waste materials from this facility were disposed in landfills on the site. One landfill was used for construction and demolition material, scrap rubber and scrap machinery. This landfill was tested and found not to contain hazardous waste. The second landfill was used for disposing waste liquid solvents. The solvents were disposed in pits and ignited. The pits were filled with soil after each such burning episodes.

The contamination problem was discovered in June 1987 by the NYSDEC Division of Water that the site's non-contact cooling water violated a State Pollution Discharge Elimination System (SPDES) permit #NY-004618. The violation was the non-contact cooling water which exceeded limits of heavy metals, halogenated organic solvents and organic solvents. In May 1988 an Order on Consent was signed between the NYSDEC Division of Water and Pawling Corp.

The Order on Consent called for the following:

- \* Investigations to define the extent, degree and source of contamination,
- Methods of removing the contamination,
- $\star$  Methods of treating the recovered groundwater,
- Description of the point of discharge of the recovered groundwater,
- Schedule of implementation.

The site classification was changed from 2a to 2 in July 1989. A class 2 site is defined as a significant threat to the public health or environment; action required. Pawling Corporation has voluntarily conducted remedial investigation of the site and has furnished the NYSDEC with the following reports:

Groundwater Investigation Report: March 3, 1988, April 19, 1988, September 2, 1988

Amended Groundwater Investigation, February 1, 1989

Limited Feasibility Study, December 31, 1990

Groundwater Investigation and Pre-Remedial Design Report, January 3, 1991

A state-funded Phase I Investigation was performed and completed in June 1988. The Pawling Corp.'s investigation reports and the state-funded investigation report are part of the Administration Record (Exhibit A) and is available for public review in the repositories. The locations of the repositories are stated in the Declaration of the Record of Decision. In April 1991 a public meeting was held in the Village of Pawling on the proposed remedial action; a thirty day comment period was offer to the public.

There has been 18 monitoring wells and two drive points installed on site. A drive point is a one inch inside diameter stainless steel pipe which is driven below the water table. The drive point is not screened. The purpose of the drive point is to measure groundwater levels and collect groundwater samples. The drive points were placed in the wetland. Pawling Corporation also conducted a soil-gas survey and has collected and analyzed surface water, soil and sediment samples. Some of the field work was overseen by the Department. A pilot pump test and air stripper test has been conducted to ascertain the performance of the air stripping alternative.

The 1988 investigations showed the presence of contamination in the groundwater. The 1988 investigations also showed that a not-in-service Corbin Road municipal well, which is ¼ mile away, for the Village of Pawling may have been impacted by the site.

#### V. CURRENT SITE STATUS

A series of investigations discovered high levels of tetrachloroethene (PCE), trichloroethene (TCE) and toluene in the area of a landfill on the site. Vinyl chloride at 4,800 ppb, trans 1,2 dichloroethene at 20,000 ppb, TCE at 41,000 ppb, PCE at 42 ppb and toluene at 170,000 ppb, were detected in a 1990 groundwater investigation. A portable gas chromoatograph was used to

detected chlorinated hydrocarbons and toluene of soils during the well installation. The highest levels detected by the gas chromoatograph were 3,009 ppm of chlorinated hydrocarbons and 1,100 ppm of toluene.

The remedial design for the selected remedial action was completed in June 1991. The remedial action for the site was begun in September 1991. Prior to construction of the remedial action, a field test was conducted to determine the effective range of air sparging and vacuum vapor extraction system. The locations of wells for the sparging and extraction system were determined based upon a soil gas survey conducted for the "Groundwater Investigation and Pre-Remedial Design Report." From the results of this field test, the original design of the air sparging and vacuum vapor extraction system was changed; the system is smaller than planned.

The construction of the selected remedial action started on October 1, 1991. The construction started with the installation of the trench and the pipe network for the air sparging and vapor vacuum extraction system. This phase of construction was overseen by the Department. The next phase of the construction was the installation of the equipment shed which will house the air stripper, carbon units, pumping equipment and electrical equipment. The last phase of construction will be the connection of the equipment, the piping and the electricity. The completion of the construction phase took place on February 21, 1992.

The Village of Pawling well on Corbin Road which is <sup>1</sup>/<sub>4</sub> mile from the site, has been sampled by the Pawling Corp in June 1991. The sampling results showed no detectable contamination.

#### VI. ENFORCEMENT STATUS

The site was placed on the New York State Inactive Hazardous Waste Disposal Site Registry in 1983 and was classified 2 - Significant threat to the public health or environment - Action required. The site was listed for violating New York State Groundwater Standards and for confirmed hazardous waste disposal. The responsible party is the Pawling Corporation. An Order on Consent was signed with the Division of Water in 1986 to investigate and to remediate the site.

#### VII. SUMMARY OF SITE RISKS

The Comprehensive Environmental Response, Compensation and Liability Act of 1980 and the New York State Environmental Conservation Law directs the Department to protect human health and the environment from current and potential exposure to hazardous waste.

There have been four carcinogens and one non-carcinogen detected at the Pawling site in the groundwater. These contaminants toxicity, mobility, persistence and concentration warrant concerns for human health and the environment.

#### Exposure Assessment:

Currently the groundwater at the site is only used for non-contacted cooling water. The site borders a NYS regulated wetland and the Swamp River. The site may be impacting the Village of Pawling, Corbin Road municipal well. Currently this well is not being used by the village. In developing the hypothetical exposure scenarios for groundwater at this site, it was assumed that nearby residents would be exposed by ingestion to water contaminated at the highest concentrations found on site.

# Toxicity Assessment:

Four carcinogens and one non-carcinogen were detected in the groundwater. The equations are listed on Table 1 and contaminants detected are listed on Table 2. Table 1, equation 1 is used by the USEPA to established chronic toxicity criteria for the ingestion of water. The highest levels detected were used in the equation as the levels ingested by a 70kg. adult.

For non-carcinogen effects, Minimum Effective Doses (MEDs) and USEPA Reference Dose Values (RFDs) are used. MED is the minimum incremental carcinogenic response observed. The RFD is the estimate of a daily exposure to the human population to be without an appreciable risk of deleterious effects during a lifetime. For carcinogen effects, USEPA Risk Specific Doses (RSDs) and USEPA Carcinogenic Potency Factors (CPFs) are used. RSD were developed by the USEPA to evaluate environmental concentrations under intake assumptions which correspond to excess lifetime cancer risks of carcinogens. The CPF was developed by USEPA Carcinogen Assessment Group to evaluate cancer risks. The toxic assessment for the site is represented on Table 2.

#### Summary of Risk Characterization:

Given the proximity of the wetland and Swamp River and the possibility of impacting of the Village of Pawling, Corbin Road well, there are high risks from the current and potential exposure, unless the Remedial Action is implemented.

# VIII. EVALUATION OF REMEDIAL ALTERNATIVES

# A. RESPONSE ACTIONS FOR THE PAWLING SITE

The following general response actions were considered for addressing groundwater contamination at the Pawling site.

- 1GW. <u>No Action</u>: No action is included as a baseline general response against which other actions can be measured.
- 2GW. <u>Institutional Actions</u>: Institutional Actions, such as fencing or deed restrictions, could potentially be feasible to limit access to the contaminated areas and monitor groundwater contamination characteristics over time.
- 3GW. Containment: Containment of contaminated groundwater.
- 4GW. <u>Collection</u>: Collection of groundwater via recovery wells and/or trenches would require treatment and disposal of the extracted water.
- 5GW. <u>Treatment</u>: Treatment of groundwater would require extraction followed by above ground treatment.

- 6GW. <u>Discharge</u>: On-site discharge would require extraction, injection wells and effective treatment.
- 7GW. <u>In-Situ Treatment</u>: In-situ treatment of groundwater. This would involve treatment of the groundwater in place and would require some groundwater extraction.

The following general response actions were considered for contaminated soils at the Pawling site:

- 1S. <u>No Action</u>: No action is included as a baseline general response against which other actions can be measured.
- 2S. <u>Institutional Actions</u>: Institutional Actions would limit access to the contaminated areas and monitor soil contamination characteristics over time.
- 3S. <u>Containment Actions</u>: Containment actions to limit the contamination migration.
- 4S. <u>Excavation Actions</u>: Excavation actions would involve removing the contaminated soil, treatment and disposal of soil either on or off the site.
- 5S. <u>In-Situ Actions</u>: In-situ actions would remove or destroy contamination from the soil without removal of the soil.

The following general response actions were considered for treating air impacts at the Pawling site:

- 1A. <u>No Action</u>: No action is included as a baseline general response against which other actions can be measured.
- 2A. <u>Treatment</u>: Treatment of air off-gas from remedial technologies is feasible.

# **B. TECHNOLOGY SCREENING FOR GROUNDWATER**

Technically implementable remedial technologies and associated processes for contaminated groundwater which were evaluated and found feasible and effective.

- 1. <u>Collection Utilizing Overburden Wells.</u> Consists of constructing recovery wells in the overburden aquifer zone for the removal of contaminated groundwater.
- 2. <u>Treatment of Groundwater Using Air Stripping.</u> Air stripping is an effective means of removing VOCs from water. Air stripping is a mass transfer process in which volatile constituents in water are transferred to the gas phase (air). Air stripping is frequently accomplished by either packed tower or air diffuser set up.

The packed tower consists of a tower filled with a packing and attached to an air blower at the base of the tower. The contaminated stream enters the top of the tower as the air enters the bottom. The counter current flow strips the VOCs from the water and

6

exhausts them through the top of the tower.

Diffused air type strippers operate by passing air from a blower through diffusers that are placed in a contaminated water stream. The air bubbling through the stream strips the VOCs from the water and exhausts them through the top of the stripper. Both air stripping technologies operate on the same properties with much the same efficiencies. The differences remain in the size and configuration of the units physical components.

- 3. <u>Treatment of Groundwater Using a Bioreactor</u>. The bioreactor process uses a microbial population to metabolize organic constituents in a waste stream by means of passing the waste stream over a fixed film of cultured microorganisms. The bioreactor unit consists of a honeycomb-like structure (the medium) sealed inside an engineered enclosure. Bacteria growing on the medium adsorb biodegradable organic contaminants from the water and convert them to inert substances such as carbon dioxide and water. An air blower attached to the base of the unit supplies oxygen to the microbial population and nutrients are added to enhance the bacterial growth.
- 4. <u>In-situ Treatment of Groundwater Using Air Sparging.</u> Air sparging consists of a network of sparge points placed with screened intervals below the groundwater table. Compressed air is introduced to the groundwater through the sparge points. The air rises to the top of the groundwater table collecting VOCs from the groundwater. The VOC laden air is either allowed to naturally leave the vadose zone soils or is collected by a soil venting system.
- 5. <u>On-site Discharge to Local River</u>. Involves piping effluent waters from the treatment system to a local river.

# C. REMEDIAL TECHNOLOGY SCREENING FOR SOIL

Technically, implementable remedial technologies and associated processes for contaminated soil in the unsaturated or vadose zone (above the water table) and saturated zone (below the water table) which were evaluated and found feasible and effective.

- 1. <u>In-situ Treatment Vapor Extraction</u>. Utilizes a network of soil vapor extraction points which are connected to a vapor extraction blower. The blower draws air from the vadose zone inducing a vacuum in the soil pore spaces. This vacuum will draw VOCs adsorbed on the soil into the pore spaces and out of the extraction point.
- 2. <u>In-situ Treatment Air Sparging/Vapor Extraction</u>. Air sparging consists of a network of sparge points placed with screened intervals below the groundwater table. Compressed air is introduced to the groundwater through the sparge points. The air rises to the top of the saturated zone and collecting the VOCs from the vadose zone within the soil. The VOC laden air is then collected by use of a vapor extraction system as described above.

# D. TECHNOLOGY SCREENING FOR AIR

Technology implementable remedial technologies and associated processes for contaminated air discharges from remedial systems which were evaluated and found feasible and effective.

1. <u>Treatment of Air Discharge Using Carbon Adsorption</u>. The process of adsorption onto carbon involves contacting an air waste stream with carbon, usually by flow through packed bed reactors. The carbon selectively adsorbs VOCs by a molecules and internal pores of carbon granules. Adsorption depends on strength of molecular attraction between adsorbant and adsorbate, molecular weight, surface area, and contact time. Once the micro pore surfaces are saturated with VOCs, the carbon must be either replaced with virgin carbon or regenerated.

2. <u>On-site Disposal. Regeneration.</u> On-site disposal by regeneration would include installation of a solvent recovery system capable of collecting VOCs from waste air streams and regenerating the carbon. The regeneration process would include low pressure steam stripping of the VOCs from the carbon, collection of the VOCs from the steam stripping process and the disposal of the collected concentrated liquid VOCs.

#### IX. CITIZEN PARTICIPATION

To inform the local community and to provide a mechanism for citizens to make the Department aware of their concerns, a citizen participation program has been implemented. In accordance with the Citizen Participation (CP) Plan developed for this project, the following goals have been accomplished:

- \* Information repositories have been established;
- ★ Documents and reports associated with the project have been placed into the repositories;
- A "contact list" of interested parties (e.g. local citizens, media, public interest groups, government agencies, economic agencies, etc.) has been created;
- ★ Periodic meetings with village and town boards and the Rotary Club to discuss status of project;
- A legal notice of the completion of the RI/FS and the preferred remedial action was published in the Pawling News Chronicle and Harlem Valley Times from March 3, 1991 to April 3, 1991;
- A public notice of the completion of the RI/FS and the preferred remedial action was distributed to the contact list;
- ★ A public comment period was established from April 4, 1991 to May 4, 1991 and a public meeting was held on April 4, 1991 to discuss the RI/FS and the preferred remedial action. A fact sheet summarizing the preferred

action was distributed at the public meeting. The minutes of the public meeting are part of the Administrative Record for the project and are in the document repositories for public inspection;

A summary of the comments/questions received during the April 4, 1991 public meeting and the comment period, as well as the responses to those comments, are included in Exhibit C. A public notice of the selected remedy and a brief summary of the remedial program will be issued to the contact list.

# X. DETAILED ANALYSIS OF SELECTED REMEDIAL ACTION

Comparison of the various remedial alternatives was done in the Limited Feasibility Study. Based upon the comments received from the public, the series of Groundwater Investigation Reports, the Limited Feasibility Study, and the criteria for selecting an alternative which meet the applicable, or relevant and appropriate requirements (ARARs), the following remedial actions were recommended:

- \* Overburden groundwater extraction through pumping from recovery wells;
- Groundwater treatment by air stripping and granular activated carbon adsorption polish;
- Contaminated soils treatment, in the vadose and saturated zones, by air sparging and soil ventilation;
- \* Off-gas treatment by solvent recovery (on-site carbon regeneration);
- \* Off-site destruction of waste solvent by incineration.

The Remedial Action was evaluated for the following criteria:

- 1. Implementability,
- 2. Short-term effectiveness,
- 3. Long-term effectiveness.

#### 1. Implementablility

#### Groundwater and Soil

Air Sparging/vapor extraction system can be implemented using common drilling and construction techniques. Care must be taken to operate the air sparging system with the vapor extraction system and groundwater control system to prevent the migration of contaminants due to air sparging.

#### Groundwater

Air stripping can be implemented using any number of vendors and common

construction techniques.

Air

Regeneration at an on-site facility can be easily implemented by construction of carbon treatment and regeneration system available from vendors and arranging the proper shipment of collected liquid VOCs to an approved facility. Several approved waste haulers are available in the area.

# 2. Short-term Effectiveness

The selected remedial action would reduce the future risk by controlling groundwater migration and reducing VOCs concentrations and mass. The selected remedial action would also hasten the reduction of VOCs concentrations and mass in soils.

#### 3. Long-term Effectiveness

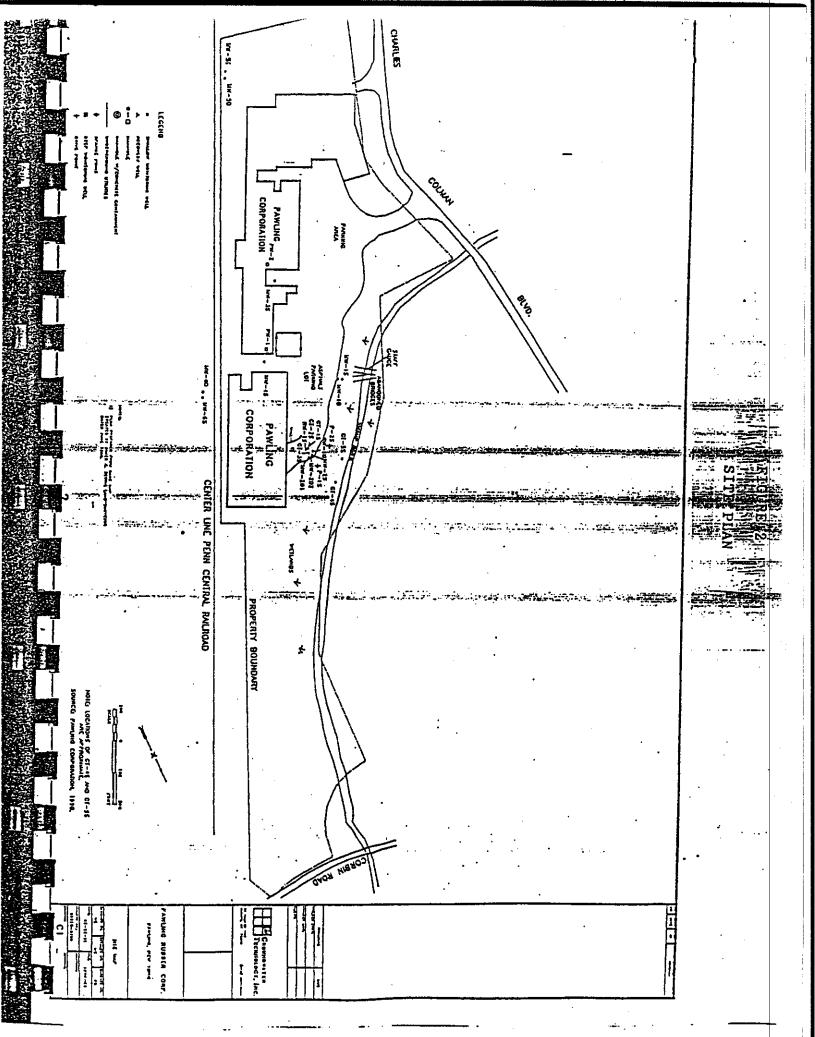

The selected alternative effectively reduce the volume of contamination in the vadose and saturated zone in soils and prevent any additional migration of VOCs in the soils and groundwater. Air Sparging/Vapor Extraction has been shown effective for the removal of VOCs from vadose and saturated zones in soils. Air stripping is a well documented and effective technology to remove VOCs from water streams. Air stripping is applicable for all the contaminants at the Pawling site. Regeneration is a proven technology for destruction of VOCs.

The selected alternative results in a remedial program which is both protective of human health and environment and which recognizes the unique problems presents at the site. To achieve the clean-up goal, groundwater monitoring wells will be sampled periodically to determine the effectiveness of the remedial action. After the first year of the remedial action, the monitoring wells data will be evaluated. If the results of the evaluation suggest that the clean-up goal will not be achieved within a five year period, the remedial action will be modified accordingly. ## Responsiveness Summary

The Responsiveness Summary for the April 4, 1991 public meeting on the Pawling Rubber Inactive Hazardous Waste Disposal Site (314002) is attached here and includes the following information:

- 1). Minutes of the public meeting with comments/ questions and responses provided during the meeting.
- 2). Written comments and responses provided during the public comment period.
- 3). Minutes of an April 23, 1991 meeting with Pawling Rubber and Pawling Village officials on the remediation project.
- 4). Record of activities which took place as a result of comments received at both the April 4 and April 23, 1991 meetings and during the comment period.

7 243 A

The meeting began with Roger Smith, President of Fawling Corporation, introducing the evening's speakers: Susan Thompson, Regulatory Affairs Manager at Pawling Corporation, Wendy Leonard, Senior Hydrologist, Groundwater Technology, Inc., and Michael Sykes, Project Engineer, Groundwater Technology, Inc. Roger then explained what would occur over the course of the meeting and stated that the audience should kindly refrain from asking questions until after all of the speakers were through.

Susan Thompson then took the floor to explain the history of Pawling Corporation and to detail the events that led up to tonight's meeting. The Corporation has been located at 157 Charles Coleman Boulevard in the Village of Pawling since 1946, producing rubber, silicone, and plastic products. The 21.5 acre site includes wetlands with Swamp River running through the property. Pawling Corporation was the sixth occupant of the building and, in 1984, Pawling Rubber Corporation changed it's name to Pawling Corporation to reflect the diverse materials the corporation was producing.

In 1987, the Village of Pawling found it necessary to construct a new well, with Corbin Road being the site for that new well. The well was installed, but the Department of Health needed to perform a series of tests before the water could be deemed safe to drink. During this testing process, they discovered chlorine solvents present in the water. The NYSDEC was brought in to determine the source of contamination. Pawling Corporation was first on the list to check as a source of contamination, although several other places were also investigated. The source of contamination was found not to be from our storm drain.

On February 24, 1988, a consent was signed by the NYSDEC mandating Phase 1 of a groundwater investigation. At this time, Pawling Corporation retained the services of Groundwater Technology, Inc., in an effort to satisfy the conditions of the consent order. The overall objectives of the groundwater investigation were to delineate the concentration and extent of any metal or solvent contamination in the groundwater, to evaluate the pathways of groundwater flow, to determine if any upgradient sources were impacting the groundwater at Pawling Corporation, and to provide information which would be required for a design of a site remediation system, if necessary.

The overall work scope designed to achieve these objectives consisted

.

etc., then they will begin drilling, pipe installation, construction of required buildings and, finally, installation of the pumping system. Once this is all completed, the solvent system, air stripper, and solvent recovery system would be installed. When the entire process passes the

final inspection, the system can be started up; this will probably occur in the middle of August 1991. The system is designed to discontinue operation if anything goes wrong anywhere in the system. If this were to occur, representatives from Pawling Corporation and/or Groundwater Technology, Inc., would be immediately notified.

Sue Thompson then opened the floor to questions from the audience. Jeff Asher began by asking what exactly was meant by the term "contaminates" and which solvents we were specifically concerned with. Sue answered that the predominate solvents found were toluene and trichloroethylene. Jeff then asked if any benzyme was found and Sue informed him that Pawling Corporation had tested for it and none was found. Jeff then asked why the "no action" alternative was not chosen since the Corporation was not yet mandated to correct this problem. Sue's response was that since Pawling Corporation is aware, their objective is to clean it up so that future generations are not affected by it.

Luther Jackson then suggested that routine public meetings be arranged in order to keep everyone abreast of the progress of this intense and complicated process. Sue stated that this is definitely possible and she had already been speaking to the Mayor about this. She added that the goal of Pawling Corporation was to keep all channels of communication open.

Rita Asher commented that the newspaper stated that this entire cleanup process was going to take ten years to complete itself. Her question was what did Pawling Corporation anticipate as their drop-off levels in this time? Wendy Leonard answered this by first stating that she was not aware of where the ten year time frame came from, but that the process should take about five years, according to the NYSDEC. She also reminded everyone that this figure was an approximate one in that Pawling Corporation wanted to avoid giving anyone false hopes. Wendy added that quarterly reports would be sent to the state and that they would be available to the public.

A concerned resident then brought up the possibility of how this entire process would affect residents of the Village of Pawling. The resident stated that the Village had been having quite a few problems and, in his opinion, this was driving the Village into the ground. He also commented that the well-being of the Village and it's residents relied heavily upon Pawling Corporation as a source of employment. He expressed his concern about the cost of this cleanup, however, Roger quickly informed him that the entire cost would be paid for by Pawling Corporation, not the village.

Next, a woman asked what would happen to the bedrock throughout this process. Sue commented that if we are aggressively cleaning the overburden, this will force some of the water into the bedrock. Wendy then added that the bedrock water is actually coming up and discharging into the stream. Roger then added that testing will be done on the bedrock and it may be possible that we will have to drill down into the bedrock after Phase I.

John Lappas stood and commented that Fawling Corporation recognized this problem, "took the bull by the horns" and is to be commended on the action they are taking without being mandated to do so.

Another village resident then questioned the possibility of making all information regarding the cleanup process available to our school children. Roger exclaimed that he would be happy to do this and that anyone interested should contact Sue Thompson.

Mark Chipkin stated that he, too, wanted to commend Pawling Corporation for taking action before a consent order was issued. The first request he had was clarification regarding a newspaper article that claimed that the village was testing its wells, but was not finding solvents. He wanted to know why the third well was pulled and Sue explained that we were not sure of the direction of the groundwater flow in the cracks. Normally, the flow goes into the stream and this means we are responsible. However, sometimes the flow can go into a North/Northwest direction. Little is known about the flow direction, therefore, we cannot determine this.

Mark then asked if we weren't using this well because solvents were found, but Roger explained to him that he would have to ask the village officials about this.

Mark stated that he was still concerned about the other two wells and anted to know if the NYSDEC had checked them for the same contaminants. A man from the audience answered "yes" they had been checked. The next step, Wendy explained, was to begin evaluating the many different remedies that could be used. All alternatives were given careful thought and investigative research and only two (2) seemed possible and acceptable based on their short term and long term effectiveness, implementability, cost, state and community acceptance, and overall security of health and environment.

The Air Sparging/Vent System is the preferred remedial alternative by the NYSDEC and Pawling Corporation. This procedure begins with an air stripper being used to remove the VOCS from the groundwater in the well field. The air stripper is a 12-stage diffused air bubble aeration system. The solvents would rather be in the air bubble, thereby, stripping the VOCS from the water and transporting them into a solvent recovery system. The next step is to pipe the discharged water from the air stripper through two (2) liquid phase carbon units as a treatment backup.

Next, sparge points are installed in the contaminated area that inject air into the ground to enhance volatilization of the VOCS from the groundwater and soils below the groundwater table. Air is then bubbled into the groundwater and this acts as a stripping device because it takes the VOCS out of the groundwater. The injected air also acts as an oxygen source for the microbial population associated with the groundwater. This helps to speed up the natural biodegradation process.

The soil vent system then draws all the soil gases from the pore spaces above the surficial water table and feeds the air through a solvent recovery system so that the organics in the air stream are absorbed. This still leaves us with VOCS present in the two remedial air streams created by the air stripper and the soil vent. To remove them, an automatic solvent recovery system must be installed and this unit is 95% effective in removing the VOCS (this percentage does meet the states limits). The VOCS are then condensed to liquid form and stored in two 55 gallon drums until they are packaged and sent to the treatment area. The solvent potentially will be recycled by Pawling Corporation and any unrecycled solvent will be transported to a permitted incineration facility.

It was then explained to the audience that this alternative is preferred and accepted by the NYSDEC and Pawling Corporation, with implementation beginning in June of 1991. After tonight's meeting, Pawling Corporation will begin to obtain building plans, building permits, of a site inspection, aerial photo review, background data review, soil borings, soil sample analysis, soil gas survey, installation of groundwater monitoring wells in both overburden and bedrock, groundwater gauging and sampling, overburden and bedrock pumping tests, and steam water and sediment sampling.

Phase 1 of the investigation included the installation of well couplets installed next to each other. Initially, Sue explained, we had three (3) well couplets. During the investigation, however, we found that the water flowed North and Northwest, therefore, only two (2) couplets were necessary. In the Northern area, we discovered the contamination. Lead was found down below, but it was below the background levels and the NYSDEC agreed that no further action would be taken against Pawling Corporation regarding this matter.

The results of these investigations found groundwater containing dissolved concentrations of volatile organic compounds (VOCS) towards the northwend of the parking-lot...This was a result of burning solvent waste in the late 1960's when there were no regulations regarding disposal of waste....Lead was detected above groundwater drinking limits in an upgradient well which suggested that there was a high background level or that an off-site source contributed to the lead levels in the groundwater...For this reason, further remedial investigation concerning lead was discontinued.

- Fawling Corporation took the initiative prior to a consent order mandating initiation of a Remedial Investigation/Feasibility Study so that the environment would not be further jeopardized. Although, as mentioned above, this procedure is not mandated by the NYSDEC, all work is being done under their guidance and approval.

What the Remedial Investigation found is that Fawling Corporation has a plume of contaminated water that feeds into Swamp River. This plume is from the overburden and bedrock. Wendy Leonard, Senior Hydrologist for Groundwater Technology, Inc., began by explaining that the company's goal was to select the best remedy and be able to explain it to the citizens of Pawling so they would be able to understand the process and results.

The first objective was to determine what impacted medias had been affected. It was found that the soil and groundwater had definitely been affected and the possibility of air contamination also needed to be considered. Mark then directed a question for Keith Brown, NYSDEC representative. Mark voiced his concern about the homes in the area and wanted to know if Fawling Corporation had been checking individual wells. He felt that if there were cracks, the contamination could leak into homeowners wells and this was a health concern. Keith stated that the NYSDEC does not handle the water quality because it simply is not their expertise. He explained that it would have to be the local Health Department's responsibility to test the wells and that they had already been contacted regarding this. Mark then reiterated the importance of the public knowing to have their water checked as soon as possible.

Mark's next concern was with reference to the waterlands and not be able to test them as it would affect the vegetation in the area. He explained that he, too, wanted to protect the waterlands, but asked Pawling Corporation to please consider a way of testing safely, as ..... children play their routinely.

Sue stated that she was not sure, and although toluene is not Cancer-causing, it can kill you. Mark then questioned the acceptable substances and Sue explained that she would have to

get back to him regarding the answer.

Sandor Deak then wanted to know if Swamp River was connected to the New York Water System and Sue informed him that it was not. He then expressed his concern about not being involved in the decisions that Pawling Corporation was making, but Sue explained that we have a Draft Citizen Participation Plan, which includes phone numbers and addresses so that citizens can contact knowledgeable people regarding questions they may have.

Sandor also expressed his concern that maybe Fawling Corporation was trying to take a less expensive route. Roger informed him that the corporation had already spent \$300,000 on this investigation so far, and that they would probably spent another \$400,000 capital, in addition to the cost of monitoring the project (approximately \$84,000 for five years).

The meeting was brought to an end with a man from the audience thanking Pawling Corporation and all of the evening's speakers for making their expertise available to the public and answering the publics questions.

Thomas C. Jorling Commissioner

MR SANDOR KOPEOCI-DEAK RFD #1, BOX 642 PAWLING NY 12569

RE: Pawling Rubber Site NO.: 314002

Dear Mr. Kopeoci-Deak:

Thank you for your letter of May 1, 1991 on the proposed remedial project at Pawling Corporation. The Department appreciates your comments.

The following are the responses to your suggestions:

The purpose of the April 4, 1991 Informational Meeting at the Village Hall, was to inform all concerned parties of the situation at the Pawling Corporation site. The Department and the New York State Department of Health will be directing and monitoring the remedial project. Comments received from concerned parties will be incorporated into the work plan as appropriate.

May 13, 1991

- 2. Pawling Corporation has assumed the responsibility of remediating the contamination associated with their former operating practices.
- 3. The same as 2.
- 4. The Department has established clean-up goals and a time table for remediation. The clean-up goals are the New York State Groundwater Standards. The Pawling Corporation was given a timeframe of five years to meet the clean-up goals.
- 5. The route of exposure which could effect residents from the site is groundwater. The County and New York Departments of Health have been requested to monitor local drinking water supplies.
- 6. There is only one home on Charles Colman Boulevard which is using a private well. All others are connected to the central water system. The New York State Department of Health will conduct a door by door

S. Kopeoci-Deak May 13, 1991 Page two

جير ويقتر والمعا

survey of the area to verify residents water source and collect water samples if necessary.

7. This issue is between the Village of Pawling and the Pawling Corporation.

If you want any additional information or would like to submit any additional comments, please contact me at (914) 255-5453.

Thank you for your cooperation in this matter.

3. Minutes of an April 23, 1991 Meeting with Pawling ... Corporation and Pawling Village Officials

### Meeting • Pawling Corporation Groundwater Remediation Project.

## April 23, 1991

Present:

Earl M. SlocumVillage OfficialJohn T. LappasVillage OfficialBart ClarkSlayton EngineerMichael KeuppVillage OfficialRon GainerSlayton EngineerTraci PerlmanPawling CorporationSusan R. ThompsonPawling Corporation

### Update: Pawling Corporation

In response to comments made during the April 4, 1991, Public Meeting, Susan Thompson reported that three main concerns have been addressed.

Ms. Reed Asher had suggested an educational program be developed for local school children. Pawling Corporation has contacted the Pawling grade school, high school, and Trinity Pawling. Preliminary arrangements have been made with both the grade school and Trinity Pawling. Ms. Boka, Pawling High School, will be called again.

A suggestion to establish a repository in the Town Hall was made by Mr. Jim Tanner. All reports regarding Pawling Corporation have been copied and left at the Town Hall for citizen review.

Mr. Mark Chipkin was concerned that local residents might be on private wells and thus were in danger. Groundwater Technology, an engineering firm retained by Pawling Corporation, did an extensive search early in the investigation to determine if there were private wells in the immediate vicinity. Their findings concluded that local residents were on municipal water supply. In order to confirm this information, a questionnaire was mailed to those in the immediate area to confirm GTI's findings. To date, 13 questionnaires have been sent. Pawling Corporation has received 9 responses, all confirming the use of municipal water supply.

# Update: Department of Environmental Conservation

Several "new players" have been identified at the Department of Environmental Conservation. These divisions now have expressed interest in the project. This may change the timetable which was proposed by Pawling Corporation because of the evaluation time required by these departments. Pawling Corporation has requested a contact list from Mr. Keith Browne, DEC project manager, so that all may be informed in a timely fashion and delays, hopefully, will be minimal.

The April 10, 1991, correspondence from Keith Browne was discussed and is attached. Response to the letter was discussed at the meeting. A written response will be sent to Mr. Browne and copies sent to Mr. Keupp.

## Groundwater Remediation Project Overview

Pawling Corporation discussed briefly the proposed site remediation measures.

### <u>Ouestions</u>

Mayor Slocum asked about the possibility of Pawling Corporation testing the abandoned well on Corbin Road. Although studies to date have focused on the area of contamination, flow pattern of the waters below, and measures to clean up the site, future studies may include testing the Corbin Road well and installing additional overburden wells on the opposite side of the Swamp River. The village agreed to assist in whatever way possible. Pawling Corporation will contact Groundwater Technology and request that a sampling program be prepared for the overburden well on Corbin Road. All collected information will be forwarded to both the DEC and Mr. Keupp for evaluation.

The future water supply needs of the village were discussed. Ron Gainer agreed that the village had drilled a new well on Reservoir Road, however, the well failed to yield the amount of water which had been expected. The village will look at either using the Corbin Road abandoned well or search for alternative sites to supply the Village's water supply needs.

Well Log Data for the Corbin Road shallow well was obtained several years ago from the Dutchess County Health Department by Pawling Corporation (enclosed). It was noted that although monitoring wells are known to exist at the site, no information can be found regarding studies which may have been done. The Village agreed to share any information that they have and Pawling Corporation will do the same.

The goals of the Village and Pawling Corporation seem to be identical: the health and safety of all in the Town and Village of Pawling as well as the protection of the environment. The meeting ended with all agreeing to continue the open lines of communication which currently exist.

### 4. Record of Follow-up Activities

Pawling Corporation carried out several additional citizen participation activities as a follow-up on comments received during the public comment period. The following record is a list of the comments provided to Pawling Corporation and the activities which took place in response.

- Q Could a document repository be established in the Town Hall?
- R A repository has been established in the Pawling Town Hall. The repository contains the Administrative Record for the project.
- Q Could Pawling provide information regarding the clean-up process to area schools?
- R An educational program has been developed which will be presented to the grade school, the high school and Trinity Pawling.
- Q Are all residents who are potentially affected by the site connected to the municipal water system?
- R Although an earlier study suggested that the local residents were on municipal water supply, Pawling Corporation conducted a written survey of 29 residences. The results of the survey, confirmed by village records, indicate one resident on a private water system with the remaining 28 on a municipal system.

The New York State Department of Health (NYSDOH), in conjunction with Pawling Corporation, sampled the residence with a private water supply. No contamination was detected.

- Q Mayor Slocum asked if Pawling Corporation could test the abandoned well on Corbin Road.
- R Pawling Corporation prepared and conducted a sampling program for the overburden well on Corbin Road.

### GROUNDWATER AND SOIL REMEDIAL SYSTEM START UP AND FIRST QUARTERLY REPORT (MARCH THROUGH JUNE - 1992) PAWLING CORPORATION 157 CHARLES COLMAN BLVD. PAWLING, NEW YORK

August 26, 1992

#### **1.0 INTRODUCTION**

The Pawling Corporation site located in Pawling, New York is on the New York State Inactive Hazardous Waste list specified as a Class 2 (Figure 1). A remedial plan was outlined and submitted to the New York State Department of Environmental Conservation (NYS DEC) entitled "Work Plan for Subsurface Remedial Design and Implementation, Pawling Corporation", dated May 25, 1989. The work plan was approved by the NYS DEC Division of Hazardous Waste Remediation prior to initiation.

The results of this work plan were utilized to select and design a remedial system for this site. An engineering report, "Remedial System Design, Pawling Corporation", dated February 26, 1991, was prepared and submitted to the NYS DEC for approval prior to system installation. The design report was approved on June 17, 1991. The approved system consisted of groundwater extraction wells, air stripper and liquid phase carbon water treatment, air sparging, soil vapor extraction and vapor phase carbon off-gas treatment.

This status report details the pilot test results, baseline conditions, remedial system installation and first quarter operational information for the soil, air and groundwater treatment systems installed at this site.

#### 2.0 REMEDIAL SYSTEM PILOT TESTS

Air sparging and soil vapor extraction (SVE) pilot testing was performed prior to system installation in order to correctly locate the sparge and vent points and to determine the required equipment specifications for air flow, vacuum and pressure. Groundwater pump testing had previously been performed and the results are documented in the "Groundwater Investigation Pre-remedial Design Report, Pawling Corporation", dated January 3, 1991.

#### 2.1 Test Protocol

The pilot testing consisted of three components: a vent test, a sparge test and a combined sparge/vent test. The vent and sparge tests were performed first to define the individual equipment specifications and to determine the most effective operational conditions of these systems. The combined test documented actual field response to the selected pressure and vacuum to verify the predicted response. Each of these tests are described below.

#### 2.1.1 Soil Vapor Extraction Test

The SVE test was performed by attaching a soil vacuum blower to the pilot test vent well (GT-2S) and running the test at three vacuum settings, 21, 35 and 44 inches of water and 34, 38, and 41 cfm, respectively. Each vacuum setting was a phase of the test which defined a ROI and an off-gas Volatile Organic Compound (VOC) concentration. These data allowed selection of the vacuum which provided maximum radius of influence and proper blower sizing. Each phase was run until stabilization occurred.

#### 2.1.2 Air Sparge Test

The air sparge test was performed by connecting a compressed air line to the top of a newly installed sparge point (SP-1). Section 3.2 describes the construction details of the sparge point. The test was performed at three pressures, 4 psi, 5 psi and 8 psi (10%, 40% and 115% over the pressure needed for the air to overcome the 8.5 foot water column). All points were monitored for pressure and VOCs. Dissolved oxygen (DO) and depth to water (DTW) were recorded in the monitoring wells at the end of each pressure setting as removal of the pressure caps interfered with the pressure readings. Each pressure test was until stabilization occurred. The induced responses to various air flows allowed for the selection of an air flow which provided the greatest radius of influence without over-pressurization.

2

### 2.1.3 Air Sparge/Soil Vapor Extraction Test

The last phase of pilot testing was implementation of a combination air sparge/SVE test. This test was conducted to record field response under actual operating conditions and to ensure that the responses obtained from the individual SVE and air sparging tests matched the combined response test. The combination test was run at 8 psi and 42 inches of vacuum, which were the maximum levels recorded during the SVE and sparge tests. The objective of this test was to ensure that a net vacuum could be monitored across the site under maximum operating conditions so that all sparge vapors were contained.

#### 2.1.4 Monitoring Network

The monitoring network utilized for the pilot tests consisted of five existing monitor wells, a nested probe screened at two intervals in the unsaturated zone, and three 0.25 inch stainless steel probes manually installed to a depth of 3 feet.

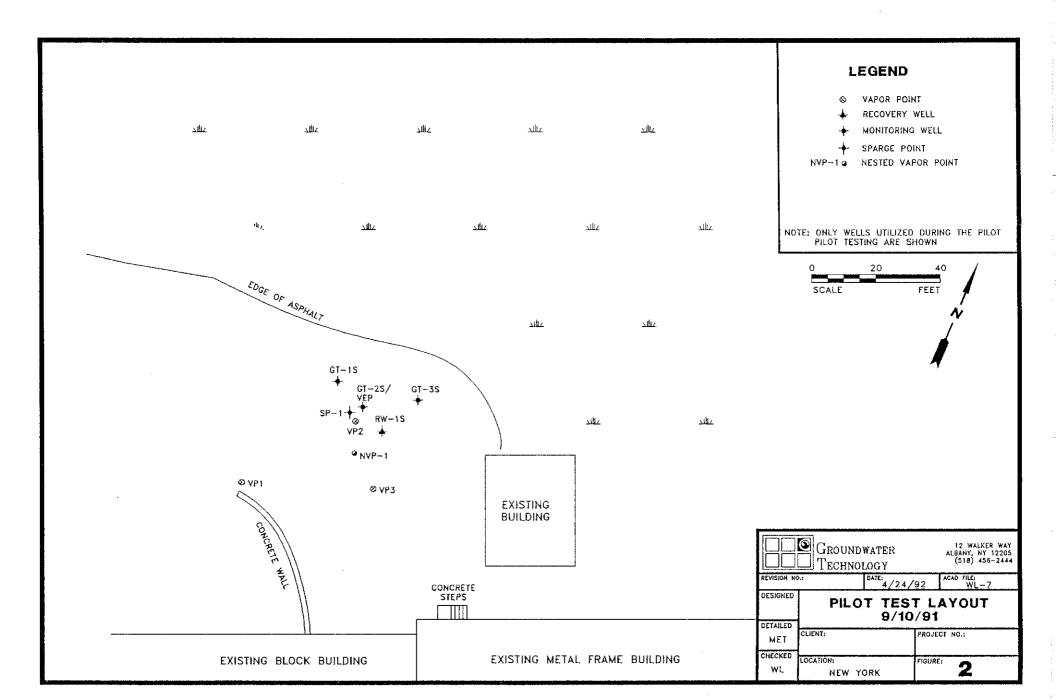

Monitoring points were selected to provide multi-directional data at varying distances from the test well. The distances were chosen based upon prior knowledge of soil permeability values, as the radius of influence is directly related to permeability. Additionally, monitoring points were installed to provide information concerning potential vertical difference in response both in the unsaturated and saturated zones. Figure 2 shows the layout of the pilot test monitoring array.

#### 2.2 Soil Vapor Extraction Test Results

Vacuum in the subsurface generally decreases exponentially with distance. To calculate an effective radius of influence and to determine anisotropic response, the natural log (In) of the vacuum was plotted versus distance. Linear regression was performed to determine the best fit lines and to evaluate correlation coefficients with different data sets to assist in defining anisotrophy in the subsurface at the site. Table 1 depicts the results of the linear regression.

The data for this site indicated that a point at 14.5 feet exhibited an anomalous reading, therefore this point was eliminated from subsequent analysis. Figure 3 also shows the determined best fit lines and the determined ROI for each vacuum setting. A vacuum of 0.1 inches of water was selected to define a significant response (ROI).

3

### TABLE 1

Vacuum	All data points	Without 14.5 foot point
21"	0.62	0.92
35"	0.87	0.97
44"	0.88	0.95

### LINEAR REGRESSION CORRELATION COEFFICIENTS

The determined ROI for each vacuum was plotted versus each vacuum setting to select the vacuum above which not greater ROI was observed. The maximum ROI obtained was 27 feet at 35 inches of water vacuum (Figure 3). VOC effluent concentrations at each vacuum setting were also evaluated. The vacuum which produced the highest effluent VOC concentration was selected for the design. This value also correlated with the most effective vacuum ROI. Figure 3 shows these results. The pilot test results indicated that the design parameters for this site should be a vacuum of 35 inches of water at 38 cfm air flow per point.

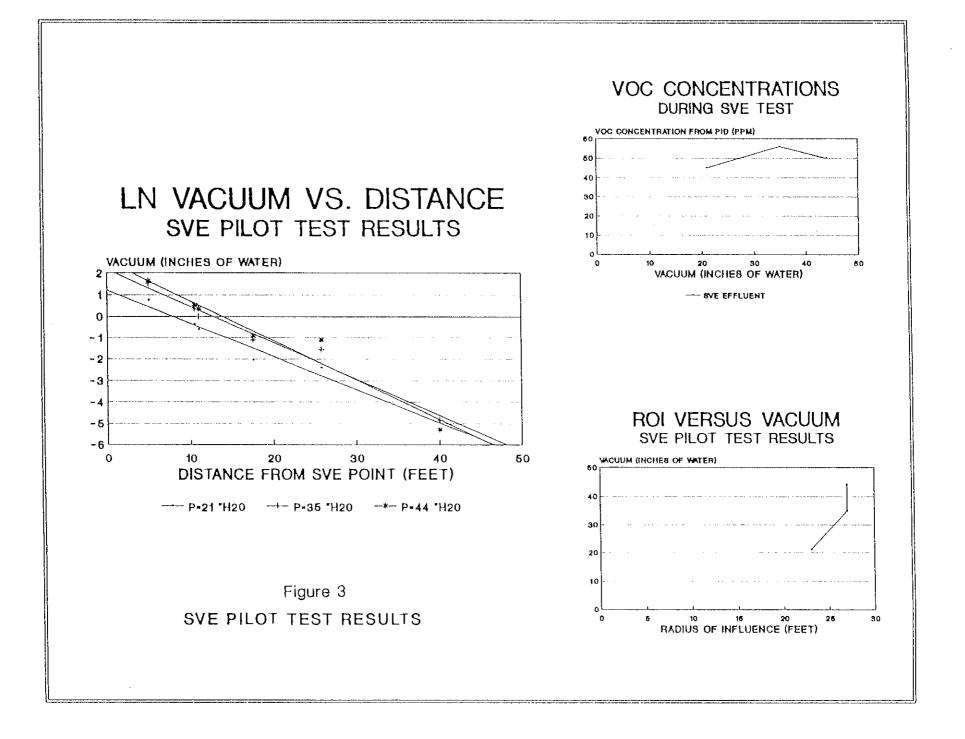

The data was further evaluated through use of a Groundwater Technology, Inc. developed air flow model which utilized the pilot test vacuum versus distance results and calculated the area through which sufficient air could be drawn to remove a selected percentage of the contaminants over a desired time period. This model determined that for an anticipated removal rate for tetrachloroethylene of 99% and 365 days of operation the design spacing for the vent points at this site was 20 feet. The air flow model provides a more conservative ROI and therefore this distance was utilized for system design.

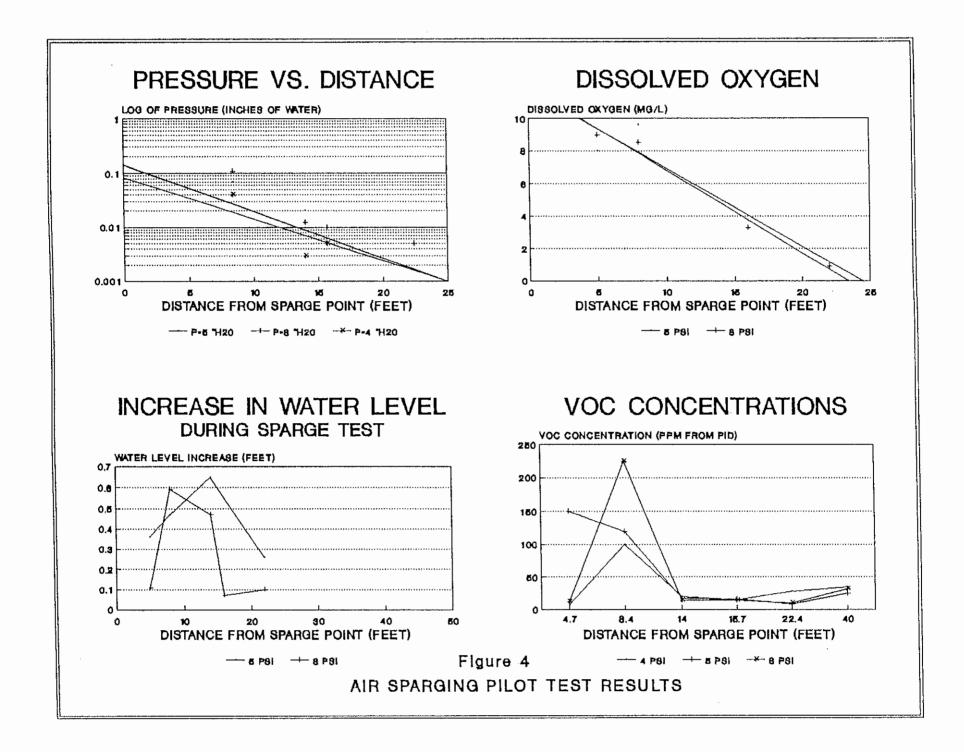

#### 2.3 Air Sparge Test Results

The air sparge test ROI was evaluated through several parameters:

- observed distance indicating increased dissolved oxygen
- observed distance indicating rising water elevations
- observed distance indicating increased VOC concentrations
- observed distance indicating pressure response.

A pressure versus distance graph was evaluated to select the pressure which provided the maximum ROI without over pressunzation (Figure 4). The determined ROIs were 11.5, 15 and 16 feet for 4, 5 and

8 psi, respectively. The ROI for each test pressure was plotted to select the pressure above which no increase in radius of response was observed (Figure 5). The determined ROI was 16 feet at the maximum pressure of 8 psi.

The graphs of the other test parameters were compared to the pressure response (Figure 4). Table 2 shows the determined ROI for each of these parameters. VOC and pressure increases indicate the lowest ROI at 14-16 feet. The ROI exhibited by DO and groundwater increases during the air sparge pilot test was 22 feet.

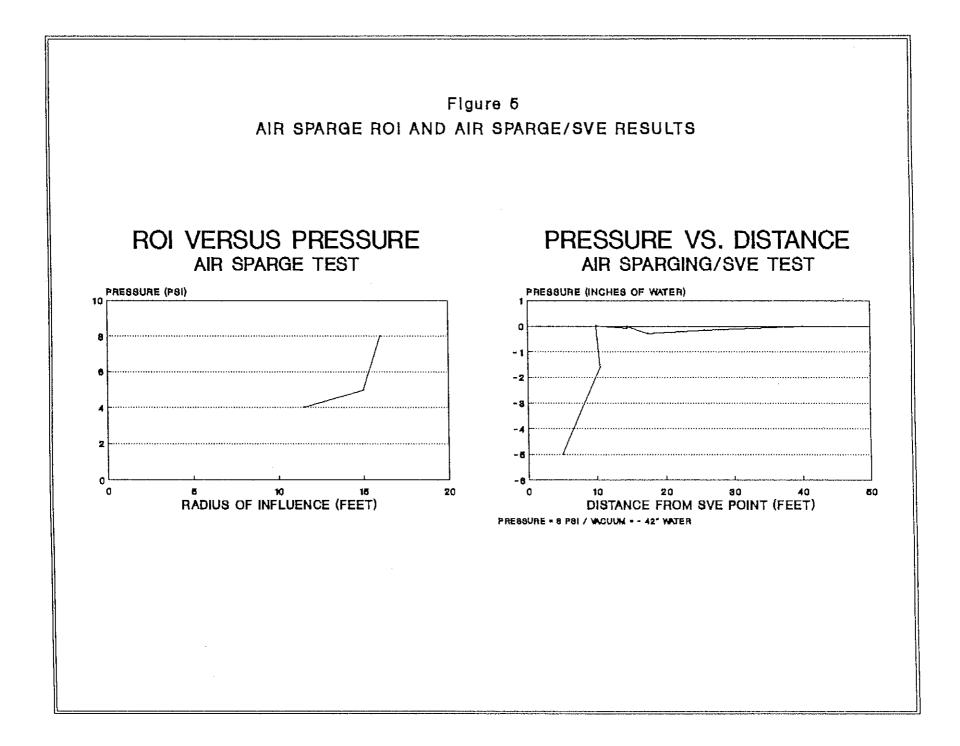

### TABLE 2

### AIR SPARGE RADIUS OF INFLUENCE DETERMINATION

PARAMETER	MAXIMUM RADIUS OF INFLUENCE (FEET)
Pressure Response	16
Dissolved Oxygen	22
Increase in Water Level	22
Increase in VOCs	14

### 2.4 Air Sparge/Soil Vapor Extraction Test Results

The air sparge/SVE test determined that net vacuum was maintained at 35 feet from the SVE point. The results are shown in Figure 5. These data document the capture of the air sparge off-gases within the design SVE ROI of 20 feet.

# 3.0 FINAL SYSTEM CONFIGURATION

## 3.1 System Overview

The final system layout and selected equipment, as determined through the pilot testing, are shown in Figure 6 and Table 3. The system consists of four major components: 1) groundwater extraction through overburden pumping wells and treatment through air stripper and carbon polish, 2) unsaturated soil treatment through a soil vapor extraction system, 3) saturated soil treatment through an air sparge system, and 4) off-gas treatment through vapor phase carbon. A description of the remedial point construction and each component of the remedial system are presented in the following sections.

2 - water meters

1 - ESI® 7 tray air stripper

2 - Hadley<sup>®</sup> 200 lb liquid phase carbon absorbers

\* 2 fer 10 micron fre Filters Programmable controller As shown in Table 3, the final system configuration was slightly different than the design layout due to subsurface variations. Site hydrogeologic conditions and saturated and unsaturated contamination identified during remedial installation were utilized to appropriately modify the design layout. During the air sparge and SVE point installation, the saturated thickness was determined to be less than the design thickness, and two small for effective air sparging. The number of air sparge points installed was therefore less than the original estimate. Additionally, the third recovery well was not installed due to lack of an overburden water table at this location.

The final monitor point system consisted of:

- one sparge point (SP-1)
- one combined sparge/soil vent point (SV-1)
- six vapor extraction points (VP-1 through VP-5) plus one existing monitor well (GT-2S/VP-6)
- two overburden recovery wells (RW-1S and RW-2S)
- one bedrock recovery well (RW-1D) (presently not a pumping well)

Monitor points were also installed to monitor the effectiveness of the remedial system. The points installed consisted of two monitor wells (GT-6S and GT-7S) and one nested vapor probe (NVP-1).

#### 3.2 Remedial and Monitor Point Construction

During the period from September 9 through 19, 1991, a Mobile B-61 hollow stem auger drill rig with split spoon sampling capabilities was utilized to install the remedial points. Additionally, an air rotary technique was utilized at selected locations where auger refusals were encountered due to the presence of boulders. Monitoring wells and vapor extraction points were constructed of two-inch diameter, PVC screen and riser with flush-threaded joints. Sparge points were constructed of two-inch diameter FRP screen and riser, with flush-threaded joints. The overburden recovery wells were constructed of six-inch diameter stainless steel screen and riser. Well construction details are summarized in Table 4. The complete well logs are included in Appendix A.

Split spoon soil samples were collected at the locations believed to contain elevated levels of volatile organic compounds, as delineated during the previous phases of investigation. Split spoon soil samples were screened in the field using a Photoionization Detector (PID - HNU with a 11.7 ev lamp) and one soil sample from each drilling location was sent to the laboratory for analysis according to the EPA Method 8240. Section 4.3 details the soil sampling results.

 NVP - Nested Vapor Point

# 3.3 Groundwater Extraction System

An Ejector System<sup>®</sup> multiple well pneumatic pumping system with U-3000 controllers and WETB 5" by 18" long ejectors was deployed to recover groundwater from two recovery wells on site (RW-1S and RW-2S). The system is powered and controlled by compressed air, and has the following components:

- Air-operated ejector vessels
- Bellows liquid level control
- Pneumatic control panel
- In line flow meters

The system is designed to recover approximately 2 gallons per minute (gpm) from each of the recovery wells. The system will consume approximately 11 cubic feet of air a minute (cfm) at a pressure of 25 pounds per square inch (psi).

#### Air-operated ejector vessels:

Each well contains an ejector vessel. The ejector vessel is a cylindrical hollow pressure vessel with two inlet and one discharge check valves. The ejector vessel is constructed of carbon steel and the valves are constructed of 304 stainless steel. The ejector is located in the well at a depth of approximately 8 feet below grade.

The ejector has two operating cycles, fill and discharge. The fill cycle occurs without any pressure on the vessel. This allows the vessel to gravity fill. When the vessel is full the vessel is pressurized by the air line and the water in the vessel is forced up through the discharge check valve into the discharge line. At the end of the discharge cycle the vessel is allowed to depressurize, vent and fill again. Flow rates from the vessel are controlled by adjusting the fill and discharge cycle times.

#### Bellows liquid level control (BBLC):

Each well contains one BBLC at the well head. The BBLC controls the ejector pumping rate by restricting the high pressure air supply from the control panel. A bubbler line indicates the column of water that is above the ejector vessel by sensing backpressure that is created as water accumulates over the ejector. The bubbler line is mounted approximately 3/8 inches above the intake for the ejector. If the bubbler line senses sufficient amount of water above the ejector (approximately 10 inches) it allows the pump to function at full capacity. At water levels less than 10 inches above the ejector intake the BBLC partially or completely restricts the high pressure discharge air to the pump. A gauge on the face of the BBLC indicates the water level above the intake in inches of water. The BBLC is mounted level to the wall of the recovery well road box.

#### In Line Flow Meters:

½-inch Master meter water flow meters were installed inside the equipment compound. For each of the recovery wells the meters will accurately measure flow rate from each well and totalize the overall volume of extracted groundwater.

## Trenching and Piping:

All lines were installed in trenches approximately 3.0 feet below grade. All lines installed in the trenches were bedded on 6-inches of clean, coarse sand prior to backfilling. A 6-inch lift of sand was also installed above the pipes. The trenches were backfilled and tamped in 1-foot lifts to grade with native soils. All trenches were located in the parking lots, therefore, the top 6-inches of fill was a compacted

crusher run sub-base for repaving. Repaving will be conducted during the fall of 1992 by Pawling Corporation.

All lines were pressure tested prior to being buried. The pressure test was performed by sealing off the line, installing a pressure gauge in the line and injecting compressed air to 10 psi. The air pressure in the line was monitored for any changes and the line and all associated fittings were visually inspected for any leaks. The pressure test was maintained for a duration of 1 hour. All lines passed the pressure test.

The groundwater extraction piping layout is shown in Figure 7, Groundwater Extraction and Sparge System Piping and Instrumentation Diagram.

# Well Completion:

Each recovery well head was enclosed in a traffic rated steel 2-foot square road box concreted into place. The road box lid is bolted closed and has gaskets to seal it form water intrusion. Each road box houses the pump, bellows liquid level controller, water flow adjustment valve, and an explosion proof junction box required for heat taping water lines. The floor of the road box is filled with gravel to drain any moisture that may enter the road box.

# 3.4 Groundwater Treatment System

# Air Stripper:

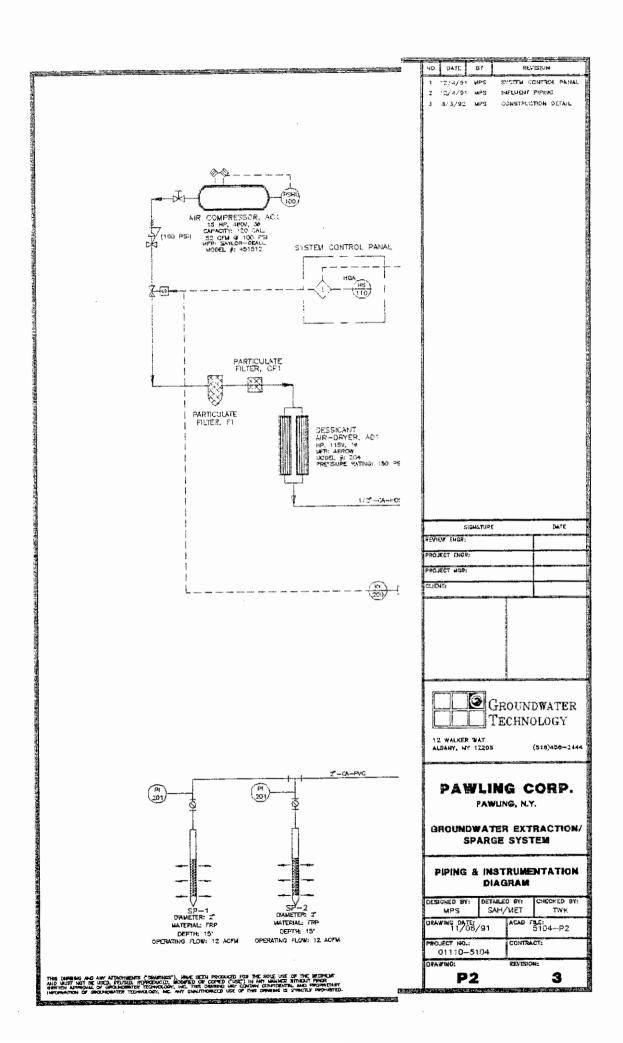

An Ejector System, Inc. (ESI) Low Profile Cascade air stripper, Model STRP-A6, is used to remove VOCs from the water system. The air stripper contains 7 stacked aeration trays each with a series of baffles and bubblers. The air stripper is designed to treat a flow rate of 4 gpm at the anticipated contaminant levels with a maximum design flow rate of 10 gpm. The ESI Cascade System comes equipped with automatic level control and shut-off.

#### Transfer Pump:

Water from the air stripper is piped to a 210 gallon transfer equalization tank. The transfer tank is constructed of high density polyethylene and is equipped with an air tight lid, a vent to the atmosphere, and the appropriate fittings to mount the transfer pump probes. The water pump allows for equalized pumping through the carbon polishing system.

# Sediment Filters:

Two sediment filter housings were installed after the transfer pump to remove any sediment or iron particulates larger than 10 microns that would be in the water stream after the air stripping system. The units are constructed of carbon steel and pressure rated to 250 psi. The filter housings each contain

several filter cartridges. A pressure gauge located on the top of each filter housing will indicate the need for cartridge change outs. During the first three months of operation one change out per month was needed.

The sediment filters and housings keep the carbon polishing units from clogging with particulates and increase the useful life of the carbon units.

#### Carbon Polishing Units:

Two liquid phase Hadley GAC units were installed after the sediment filters. Discharge from the filter units is piped through both GAC units as a treatment backup to insure a water discharge within the acceptable discharge limits. Any residual VOCs remaining in the water stream after the air stripper are adsorbed by the carbon. Each of the units contain 200 lbs of liquid phase GAC in a pressure rated fiberglass tank. The units are equipped with pressure gauges before, between and after the units to monitor the need for a change out. Each of the units can operate with pressures up to 150 psi.

## Discharge Piping:

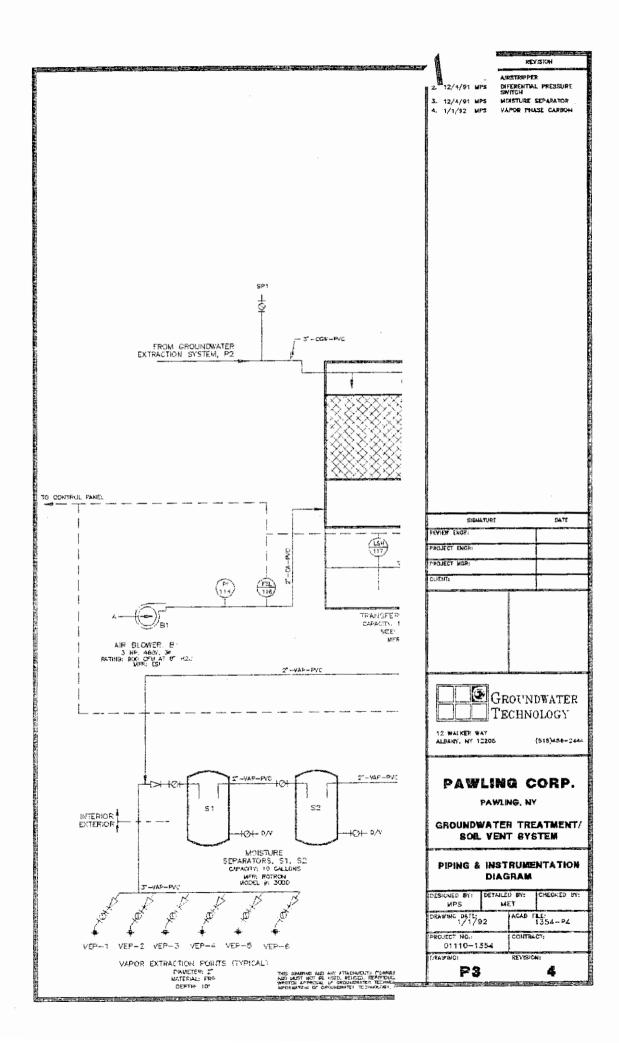

Effluent from the carbon polishing system is discharged to the Swamp River approximately 150 feet north of the equipment compound. The discharge pipe was constructed of 2-inch carbon steel pipe. The pipe was mounted on wooden pilings spaced approximately 12 feet apart. These pilings carry the discharge pipe to the Swamp River minimizing any impact to the wetlands area that surrounds the discharge point.

The discharge line is externally insulated and heat taped to prevent freezing of the line during the winter months. The heat tape is controlled from a plug assembly and thermostat located inside the treatment compound. The treatment system piping is shown on Figure 8, Groundwater Treatment and Soil Vent System Piping and Instrumentation Diagram.

## 3.5 Soil Vapor Extraction System

#### Vapor Extraction Points:

Six (6) Vapor Extraction Points (VEPs), plus one monitor well, were installed in the impacted zone of the site (Figure 6, Remedial System Site Layout). The VEPs extract existing VOCs from the soil and any additional VOCs that are produced from sparging activities. The number, spacing and location of VEPs was determined after a field radius of influence (ROI) test (Section 2.1). Section 3.2 details the VEPs construction.

#### Piping:

Each VEP was piped via 2-inch, Schedule 80, PVC piping to a 4-inch, Schedule 80 PVC header pipe located in the treatment compound. Each VEP is individually controlled by a ball valve located near the header pipe.

All lines were installed in trenches approximately 3 feet below grade. All lines installed in the trenches were bedded on 6-inches of clean coarse sand prior to backfilling. A 6-inch lift of sand was also installed above the pipes. The trench was backfilled and tamped in 1 foot lifts to grade with native soils. In locations where the trenches were located in roadways or parking lots the top 6-inches of fill was a compacted crusher run base provided for repaving.

#### Moisture Separators:

Two 30-gallon moisture separators, Model MS 300 D, were installed in line after the soil vent header pipe and before the soil vent blower to reduce the moisture in the vapor stream. The separators allow water vapor to condensate and collect. A manually operated drain valve is located on the bottom of the separators to remove the collected moisture during routine maintenance visits. Two site glasses were installed to monitor the increase in water without interrupting the vapor extraction system.

this A:

## Soil Vapor Extraction Blower:

A 5 Hp, 480 volt regenerative soil vent blower, Model DR 707, was installed to extract up to 210 cfm (at 35" vacuum) of vapor from the impacted soils via the soil vent network. The blower will be capable of producing a vacuum on the system of up to -60 inches of water column (approximately 2.2 psi).

The soil vapor extraction blower is rated for Class 1, Division 1, Group D, hazardous locations. The blower is equipped with a particulate filter to remove any sand or dirt particulate that may be present in the vapor stream before it reaches the blower. Two vacuum gauges mounted on the blower inlet pipes before and after the particulate filter indicate the vacuum in the line and the need for the filter to be cleaned.

The soil vapor extraction blower is equipped with an override system that automatically shuts down the soil vent system in the event that the off-gas treatment system becomes inoperable. Figure 8 shows the Soil Vapor Extraction Piping and Instrumentation Diagram.

## 3.6 Air Sparging System

#### Sparge Points:

Two sparge points were installed in the impacted area of the site. Each point can deliver 5-12 cfm of air to the water table. The sparge point construction is detailed in Section 3.2. The bottom of each sparge

point is approximately 6 feet below the surface of the groundwater.

An electronic timer and solenoid valve allow intermittent airflow of the impacted area. The timer is programmable to allow for varied air flow intervals. Several different durations and intervals have been evaluated during this start-up.

#### Air Compressor:

A 15 Hp, 460 volt Saylor Beall, Model 4515 20, electric air compressor capable of producing 52 cfm compressed air at 100 psi was installed to operate the pumping and sparging systems. The air compressor is equipped with a fan cooled aftercooler that cools the compressed air and condenses some of the water vapor in the compressed air. This condensate is removed by a water separator. The compressor is mounted on a 200-gallon compressed air storage tank to allow for the steady operation of the compressor and keep storage of air for any peak operation needs.

<u>Desiccant Air Dryer:</u> A desiccant air dryer, Model 204, and particulate filters were installed after the air compressor to remove moisture, residual oil and particulates from the air stream. The air dryer conditions the operating air to provide more efficient operation with lower operating maintenance.

# Piping:

Compressed air is piped via 1-inch Schedule 80 PVC pipe to the sparge points. All lines were installed in trenches approximately 3 feet below grade. All lines installed in the trenches were bedded on 6inches of clean coarse sand prior to backfilling. A 6-inch lift of sand was also installed above the pipes. The trench was backfilled and tamped in 1-foot lifts to grade with native soils. In locations where the trenches were located in roadways or parking lots the top 6-inches of fill was compacted crusher run base provided for repaving. Piping which is above ground in the compound is galvanized steel. Figure 7 shows the Sparge System Piping and Instrumentation Diagram.

#### 4.0 INITIAL SUBSURFACE CONDITIONS

The effectiveness of the installed remedial system will be evaluated relative to the initial subsurface conditions. This section presents the baseline groundwater gradient, groundwater quality and soil quality which were identified prior to start up of the remedial system.

#### 4.1 Groundwater Gradient

A complete groundwater gauging round was performed on March 9, 1992 prior to remedial system startup to document the initial site conditions. The gauging data are included in Appendix B. The overall site overburden and bedrock groundwater flow directions were similar to previous gaugings and indicated flow to the north toward the Swamp River. The gradients were slightly lower than previously measured, 0.35 % and 0.34 %, respectively for the overburden and deep bedrock aquifers.

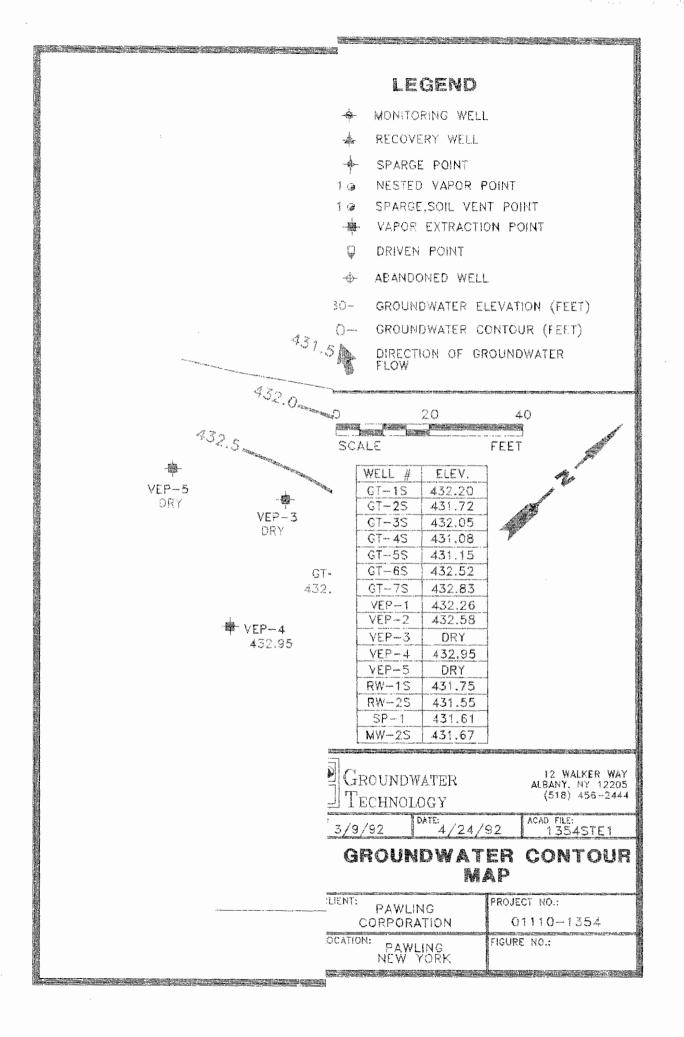

A contour map of the overburden groundwater elevations is shown in Figure 9. The gradient across this area, as measured between VEP-4 and GT-4S was 1 %. The additional monitor points determined that the overburden aquifer is not existent in the area around VEP-3 and VEP-5 due to the presence of a bedrock mound.

A comparison of the groundwater elevations in the deep bedrock and the overburden indicates that an upward vertical gradient of approximately 0.18 feet is still present across the site with the exception of the area around MW-2D1 where a downward gradient of 0.71 feet was observed. A comparison of the deep and shallow bedrock elevations, as measured at MW-2D1 and MW-2D2, shows that there is only a 0.01 foot upward vertical gradient within the bedrock; however, a comparison between MW-2D2 and RW-1D indicated an upward vertical gradient of 0.15 feet. It is not clear at this time what is causing these differences in vertical gradients.

#### 4.2 Groundwater Quality

Groundwater samples were collected from select wells on March 10, 1992 in order to document concentrations of dissolved level VOCs prior to system start-up. Complete laboratory results as well as a table of all historical laboratory results are included in Appendix C. Figure 10 shows a contour map of the total VOC concentrations. The major portion of the plume is situated between GT-7S and RW-1S, where detected concentrations were 299,000 - 526,000 parts per billion (ppb). GT-4S and GT-5S denote the downgradient edge of the plume; detected concentrations at these locations were 21 and 31 ppb.

The specific VOCs which were detected included toluene, trichloroethene (TCE), trans -1, 2 - dichloroethylene (trans-1,2 - DEC), methylene chloride, vinyl chloride, and carbon tetrachloride. Table 5 shows the concentrations which were detected in each well. These compounds have all been previously

# Table 5

TOTAL VOCs	299,100	100	225,483	100	526,000	100	61,600	21	31	184

Note: All results are expressed in ug/L

detected on-site with the exception of methylene chloride and carbon tetrachloride.

The percentages of each compound (in relation to the total detected VOCs) for GT-7S and RW-1S are also shown in Table 5. Toluene constituted approximately 80% of the dissolved VOCs; TCE approximately 11% and trans-1, 2 - DCE approximately 5%.

The June 1990 VOC concentrations detected in RW-1S are also shown in Table 5. The total VOCs were slightly higher in 1992 than in 1990 (299,100 vs. 225,483 ppb, respectively). The individual percentages of detected VOCs were similar, with the exception that low levels of several other VOCs had previously been identified in 1990. The dilution and higher detection limits reported for the 1992 data may have masked the detection of these compounds during the 1992 sampling.

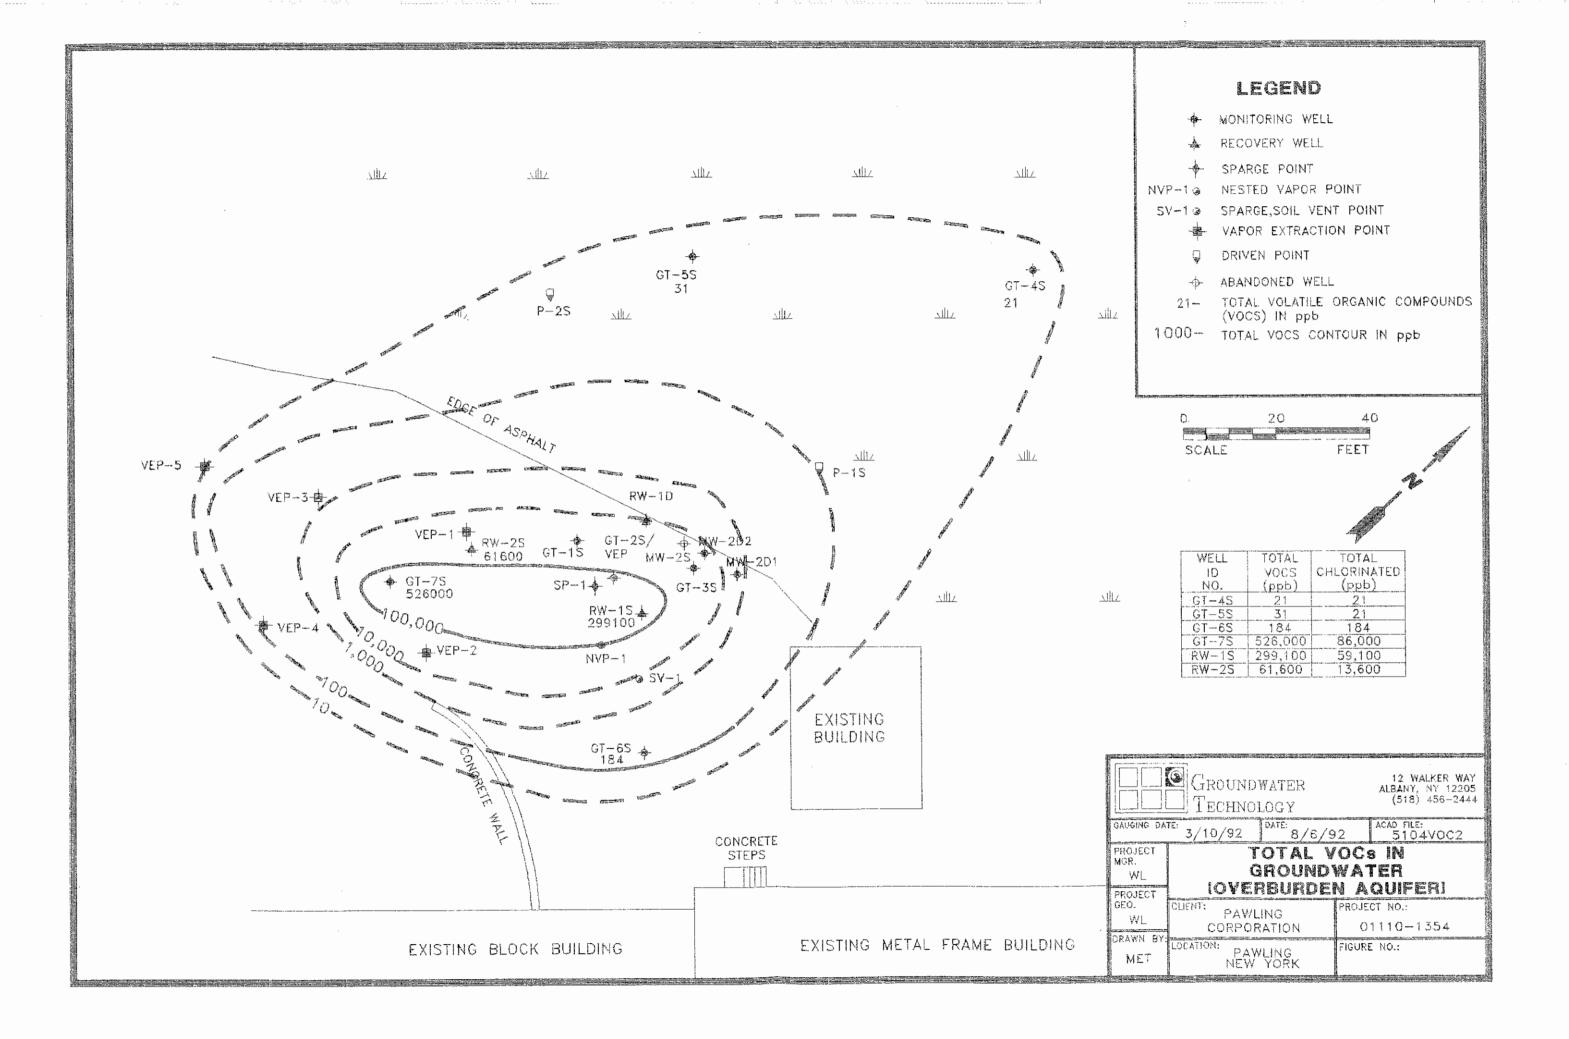

A more detailed comparison of the ratios of toluene, chlorinated compounds, and vinyl chloride and trans -1, 2 DCE, (two breakdown products), was performed to aid in evaluating contaminant degradation and removal (Figures 11 a, b, and c). At GT-7S, the assumed source area, the vinyl chloride and trans -1, 2 DCE concentrations (DCE) were very low, 0 and 3 % of the total chlorinated compounds, respectively. Slightly downgradient, at RW-1S the concentrations of this breakdown compounds constituted 10 and 15% of the total chlorinated compounds. At the edge of the plume, at GT-5S, the percentages were 0 and 30%. These ratios will be evaluated throughout the remediation process.

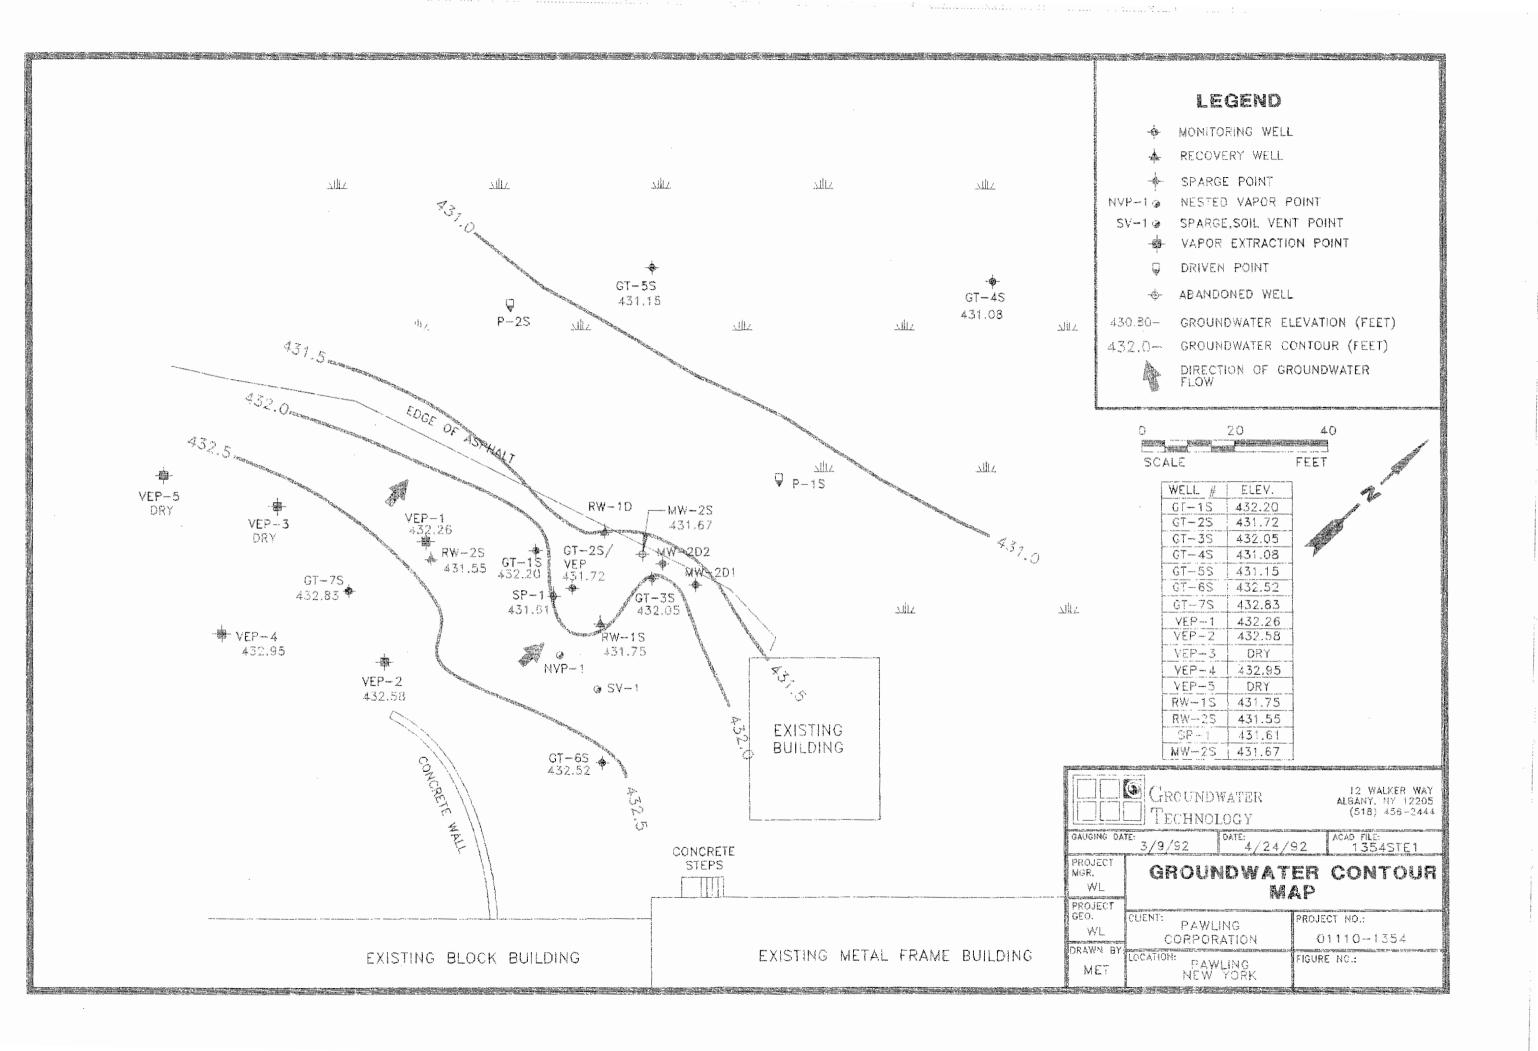

A groundwater sample was also collected from the upper bedrock aquifer, RW-1D, in order to document the initial concentrations prior to system start-up. Total detected VOCs were 3,680 ppb. This compares to 1,804 ppb in June 1990. Toluene constituted 73% of the total VOCs, and vinyl chloride and trans -1, 2 DCE constituted the remaining 27%. No other chlorinated VOCs were detected.

#### 4.3 Soil Quality

During remedial point installation soil sampling was performed to further delineate the subsurface extent of VOC impacts. A summary of the monitored intervals, PID readings and laboratory analytical results are presented in Table 6 (Summary of Soil Monitoring Results). The complete soil laboratory analytical reports are presented in Appendix C.

As indicated in Table 6, soil screening, using the PID, indicated elevated (above 100 ppmv) volatile organic levels at the locations of NVP-1, SP-1, VEP-1 and GT-7S. Concentrations of approximately 50 ppmv were detected at the locations of SV-1 and VEP-3. Toluene was the compound detected at the highest concentration, of 7,580 ppb and 1,990 ppb, at the locations of NVP-1 and SP-1. PID results exhibited much higher concentrations than the laboratory data.

# **5.0 CONTAMINANT DISTRIBUTION**

ne esta de la completa de la contra completa de contra de la contra de la contra de la contra de la contra de c

The effectiveness of the installed remedial system will be evaluated relative to the cleanup of the identified VOCs in the subsurface. VOCs released to the subsurface can be present in any of four phases: dissolved in groundwater (dissolved phase), adsorbed onto soil particles (adsorbed phase), layers of non-aqueous phase liquids (liquid phase), or as vapors (vapor phase). This section details the identified phases, extent and estimated volume of VOCs which are present in the subsurface at this site and which define the baseline conditions for evaluating remedial effectiveness.

# 5.1 Methodologies for Calculating Contaminant Volumes

sin histori ta sang katalangkan berkeri keningkan berkeri baran katalan katalan keningkan sang bara sang bara s

# 5.1.1 Dissolved Phase

#### **Overburden Aquifer**

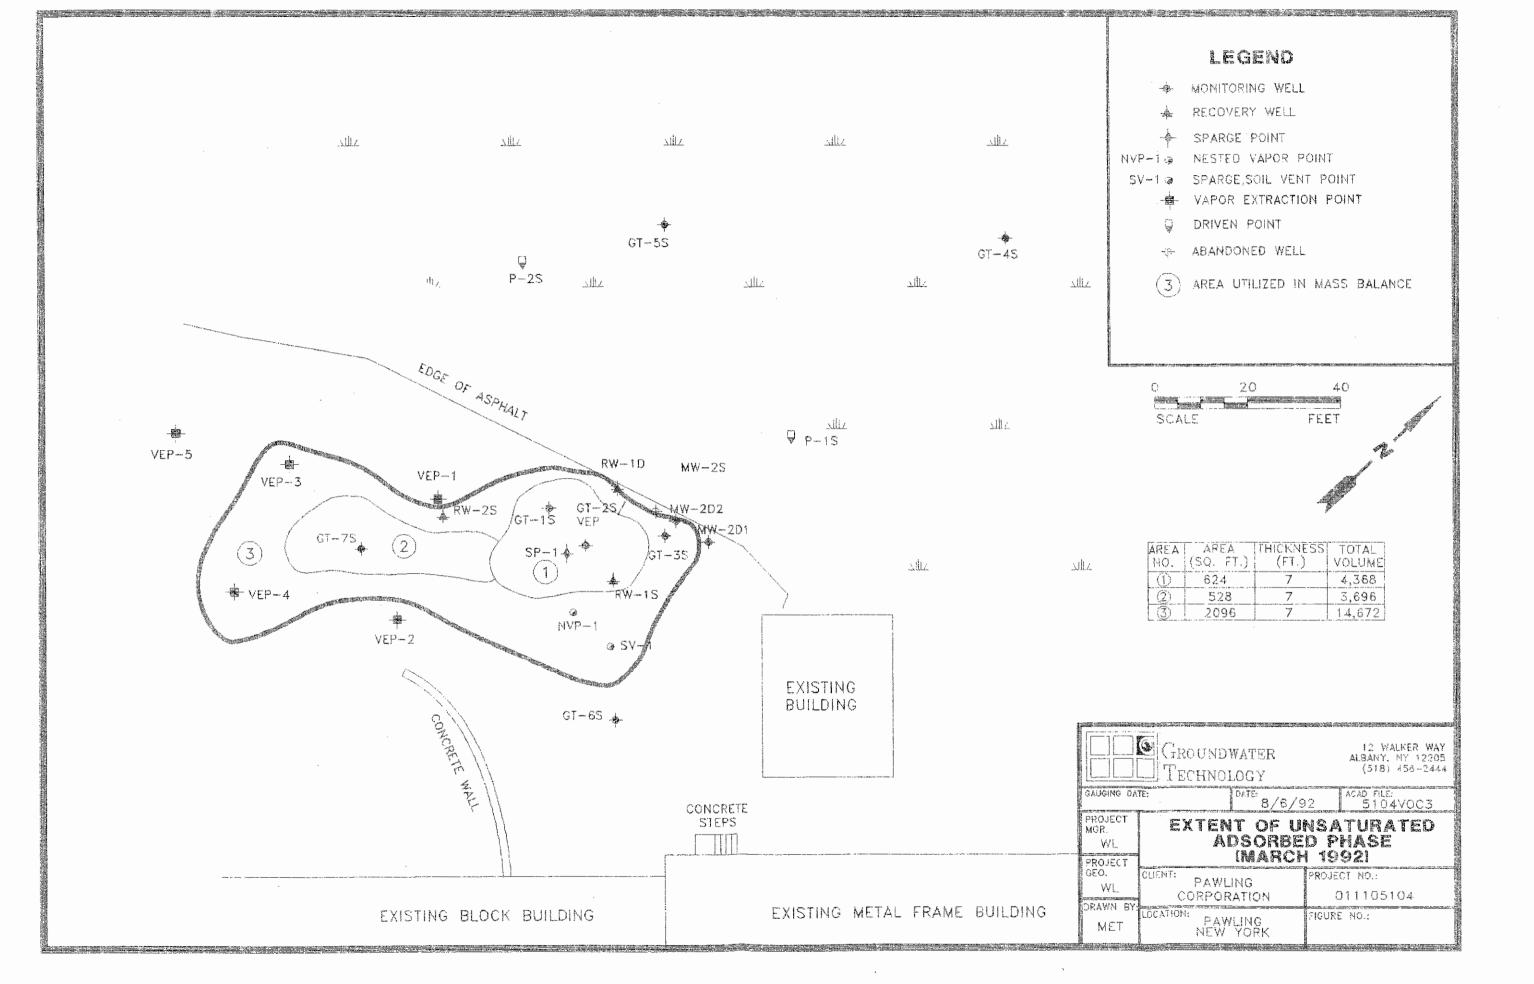

The areal extent of the dissolved phase was identified by the initial (March 1992) groundwater sampling. The results are portrayed on the Total VOCs in Groundwater (Overburden Aquifer) map (Figure 10). The areas between contoured intervals, the average concentration between contour lines and the saturated thickness, as shown on the cross sections (Figures 12 and 13), were utilized to calculate the total volume of VOCs present in the dissolved phase. Appendix D contains the calculations.

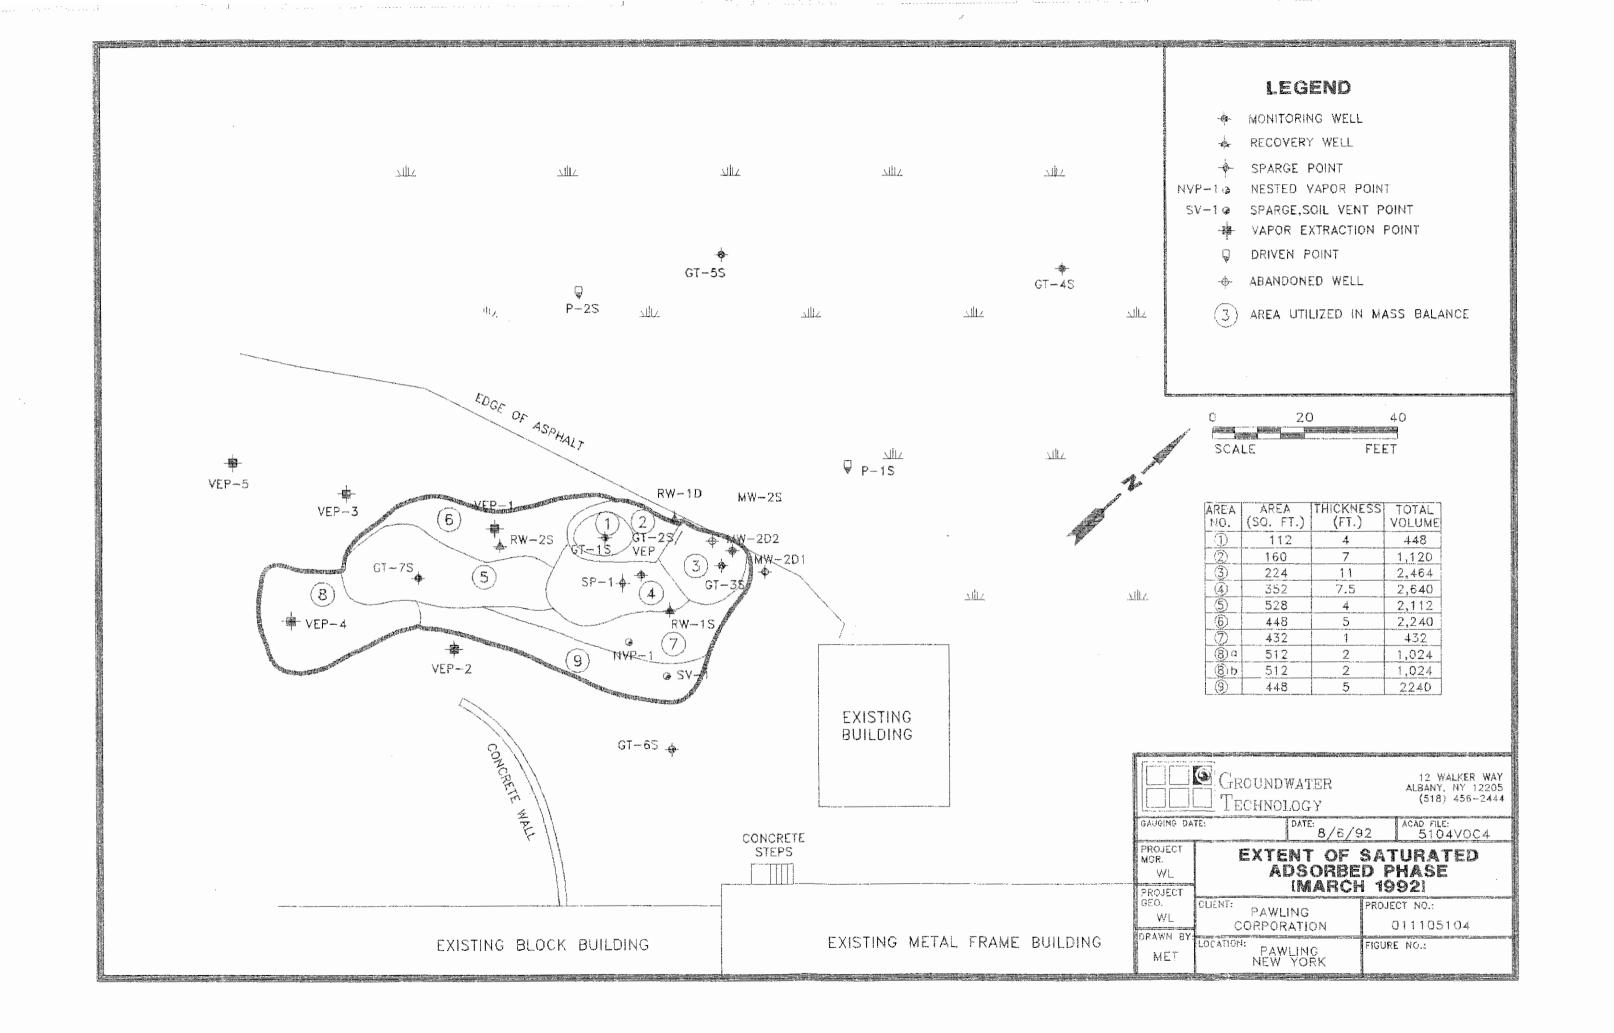

#### Bedrock Aquifer

An attempt was made to estimate the volume of VOCs in the bedrock. Much less data are available concerning subsurface conditions, therefore, a range of values was produced utilizing different impacted areas and porosities. Appendix D contains the calculations.

#### 5.1.2 Adsorbed Phase

The field screening VOC data from soil samples were utilized to define the areal extent of the adsorbed phase. Figures 14 and 15 shows the defined areas of adsorbed phase VOCs in the saturated and unsaturated zones. The unsaturated and saturated zones were delineated separately because they are remediated by different technologies. For calculation of the contaminant volumes the total areas were divided into subareas based upon different VOC concentrations. The cross sections were utilized to determine the impacted thicknesses. Appendix D contains the contaminant loading calculations.

# 5.2 Contaminant Volumes

## Overburden

The calculated contaminant volumes determined for this site are shown in Table 7. The saturated adsorbed phase contained the highest amount of VOCs, 1774 pounds. The unsaturated adsorbed phase contained 700 pounds, while the dissolved phase contained only 45 pounds. The total VOCs identified in the subsurface were 2,519 pounds. Figure 16 shows the relative distribution of the phases. The vapor phase and liquid phase were nonexistent or negligible.

# **Bedrock**

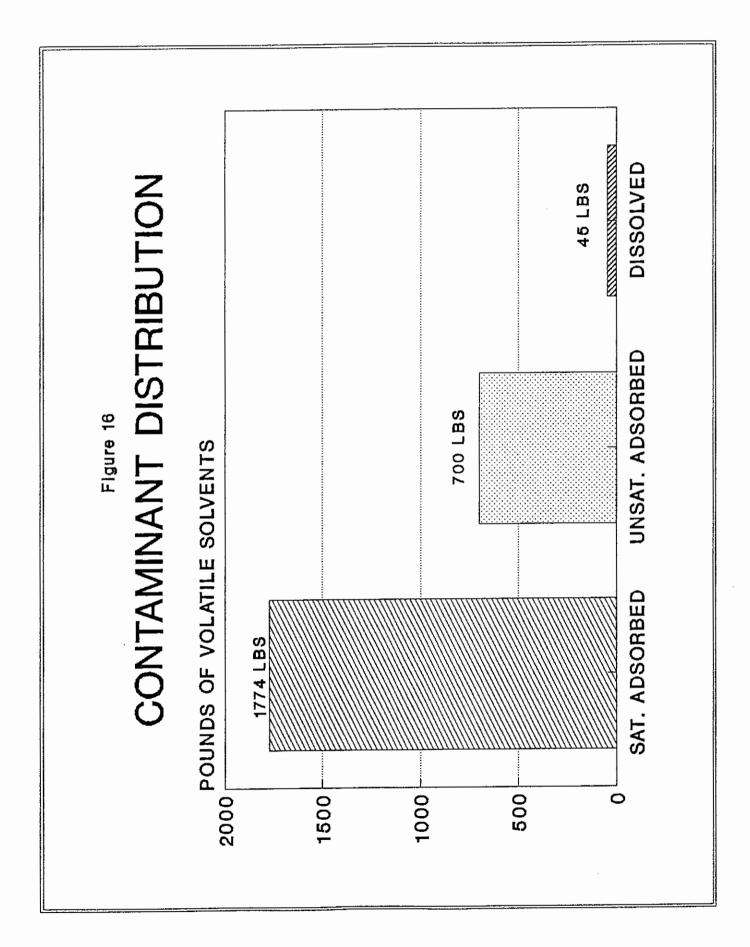

The contaminant mass calculations for the bedrock aquifer provided the following range of estimates of dissolved phase VOCs; 2 to 25 pounds. Due to the low porosity and small surface area of contaminant contact with the rock, it is assumed that the absorbed phase VOC volume is small. These numbers are rough estimates but do provide a good indication of the relative contaminant loading in the bedrock.

# TABLE 7

. .

# CONTAMINANT DISTRIBUTION IN THE OVERBURDEN

PHASE	AMOUNT (pounds)	PERCENTAGE OF TOTAL
Dissolved Phase	45	1.8
Unsaturated Adsorbed Phase	700	27.8
Saturated Adsorbed Phase	1,774	70.4
Liquid Phase	Negligible	Negligible
Total VOCs	2,519	100

# 6.0 REMEDIAL SYSTEM PERFORMANCE

The remedial system has been in operation since March 9, 1992. During this initial 3 months of operation each of the individual remedial systems (groundwater extraction, groundwater treatment, soil vapor extraction, and air sparging) have been operated and data associated with the operation has been collected. This section presents the initial start-up data and first 3 months of system performance.

# 6.1 Groundwater Extraction System

### 6.1.1 Operation Summary

The groundwater extraction system was started on March 11, 1992. During the first month of operation the system ran only intermittently while the programmable overide protection system was tested and debugged. The system ran continuously during the rest of the monitoring period with one down time period experienced from May 11 to May 21 due to a problem with the air stripper transfer pump.

#### 6.1.2 Verification of Hydraulic Control

In order to verify hydraulic control and complete capture of the overburden dissolved plume, groundwater gauging was performed. The groundwater elevations were contoured and flow lines plotted. Figure 17 shows the resultant map. Impacted groundwater is being captured as designed.

#### 6.1.3 Flow Rates/Total Gallons Extracted

The initial start-up flow rates for RW-1S and RW-2S were 1.7 gpm and 0 gpm, respectively. The average flow rates observed over this monitoring period were 1.0 gpm and 0.3 gpm, respectively. The flow rates are lower than the pilot test design flow rate of 2 gpm. This is due to the fact that there is limited recharge to the overburden aquifer in this area. This is evidenced particularly at RW-2S which is dry most of the time except after a rainfall event. The bedrock high appears to affect the overburden groundwater table, as discussed in section 4.1.

Over this monitoring period a total of 77,030 gallons of water have been extracted from the subsurface. Table 8 shows the gallons extracted from each well over time.

### 6.1.4 Extracted VOC Concentrations/Removal Rate

The dissolved concentrations being extracted from the subsurface were evaluated through collection and sampling of water entering the air stripper (A/S influent). Sampling was performed on March 11, 1992. A triplicate sampling was performed to quantify the variation in the results. The detected concentrations are shown in Table 9. There was quite a range in concentrations between the three samples, particularly for TCE.

# Table 9

## Dissolved Concentrations from Groundwater Extraction System March 11, 1992

Sample	Toluene (ug/l)	TCE (ug/l)	Trans -1,2- DCE (ug/l)	Vinyl Chloride (ug/l)	Total VOCs (ug/l)
A/S Influent #1	130,000	5,200	10,100	3,400	148,700
A/S Influent #2	99,000	2,600	7,900	< 10,000	109,500
A/S Influent #3	170,000	23,000	11,000	< 10,000	204,000
Mean	133,000	10,267	9,667	N/A	154,067
Standard Deviation	35,595	11,104	1,595	N/A	47,478

The mean total VOC concentration was utilized to calculate the pounds of VOCs removed from the subsurface during this monitoring period. A total of 99.16 pounds have been removed through the groundwater extraction system. Table 8 shows the removal rates over time. As the removal rate is based upon the influent concentration, which did show a range from 109,500 to 214,000 ug/l, the actual pound removal may be 70.5 to 131 pounds. These values are higher than the initial estimate of dissolved phase VOCs due to additional dissolution of VOCs from the adsorbed phase.

# 6.2 Groundwater Treatment System

The air stripper removal efficiency was evaluated through comparison of influent and effluent water quality to the air stripper. The removal efficiencies ranged from 99.54 to 100 %, depending upon the compound. Table 10 shows the removal efficiencies by compound.

The removal efficiency of the entire treatment system, carbon polish plus air stripper, was 100 %. The VOC effiuent concentrations sampled monthly to meet discharge requirements showed non detectable levels. Table 11 shows the sampling dates. The analytical laboratory data are included in Appendix D.

Based upon the initial analytical data and air stripper removal efficiency, the carbon polish has been loaded with less than 0.1 pounds of VOCs. Each carbon cannister should be able to remove approximately 20 pounds of VOCs.

March 11 Sampling	Toluene (ug/l)	% Removal	TCE (ug/l)	% Removal	Trans-1,2- DCE (ug/l)	% Removal	Vinyl Chloride (ug/l)	% Removal

# 6.3 Soil Vapor Extraction System

## 6.3.1 System Operation

The SVE system was started on March 9, 1992 and maintained continual operation throughout this monitoring period. The air flow rate recorded before the blower was 108 cfm. This compares to design air flow rate of 175 scfm. The rate is lower than the design value, undoubtedly due to the close spacing of vapor extraction points,

which, in combination, are withdrawing more air than can recharge the subsurface, thus producing an overall flow rate lower than the potential rate. The operational vacuum throughout the monitoring period was 50 inches of water. This vacuum is higher than the design value of 35 inches because it was decided that a higher vacuum would increase the vapor removal rate.

### 6.3.2 Verification of Radius of Influence

The radius of influence (ROI) of the SVE system was measured in the field by recording vacuum readings at several monitor points. The results are shown in Table 12. These results show that greater vacuum has been oberved than the pilot test estimated. The combination of multiple vapor extraction points is creating a greater vacuum response in the subsurface.

If the observed readings are extrapolated to the 0.1 inch water column effective ROI, the actual SVE system has a ROI of 32 feet (versus the pilot test value of 27 feet). The verification of the actual ROI ensures that all unsaturated soils are adequately being vented.

Vacuum readings were also recorded at the monitoring points during air sparging operation. The vacuum readings decreased only slightly, indicating that net vacuum was maintained during sparging, ensuring the that all air sparge vapors are being captured.

#### 6.3.3 Extracted VOC Concentrations and Removal Rates

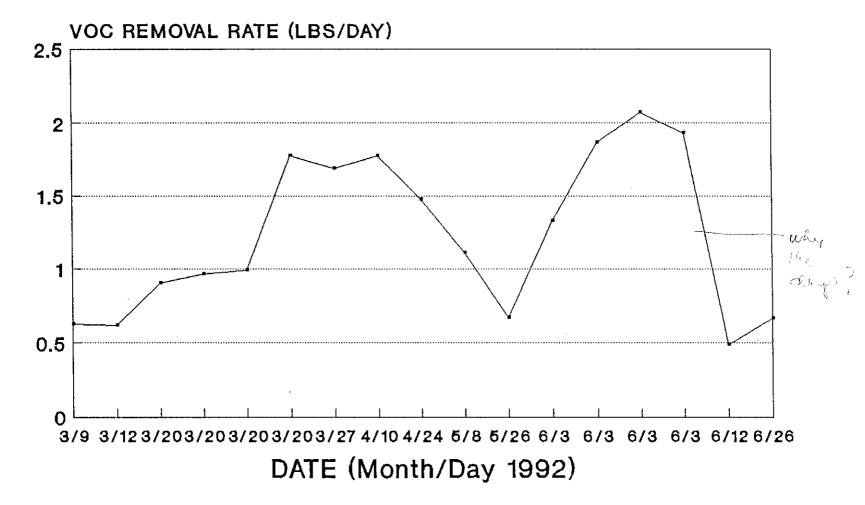

The VOC concentrations extracted by the entire SVE system ranged from 8 to 38 ppmv as recorded with a PID with a 11.7 head. FID data were also collected. Originally the FID values were much greater than measured by the PID due to the presence of methane. After two months of operation, the two instruments recorded similar VOC levels, with the FID showing slightly higher levels ranging from 20 to 32 ppmv. Table 13 reports all of the VOC levels recorded. Air samples were collected and analyzed in the laboratory on several dates. Table 14 shows the analytical results. The detected concentrations are significantly lower than the corresponding field readings. The identified compounds and their percent of the total VOCs were: toluene 40 - 75 %, TCE 25 - 34 % and trans-1,2-DCE 0 - 29 %, varying with the sampling date. These three compounds were the only detected VOCs.

# Figure 17 SVE SYSTEM REMOVAL

# Table 14

# Laboratory Results of Total VOCs in SVE Effluent

(ug/l)

Date	Vent	Vent and Sparge	
Sept. 11, 1991	1,565	2,015	
March 11, 1992	140	123	
June 3, 1992	43	53	

The VOC data collected from the field and the measured flow rate were used to calculate the pounds of VOCs removed from subsurface. The total through June 26, 1992 was 118 pounds. Table 13 shows the calculated pounds throughout the monitoring period. Please note that the air flow specified on this table is the total system air flow which includes bleed air.

A trend of the daily VOC removal rate is shown in Figure 18. The daily pound removal rate has ranged from 0.5 to slightly higher than 2 pounds. These values almost exclusively reflect unsaturated adsorbed removal, as the air sparge system was operational for only short times during this monitoring period. However, the increases observed on March 20 and June 3 were due to the air sparge system being operational.

# 6.3.4 Individual Vapor Extraction Point Operation

A summary of the individual vapor extraction point operation is shown in Table 15. These data represent SVE operation only as the sparge system was not in operation. Individual vacuum, VOC levels and air flow are shown on this table. The vacuum data shows that the initial vacuums were below the design vacuum, but after continued system operation all points exhibited the design vacuum reponse (35 inches w.c.). The VOC data indicates that VEP-6 and VEP-3 are withdrawing the highest VOC levels with maximum reported PID concentrations of 70 and 27 ppmv, respectively. The other points are extracting low levels of volatiles, approximately 1 to 2 ppmv. These data correlate with the contaminant distribution data which determined that the majority of the VOCs were not in the unsaturated soil.

### 6.3.5 Carbon Dioxide and Oxygen Utilization

In order to provide an indication of the biological activity and degradation occurring on site, carbon dioxide and oxygen concentrations were measured in the extracted SVE air stream. The carbon dioxide was measured

utilizing draeger tubes; the oxygen concentration was measured utilizing an explosimeter. Table 16 shows the reported values.

The oxygen levels show a 0.5 and 0.7 decrease from background levels, indicating oxygen utilization by bacteria. The carbon dioxide percentages were 0.17 and 0.27 percentage points above ambient air background levels, also indicating bacterial activity. With the measured data it is not possible to determine whether the bacterial activity is from degradation of VOCs or natural soil organic material.

### 6.4 Air Sparge System

#### 6.4.1 Operation Summary

The air sparge system was operating only intermittently during this monitoring period. Groundwater extraction system down time and the need to verify the actual air injection rates were the cause of the intermittent operation. The system was in operation for 21 days and evaluation of the subsurface response was performed during these operating times.

# 6.4.2 Verification of Radius of Influence

The actual operational ROI was compared with the design ROI to verify effective system operation. The air sparge was operated at varying flows ranging from 12 to 24 cfm. At the end of each flow rate interval the dissolved oxygen concentration in the groundwater was monitored at varying distances. Table 17 shows the recorded values. The data indicate that at a flow rate of 20 cfm an effective ROI of 20 feet was measured (based upon an increase of at least 1 mg/l dissolved oxygen). This correlates with the design data, 24 cfm and 22 foot ROI. Additional dissolved oxygen data was collected to define background levels and to indicate the air sparge influence. Table 18 shows the results.

# Reverification of Air Sparge ROI - Increase in Dissolved Oxygen Concentrations (ug/l)

Air Flow Rate (cfm)	GT-1S (10 ft)	GT-6S (15 ft)	GT-3S (20 ft)
12	1.0	0.5	0
16	6.8	1.2	0.6
20	8.4	1.9	3.5
24	9.6	1.9	5.2

## 6.4.3 System Effectiveness

The SVE removal rate is the primary indicator of an effective air sparge system. As discussed in section 6.3.3, during several sparge system operation periods increases in the pounds removal rates of VOCs were observed. When the sparge system operates for a longer period, a better evaluation can be performed.

## 6.5 Off-Gas Treatment System

# 6.5.1 Total System Effluent Concentrations

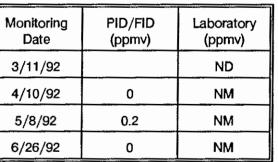

A temporary vapor phase carbon was installed to treat the off-gas from the treatment system. The off-gas concentration from the total remedial system, after the vapor phase carbon, was monitored monthly to document the VOC levels emmitted into the atmosphere. Table 19 contains the monitoring results.

#### Table 19

NM = not measured

# 6.5.2 Evaluation of Total Loading to Vapor Phase Carbon Unit

The vapor phase carbon was temporarily installed in order to collect off-gas concentration data to better evaluate permanent off-gas treatment systems. In order to do this, the total pounds of VOCs emmitted from the SVE system and air stripper were combined and an estimate of the total amount of carbon used to treat these VOCs was obtained. The total amount of carbon utilized during this monitoring period was 1,800 pounds. The vapor phase carbon cannister contains 2,000 pounds, therefore the first cannister is 90 % spent. The monthly carbon utilization was approximately 600 pounds. These calculations are based upon a carbon loading rate of 12 % by weight. A cost analysis of continued useage of vapor phase carbon will be developed prior to selection of the permanent alternative.

annanneachar course - techoraceachtit

# 6.6 Summary of Remedial System Effectiveness

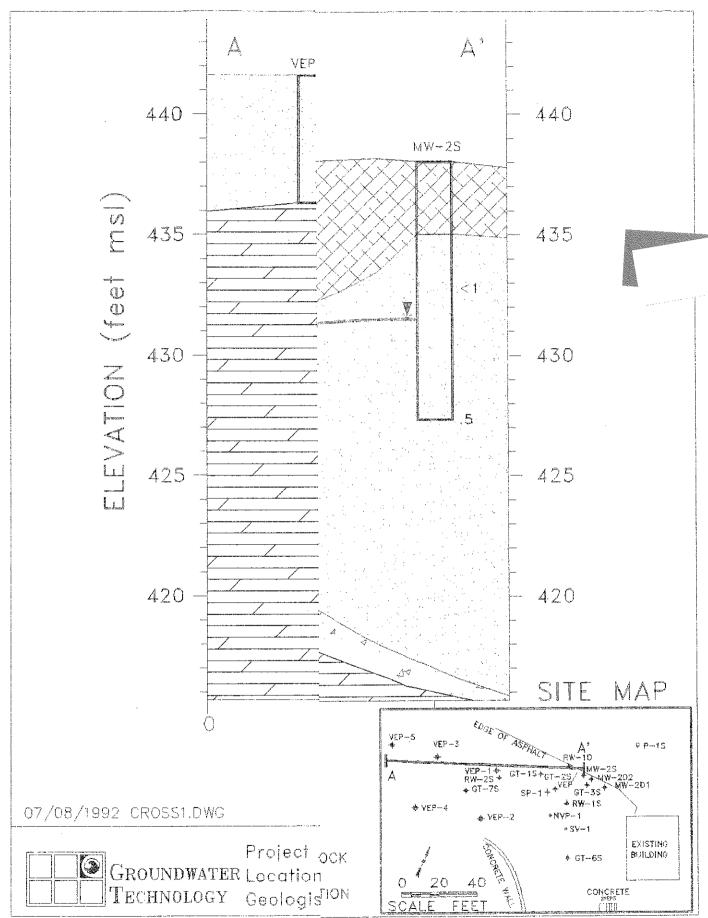

Through June 1992, the remedial system at this site has removed 217 pounds of VOCs from the subsurface (118 pounds through soil vapor extraction and 99 pounds through groundwater extraction). The 217 pounds of the estimated 2,519 total pounds identified in the subsurface represents over 8 %.

To document the remedial effectiveness, a groundwater sampling round was performed on June 30, 1992. Concentrations decreased in GT-7S by 28 % and 94 % in GT-6S. Figure 19 shows the VOC contour map of the results. Additional data will need to be evaluated to document declining trends.

Cross sections were developed to more clearly present the field screening results, both from the remedial installation and prior subsurface explorations. Figures 12 and 13 show cross sections running north-south and east-west across the study area. The highest concentrations were below the water table in the area around GT-1S. These cross sections show that the areal and vertical extent of subsurface soil impact has been indentified. The cross sections were additionally utilized to define the adsorbed phase mass loading which is discussed in Section 5.0.

# 1.0 INTRODUCTION

The Pawling Corporation site located in Pawling, New York is on the New York State Inactive Hazardous Waste list specified as a Class 2 (Figure 1). A remedial plan was outlined and submitted to the New York State Department of Environmental Conservation (NYS DEC) entitled "Work Plan for Subsurface Remedial Design and Implementation, Pawling Corporation", dated May 25, 1989. The work plan was approved by the NYS DEC Division of Hazardous Waste Remediation prior to initiation.

The results of this work plan were utilized to select and design a remedial system for this site. An engineering report, "Remedial System Design, Pawling Corporation", dated February 26, 1991, was prepared and submitted to the NYS DEC for approval prior to system installation. The design report was approved on June 17, 1991. The approved system consisted of groundwater extraction wells, air stripper and liquid phase carbon water treatment, air sparging, soil vapor extraction and vapor phase carbon off-gas treatment.

This status report details the pilot test results, baseline conditions, remedial system installation and first quarter operational information for the soil, air and groundwater treatment systems installed at this site.

## 2.0 REMEDIAL SYSTEM PILOT TESTS

Air sparging and soil vapor extraction (SVE) pilot testing was performed prior to system installation in order to correctly locate the sparge and vent points and to determine the required equipment specifications for air flow, vacuum and pressure. Groundwater pump testing had previously been performed and the results are documented in the "Groundwater Investigation Pre-remedial Design Report, Pawling Corporation", dated January 3, 1991.

#### 2.1 Test Protocol

The pilot testing consisted of three components: a vent test, a sparge test and a combined sparge/vent test. The vent and sparge tests were performed first to define the individual equipment specifications and to determine the most effective operational conditions of these systems. The combined test documented actual field response to the selected pressure and vacuum to verify the predicted response. Each of these tests are described below.

#### 2.1.1 Soil Vapor Extraction Test

The SVE test was performed by attaching a soil vacuum blower to the pilot test vent well (GT-2S) and running the test at three vacuum settings, 21, 35 and 44 inches of water and 34, 38, and 41 cfm, respectively. Each vacuum setting was a phase of the test which defined a ROI and an off-gas Volatile Organic Compound (VOC) concentration. These data allowed selection of the vacuum which provided maximum radius of influence and proper blower sizing. Each phase was run until stabilization occurred.

#### 2.1.2 Air Sparge Test

The air sparge test was performed by connecting a compressed air line to the top of a newly installed sparge point (SP-1). Section 3.2 describes the construction details of the sparge point. The test was performed at three pressures, 4 psi, 5 psi and 8 psi (10%, 40% and 115% over the pressure needed for the air to overcome the 8.5 foot water column). All points were monitored for pressure and VOCs. Dissolved oxygen (DO) and depth to water (DTW) were recorded in the monitoring wells at the end of each pressure setting as removal of the pressure caps interfered with the pressure readings. Each pressure test was until stabilization occurred. The induced responses to various air flows allowed for the selection of an air flow which provided the greatest radius of influence without over-pressurization.

# 2.1.3 Air Sparge/Soil Vapor Extraction Test

The last phase of pilot testing was implementation of a combination air sparge/SVE test. This test was conducted to record field response under actual operating conditions and to ensure that the responses obtained from the individual SVE and air sparging tests matched the combined response test. The combination test was run at 8 psi and 42 inches of vacuum, which were the maximum levels recorded during the SVE and sparge tests. The objective of this test was to ensure that a net vacuum could be monitored across the site under maximum operating conditions so that all sparge vapors were contained.

#### 2.1.4 Monitoring Network

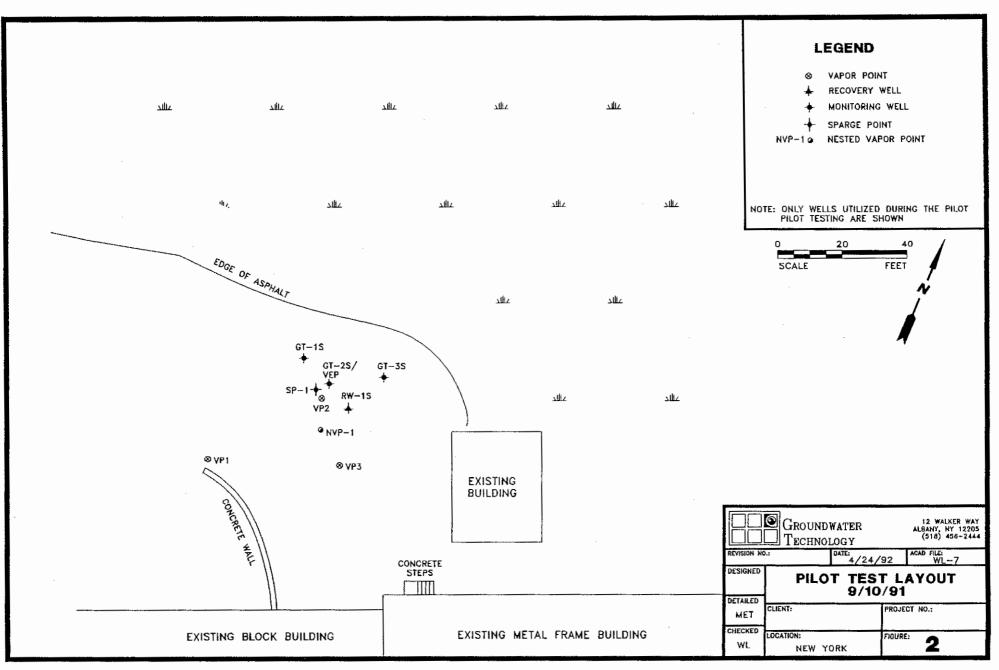

The monitoring network utilized for the pilot tests consisted of five existing monitor wells, a nested probe screened at two intervals in the unsaturated zone, and three 0.25 inch stainless steel probes manually installed to a depth of 3 feet.

Monitoring points were selected to provide multi-directional data at varying distances from the test well. The distances were chosen based upon prior knowledge of soil permeability values, as the radius of influence is directly related to permeability. Additionally, monitoring points were installed to provide information concerning potential vertical difference in response both in the unsaturated and saturated zones. Figure 2 shows the layout of the pilot test monitoring array.

#### 2.2 Soil Vapor Extraction Test Results

Vacuum in the subsurface generally decreases exponentially with distance. To calculate an effective radius of influence and to determine anisotropic response, the natural log (In) of the vacuum was plotted versus distance. Linear regression was performed to determine the best fit lines and to evaluate correlation coefficients with different data sets to assist in defining anisotrophy in the subsurface at the site. Table 1 depicts the results of the linear regression.

The data for this site indicated that a point at 14.5 feet exhibited an anomalous reading, therefore this point was eliminated from subsequent analysis. Figure 3 also shows the determined best fit lines and the determined ROI for each vacuum setting. A vacuum of 0.1 inches of water was selected to define a significant response (ROI).

# TABLE 1

# LINEAR REGRESSION CORRELATION COEFFICIENTS

Vacuum	All data points	Without 14.5 foot point
21"	0.62	0.92
35"	0.87	0.97
44"	0.88	0.95

The determined ROI for each vacuum was plotted versus each vacuum setting to select the vacuum above which not greater ROI was observed. The maximum ROI obtained was 27 feet at 35 inches of water vacuum (Figure 3). VOC effluent concentrations at each vacuum setting were also evaluated. The vacuum which produced the highest effluent VOC concentration was selected for the design. This value also correlated with the most effective vacuum ROI. Figure 3 shows these results. The pilot test results indicated that the design parameters for this site should be a vacuum of 35 inches of water at 38 cfm air flow per point.

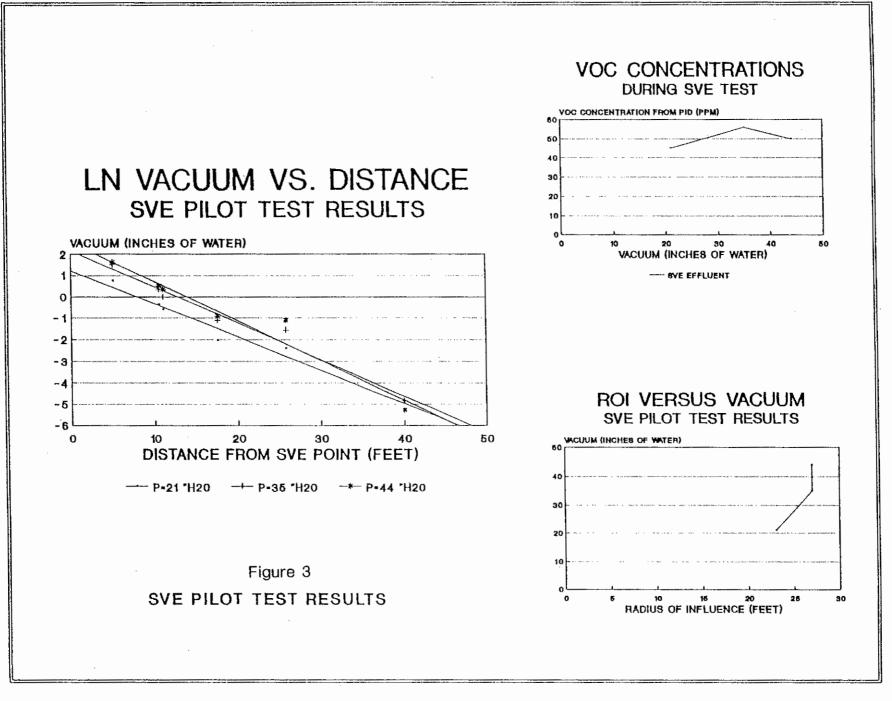

The data was further evaluated through use of a Groundwater Technology, Inc. developed air flow model which utilized the pilot test vacuum versus distance results and calculated the area through which sufficient air could be drawn to remove a selected percentage of the contaminants over a desired time period. This model determined that for an anticipated removal rate for tetrachloroethylene of 99% and 365 days of operation the design spacing for the vent points at this site was 20 feet. The air flow model provides a more conservative ROI and therefore this distance was utilized for system design.

## 2.3 Air Sparge Test Results

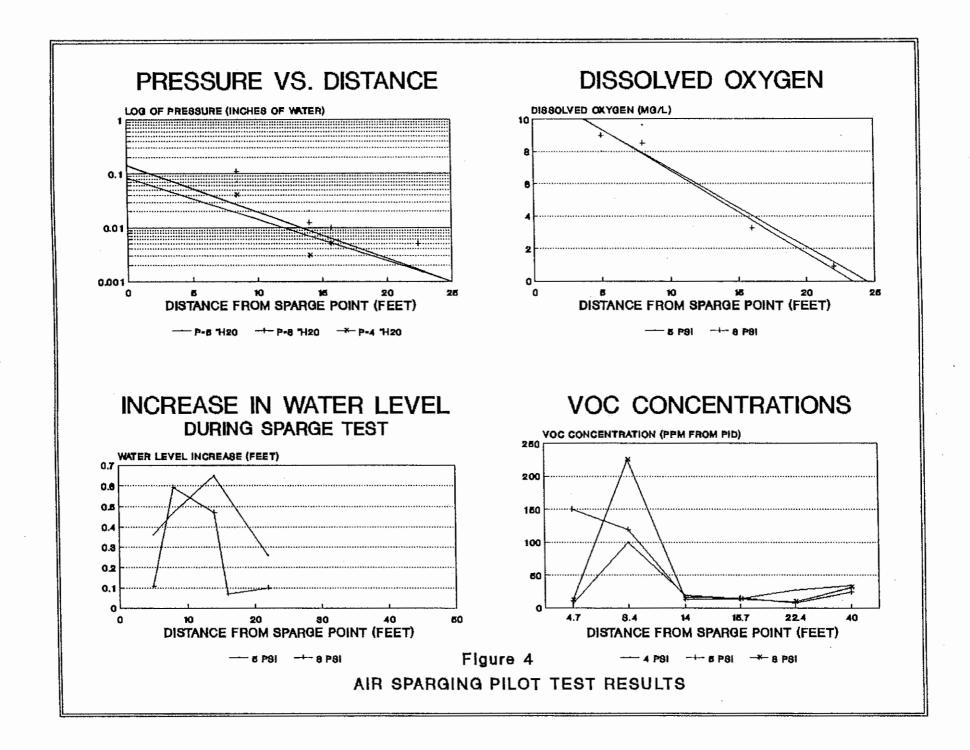

The air sparge test ROI was evaluated through several parameters:

- observed distance indicating increased dissolved oxygen
- observed distance indicating rising water elevations
- observed distance indicating increased VOC concentrations
- observed distance indicating pressure response.

A pressure versus distance graph was evaluated to select the pressure which provided the maximum ROI without over pressurization (Figure 4). The determined ROIs were 11.5, 15 and 16 feet for 4, 5 and

.

8 psi, respectively. The ROI for each test pressure was plotted to select the pressure above which no increase in radius of response was observed (Figure 5). The determined ROI was 16 feet at the maximum pressure of 8 psi.

The graphs of the other test parameters were compared to the pressure response (Figure 4). Table 2 shows the determined ROI for each of these parameters. VOC and pressure increases indicate the lowest ROI at 14-16 feet. The ROI exhibited by DO and groundwater increases during the air sparge pilot test was 22 feet.

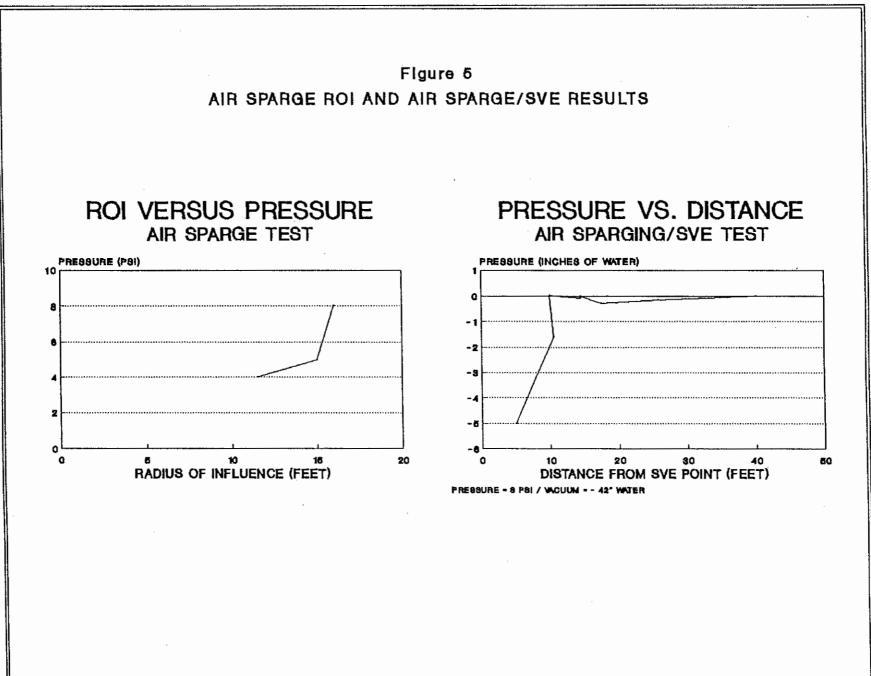

#### TABLE 2

# 2.4 Air Sparge/Soil Vapor Extraction Test Results

The air sparge/SVE test determined that net vacuum was maintained at 35 feet from the SVE point. The results are shown in Figure 5. These data document the capture of the air sparge off-gases within the design SVE ROI of 20 feet.

# 3.0 FINAL SYSTEM CONFIGURATION

#### 3.1 System Overview

The final system layout and selected equipment, as determined through the pilot testing, are shown in Figure 6 and Table 3. The system consists of four major components: 1) groundwater extraction through overburden pumping wells and treatment through air stripper and carbon polish, 2) unsaturated soil treatment through a soil vapor extraction system, 3) saturated soil treatment through an air sparge system, and 4) off-gas treatment through vapor phase carbon. A description of the remedial point construction and each component of the remedial system are presented in the following sections.

As shown in Table 3, the final system configuration was slightly different than the design layout due to subsurface variations. Site hydrogeologic conditions and saturated and unsaturated contamination identified during remedial installation were utilized to appropriately modify the design layout. During the air sparge and SVE point installation, the saturated thickness was determined to be less than the design thickness, and two small for effective air sparging. The number of air sparge points installed was therefore less than the original estimate. Additionally, the third recovery well was not installed due to lack of an overburden water table at this location.

The final monitor point system consisted of:

- one sparge point (SP-1)
- one combined sparge/soil vent point (SV-1)
- six vapor extraction points (VP-1 through VP-5) plus one existing monitor well (GT-2S/VP-6)
- two overburden recovery wells (RW-1S and RW-2S)
- one bedrock recovery well (RW-1D) (presently not a pumping well)

Monitor points were also installed to monitor the effectiveness of the remedial system. The points installed consisted of two monitor wells (GT-6S and GT-7S) and one nested vapor probe (NVP-1).

#### 3.2 Remedial and Monitor Point Construction

During the period from September 9 through 19, 1991, a Mobile B-61 hollow stem auger drill rig with split spoon sampling capabilities was utilized to install the remedial points. Additionally, an air rotary technique was utilized at selected locations where auger refusals were encountered due to the presence of boulders. Monitoring wells and vapor extraction points were constructed of two-inch diameter, PVC screen and riser with flush-threaded joints. Sparge points were constructed of two-inch diameter FRP screen and riser, with flush-threaded joints. The overburden recovery wells were constructed of six-inch diameter stainless steel screen and riser. Well construction details are summarized in Table 4. The complete well logs are included in Appendix A.

Split spoon soil samples were collected at the locations believed to contain elevated levels of volatile organic compounds, as delineated during the previous phases of investigation. Split spoon soil samples were screened in the field using a Photoionization Detector (PID - HNU with a 11.7 ev lamp) and one soil sample from each drilling location was sent to the laboratory for analysis according to the EPA Method 8240. Section 4.3 details the soil sampling results.

# 3.3 Groundwater Extraction System

An Ejector System<sup>®</sup> multiple well pneumatic pumping system with U-3000 controllers and WETB 5" by 18" long ejectors was deployed to recover groundwater from two recovery wells on site (RW-1S and RW-2S). The system is powered and controlled by compressed air, and has the following components:

- Air-operated ejector vessels
- Bellows liquid level control
- Pneumatic control panel
- In line flow meters

The system is designed to recover approximately 2 gallons per minute (gpm) from each of the recovery wells. The system will consume approximately 11 cubic feet of air a minute (cfm) at a pressure of 25 pounds per square inch (psi).

# Air-operated ejector vessels:

Each well contains an ejector vessel. The ejector vessel is a cylindrical hollow pressure vessel with two inlet and one discharge check valves. The ejector vessel is constructed of carbon steel and the valves are constructed of 304 stainless steel. The ejector is located in the well at a depth of approximately 8 feet below grade.

The ejector has two operating cycles, fill and discharge. The fill cycle occurs without any pressure on the vessel. This allows the vessel to gravity fill. When the vessel is full the vessel is pressurized by the air line and the water in the vessel is forced up through the discharge check valve into the discharge line. At the end of the discharge cycle the vessel is allowed to depressurize, vent and fill again. Flow rates from the vessel are controlled by adjusting the fill and discharge cycle times.

#### Bellows liquid level control (BBLC):

Each well contains one BBLC at the well head. The BBLC controls the ejector pumping rate by restricting the high pressure air supply from the control panel. A bubbler line indicates the column of water that is above the ejector vessel by sensing backpressure that is created as water accumulates over the ejector. The bubbler line is mounted approximately 3/8 inches above the intake for the ejector. If the bubbler line senses sufficient amount of water above the ejector (approximately 10 inches) it allows the pump to function at full capacity. At water levels less than 10 inches above the ejector intake the BBLC partially or completely restricts the high pressure discharge air to the pump. A gauge on the face of the BBLC indicates the water level above the intake in inches of water. The BBLC is mounted level to the wall of the recovery well road box.

#### In Line Flow Meters:

<sup>1/2</sup>-inch Master meter water flow meters were installed inside the equipment compound. For each of the recovery wells the meters will accurately measure flow rate from each well and totalize the overall volume of extracted groundwater.

#### Trenching and Piping:

All lines were installed in trenches approximately 3.0 feet below grade. All lines installed in the trenches were bedded on 6-inches of clean, coarse sand prior to backfilling. A 6-inch lift of sand was also installed above the pipes. The trenches were backfilled and tamped in 1-foot lifts to grade with native soils. All trenches were located in the parking lots, therefore, the top 6-inches of fill was a compacted

crusher run sub-base for repaying. Repaying will be conducted during the fall of 1992 by Pawling Corporation.

All lines were pressure tested prior to being buried. The pressure test was performed by sealing off the line, installing a pressure gauge in the line and injecting compressed air to 10 psi. The air pressure in the line was monitored for any changes and the line and all associated fittings were visually inspected for any leaks. The pressure test was maintained for a duration of 1 hour. All lines passed the pressure test.

The groundwater extraction piping layout is shown in Figure 7, Groundwater Extraction and Sparge System Piping and Instrumentation Diagram.

#### Well Completion:

Each recovery well head was enclosed in a traffic rated steel 2-foot square road box concreted into place. The road box lid is bolted closed and has gaskets to seal it form water intrusion. Each road box houses the pump, bellows liquid level controller, water flow adjustment valve, and an explosion proof junction box required for heat taping water lines. The floor of the road box is filled with gravel to drain any moisture that may enter the road box.

## 3.4 Groundwater Treatment System

#### Air Stripper:

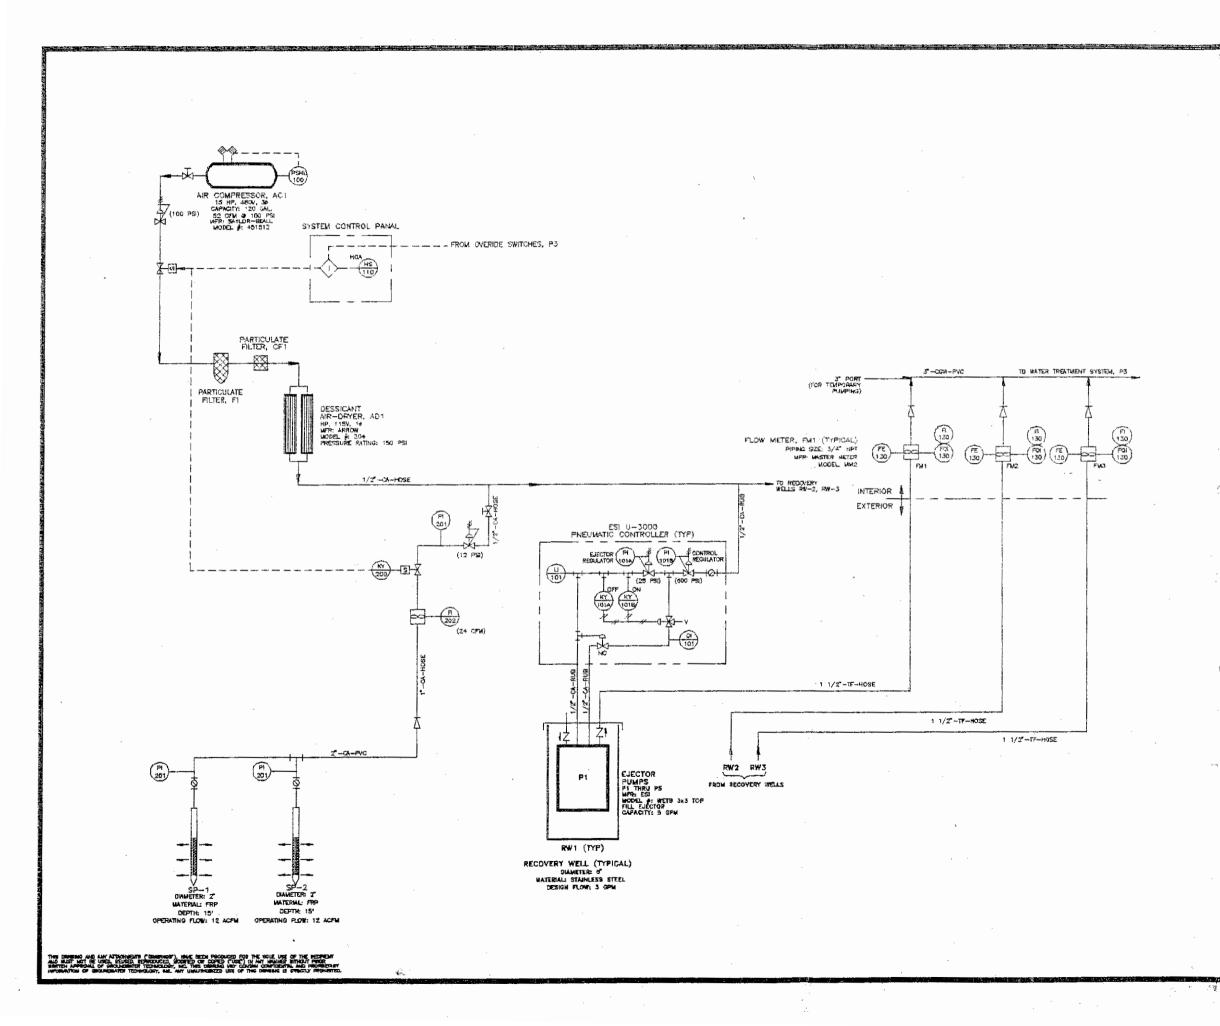

An Ejector System, Inc. (ESI) Low Profile Cascade air stripper, Model STRP-A6, is used to remove VOCs from the water system. The air stripper contains 7 stacked aeration trays each with a series of baffles and bubblers. The air stripper is designed to treat a flow rate of 4 gpm at the anticipated contaminant levels with a maximum design flow rate of 10 gpm. The ESI Cascade System comes equipped with automatic level control and shut-off.

#### Transfer Pump:

Water from the air stripper is piped to a 210 gallon transfer equalization tank. The transfer tank is constructed of high density polyethylene and is equipped with an air tight lid, a vent to the atmosphere, and the appropriate fittings to mount the transfer pump probes. The water pump allows for equalized pumping through the carbon polishing system.

# Sediment Filters:

Two sediment filter housings were installed after the transfer pump to remove any sediment or iron particulates larger than 10 microns that would be in the water stream after the air stripping system. The units are constructed of carbon steel and pressure rated to 250 psi. The filter housings each contain

several filter cartridges. A pressure gauge located on the top of each filter housing will indicate the need for cartridge change outs. During the first three months of operation one change out per month was needed.

The sediment filters and housings keep the carbon polishing units from clogging with particulates and increase the useful life of the carbon units.

#### Carbon Polishing Units:

Two liquid phase Hadley GAC units were installed after the sediment filters. Discharge from the filter units is piped through both GAC units as a treatment backup to insure a water discharge within the acceptable discharge limits. Any residual VOCs remaining in the water stream after the air stripper are adsorbed by the carbon. Each of the units contain 200 lbs of liquid phase GAC in a pressure rated fiberglass tank. The units are equipped with pressure gauges before, between and after the units to monitor the need for a change out. Each of the units can operate with pressures up to 150 psi.

#### Discharge Piping:

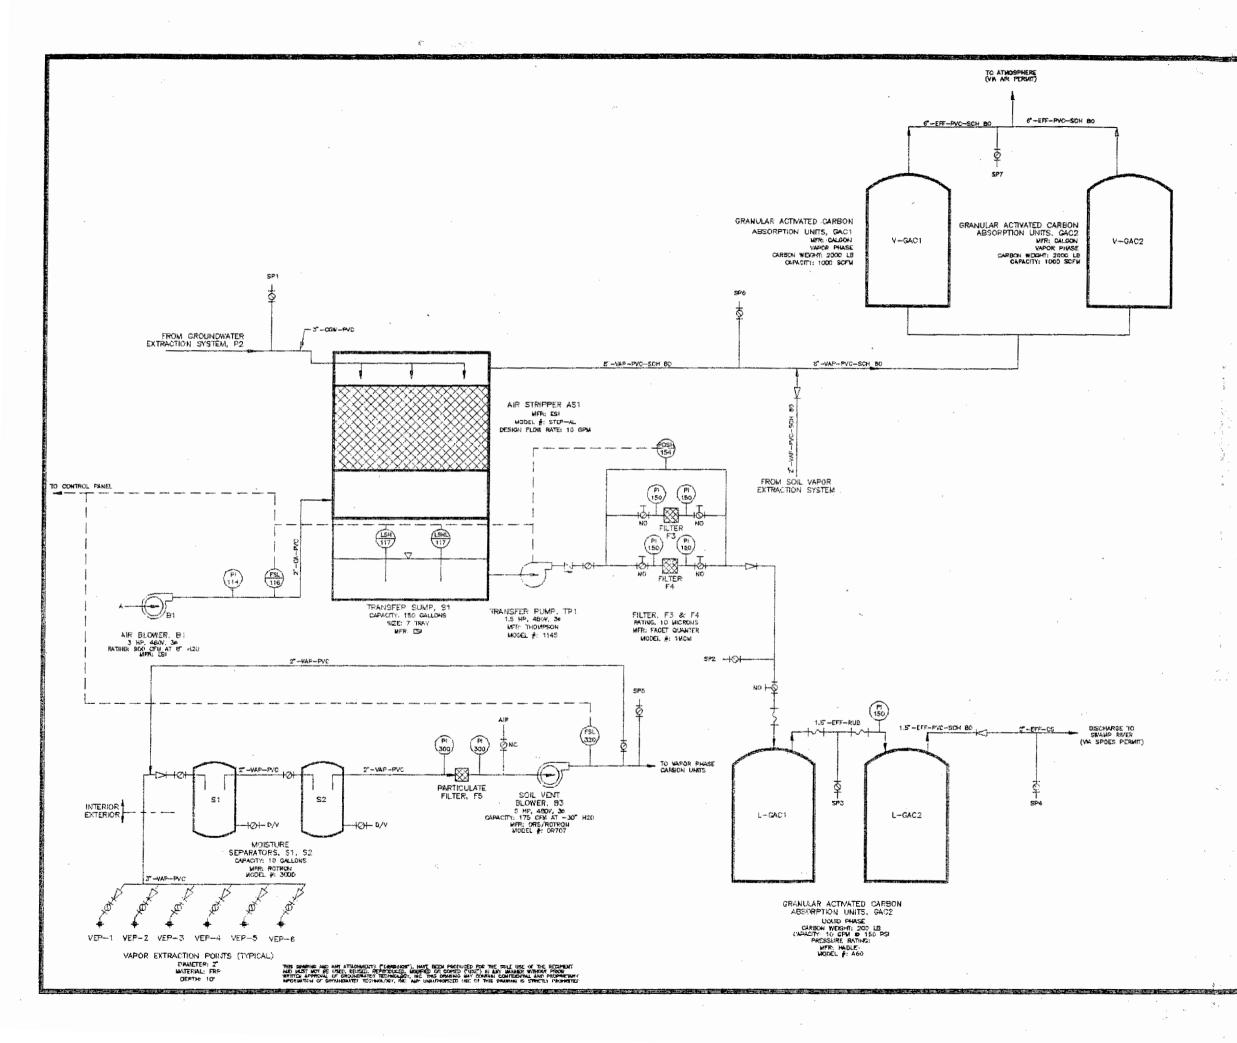

Effluent from the carbon polishing system is discharged to the Swamp River approximately 150 feet north of the equipment compound. The discharge pipe was constructed of 2-inch carbon steel pipe. The pipe was mounted on wooden pilings spaced approximately 12 feet apart. These pilings carry the discharge pipe to the Swamp River minimizing any impact to the wetlands area that surrounds the discharge point.

The discharge line is externally insulated and heat taped to prevent freezing of the line during the winter months. The heat tape is controlled from a plug assembly and thermostat located inside the treatment compound. The treatment system piping is shown on Figure 8, Groundwater Treatment and Soil Vent System Piping and Instrumentation Diagram.

#### 3.5 Soil Vapor Extraction System

#### Vapor Extraction Points:

Six (6) Vapor Extraction Points (VEPs), plus one monitor well, were installed in the impacted zone of the site (Figure 6, Remedial System Site Layout). The VEPs extract existing VOCs from the soil and any additional VOCs that are produced from sparging activities. The number, spacing and location of VEPs was determined after a field radius of influence (ROI) test (Section 2.1). Section 3.2 details the VEPs construction.

## Piping:

Each VEP was piped via 2-inch, Schedule 80, PVC piping to a 4-inch, Schedule 80 PVC header pipe located in the treatment compound. Each VEP is individually controlled by a ball valve located near the header pipe.

All lines were installed in trenches approximately 3 feet below grade. All lines installed in the trenches were bedded on 6-inches of clean coarse sand prior to backfilling. A 6-inch lift of sand was also installed above the pipes. The trench was backfilled and tamped in 1 foot lifts to grade with native soils. In locations where the trenches were located in roadways or parking lots the top 6-inches of fill was a compacted crusher run base provided for repaving.

## Moisture Separators:

Two 30-gallon moisture separators, Model MS 300 D, were installed in line after the soil vent header pipe and before the soil vent blower to reduce the moisture in the vapor stream. The separators allow water vapor to condensate and collect. A manually operated drain valve is located on the bottom of the separators to remove the collected moisture during routine maintenance visits. Two site glasses were installed to monitor the increase in water without interrupting the vapor extraction system.

#### Soil Vapor Extraction Blower:

A 5 Hp, 480 volt regenerative soil vent blower, Model DR 707, was installed to extract up to 210 cfm (at 35" vacuum) of vapor from the impacted soils via the soil vent network. The blower will be capable of producing a vacuum on the system of up to -60 inches of water column (approximately 2.2 psi).

The soil vapor extraction blower is rated for Class 1, Division 1, Group D, hazardous locations. The blower is equipped with a particulate filter to remove any sand or dirt particulate that may be present in the vapor stream before it reaches the blower. Two vacuum gauges mounted on the blower inlet pipes before and after the particulate filter indicate the vacuum in the line and the need for the filter to be cleaned.

The soil vapor extraction blower is equipped with an override system that automatically shuts down the soil vent system in the event that the off-gas treatment system becomes inoperable. Figure 8 shows the Soil Vapor Extraction Piping and Instrumentation Diagram.

# 3.6 Air Sparging System

# Sparge Points:

Two sparge points were installed in the impacted area of the site. Each point can deliver 5-12 cfm of air to the water table. The sparge point construction is detailed in Section 3.2. The bottom of each sparge

point is approximately 6 feet below the surface of the groundwater.

An electronic timer and solenoid valve allow intermittent airflow of the impacted area. The timer is programmable to allow for varied air flow intervals. Several different durations and intervals have been evaluated during this start-up.

#### Air Compressor:

A 15 Hp, 460 volt Saylor Beall, Model 4515 20, electric air compressor capable of producing 52 cfm compressed air at 100 psi was installed to operate the pumping and sparging systems. The air compressor is equipped with a fan cooled aftercooler that cools the compressed air and condenses some of the water vapor in the compressed air. This condensate is removed by a water separator. The compressor is mounted on a 200-gallon compressed air storage tank to allow for the steady operation of the compressor and keep storage of air for any peak operation needs.

<u>Desiccant Air Dryer:</u> A desiccant air dryer, Model 204, and particulate filters were installed after the air compressor to remove moisture, residual oil and particulates from the air stream. The air dryer conditions the operating air to provide more efficient operation with lower operating maintenance.

# Piping:

Compressed air is piped via 1-inch Schedule 80 PVC pipe to the sparge points. All lines were installed in trenches approximately 3 feet below grade. All lines installed in the trenches were bedded on 6inches of clean coarse sand prior to backfilling. A 6-inch lift of sand was also installed above the pipes. The trench was backfilled and tamped in 1-foot lifts to grade with native soils. In locations where the trenches were located in roadways or parking lots the top 6-inches of fill was compacted crusher run base provided for repaying. Piping which is above ground in the compound is galvanized steel. Figure 7 shows the Sparge System Piping and Instrumentation Diagram.

# 4.0 INITIAL SUBSURFACE CONDITIONS

The effectiveness of the installed remedial system will be evaluated relative to the initial subsurface conditions. This section presents the baseline groundwater gradient, groundwater quality and soil quality which were identified prior to start up of the remedial system.

#### 4.1 Groundwater Gradient

A complete groundwater gauging round was performed on March 9, 1992 prior to remedial system startup to document the initial site conditions. The gauging data are included in Appendix B. The overall site overburden and bedrock groundwater flow directions were similar to previous gaugings and indicated flow to the north toward the Swamp River. The gradients were slightly lower than previously measured, 0.35 % and 0.34 %, respectively for the overburden and deep bedrock aquifers.

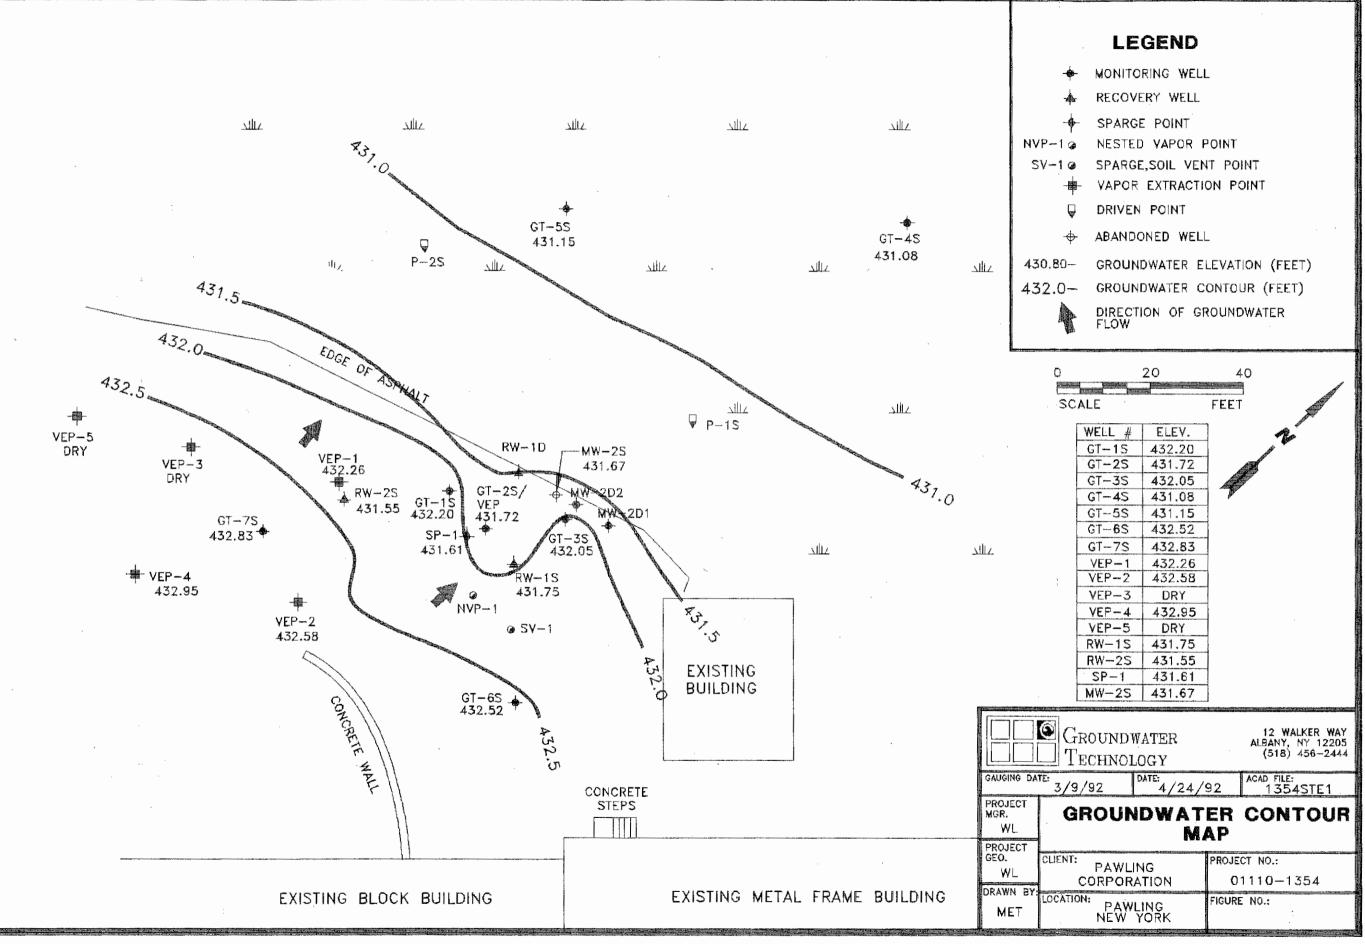

A contour map of the overburden groundwater elevations is shown in Figure 9. The gradient across this area, as measured between VEP-4 and GT-4S was 1 %. The additional monitor points determined that the overburden aquifer is not existent in the area around VEP-3 and VEP-5 due to the presence of a bedrock mound.

A comparison of the groundwater elevations in the deep bedrock and the overburden indicates that an upward vertical gradient of approximately 0.18 feet is still present across the site with the exception of the area around MW-2D1 where a downward gradient of 0.71 feet was observed. A comparison of the deep and shallow bedrock elevations, as measured at MW-2D1 and MW-2D2, shows that there is only a 0.01 foot upward vertical gradient within the bedrock; however, a comparison between MW-2D2 and RW-1D indicated an upward vertical gradient of 0.15 feet. It is not clear at this time what is causing these differences in vertical gradients.

## 4.2 Groundwater Quality

Groundwater samples were collected from select wells on March 10, 1992 in order to document concentrations of dissolved level VOCs prior to system start-up. Complete laboratory results as well as a table of all historical laboratory results are included in Appendix C. Figure 10 shows a contour map of the total VOC concentrations. The major portion of the plume is situated between GT-7S and RW-1S, where detected concentrations were 299,000 - 526,000 parts per billion (ppb). GT-4S and GT-5S denote the downgradient edge of the plume; detected concentrations at these locations were 21 and 31 ppb.

The specific VOCs which were detected included toluene, trichloroethene (TCE), trans -1, 2 - dichloroethylene (trans-1,2 - DEC), methylene chloride, vinyl chloride, and carbon tetrachloride. Table 5 shows the concentrations which were detected in each well. These compounds have all been previously

# Table 5

# VOC Concentrations in Groundwater March, 1992

Note: All results are expressed in ug/L

detected on-site with the exception of methylene chloride and carbon tetrachloride.

The percentages of each compound (in relation to the total detected VOCs) for GT-7S and RW-1S are also shown in Table 5. Toluene constituted approximately 80% of the dissolved VOCs; TCE approximately 11% and trans-1, 2 - DCE approximately 5%.

The June 1990 VOC concentrations detected in RW-1S are also shown in Table 5. The total VOCs were slightly higher in 1992 than in 1990 (299,100 vs. 225,483 ppb, respectively). The individual percentages of detected VOCs were similar, with the exception that low levels of several other VOCs had previously been identified in 1990. The dilution and higher detection limits reported for the 1992 data may have masked the detection of these compounds during the 1992 sampling.

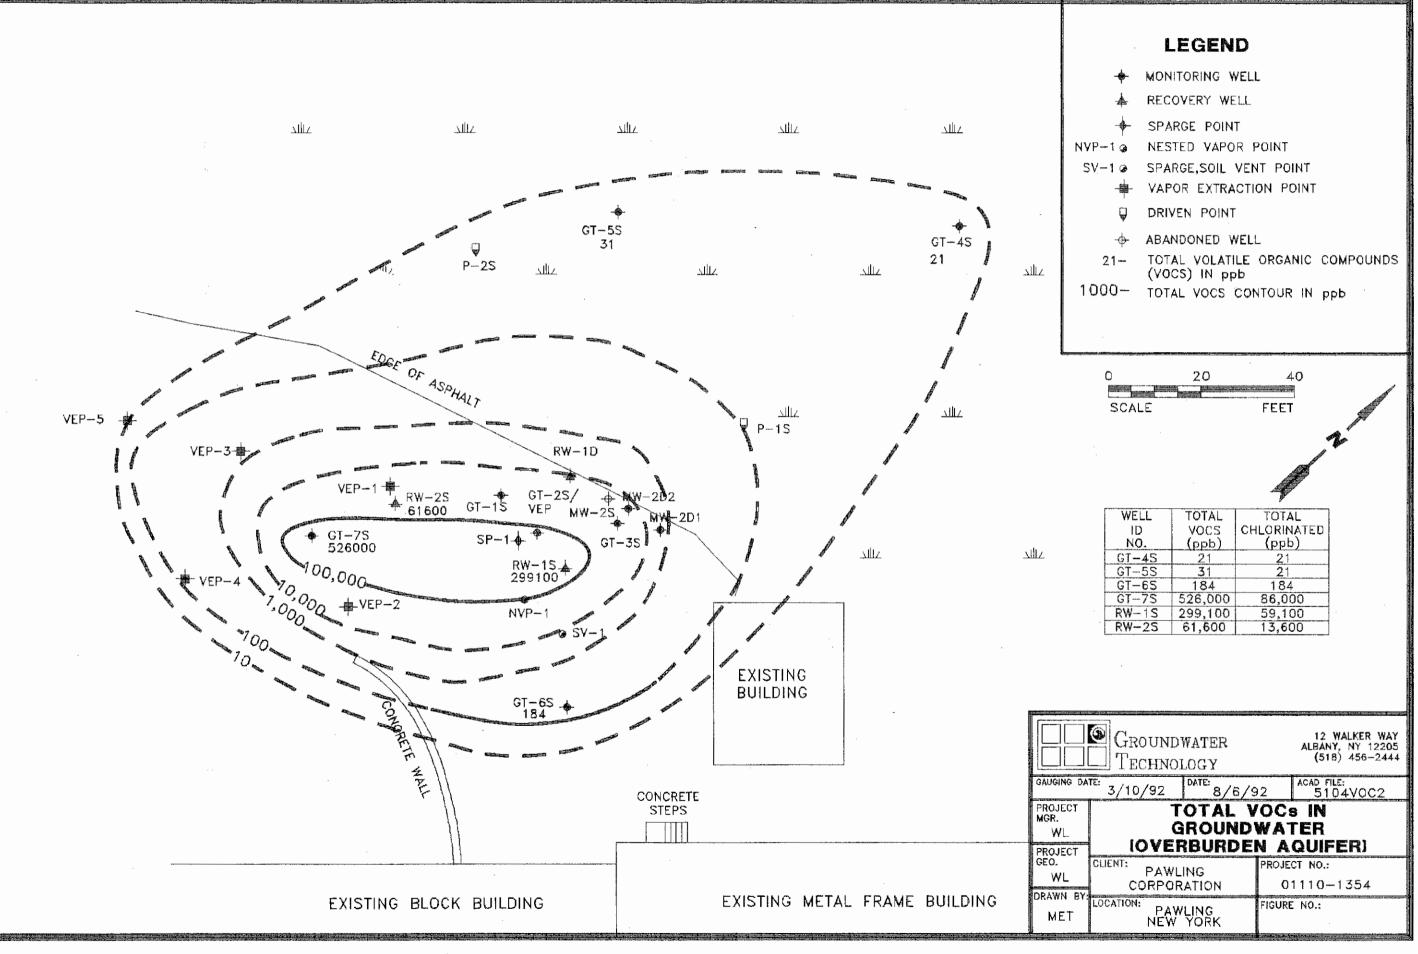

A more detailed comparison of the ratios of toluene, chlorinated compounds, and vinyl chloride and trans -1, 2 DCE, (two breakdown products), was performed to aid in evaluating contaminant degradation and removal (Figures 11 a, b, and c). At GT-7S, the assumed source area, the vinyl chloride and trans -1, 2 DCE concentrations (DCE) were very low, 0 and 3 % of the total chlorinated compounds, respectively. Slightly downgradient, at RW-1S the concentrations of this breakdown compounds constituted 10 and 15% of the total chlorinated compounds. At the edge of the plume, at GT-5S, the percentages were 0 and 30%. These ratios will be evaluated throughout the remediation process.

A groundwater sample was also collected from the upper bedrock aquifer, RW-1D, in order to document the initial concentrations prior to system start-up. Total detected VOCs were 3,680 ppb. This compares to 1,804 ppb in June 1990. Toluene constituted 73% of the total VOCs, and vinyl chloride and trans -1, 2 DCE constituted the remaining 27%. No other chlorinated VOCs were detected.

## 4.3 Soil Quality

During remedial point installation soil sampling was performed to further delineate the subsurface extent of VOC impacts. A summary of the monitored intervals, PID readings and laboratory analytical results are presented in Table 6 (Summary of Soil Monitoring Results). The complete soil laboratory analytical reports are presented in Appendix C.

As indicated in Table 6, soil screening, using the PID, indicated elevated (above 100 ppmv) volatile organic levels at the locations of NVP-1, SP-1, VEP-1 and GT-7S. Concentrations of approximately 50 ppmv were detected at the locations of SV-1 and VEP-3. Toluene was the compound detected at the highest concentration, of 7,580 ppb and 1,990 ppb, at the locations of NVP-1 and SP-1. PID results exhibited much higher concentrations than the laboratory data.

Cross sections were developed to more clearly present the field screening results, both from the remedial installation and prior subsurface explorations. Figures 12 and 13 show cross sections running north-south and east-west across the study area. The highest concentrations were below the water table in the area around GT-1S. These cross sections show that the areal and vertical extent of subsurface soil impact has been indentified. The cross sections were additionally utilized to define the adsorbed phase mass loading which is discussed in Section 5.0.

#### 5.0 CONTAMINANT DISTRIBUTION

The effectiveness of the installed remedial system will be evaluated relative to the cleanup of the identified VOCs in the subsurface. VOCs released to the subsurface can be present in any of four phases: dissolved in groundwater (dissolved phase), adsorbed onto soil particles (adsorbed phase), layers of non-aqueous phase liquids (liquid phase), or as vapors (vapor phase). This section details the identified phases, extent and estimated volume of VOCs which are present in the subsurface at this site and which define the baseline conditions for evaluating remedial effectiveness.

#### 5.1 Methodologies for Calculating Contaminant Volumes

#### 5.1.1 Dissolved Phase

#### Overburden Aquifer

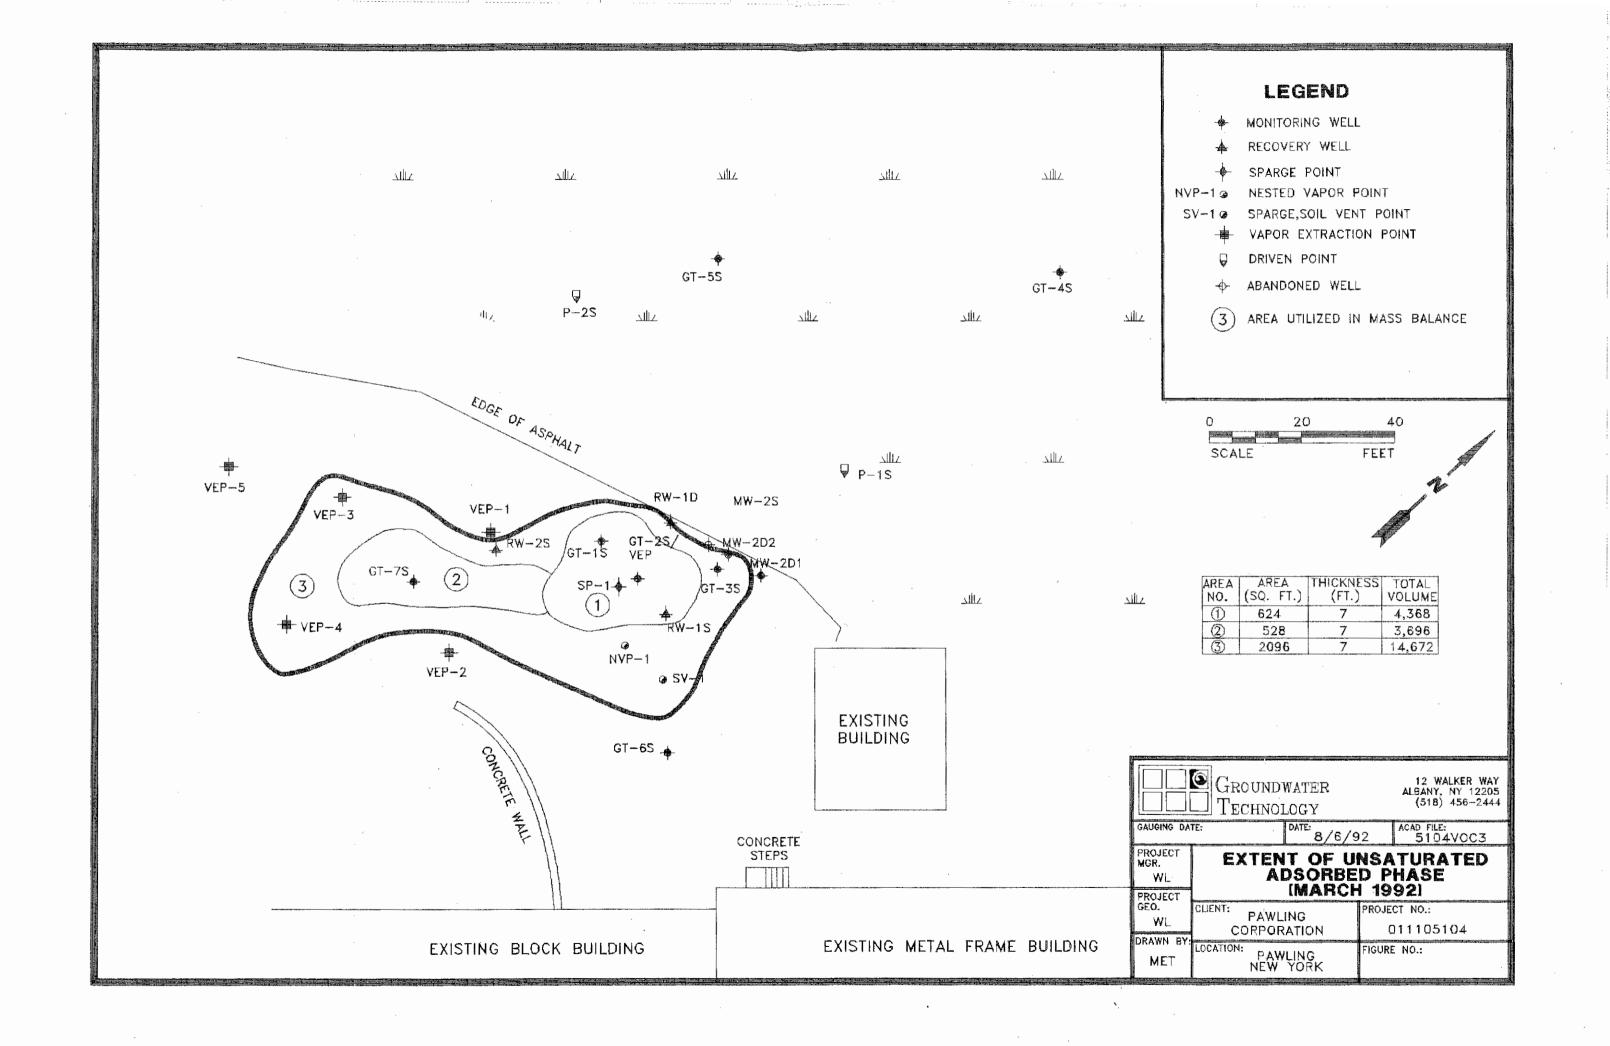

The areal extent of the dissolved phase was identified by the initial (March 1992) groundwater sampling. The results are portrayed on the Total VOCs in Groundwater (Overburden Aquifer) map (Figure 10). The areas between contoured intervals, the average concentration between contour lines and the saturated thickness, as shown on the cross sections (Figures 12 and 13), were utilized to calculate the total volume of VOCs present in the dissolved phase. Appendix D contains the calculations.

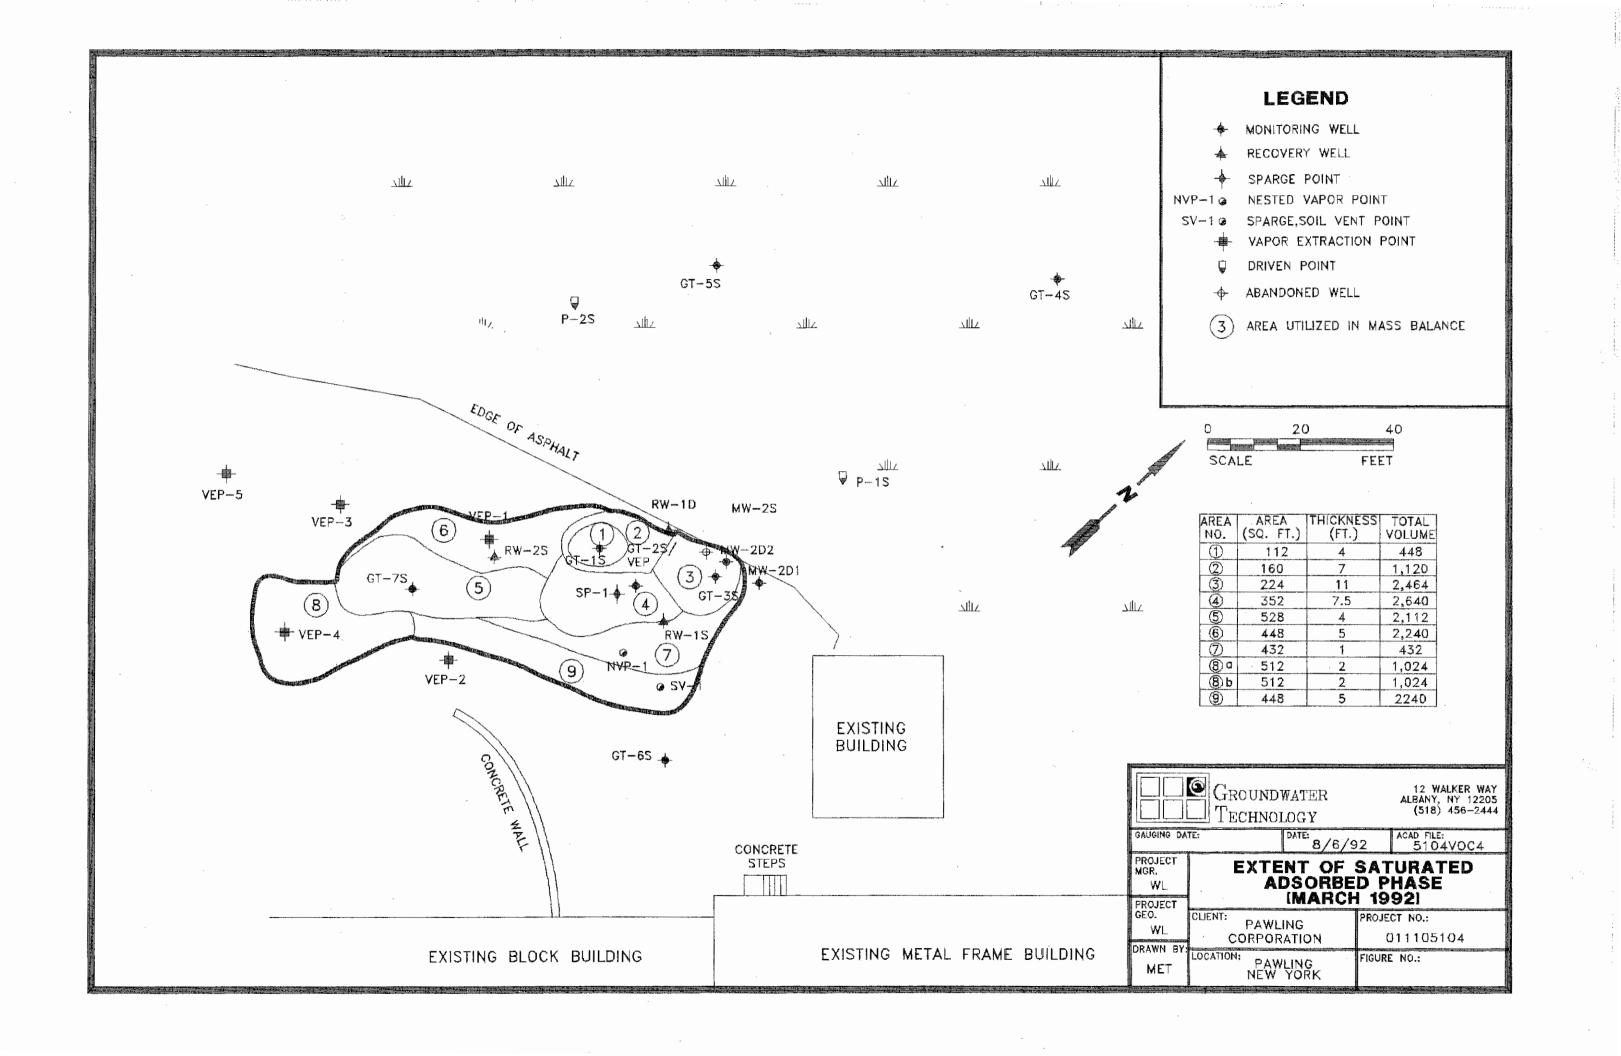

#### Bedrock Aquifer

An attempt was made to estimate the volume of VOCs in the bedrock. Much less data are available concerning subsurface conditions, therefore, a range of values was produced utilizing different impacted areas and porosities. Appendix D contains the calculations.

#### 5.1.2 Adsorbed Phase

The field screening VOC data from soil samples were utilized to define the areal extent of the adsorbed phase. Figures 14 and 15 shows the defined areas of adsorbed phase VOCs in the saturated and unsaturated zones. The unsaturated and saturated zones were delineated separately because they are remediated by different technologies. For calculation of the contaminant volumes the total areas were divided into subareas based upon different VOC concentrations. The cross sections were utilized to determine the impacted thicknesses. Appendix D contains the contaminant loading calculations.

#### 5.2 Contaminant Volumes

#### <u>Overburden</u>

The calculated contaminant volumes determined for this site are shown in Table 7. The saturated adsorbed phase contained the highest amount of VOCs, 1774 pounds. The unsaturated adsorbed phase contained 700 pounds, while the dissolved phase contained only 45 pounds. The total VOCs identified in the subsurface were 2,519 pounds. Figure 16 shows the relative distribution of the phases. The vapor phase and liquid phase were nonexistent or negligible.

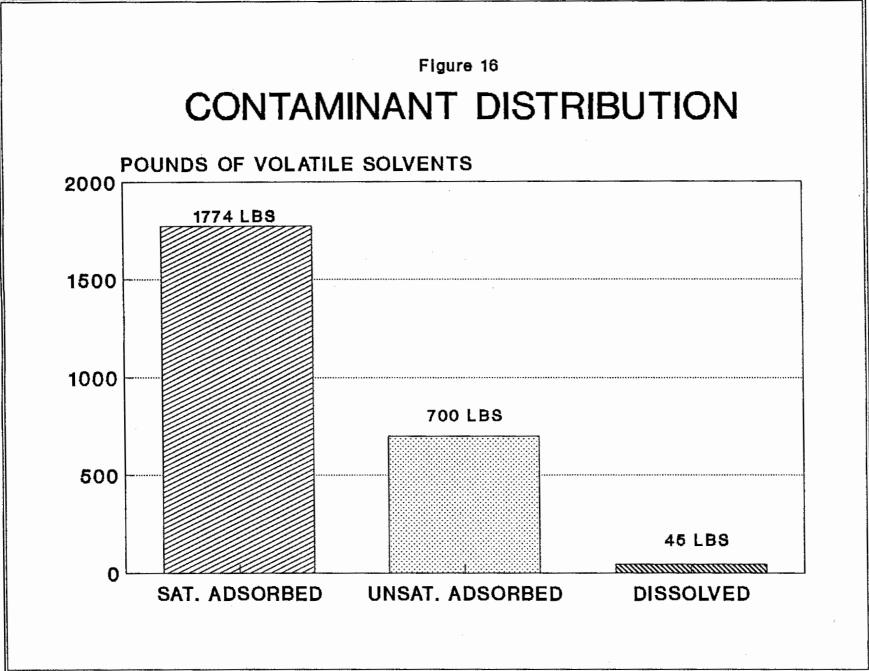

#### Bedrock

The contaminant mass calculations for the bedrock aquifer provided the following range of estimates of dissolved phase VOCs; 2 to 25 pounds. Due to the low porosity and small surface area of contaminant contact with the rock, it is assumed that the absorbed phase VOC volume is small. These numbers are rough estimates but do provide a good indication of the relative contaminant loading in the bedrock.

## TABLE 7

### CONTAMINANT DISTRIBUTION IN THE OVERBURDEN

PHASE	AMOUNT (pounds)	PERCENTAGE OF TOTAL
Dissolved Phase	45	1.8
Unsaturated Adsorbed Phase	700	27.8
Saturated Adsorbed Phase	1,774	70.4
Liquid Phase	Negligible	Negligible
Total VOCs	2,519	100

#### 6.0 REMEDIAL SYSTEM PERFORMANCE

The remedial system has been in operation since March 9, 1992.) During this initial 3 months of operation each of the individual remedial systems (groundwater extraction, groundwater treatment, soil vapor extraction, and air sparging) have been operated and data associated with the operation has been collected. This section presents the initial start-up data and first 3 months of system performance.

#### 6.1 Groundwater Extraction System

#### 6.1.1 Operation Summary

The groundwater extraction system was started on March 11, 1992. During the first month of operation the system ran only intermittently while the programmable overide protection system was tested and debugged. The system ran continuously during the rest of the monitoring period with one down time period experienced from May 11 to May 21 due to a problem with the air stripper transfer pump.

#### 6.1.2 Verification of Hydraulic Control

In order to verify hydraulic control and complete capture of the overburden dissolved plume, groundwater gauging was performed. The groundwater elevations were contoured and flow lines plotted. Figure 17 shows the resultant map. Impacted groundwater is being captured as designed.

#### 6.1.3 Flow Rates/Total Gallons Extracted

The initial start-up flow rates for RW-1S and RW-2S were 1.7 gpm and 0 gpm, respectively. The average flow rates observed over this monitoring period were 1.0 gpm and 0.3 gpm, respectively. The flow rates are lower than the pilot test design flow rate of 2 gpm. This is due to the fact that there is limited recharge to the overburden aquifer in this area. This is evidenced particularly at RW-2S which is dry most of the time except after a rainfall event. The bedrock high appears to affect the overburden groundwater table, as discussed in section 4.1.

Over this monitoring period a total of 77,030 gallons of water have been extracted from the subsurface. Table 8 shows the gallons extracted from each well over time.

#### 6.1.4 Extracted VOC Concentrations/Removal Rate

The dissolved concentrations being extracted from the subsurface were evaluated through collection and sampling of water entering the air stripper (A/S influent). Sampling was performed on March 11, 1992. A triplicate sampling was performed to quantify the variation in the results. The detected concentrations are shown in Table 9. There was quite a range in concentrations between the three samples, particularly for TCE.

#### Dissolved Concentrations from Groundwater Extraction System March 11, 1992

The mean total VOC concentration was utilized to calculate the pounds of VOCs removed from the subsurface during this monitoring period. A total of 99.16 pounds have been removed through the groundwater extraction system. Table 8 shows the removal rates over time. As the removal rate is based upon the influent concentration, which did show a range from 109,500 to 214,000 ug/l, the actual pound removal may be 70.5 to 131 pounds. These values are higher than the initial estimate of dissolved phase VOCs due to additional dissolution of VOCs from the adsorbed phase.

#### 6.2 Groundwater Treatment System

The air stripper removal efficiency was evaluated through comparison of influent and effluent water quality to the air stripper. The removal efficiencies ranged from 99.54 to 100 %, depending upon the compound. Table 10 shows the removal efficiencies by compound.

The removal efficiency of the entire treatment system, carbon polish plus air stripper, was 100 %. The VOC effluent concentrations sampled monthly to meet discharge requirements showed non detectable levels. Table 11 shows the sampling dates. The analytical laboratory data are included in Appendix D.

Based upon the initial analytical data and air stripper removal efficiency, the carbon polish has been loaded with less than 0.1 pounds of VOCs. Each carbon cannister should be able to remove approximately 20 pounds of VOCs.

## Air Stripper Effluent Concentrations and Percent Removal Efficiency

March 11 Sampling	Toluene (ug/l)	% Removal	TCE (ug/l)	% Removal	Trans-1,2- DCE (ug/l)	% Removal	Vinyl Chloride (ug/l)	% Removal

GT-7S	20	0.3	8.2	8

#### 6.3 Soil Vapor Extraction System

#### 6.3.1 System Operation

The SVE system was started on March 9, 1992 and maintained continual operation throughout this monitoring period. The air flow rate recorded before the blower was 108 cfm. This compares to design air flow rate of 175 scfm. The rate is lower than the design value, undoubtedly due to the close spacing of vapor extraction points,

which, in combination, are withdrawing more air than can recharge the subsurface, thus producing an overall flow rate lower than the potential rate. The operational vacuum throughout the monitoring period was 50 inches of water. This vacuum is higher than the design value of 35 inches because it was decided that a higher vacuum would increase the vapor removal rate.

#### 6.3.2 Verification of Radius of Influence

The radius of influence (ROI) of the SVE system was measured in the field by recording vacuum readings at several monitor points. The results are shown in Table 12. These results show that greater vacuum has been oberved than the pilot test estimated. The combination of multiple vapor extraction points is creating a greater vacuum response in the subsurface.

If the observed readings are extrapolated to the 0.1 inch water column effective ROI, the actual SVE system has a ROI of 32 feet (versus the pilot test value of 27 feet). The verification of the actual ROI ensures that all unsaturated soils are adequately being vented.

Vacuum readings were also recorded at the monitoring points during air sparging operation. The vacuum readings decreased only slightly, indicating that net vacuum was maintained during sparging, ensuring the that all air sparge vapors are being captured.

#### 6.3.3 Extracted VOC Concentrations and Removal Rates

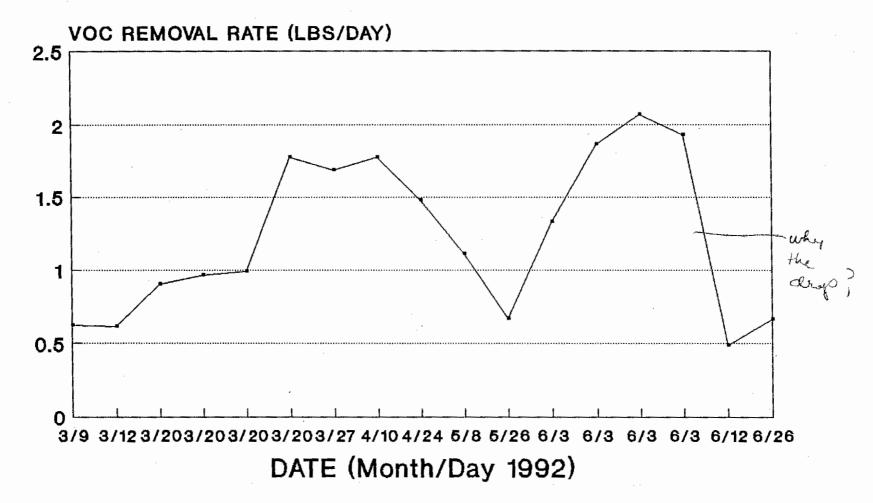

The VOC concentrations extracted by the entire SVE system ranged from 8 to 38 ppmv as recorded with a PID with a 11.7 head. FID data were also collected. Originally the FID values were much greater than measured by the PID due to the presence of methane. After two months of operation, the two instruments recorded similar VOC levels, with the FID showing slightly higher levels ranging from 20 to 32 ppmv. Table 13 reports all of the VOC levels recorded. Air samples were collected and analyzed in the laboratory on several dates. Table 14 shows the analytical results. The detected concentrations are significantly lower than the corresponding field readings. The identified compounds and their percent of the total VOCs were: toluene 40 - 75 %, TCE 25 - 34 % and trans-1,2-DCE 0 - 29 %, varying with the sampling date. These three compounds were the only detected VOCs.

# Figure 17 SVE SYSTEM REMOVAL

#### Laboratory Results of Total VOCs in SVE Effluent

(ug/l)

Date	Vent	Vent and Sparge		
Sept. 11, 1991	1,565	2,015		
March 11, 1992	140	123		
June 3, 1992	43	53		

The VOC data collected from the field and the measured flow rate were used to calculate the pounds of VOCs removed from subsurface. The total through June 26, 1992 was 118 pounds. Table 13 shows the calculated pounds throughout the monitoring period. Please note that the air flow specified on this table is the total system air flow which includes bleed air.

A trend of the daily VOC removal rate is shown in Figure 18. The daily pound removal rate has ranged from 0.5 to slightly higher than 2 pounds. These values almost exclusively reflect unsaturated adsorbed removal, as the air sparge system was operational for only short times during this monitoring period. However, the increases observed on March 20 and June 3 were due to the air sparge system being operational.

#### 6.3.4 Individual Vapor Extraction Point Operation

A summary of the individual vapor extraction point operation is shown in Table 15. These data represent SVE operation only as the sparge system was not in operation. Individual vacuum, VOC levels and air flow are shown on this table. The vacuum data shows that the initial vacuums were below the design vacuum, but after continued system operation all points exhibited the design vacuum reponse (35 inches w.c.). The VOC data indicates that VEP-6 and VEP-3 are withdrawing the highest VOC levels with maximum reported PID concentrations of 70 and 27 ppmv, respectively. The other points are extracting low levels of volatiles, approximately 1 to 2 ppmv. These data correlate with the contaminant distribution data which determined that the majority of the VOCs were not in the unsaturated soil.

#### 6.3.5 Carbon Dioxide and Oxygen Utilization

In order to provide an indication of the biological activity and degradation occurring on site, carbon dioxide and oxygen concentrations were measured in the extracted SVE air stream. The carbon dioxide was measured

utilizing draeger tubes; the oxygen concentration was measured utilizing an explosimeter. Table 16 shows the reported values.

The oxygen levels show a 0.5 and 0.7 decrease from background levels, indicating oxygen utilization by bacteria. The carbon dioxide percentages were 0.17 and 0.27 percentage points above ambient air background levels, also indicating bacterial activity. With the measured data it is not possible to determine whether the bacterial activity is from degradation of VOCs or natural soil organic material.

#### Table 16

#### 6.4 Air Sparge System

#### 6.4.1 Operation Summary

The air sparge system was operating only intermittently during this monitoring period. Groundwater extraction system down time and the need to verify the actual air injection rates were the cause of the intermittent operation. The system was in operation for 21 days and evaluation of the subsurface response was performed during these operating times.

#### 6.4.2 Verification of Radius of Influence

The actual operational ROI was compared with the design ROI to verify effective system operation. The air sparge was operated at varying flows ranging from 12 to 24 cfm. At the end of each flow rate interval the dissolved oxygen concentration in the groundwater was monitored at varying distances. Table 17 shows the recorded values. The data indicate that at a flow rate of 20 cfm an effective ROI of 20 feet was measured (based upon an increase of at least 1 mg/l dissolved oxygen). This correlates with the design data, 24 cfm and 22 foot ROI. Additional dissolved oxygen data was collected to define background levels and to indicate the air sparge influence. Table 18 shows the results.

Air Flow Rate (cfm)	GT-1S (10 ft)	GT-6S (15 ft)	GT-3S (20 ft)
12	1.0	0.5	0
16	6.8	1.2	0.6
20	8.4	1.9	3.5
24	9.6	1.9	5.2

#### Reverification of Air Sparge ROI - Increase in Dissolved Oxygen Concentrations (ug/I)

#### 6.4.3 System Effectiveness

The SVE removal rate is the primary indicator of an effective air sparge system. As discussed in section 6.3.3, during several sparge system operation periods increases in the pounds removal rates of VOCs were observed. When the sparge system operates for a longer period, a better evaluation can be performed.

#### 6.5 Off-Gas Treatment System

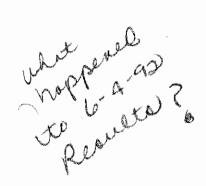

#### 6.5.1 Total System Effluent Concentrations

A temporary vapor phase carbon was installed to treat the off-gas from the treatment system. The off-gas concentration from the total remedial system, after the vapor phase carbon, was monitored monthly to document the VOC levels emmitted into the atmosphere. Table 19 contains the monitoring results.

#### Table 19

#### **Off-Gas Effluent Monitoring Results**

Monitoring Date	PID/FID (ppmv)	Laboratory (ppmv)
3/11/92		ND
4/10/92	0	NM
5/8/92	0.2	NM
6/26/92	0	NM

NM = not measured

31

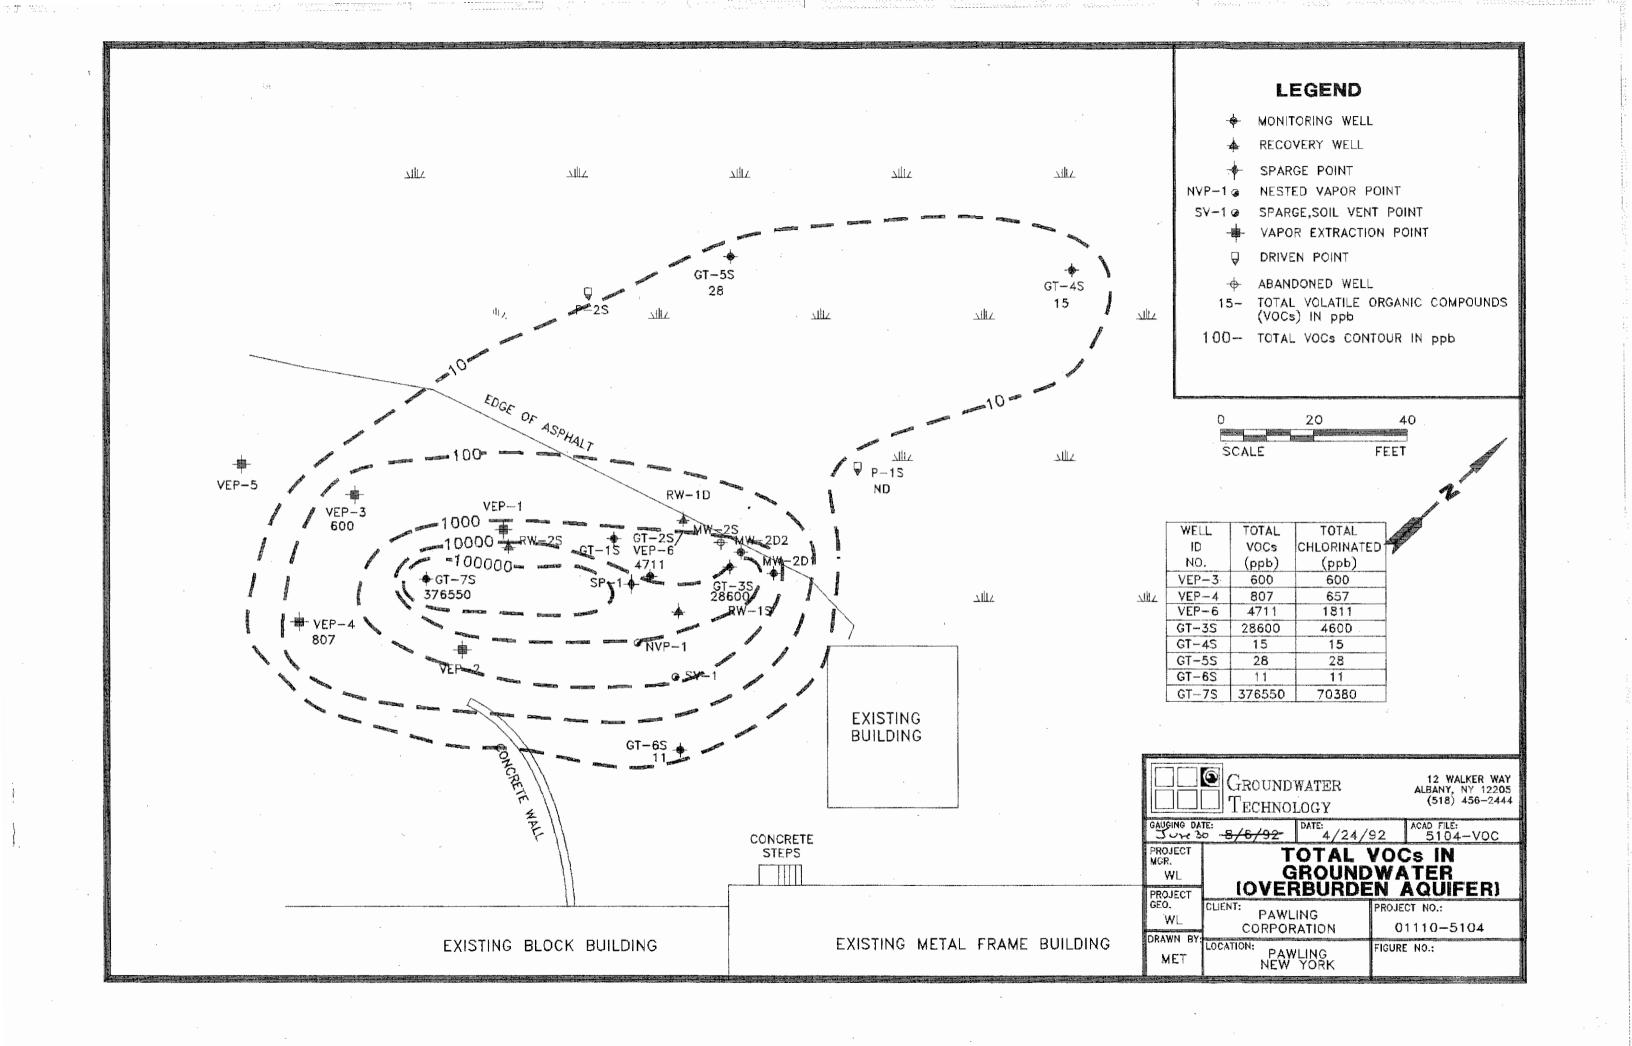

#### 6.5.2 Evaluation of Total Loading to Vapor Phase Carbon Unit

The vapor phase carbon was temporarily installed in order to collect off-gas concentration data to better evaluate permanent off-gas treatment systems. In order to do this, the total pounds of VOCs emmitted from the SVE system and air stripper were combined and an estimate of the total amount of carbon used to treat these VOCs was obtained. The total amount of carbon utilized during this monitoring period was 1,800 pounds. The vapor phase carbon cannister contains 2,000 pounds, therefore the first cannister is 90 % spent. The monthly carbon utilization was approximately 600 pounds. These calculations are based upon a carbon loading rate of 12 % by weight. A cost analysis of continued useage of vapor phase carbon will be developed prior to selection of the permanent alternative.

#### 6.6 Summary of Remedial System Effectiveness

Through June 1992, the remedial system at this site has removed 217 pounds of VOCs from the subsurface (118 pounds through soil vapor extraction and 99 pounds through groundwater extraction). The 217 pounds of the estimated 2,519 total pounds identified in the subsurface represents over 8 %.

To document the remedial effectiveness, a groundwater sampling round was performed on June 30, 1992. Concentrations decreased in GT-7S by 28 % and 94 % in GT-6S. Figure 19 shows the VOC contour map of the results. Additional data will need to be evaluated to document declining trends.

## **1.0 BACKGROUND**

The New York State Department of Environmental Conservation (NYSDEC) issued a consent order Case #3-1498/8712 to Pawling Corporation on February 24, 1988. This consent order alleged that non-contact cooling water discharged to the Swamp River through SPDES Permit #NY-000-4616 contained copper, zinc, and organic solvents. The NYSDEC also contended that storm water runoff from Pawling Corporation property, containing copper, lead, and iron in concentrations exceeding State ground water discharge limits, discharged into the ground water via a dry well.

The NYSDEC consent order required Pawling Corporation to perform a ground water investigation to identify the extent and source of the ground water contamination. Pawling Corporation contracted Groundwater Technology (GTI) (which later became Fluor Daniels, then IT Group which later was changed to Shaw Environmental) to perform the ground water investigation. A summary of the findings of this investigation are presented in a report titled "Ground Water Investigation, Pawling Corporation, Pawling, New York" dated September 2, 1988. Further delineation of potential upgradient sources was recommended as the final work step in the Preliminary Remedial Investigation.

## 1.1 Remedial Investigation

GTI reviewed background information and inspected the Pawling facility in May of 1988. Based on the information obtained, GTI installed borings into the overburden and bedrock at the Pawling Corporation facility in June of 1988. Monitoring locations were placed adjacent and down gradient to the suspected contaminant sources. Several of these borings were completed as monitor wells.

In June of 1988, the monitor wells were gauged and sampled. Water samples were also collected from production wells on site. Water and sediment samples from the stream were also collected during this monitor well sampling event. Some results exceeded the NYSDEC Water Quality Standards for toluene and 1,1,1-trichloroethene.

The objectives of the initial ground water study included:

- delineation of the concentration and extent of metal and solvent contamination in the ground water
- 2. determination of upgradient source potential impact to the Pawling property

- 3. evaluation of pathways of contaminant migration
- 4. obtaining information required for site remediation design

The initial ground water study met most of these objectives, however, an additional upgradient well couplet was installed to determine if off-site sources were contributing to the ground water contamination observed on the site.

The study also indicated that the ground water at the facility had a north-northwesterly flow direction with a 0.60 % gradient in the overburden aquifer and a 0.55% gradient in the bedrock aquifer.

In June of 1988, ground water quality information collected from the Pawling Corporation monitor and production wells indicated generally low levels of Priority Pollutant Volatile Organics across the site, with high levels in the vicinity of MW-2S, MW-2D1 and MW-2D2. Toluene and chlorinated compounds comprised the VOC's found. The area determined to be of the highest pollution was an area suspected of trenching and burning. Solvents were alleged to have been burned in these trenches in the late 1960's.

## **1.2 Remedial Investigation and Feasibility Study**

A remedial Plan was outlined and submitted to the NYSDEC entitled "Work Plan for Subsurface Remedial Design and Implementation, Pawling Corporation", dated May 25, 1989. This work plan was approved by the NYSDEC Division of Hazardous Waste prior to initiation.

The results of this work plan were utilized to select and design a remedial system for this site. An engineering report, "Remedial System Design, Pawling Corporation", dated February 26, 1991, was prepared and submitted to the NYSDEC. The plan was approved by the NYSDEC on June 17, 1991. The approved system consisted of groundwater extraction wells, air stripper and liquid phase carbon water treatment, air sparging, soil vapor extraction and vapor phase carbon off-gas treatment. The final monitor point system consisted of:

- one sparge point (SP-1)
- one combined sparge/soil vent points (VP-1 through VP-5) plus one existing monitor well (GT-2/VP-6)
- two overburden recovery wells (RW-1S and RW-2S)
- one bedrock recovery well (RW-1D) (presently not a pumping well)
- two bedrock monitoring wells (MW-2D1 and MW-2D2)

Monitor points were also installed to monitor the effectiveness of the remedial system. The points installed consisted of two monitor wells (GT-6S and GT-7S) and one nested vapor probe (NVP-1).

# 1.3 Ground Water Gradient

A complete ground water gauging round was performed on March 9, 1992 prior to remedial system start-up to document the initial site conditions. The overall site overburden and bedrock groundwater flow directions were similar to that of previous gaugings and indicated flow to the north toward Swamp River.

A comparison of the groundwater elevations in the deep bedrock and the overburden indicated that an upward vertical gradient of approximately 0.18 feet was present across the site.

## 1.4 Contaminant Volumes

The calculated contaminant volumes for the overburden were determined. The saturated phase contained the highest amount of VOC's, 1774 pounds. The unsaturated phase contained 700 pounds while the dissolved phase contained only 45 pounds. The total VOC's identified in the subsurface were found to be approximately 2,519 pounds.

The estimated contaminant mass calculations for the bedrock aquifer dissolved phase was 2 to 25 pounds. Due to the low porosity and small surface area of contaminant contact within the rock, it was assumed that the absorbed phase VOC volume was small.

## 1.5 Ground Water Recovery System

The groundwater extraction system, which include the air stripper, and the soil vent and air sparging system, was started on March 11, 1992 and is currently still in operation.

## **1.6 Dual Phase Extraction System**

A Temporary Dual Phase Extraction System was installed on GT-7S in August of 1995 because it was thought that it would enhance remediation at the site. The system was temporary and ran from August 1995 until November 1995 and again the following summer. In November of 1998 a permanent installation of the DPE System was completed. The DPE has run on and off again due to mechanical difficulties. It has been in operation since September 2004.

Operation of the DPE on a more regular, year round basis was implemented to address the final "hot spot" on the site. Remediation of this GT-7S area is the last step necessary prior to obtaining clean closure for the site.

## 2.0 System Efficiency

The ground water treatment system has been in operation since March of 1992. No significant concentrations have been removed by the groundwater treatment system since the autumn of 1997. This data indicates that the ground water treatment system has been successful in removing the majority of VOC's from the ground water within the zone of influence for pumping wells RW-1S and RW-2S.

The Soil Vent Extraction (SVE) System has also been operational since March of 1992. Currently, the data indicates that asymptotic removal conditions have been achieved utilizing this current treatment equipment.

Operation of the DPE system in the area of GT-7S appears to be helping to decrease the VOC concentrations surrounding GT-7S. Continued operation of the DPE also appears to be helping to decrease VOC concentrations in RW-1S and RW-2S. RW-1S has shown VOC concentrations below method detection limits for quite some time. RW-2S has been at or below 26 ppb for quite some time with most results below the detection limit. Concentrations in RW-1D have also shown a steady decline, with a high level of 461 ppb in May of 2001 that decreased to very low levels in October of 2004 (see table 2).

The DPE had not been running for about nine months in 2004 due to constant system mechanical failures. All those issues were resolved and the system was placed back on line in September of 2004. Results pre-September showed a steady decline with a "spike" after the system was brought back up. With the system up and running, these levels are projected to decrease over the next few months.

### 3.0 Bedrock Remediation

In December of 2000, The IT Group submitted a proposal to the NYSDEC (see Section 1) titled "Recommended Remedial Plan for OU-2 Bedrock Aquifer, Pawling Corporation" in which IT Corporation recommended that a Natural Attenuation Monitoring Plan be implemented. The deep wells on site have been continuously monitored and lab results indicate that VOC levels are very low. The current data suggests that the overburden remediation systems have effectively cleaned up the bedrock as well due to the upward vertical gradient which has been identified on the site. Based upon these site conditions, lack of down gradient receptors and the desire to protect the Great Swamp, Pawling Corporation has requested that the NYSDEC approve the preparation of this approach.

Mr. Jim Schreyer Construction Inspector New York State Department of Environmental Conservation Division of Environmental Remediation, Region 3 21 South Putt Corners Road New Paltz, NY 12561-1696

# Subject: Recommended Remedial Plan for OU-2 Bedrock Aquifer Pawling Corporation, Site Number 3-14-002 Village of Pawling, Dutchess County IT Corporation Project: 11105104

Dear Mr. Schreyer:

IT Corporation is submitting this recommended remedial strategy for the Operable Unit-2 (OU-2) Bedrock Aquifer on behalf of Pawling Corporation. IT Corporation has evaluated numerous assessment and remedial options for the Bedrock Aquifer at this site and is recommending Natural Attenuation as the preferred approach. Natural attenuation refers to naturally-occurring processes in soil and groundwater environments that act without human intervention to reduce the mass, toxicity, mobility, volume, or concentration of contaminants in those media. These insitu processes include biotransformation, dispersion, dilution, adsorption, volatilization, and chemical or biological stabilization or destruction of contaminants (U.S.EPA, 1998)1.

Biotransformation can often be a dominant process in the natural attenuation of chlorinated solvents. At chlorinated solvent contaminated sites, most of the solvent degradation occurs by reductive dechlorination (U.S.EPA, 1998)1. Reductive dechlorination is a microbially-mediated reaction whereby a chlorine atom on the chlorinated solvent is replaced by a hydrogen atom (Vogel and McCarty, 1987)2. The major dechlorination pathway is:

PCE ---- TCE ---- Cis,1,2-DCE ---- Vinyl Chloride ---- Ethene

1 U.S. EPA, 1998, Technical Protocol for Evaluating Natural Attenuation of Chlorinated Solvents in Ground Water. EPA/600/R-98/128, September, 1998.

2 Vogel, T.M. and P.L. McCarty, 1987, Abiotic and Biotic Transformations of 1,1,1-Trichloroethane under Methanogenic Conditions, Environ. Sci. technol., 21(12):1208-1213.

To support remediation by natural attenuation, it must be scientifically demonstrated that attenuation of the site contaminants is occurring at rates sufficient to be protective of human health and the environment. According to the "Technical Protocol for Evaluating Natural Attenuation of Chlorinated Solvents in Groundwater" (U.S.EPA, 1998), three lines of evidence can be used to support natural attenuation of chlorinated solvents including:

IT Corporation A Member of The IT Group

- 1. Observed reductions in contaminant concentrations along the flow path downgradient from the source of contamination.
- 2. Documented loss of contaminant mass at the field scale using:
  - a) Chemical and geochemical analytical data including decreasing parent compound concentration, increasing daughter compound concentrations, depletion of electron acceptors and donors, and increasing metabolic byproduct concentrations; and/or;
  - b) A rigorous estimate of residence time along the flow path to document contaminant mass reduction and to calculate biological decay rates at the field scale.
- 3. Laboratory microcosm or field data that support the occurrence of biotransformation and give rates of biotransformation.

Natural attenuation has been approved by EPA and numerous state agencies as an acceptable remedy at many sites assuming some scientific evidence of the processes can be presented.

Existing site-specific support for this remedy includes the following:

- The site hydrogeology and assessment data determined that the only source of chlorinated solvents was in the overburden. Bedrock groundwater flow is upward into the Swamp River and shallow overburden. Source cleanup of the overburden will remove the source of the dissolved levels which are found in the bedrock (which are present due to past pumping of deep bedrock production wells for water supply to the Pawling Corporation facility).
- The bedrock contains only low levels of chlorinated solvents which is conducive to cleanup by a less aggressive remedial strategy such as natural attenuation. The most recent sampling results collected on August 29, 2000 detected only cis-1,2-Dichloroethene and vinyl chloride, at 42 and 24 ug/L, respectively.

M:/93bc/Pawling/ProposedBedrockPlan2\_Nov00

<sup>1</sup> U.S. EPA, 1998, Technical Protocol for Evaluating Natural Attenuation of Chlorinated Solvents in Ground Water. EPA/600/R-98/128, September, 1998.

<sup>2</sup> Vogel, T.M. and P.L. McCarty, 1987, Abiotic and Biotic Transformations of 1,1,1-Trichloroethane under Methanogenic Conditions, Environ. Sci. technol., 21(12):1208-1213.

- The presence of cis-1,2-Dichloroethene and vinyl chloride which are TCE/PCE breakdown products indicates that degradation is occurring.
- The bedrock aquifer discharges into the wetlands downgradient of the site. The high organic content and complex pathways of flow within this system will allow continued degradation of the low concentrations of chlorinated solvents that have been detected in the bedrock near the former source area.
- The wetland that is situated adjacent to and downgradient of the Pawling Corporation site is the Great Swamp. The Swamp is currently not impacted by the existing chlorinated solvent plumes. This was documented by surface water and sediment sampling. If additional assessment and drilling in the swamp is required it will create the potential for extensive impacts to this protected wetland due to the disruption of native animal and plant species, as well as physical damage to the environs. IT Corporation solicited bids from several different drilling companies and all indicated that mobilization of personnel and drilling equipment into the Great Swamp will require the need for heavy equipment, access roads and construction of drilling platforms within the confines of the wetland area. This impact is far more of an environmental issue than the existing conditions. Pawling Corporation is very active in the protection of the Great Swamp and has provided additional information on this ecosystem (Attachment 1).

IT Corporation is recommending that a Natural Attenuation Monitoring Plan be prepared which provides all available documentation of natural attenuation processes occurring at the site. Some additional sampling of natural attenuation field parameters, such as oxidation reduction potential, methane, TOC, and chloride, will be proposed to assist in documenting the processes. Based upon the site conditions and desire to protect the Great Swamp, Pawling Corporation is requesting that the New York State Department of Environmental Conservation approve the preparation of the proposed approach.

If you wish to further discuss this proposed plan, please contact Wendy Leonard at (305) 818-2616.

Sincerely, IT Corporation

for

Wendy Leonard Senior Hydrogeologist

# A GUIDEBOOK TO THE GREAT SWAMP OF PUTNAM AND DUTCHESS COUNTIES,

Lower Hudson Chapter 41 South Moger Avenue Mt. Kisco, New York 10549 914-244-3271 FAX 914-244-3275

in contrast to the high costs of clean-up and remediation. Conservation of natural cases, the economic costs of wetlands protection are negligible or cost-effective which affect all of us, could be reduced or eliminated through education and participation of landowners, public officials, and involved citizens. In many resources does not automatically result in economic privation - not should it. During the past three centuries, over half of the nation's wetlands have been lost to agricultural, commercial, and residential development. New York State alone made aware of the significant services that wetlands provide for our communihas lost over 60% of its wetlands. Only in the past few decades have we been ties. These benefits, some of which are unique to wetland systems, include: BACKGROUND AND DESCRIPTION reducing the severity and frequency of floods recreational and educational amenities recharging of aquifers and reservoirs s filtration and settling of pollutants preducing the severity of droughts tenewable resources wildlife habitat scenic views

In light of this new appreciation of wedands and their functions, public agencies and private organizations have invested considerable resources in trying to protect wetlands throughout the country during the past thirty years. Regulations, such as the Clean Water Act and New York State Environmental Conservation Law, have helped to protect natural resources such as the Great Swamp for local communities that depend on them for economic and ecological vitality. Many municipalities, nonprofit organizations, businesses, and individuals have also made significant investments over the years to preserve the Great Swamp. These successes, however, are mirrored by decreases in water quality resulting from land use practices upstream of the wetlands, and elsewhere in the watersited. Specifically, pollutants, erosion, and runoff from buffer areas continue to lead to serious impairment and degradation of the wetland. These problems,

The Great Swamp is a freshwater wetland of approximately 4,800 acres located in Putnam and Dutchess Counties, New York. As with most watersheds, it is not defined by political or regulatory boundaries. The Great Swamp watershed includes parts of the towns of Southeast, Patterson, Pawling, and Dover in New York State, as well as a portion of Fairfield County in Connecticut. The wetland is actually divided into two drainages: one flowing north to the Housatonic River, then to Long Island Sound, and the other traveling south to the East Branch Croton Reservoir, which supplies 10% of New York City's drinking water. Many people in Putnam and Westchester Counties also depend on the Great Swamp watershed for drinking water supplies. The Great Swamp is one of the state's largest freshwater wetlands, and is fed by numerous streams of high water quality, with portions of the wetland designated as Class I by the State Department of Environmental Conservation. Dutchess and Putnam Counties have designated their respective lands in the Great Swamp as Critical Environmental Areas. The United States Fish and Wildlife Service recognizes the Great Swamp as a priority wetland in its 1990 Regional Concept Plan. The Great Swamp has been included as an area deserving protection in the 1986 New York State Environmental Quality Bond Act, as well as the more recent New York State Open Space Plan and Environmental Protection Fund.

The New York Natural Heritage Program has identified a number of rare species in the Great Swamp watersheds (north and south flows). These are summarized in the table below.

Threats to wetland integrity and water quality in the Great Swamp derive primarily from increases in water pollution and discharges, the result of changes in land use practices in the watershed over the past few decades. Although state and local government (and New York City, in the case of the southern flow) are involved in regulating certain land use activites in and near the wetlands, such regulations can be limited in their effectiveness. In some cases, lack of funding has led to enforcement difficulties. In any event, it is local residents who have the largest stake in protecting the Great Swamp. To a great extent, protection of the water quality and natural resources of the Great Swamp is now largely the responsibility of local communities that depend on it for drinking water, filtration, active and passive recreation, esthetics, open space, and economic return.

# Your Wetlands

The following pages provide a listing of sites that are available to the public for access it the Great Swamp. The wetlands, rivers, and streams provide tremendous resources for hiking, canoeing, birding, angling, and hunting. Take time to both enjoy the Great Swamp and its myriad of natural areas, and to become involved in protecting it. The sites you visit have been protected through the work of individuals such as yourself who serve the public, whether as volunwork of individuals such as yourself who serve the public, whether as volunteers, donors, or as part of a non-profit or municipal government body. Many others in the private sector are working to ensure the continued health and high water quality standards of the Great Swamp. We encourage you to become involved with the many ongoing efforts to protect the Great Swamp. This involved with the many ongoing efforts to protect the Great Swamp. # What You Can Do

- Support or volunteer for organizations working to protect the wetlands and water quality of the Great Swamp
- If you are a landowner with property in or near the wetland system, consider working with one of the active organizations to protect or improve management of wetlands and buffer areas on your land
- Voice your opinions to or become involved in local government
- Teach your children, or children you know, about the importance of wetlands
- Help to initiate or encourage school and community programs that focus on the Great Swamp

# VISION

Enhancement of the communities, economy and environment within the Great Swamp Watershed through conservation of the wetland ecosystem and environmentally compatible economic growth.

# **Executive Summary**

The Great Swamp is an ecological treasure nestled in the fast-developing southern Harlem Valley. One of the largest wetlands in New York State, it is located less than 60 niles from New York City in eastern Putnam and Dutchess counties. The wetland stretches nearly 20 miles across the five municipalities of Southeast, Patterson, Pawling Town, Pawling Village, and Dover.

The Great Swamp s set in a 62,343-acre watershed covering portions of both New York and Connecticut. Defined by topography, the watershed is the total surface area draining into the Great Swamp wetland. The Great Swamp Watershed contains two distinct basins: one flowing north and the other flowing south. The south flow basin is part of New Yorl: City's Croton watershed, supplying drinking water to Putnam and Westchester counties and New York City.

The Great Swamp provides ecological services that directly and indirectly benefit every watershed resident. The G eat Swamp improves water quality, recharges the aquifer, reduces flooding, provides habitst for plants and animals, and creates open space areas for recreation and scenic views. These serv ces also contribute to increased property values and provide opportunities for tourism. For the 40,000 residents who live near it and the more that one million people who depend on it for drinking water, the Great Swamp is a vital natural resource

Despite the value of this ecosystem, the Great Swamp is threatened. The watershed is at the edge of advancing suburban development expanding north from Westchester County and New York City. The area' rural quality of life and easy access to major commercial centers makes the watershed an attractive place to live. The watershed's attractivenesis, however, has fueled rapid population growth. Population in Patterson, for example, increased 204% between 1960-1990. If population in the watershed continues to grow at current rates, it will double in just 45 years.

Population growth generally leads to additional residential and commercial development. Much of this development is likely to occur along or near Route 22, an important commercial and transportation corridor that closely parallels the eastern edge of the Great Swamp. Regardless of where it is located, development that is poorly planned or incompatible w th environmental conditions is likely to impact the hydrology, wildlife, and habitat of the watersled, as well as reduce open space and obstruct scenic views. In addition, poorly planned development often increases the costs of government services such as education, fire, police, water, and sewage treatment. Taken together, such development tends to reduce the overall quality of life for watershed residents.

Growth and development trends in the watershed are likely to continue. Thus, conservation of the Great Swamp and enhancement of the local quality of life depend on development and economic growth that are compatible with the environment and consistent with community goals. The sustained health of each element – community, economy, and environment – is tied to the vitality of the others and must be pursued simultaneously. This premise underlies the initiatives proposed in this conservation strategy.

## **RECOMMENDED STRATEGIES**

Six initiatives are proposed to conserve the Great Swamp and foster compatible economic growth:

Increase public awareness of the Great Swamp

Foster local leadership on wetland and watershed protection

■ Strengthen wetland protections

Improve water quality

Protect plant and animal habitat

Encourage compatible economic development and improved land-use planning

# NCREASE PUBLIC AWARENESS OF THE GREAT SWAMP

The Great Swamp is a valuable resource, yet few people know exactly where it is, how to access it, or why it is important to protect. Much of the Great Swamp is privately owned and few recreation access points have even minimal information or amenities. Route 22 and Metro-North Railroad provide views of the wetland, but few travelers are aware of the vast ecosystem they are passing by. For teachers interested in using the Great Swamp as a learning resource, there is little coordination or support. To increase the public's understanding of the Great Swamp and enhance its value as a recreation and education resource, the following are proposed:

**Expand community outreach activities:** Expand naturalist-led excursions such as canoe trips and wildflower hikes, continue wetland cleanup days, and establish volunteer community monitoring programs such as water quality monitoring and

iv

### 10/12/2000 05:11 FAX 845 855 1937

### PAWLING CORP

Executive

Summarv

## macroinvertebrate monitoring.

**Create signage and publicity:** Post road signs identifying the Great Swamp and create a Great Swamp poster for Metro-North Railroad.

Improve managed recreation access: Improve canoe launch sites, maintain vegetative debris in river channels, establish the Maybrook Rail Trail, acquire additional, public recreation lands, and expand greenways and trails.

**Promote education:** Incorporate the Great Swamp into the local school curriculum, develop Great Swamp resource materials, establish a Great Swamp interpretive center, and organize a Great Swamp educators conference.

# OSTER LOCAL LEADERSHIP ON WETLAND AND WATERSHED PROTECTION

The Great Swamp is not constrained by political boundaries. The wetland traverses five municipalities and two counties and its watershed extends into sixteen different political jurisdictions across both New York and Connecticut. Actions in one jurisdiction may have environmental and fiscal impacts far beyond municipal borders. Pollutants, for example, can originate anywhere in the watershed and be carried by streams and groundwater into the wetland. Incompatible land uses and development can obstruct scenic views and reduce land values on a regional basis.

Each municipality has taken important steps to

# Official Recognition of the Great Swamp

PRIORITY CONSERVATION PROJECT: New York State Open Space Conservation Plan, 1992, 1995, 1998.

IMPORTMINT BIRD AREA: National Audubon Society, 1997.

CRITICAL ENVIRONMENTAL AREA, DUTCHESS COUNTY: Dutchess County Legislature, 1991.

CRITICAL ENVIRONMENTAL AREA, PUTNAM COUNTY: Putnam County Legislature, 1988.

PRIORITY WETLAND: United States Fish and Wildlife Service, Northeast Region, Regional Wetlands Concept Plan, 1990.

"IMPORTANT, SCARCE AND VULNERABLE" WETLAND: United States Fish and Wildlife Ser-: vice, Emergency Wetlands Resource Act, 1990.

SIGNIFICANT NATURAL AREA: Dutchess County Environmental Management Council, 1983.

NOMINATED AS A NATIONAL NATURAL LANDMARKI United States Department of Interior, 1982.

cLASS I WETLAND: New York State Department of Environmental Conservation. conserve its natural heritage, but most of these steps have been taken independently and are not implemented consistently across municipal borders. Thus, the benefits of these policies are limited to their area of implementation and may be undermined by conflicting policies in neighboring jurisdictions.

Hoth elected officials and community members have a role to play in establishing local environmental and economic policies. These policies will be more effective if implemented consistently across all watershed municipalities. To foster leadership toward a watershed perspective, the following are proposed:

Establish a Great Swamp Watershed Advisory Council: Establish a forum to facilitate communication, cooperation, and coordinated land-use planning amongst watershed communities.

Strengthen Friends of the Great Swamp (FrOGS):

Enhance this community coalition's ability to guide conservation and environmentally compatible development with additional funds to support research, education, and outreach activities, creation of an information center, and inclusion on distribution lists for development proposals affecting the Great Swamp.

Form a Wetland Watch Citizen Network: Form a network of trained citizens to augment state and local efforts to prevent illegal dumping, reduce pollution, and ensure that local natural resources are conserved.

# STRENGTHEN WETLAND PROTECTIONS

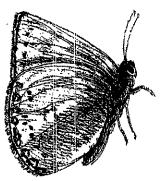

Prior to the mid-1970s, many people considered wetlands to be wastelands – lands that had little value unless drained, filled, developed, or converted to agricultural uses. This misconception contributed to a loss of more than half the wetland area in the continental United States existing prior to European settlement. This nation-wide decline in wetland area resulted in reduced populations of waterfowl, fish, and wildlife and caused an increase in destructive flooding, polluted waters, and erosion.

Local, state, and federal governments responded to these concerns with policies and regulations to protect the functions and values of wetland systems. These policies have slowed but not stopped the cumulative loss of wetlands. In Patterson and Southeast, 753 acres of wetland were lost between 1963 and 1991 (Smith and DeGloria, 1993).

In New York, wetlands 12.4 acres or larger are mapped and regulated by the state. Although these protected areas include 4,202 acres of the Great Swamp (known as DP-22), a recent analysis suggests that the full extent of the Great Swamp is actually 6,768 acres -38% larger than that mapped by the state (see box on p.2). This discrepancy leaves many wetland areas without state protection.

Even with state and federal oversight, primary responsibility for wetland and natural resource

protection rests with local officials. In the Great Swamp Watershed, these protections vary considerably across municipalities, leading to incomplete and inconsistent protection for wetlands and natural resources.

The cumulative impacts of land-use decisions must be taken into account at all levels to ensure adequate protection of wetlands and the valuable services they previde. Recommendations to strengthen wetland protections focus at the local, state, and federal levels:

Improve implementation of state and federal wetland programs: Re-deline ate the boundaries of the Great Swamp (DP-22) and other wetlands based on new data, re-classify we lands connected to the Great Swamp as Class I wetlands to provide them with a higher degree of protection, exempt the Great Swamp from U.S. Army Corps of Engineers Nationwide Permit:, and protect wetland buffers. Strengthen and harmonize local regulatory controls and enforcement: A: the local level, wetland and natural resource protections could be enhanced if each municipality vere to regulate wetlands 1/4 acre or larger, exter d wetland and stream buffer zones where appropriate, restrict building in floodplains, establish wetland overlay zones, adopt no net loss of wetlands policy, and establish a wetland tax policy.

# MPROVE VYATEL QUALITY

Water is an essential resource for personal, economic, and ecological reasons. Wetlands such as the Great Swamp p ay a vital role in maintaining good water quality.

Based on stream sampling data, water quality in the south flow of the Great Swamp is mixed. Nutrients and polli tants in the Great Swamp's East Branch Croton River are measurably elevated downstream as compared with headwater values (New York City Department of Environmental Protection, 1933). However, with the exception of phospl orus, water quality parameters generally remain within an acceptable range based on designated uses and ecological functions. Nonetheless, recent stream sampling data (New York City Department of Environmental Protection, 1998) show that conductivity, temperature, pH, dissolved oxygen, fecal coliform and phosphorus were all measured outside of this range at some time between 1993 and 1997.

Water quality in the Great Swamp is affected by the accumulation of pollutants and nutrients originating throughout the watershed. Major sources of pollution include sentic waster disposal systems, road salt, animal wante from horse and livestock farming, impervious surfaces, golf courses and residential lawns. Sixteen sewage treatment plants discharge into the Great Swamp or its tributaries. Together, these plants accumulated 222 violations of their effluent discharge (SPDES) permits between 1995-1998 (New York State Department of Environmental Conservation, 1998, 1999).

To improve water quality in the Great Swamp and throughout the watershed, the following are proposed: **Reduce pollution from septic systems:** Reduce excessive pollution discharge from septic systems by ensuring adequate septic spacing, establishing regular pumping and inspections, creating septic pump-out districts, and promoting septic education programs. **Reduce pollution from road salt:** Reduce road salt in the Great Swamp by removing salt piles from locations near the wetland, covering salt piles, exploring alternatives to the use of salt, marking roadways near the Great Swamp as low salt areas, and limiting sand-salt mixes.

**Reduce pollution from livestock waste and agricultural run-off:** Reduce pollution from farm activities by creating natural vegetation buffers, modifying tillage practices, and constructing on-farm catchments.

Reduce pollution from storm-water run-off: Prevent untreated storm-water run-off from entering wetlands and streams by creating first flush catchments and maintaining stormwater systems.

**Reduce other sources of pollution:** Reduce pollution inputs throughout the watershed by enrolling golf courses in environmental certification programs, limiting railroad herbicide spraying, preventing dumping, holding additional hazardous waste disposal days, and improving Putnam Lake water quality.

**Protect and monitor water resources:** Provide enhanced protection to streams by re-classifying trout streams to require higher water quality standards and establish a monitoring program for water resources in both the north and the south flow basin.

# ROTECT PLANT AND ANIMAL HABITAT

Wetlands are among the most biologically productive ecosystems on Earth (Tiner, 1997). The Great Swamp wetland and watershed supports 31 different natural vegetation communities (Olivero, 1998) and numerous documented species of amphibian, reptile, butterfly, dragonfly, and bird. However, the survival of many plant and animal species in the Great Swamp is threatened by the loss, fragmentation and degradation of habitat.

Ecological protection priorities focus on 46 rare plant and animal species and significant natural communities found in the Great Swamp Watershed. The Great Swamp contains ideal habitat for known populations of bog turtle (Clemmys muhlenbergii), a federally protected species under the Endangered Species Act. It supports 19 rare plant species and eight significant natural communities. A recent study in the Great Swamp (Klemens, et al., 1999) found that large, relatively undisturbed landscape blocks support the greatest diversity of

wildlife. Disturbance factors such as roads, development, invasive species, and pollution all tend to increase fragmentation, reduce habitat cover, and inhibit migration between habitat types. Species requiring specific habitat types or combinations of habitat types will tend to be eliminated first, leaving only the generalized or common species.

Integrating conservation and compatible economic growth requires sufficient knowledge of species habitat needs and the effects of various land uses on biological integrity. This information guides protection efforts and informs land use polices. To conserve the Great Swamp's biological diversity, the following are proposed:

Acquire habitat and recreation land: Create a land protection and management plan, acquire lands forfeited due to tax delinquency, and pursue land conservation efforts among land trusts and conservation organizations.

Protect and monitor species and habitat: Conduct additional species surveys, continue studying the effects of land-use practices on biological diversity, protect the bog turtle and its habitat, post turtle crossing signs, identify and protect vernal pools, control invasive species, and incorporate ecological concerns during railroad maintenance.

# ENCOURAGE COMPATIBLE ECONOMIC DEVELOPMENT AND LAND-USE PLANNING

Compatible development is the production of goods and services, the creation and mainterlance of businesses, and the pursuit of land uses that conserve the environment, enhance the local economy and achieve community goals (Center for Compatible Economic Development, 1997). This three-pronged approach recognizes that maintaining a high quality of life requires that each of these components – community, economy, and environment – be in balance and reinforce one another.

Residential and commercial development often results in loss of natural areas, increased impervious surfaces, and fragmentation of habitat. However, if new growth is managed in a waterished context, homes and businesses can be located and designed to have a minimal impact on streams, wetlands, and waterbodies. A key component of achieving compatible development is waterished planning. This process directs proposed development to the least sensitive areas and attempts to control the amount and location of impervious cover in a watershed. Some areas are designated as growth areas, while others are partly or fully protected from future development (Schueler, 1998).

Wetland regulation and other forms of land conservation are commonly perceived to be detrimental to the municipal tax base. However, studies show that residential land uses consistently cost more in services than they pay in taxes (American Farniland Trust, 1997). Across New York State, taxes are generally higher in towns that have more residents, more commercial property, and more jobs (Brighton, 1997). On the other hand, studies show that the fiscal impact of conservation and compatible development is, on net, generally positive (Schueler, 1998; Caputo, 1979).

To promote compatible economic development and regional land-use planning, the following are proposed:

Design a watershed conservation and development plan: A comprehensive watershed land-use plan should be devised that identifies sensitive wetlands, natural resources, floodplains, steep slopes, wildlife migration corridors, conservation open space, and other unbuildable areas. The remaining buildable lands should be identified and developers should be encouraged through a variety of incentive mechanisms to direct residential, commercial, and industrial development toward those areas.

Adopt a Great Swamp Critical Environmental Area Management Plan: Putnam and Dutchess counties should adopt management plans for the Great Swamp Critical Environmental Area.

Incorporate Great Swamp conservation in the Croton #Ian for the New York City Watershed: Because the Great Swamp is a significant wetland that plays an important role in maintaining water quality in New York City's Croton Watershed, special attention should be paid to incorporating Great Swamp conservation efforts into the Croton planning process in Patterson and Southeast.

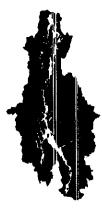

Utilize available land-use planning tools: Numerous land-use planning tools are available to municipalities and should be considered when appropriate. These include overlay zoning, floating zones, cluster development, incentive zoning, transfer of development rights, agricultural zones, and intermunicipal agreements.

# Executive Summary

vii

# VISION

Conservation of the Great Swamp's large wetland and watershed system through local community support and municipal leadership across political boundaries.

# The Wetland and its Watershed

# HE GREAT SWAMP AND THE SOUTHERN HARLEM VALLEY

The Great Swamp is an ecological treasure. Set in a dynamic landscap: of farms, hamlets, forests and commerce, the Creat Swamp is a vast wetland ecosystem that plays a valuable role in maintaining water quality, flood control, wildlife habitat, recreation and rural quality of life. For the 40,000 residents who live near it and the more than one million people who depend on it for drinking water, it is a vital natural resource.

The Great Swamp is one of the largest freshwater wetlands in New York State. Nearly twenty miles long, its 6,768 acres traverse the five municipalities of Southeast Patterson, Pawling Village, Pawling Town, and Dover in eastern Dutchess and Putnam counties. New York State ranks the Great Swamp as a Class I vetland, meaning it provides the most critical of the state's wetland benefits.

Identified as DP 22 by New York State, the Great Swamp wetlan I spans two watersheds that divide imperceptibly at Pawling; into a north and a south flow. In the north flow basin, the Swamp River runs through the Great Swamp, originating near Mount Tom and winding northward through the wetland from Pawling to Wingdale and Dover Furnace. A small dam near Dutchess County Route 26 artificially creates the northern boundary of the Great Swamp vetland. The Swamp River, however, continues north where it enters the Ten Mile River, eventually joining the Housatonic River and ultimately the Long Island Sound.

In the south flow basin, the East Branch Croton River flows through the Great Swamp, originating near Purgatory Hill and traveling through Pawling Village before entering the wetland and continuing south through the towns of Pawling, Patterson and Southeast. The Muddy Brook extension of the Great Swamp flows north from Ice Pond and joins the East Branch Croton River near Pine Island. The wetland's southern extent ends at Milltown Road where water flows into the East Branch Reservoir. The south flow basin of the Great Swamp is the northern-most source of the Croton System, part of New York City's drinking water supply.

The combined north and south flowing basins (hereafter referred to as the Great Swamp Watershed) cover a total land area of 62,343 acres (approximately 97 square miles). The Watershed is nestled in the Harlem Valley and extends into sixteen different political jurisdictions, including seven municipalities within New York and three within Connecticut. The watershed is bounded to the south by the entrance to the East Branch Reservoir and the hills along the south side of Federal Hill Road in Southeast. To the north, it is bounded by Dutchess County Route 26 and the hills above Dover Furnace in Dover. The watershed is bounded to the Harlem Valley, extending into Union Vale, Beekman, and Kent to the west and into Sherman, New Fairfield, and Danbury Connecticut to the east.

Elevations in the watershed range from a low of 390 feet above sea level at the wetlands southern endpoint in Southeast to a high of 1,336 feet along the eastern ridgeline in northeast Patterson. Elevations in the Great Swamp wetland range from 440 feet at the directional divide in Pawling to 390 feet at the southern endpoint and 417 feet at the northern endpoint in Dover.

The Great Swamp is part of a network of wetlands, rivers and waterbodies throughout its watershed. Defined by topography, the Great Swamp Watershed represents the landscape's total surface area that drains into the Great Swamp wetland. Much of the rain and snow falling anywhere within the watershed flows into tributaries or underground through the soil, eventually discharging into the wetland. The watershed is comprised of 18 sub-basins, each with a network of tributary streams draining into the Great Swamp (see map p.26). More than 800 wetlands are located within the Great Swamp Watershed.

Upland areas of the watershed are integral components of the wetlands ecology. As water drains to the lowest point in the watershed – the Great Swamp – it picks up tiny particles of soil, oil, road salt, animal manure, fertilizers, pesticides, and other pollutants from upland areas. Because much of the water in the Great Swamp originates in the upland areas of the watershed, land uses and pollution sources throughout the watershed affect water quality in the wetland and in the aquifer. Upland areas of the watershed are also critical habitat for wetland species such as birds, reptiles, amphibians, and mammals. The term wetland refers to a variety of aquatic and semi-aquatic systems that includes bogs, swamps marshes, fens, peatlands, wet meadows and floodplain forests. These systems can vary markedly ir size, landscape position, and type of vegetation They can also vary in frequency and degree of water present, ranging from permanently flocded to seasonally or intermittently flooded. Some wetlands such as vernal pools, appear dry at certain times of year, but still provide vital wetland functions.

Wetlands are typically defined by a combination of three elements: water, vegetation, and soil As the name implies, wetlands are lands where periodic saturation with water is the dominant factor Because water is generally present at the surface or in the root zone, wetlands support vegetation that is adapted to wet conditions (hydrophytes) (Mitsch and Gosselink, 1993). Wetlands are generally associated with hydric soils that differ from adjacent upland soils. For regulatory delineation purposes, the U.S. Army Corps of Engineers evaluates each of these features. New York State defines a wetland primarily on the presence of aquatic or semi-aquatic vegetation. Soils or hydrology are used in cases where vegetation is not definitive.

Freshwater wetlands such as the Great Swamp are often transitional areas, forming a continuous gradient between uplands and open water (Mitsch and Gosselink, 1993). They support both terrestrial and aquatic species of plants and animals and they can vary in size depending on the level and frequency of flooding. As such, they can be difficult to delineate accurately. Previous studies suggest that New York State wetland maps significantly underestimate the full extent of the Great Swamp and other wetlands in the watershed (see box this page).

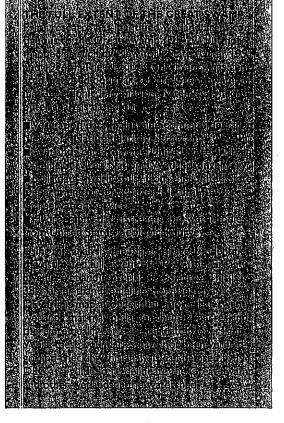

# Benefits of the great swamp

The Great Swamp provides numerous ecological services that directly and indirectly benefit every watershed resident. These services, provided free by nature, enhance the surrounding communities, their economies, and the overall environment. These services include:

■ Water filtration: The Great Swamp improves water quality by slowing water velocity and facilitating complex biochemical processes. In slow moving water, sediments and pollutants settle to the wetland bottom where soils and vegetation absorb, sequester, or transform certain harmful pollutants.

**Ground-water recharge:** In times of drought, the Great Swamp recharges ground-water aquifers and buffers the effects of low rainfall periods.

**Flood control**: Much of the Great Swamp is a

broad floodplain forest that detains and absorbs stormwater run-off. The wetland vegetation and flat gradient reduce the water's velocity, thereby reducing erosion and the potentially destructive effects of floodwaters on downstream or adjacent property. This function is particularly important for lands downstream from developed areas because impervious surfaces such as buildings and parking lots tend to increase the quantity and velocity of stormwater run-off.

# Flabitat for plants, animals and rare species: The Great Swamp is part of a highly productive wetland and upland ecosystem that supports a remarkable diversity of plants and animals. Through decomposition of abundant organic matter, the Great Swamp provides nutrients for vegetation and food for small invertebrates and forage-fish that in turn become food for animals higher up the food chain. Many wildlife species require wetlands for survival, while others use it as a safe connective corridor between neighboring habitats. Many migratory bird species use the Great Swamp as a refueling stop. Rare species such as the bog turtle and rare natural communities such as fens are integral parts of the Great Swamp's biological diversity.

**Recreation, open space and scenic views:** The vast natural areas of the Great Swamp wetland and watershed offer extensive opportunities for canoeing, hiking, hunting, fishing, bird watching, painting, photography and solitude.

Education: The Great Swamp is a diverse biolog-

The Wetland and its Watershed

ical laboratory used by students, teachers and researchers in local elementary and secondary schools as well as colleges, universities, and research institutes throughout the area. Studies and lessons regarding biology, ecology, archeology, local history, geology, water sciences, environmental studies, art, and other topics have been conducted in the Great Swamp.

■ Benefits to business and the local economy: Because water filtration, flood control, and groundwater recharge are provided naturally, the Great Swamp reduces the need for tax revenue to supply these functions through costly technology. By maintaining open space and scenic beauty, it keeps property values high. And because of the recreational opportunities it affords such as hunting, fishing, birding, canoeing, hiking, and wildlife viewing, it also attracts visitors to the area who in turn contribute to the local economy.

# THE HUMAN CONTEXT

#### HISTORY<sup>1</sup>

Humans are believed to have settled near the Great Swamp for more than 8,000 years (Tompkins, 1979). Pottery artifacts and other evidence of early occupation I are been found at rock shelters and other sites near the wetland in Southeast, Patterson and Pawing. Algonquian-speaking Native Americans of the Wappinger Confederacy settled in the area long ago, probably attracted by the wetlands abundant supply of root plants, fish, waterfowl and fur-be aring maramals.

European settlement was facilitated by Henry Hudson's exploration of the Hudson River in 1609. By 1633, the borders of New York and Dutchess County we e established. The Treaty of Dover in 1734 added the strip of land known as the "Oblong', and in 1812 the Philipse Patent split off from Dutche s County to become Putnam County. Quakers inumigrated to the area in the 1750s, as did other: from New England and Long Island. Small settlements developed near streams and well-traveled roads. Iron mines and foundries were establ shed, as were mills, agriculture and cattle farms.

The earliest written mention of the "Great Swamp" is found in the Indian-Dutch Treaty of 1617 (Bodor), which stated that furs from the Great Swamp "were nost desirable" (Hillery, undated). The Great Swamp covered a large extent of area on both sides of the East Branch Croton River, and residents believed that valuable and fertile land would be created if the wetland were drained. In 1793, the New Yorl: State Legislature approved a petition from reside its stating that the channels of the Croton and it: tributary; Muddy Brook, were "greatly obstructed by fallen trees and ancient beaver dams, and that if these obstructions could be removed, and the channels cleared and straightened, a large amount of land could be made into valuable pasturage" (Pelletreau, 1886). Funds were appropriated and some attempts were made to drain the Great Swamp, but without success. More attempts were made in the 1840s, also without success (Putnam Ledger, 1978). Plans for a canal along the Harlem Valley were proposed but then abandoned (Wilson, 1907).

The arrival of the railroad in 1848, built through the Great Swamp, connected lower Dutchess, Putnam, and Westchester counties to New York City and opened the city's markets to Harlem Valley goods. By the 1850s the railroad was carrying 3 million passengers each year in addition to iron ore, animals, lumber, and dairy products. The railroad fueled the region's economic and population growth and transformed Harlem Valley's cattle industry into New York State's largest milk producing area. Tourism and second homes were also made possible by the railroad, which put Quaker Hill and other areas of the watershed within comfortable reach of New York City.

By the mid-19th century, the area's milk, dairy, and iron industries were all thriving and many Harlem Valley residents were prospering. At the same time, New York City's population was burgeoning and outbreaks of cholera, typhoid, and yellow fever were common due to polluted wells and water supply. The city's response was to seek water from outside the city by damming the Croton River and building a 40.5 mile long aqueduct to Manhattan. This soon proved insufficient, and in 1885 construction of the New Croton System commenced. Completed in 1911, the system consisted of a network of 12 reservoirs, including the East Branch Reservoir, which receives waters from the south flow of the Great Swamp Watershed (Southeast Museum, 1998).

The economic and physical landscape of eastern Putnam County was dramatically altered by construction of the Croton reservoirs. Much of the low-lying farmland was flooded, and reservoir-adjacent properties were condemned to protect water quality. East Branch Reservoir was sited in the former location of Southeast Center, the original center of the town. Over two hundred buildings, including churches, stores, and homes, were either destroyed or relocated to accommodate the reservoir. By the late 1880s, Southeast's population had dropped considerably due to the loss of farmland and destruction of important industries (Southeast Museum, 1998).

## WATERSHED COMMUNITIES AND THE REGIONAL ECONOMY

Primarily rural and residential, the Great Swamp Watershed is currently at the edge of advancing suburban development migrating north from

New York City and Westchester County. Comprising the communities of Southeast, Patterson, Pawling, and Dover, the area offers a rural quality of life, lower housing prices than to the south, and proximity to the New York metropolitan area. The suburban advance has affected the southern watershed communities more than the northern communities. In 1998 Putnam County had the highest population growth rate and the highest median income in New York State (U.S. Census).

Watershed residents are within commuting distance of major commercial and employment centers such as Danbury Connecticut, White Plains, Poughkeepsie, and New York City. According to the 1990 U.S. Census, 43% of Paviling workers commute more than 30 minutes to work. The average commute to work for Patterson residents is 33 minutes. In Patterson, 69% worked outside Putnam County including 17% who worked outside New York State.

New York State Route 22 is the major northsouth transportation corridor and the primary commercial route in the watershed. Constructed over the old Harlem Valley Drovers Road used by farmers and dairymen taking produce to New York City markets, Route 22 links the watershed towns and closely parallels the Great Swamp wetland. Much of the future commercial and industrial development is likely to occur along or near this road. Transportation planners are preparing to accommodate recent population growth by widening Route 22 and extending Metro-North commuter railroad service between the watershed towns and New York City (Peters, 1997), thus facilitating growth trends to continue further north.

Commercial activities in the watershed consist primarily of light industry, agriculture, retail and services. Small, growing companies are locating in the watershed and more workers are telecommuting or traveling to the city only when necessary. The tourism and second home industry is growing, as are service businesses that cater to dommuters (Schibanoff, 1997).

The area's scenic resources, open spaces, and historic sites give tourism the highest potential for future economic growth in the Harlem Valley, according to a study of economic development in Dover, Amenia, Northeast, and Pine Plains (Abeles Phillips Preiss & Shapiro, 1991). A recent analysis (Davidson-Peterson Associates, Inc., 1997) shows tourism in Dutchess County grew 38% over the last five years. Tourism is the second largest job producing sector of the county's economy after manufacturing, supporting 9,148 jobs. Dutchess County attracted 3.1 million visitors who spent \$334.6 million in 1997. While not specific to the Great Swamp Watershed, this data highlights the potential economic benefits of promoting and protecting the recreational opportunities and science

# Pawling Corporation: A Great Swamp Neighbor

The Pawling Corporation, a rubber and plastic products manufacturer, has been located adjacent to the Great Swamp in the Village of Pawling since 1945. Like many businesses prior to the 1970s, it did not appreciate the value of wetlands. In the late 1960's Pawling Corporation burned solvent waste on site. In 1988, these practices were linked to excessive concentrations of volatile organic compounds in on-site ground-water. The company began remediation of the contaminated ground-water in 1992. Further investigation revealed that the Great Swamp's soils and organic processes actually reduced the spread and impact of the pollutants and substantially reduced the cost of the cleanup.

With the cleanup process nearly complete, Pawing Corporation has found that it continues to benefit by keeping the wetland clean. It has initiated community and employee education programs such as "Swamp: Sponge or Filter" and "A Safe Environment: Guide to the Great Sv/amp" to create greater awareness of the value of wetlands. The financial, environmental, and aesthetic benefits of the Great Swamp have led the Pawling Corporation into a partnership with the wetland for their mutual benefit and success. Pawling Corporation is also a member of Friends of the Great Swamp.

beauty of the Harlem Valley. Tourism is an area in which economic growth can be compatible with conservation of natural resources.

### PUBLIC OPINION: LOCAL ATTITUDES TOWARD CONSERVATION AND DEVELOPMENT

In September 1997, a public opinion survey<sup>2</sup> was conducted throughout the Great Swamp Watershed to gauge community attitudes toward conservation and development issues (The Kitchens Group, 1997). The survey of registered voters living in the watershed revealed that most community members desire a rural quality of life, strong natural resource protections, clean water, and a balance between economic growth and environmental protection.

The survey found that the Great Swamp is a well-known landmark in the local area. Eighty-five percent of residents polled consider the Great Swamp part of the community's heritage. More than one-third (36 percent) visited the Great Swamp within the past year. They also believe the Great Swamp plays an important role in their quality of life. They say it prevents flooding (89%), protects wildlife habitat and endangered species (93%), contributes to the scenic beauty of the area (94%), and provides outdoor recreational opportunities (88%).

# The Wetland and its Watershed

# COMMEN NAME

# II. Animals, Plants and Natural Communities Found in the Great Swamp

# OC CUIRENCE STATUS

Accidental occurrence with only one or two sightings in the past three years during the breeding season.

Breeding activity is confirmed or expected due to regular signing during the breeding season.

Seen during the migration season in

targer numbers than in breeding season. Integular occurrence during

the non-breeding season.

Possible breeder based on a few sightings during the breeding seasori, year round resident and

breader.

Visitor seen regularly during breeding season, but not showing any characteristics of breeding activity. Overwinters in the Great Swamp in much greater or smaller numbers than in breeding seasorl.

Source: NY Natural Heritage Program

timing and predictability, and rate of change of hydrologic conditions) can be caused by development, drawdown of ground-water by underground wells, and channeling of streams. Alterations in water flow regime may directly kill species that depend on specific flow conditions or may indirectly alter natural communities by creating conditions suitable for less desirable species.

■ Invasive species and competition: Common reed (*Phragmites australis*) and purple loosestrife (*Lythrum salicaria*) represent the two most abundant invasive species threatening the integrity of the Great Swamp. At least 573 acres of wetland in the watershed contain one or both of these invasive plants (Olivero, 1998). Brown trout (Salmo trutta), introduced by the state for sport fishing, compete with native fish. Orconectes rusticus, an invasive species of crayfish, has recently entered the watershed and may soon cause the extirpation of some native species of crayfish (Murphy, 1998). Zebra mussels (Dreissena polymorpha), while not yet present, may also pose a future threat to aquatic species if they are introduced.

■ Direct mortality can result from a number of threats mentioned above. Road crossings, hunting, trapping, fishing, species collection, off-road vehicles, trampling, and predation also cause direct mortality to plants and animals.

# The Bog Turtle: A Species Under Threat

In 1997, the bog turtle (*Gemmys muhlenbergii*) was listed under the federal Endangered Species Act as a "threatened" species. It is also officially listed as an endangered species in New York and is listed on Appendix 1 of the Convention on International Trade in Endangered Species (CITES). Based on documented losses of bog turtles and their habitat, the northern population, which ranges from Maryland to New York and western Massachusetts, has declined by at least 50 percent over the last 20 years (U.S. Fish and Wildlife Service, in Bay Journal, 1997). Many consider it the rarest North American turtle.

First identified by scientists in 1801, the bog turtie is one of North America's smallest turtles with the upper shell of adults measuring just 3 to 4.5 inches long. The bog turtle is distinguishable from other species by a large orange, yellow, or red spot on its neck. It is capable of living twenty years or more in the wild (Klemens, 1993).

**RANGE:** The bog turtle is found in twelve states sparsely distributed over a discontinuous geographic range extending from New England to northern Georgia, A 250-mile gap between southern Virginia and northern Maryland separates the species into distinct northern and southern populations. In New York, the bog turtle is concentrated primarily in the southeastern corner of the state. They have been documented in Columbia, Dutchess, Putnam, and Orange counties, but are believed to be extirpated from Westchester and Rockland counties (Klemens, 1993). Small populations still survive in western New York, but are in decline. Nearly all southeastern New York's bog turtle habitat (99%) occurs on private lands; the remaining one percent is found on state lands (Breisch et: al., 1994; Federal Register, 1997).

■ HABITAT: Bog turtles are usually found in wetland areas that are a mix of micro-habitats which include dry pockets, saturated areas, and areas that are periodically flooded. They generally live in small, ground-water-fed wetlands with shallow rivulets of water, lots of mud to burrow into, and sun-bathed sedge tussocks on which they lay their eggs. Bog turtles appear to require calcareous (calcium carbonate charged) ground-water in at least portions of their habitat complex. They depend upon this diverse hydrological system, ! utilizing shallow water in spring and returning to deeper water in winter (Klemens, 1993; Kiviat, 1993; Utter, 1994)

The Great Swamp watershed is ideal habitat for the bog turtle. The calcareous bedrock, the broad, relatively flat basin with low gradient, slow moving streams, relatively large number of calcareous seeps and network of streamside riparian corridors provides the basis for suitable bog turtle habitat (Utter, 1994).

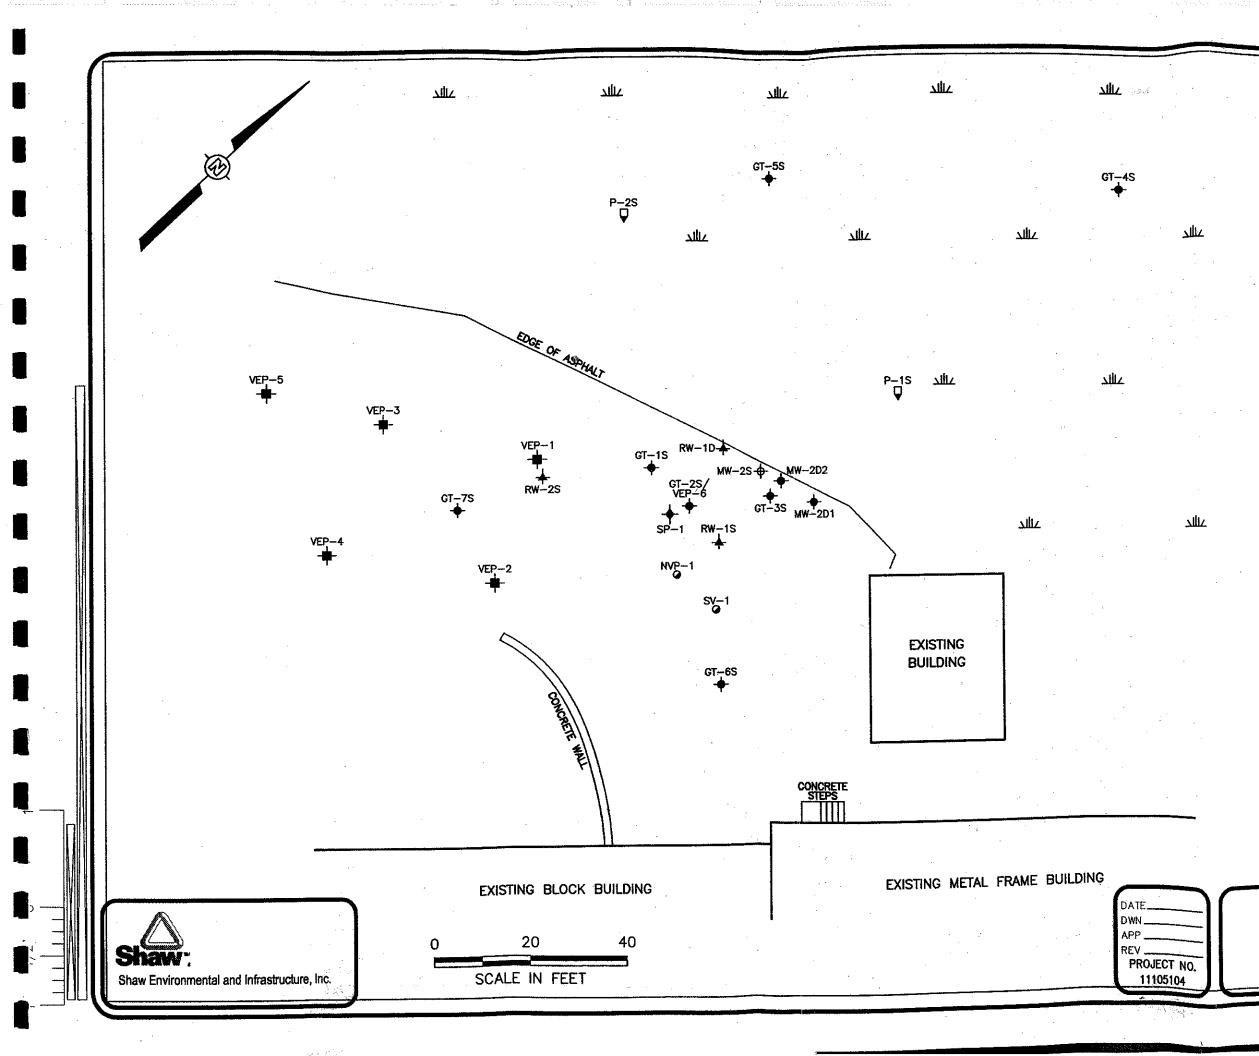

THREATS: Loss and fragmentation of its wetland habitat, coupled with illegal collection by poachers and mortality while crossing roads, are the main

causes of the bog turtle's decline. Degradation of their habitat is often caused by the cumulative effects of land use changes outside wetlands as well as human alteration of unprotected wetlands and colonization of fen areas by invasive species such as common reed (Phragmites australis) or purple loosestrife (l.ythrum salicaria). These changes can alter water chemistry and flow and create barriers to trav-

el between different habitat types. Nearby development also threatens the turtle by creating habitat for skunks, raccoons, opossums and other specie: that may prey upon bog turtle eggs.

■ ENDANGERED SPECIES ACT: The federal "threatened" listing under the Endangered Species Act means that federal agencies must consult with U.S. Fish and Wildlife Service on federally funded projects such as highway construction which could affect a listed species or its habitat. Activities which may jeopardize a listed species or its habitat are not authorized under Nationwide Permits. Any work that may affect the bog turtle must involve notification of the U.S. Army Corps of Engineers and coordination with the U.S. Fish and Wildlife Service. The listing makes sale of bog turtles illegal. Funding for research, habitat restoration and land protection measures may also become available.

# Subject: Status Report April 2003 through March 2004 Shaw Environmental, Inc. Project: 11105104

Dear Susan:

This status report details the results of operation of the groundwater pumping and treatment system and dual phase extraction (DPE) system for the period from April 2003 through March 2004. A copy was forwarded to the New York State Department of Environmental Conservation (NYSDEC).

The remedial system has been in operation since March 9, 1992. During the current twelve month reporting period the groundwater treatment system and the DPE system were operational for two out of the twelve months, due to various mechanical problems causing the system to shut down between monthly O&M visits. As per approval of the NYSDEC, the Scill Vapor Extraction System was permanently shut down in June 2003.

The following sections present data associated with each component of the system from April 1, 2003 through March 31, 2004, as well as throughout the entire system operation.

Pawling Corporation, 157 Charles Colman Bivd., Pawling, NY N:\PROJ.PawlingCorp\2004 Report\PawlingRcpt2004-Draft to ST.doc

2

## Groundwater Extraction System

Operation and maintenance (O&M) site visits were performed on April 21, May 14, June 4, July 30, September 30, October 12, November 20 and December 16, 2003. O&M visits were performed in 2004 on January 14, February 25 and March 27. There were mechanical problems with operation of the air compressor that powers the pneumatic groundwate extraction pumps; readings were not obtained for the months of July 2003 through February 2004. The numerous mechanical problems were addressed and corrected in February and March 2004.

Quarterly groundwater gauging performed during this monitoring period indicated that the water table elevation fluctuated, and was fairly consistent with historical seasonal trends. Figure 1 shows the layout of recovery, monitoring, air sparge and soil vapor extraction wells at the project site. Figure 2 presents the groundwater elevation trends over time. The groundwater gauging data are presented in Table 1.

The dissolved volatile organic compound (VOC) concentrations in the on-site recovery galler / are evaluated through quarterly sampling and analysis of groundwater from recovery wells RW-1S and RW-2S. Quarterly sampling was performed on June 4 and November 20, 2003 and on February 26, 2004. Samples were not obtained during the November 2003 quarterly sampling event because the wells could not be accessed. The concentrations of VOCs in RW-1S were non-detect for November 2003 and February 2004; in June 2003 the total VOCs in well RW-1S was 1.1 micrograms per liter (ug/l). The concentration of total VOCs in RW-2S remained non-detect for all three sampling quarters. A summary of VOC concentrations reported for RW-1S and RW-2S is provided on Table 2. Table 1 shows the reported VOC concentrations of each compound detected. Laboratory results are included as **Appendix A**.

## Groundwater Treatment System

Operation of the groundwater treatment system occurred during the period of April through June 2003 and again in March 2004. As discussed above, numerous mechanical difficulties with the system were encountered, and repairs were made in February and March 2004. Influent VOC concentrations to the air stripper were non-detect for the months that the two active recover / wells were functioning (RW-1S and RW-2S).

Pawling Corporation, 157 Charles Colman Blvd., Pawling, NY N:\PROJ\PawlingCorp\2004 Report\PawlingRept2004-Draft to ST.doc

١Ë

, r. <sub>1</sub>.

During the current reporting period, the groundwater pumping system functioned during the period of April through June 2003 and again in February through March 2004. The total mass removal of VOCs for RW-1S was 1.62 x 10<sup>-6</sup> pounds of VOCs. Regarding well RW-2S, the concentration of VOCs detected in quarterly groundwater samples obtained for well RW-2S was non-detect for the entire twelve month period, as indicated on **Table 2**, therefore, the total VOC; extracted from this well was zero. **Table 3** presents the groundwater treatment system pumping data and VOC removal data for the life of the project. As indicated on this table, no significant concentrations of VOCs have been removed by the groundwater treatment system since the auturn of 1997. This data indicates the groundwater treatment system has been successful in removing the majority of VOCs from groundwater within the zone of influence for pumping well s RW-1S and RW-2S. Therefore, operation of this system is not considered to be contributing to additional site remediation.

Effluent samples were collected to track the performance of the groundwater treatment system and insure system discharges were within permitted levels. Due to mechanical problems with the system, the groundwater treatment system operated for only portion of the year, and effluent t samples were obtained in April & May 2003 and March 2004. All system effluent samples collected during the reporting period showed VOC concentrations below method detection limits for all events. Monthly sample results have been tabulated and are presented in Table 4.

## Dual Phase Extraction System

Previous temporary dual phase extraction system operation confirmed that DPE would enhance remediation at the site. Therefore, a temporary DPE system was installed on GT-7S (August 16, 17, and 18, 1995), and started up on August 23, 1995. Due to the decreasing performance of GT-7S, this extraction point was re-drilled on May 28, 1996, and replaced with a 3-incr-diameter, stainless steel well screen with galvanized steel well casing. This system was activated on September 6, 1996 and was operational through November 7, 1996.

Installation of the permanent DPE system was completed in November 1998. Electrical connections were completed by Pawling Corporation during December 1999. Start up and operation of the DPE system was performed on June 2, 2000 after installation of a new transfer pump motor and associated electrical connections.

Operation of the DPE system has been sporadic over the current monitoring period due to numerous mechanical difficulties and breakdowns encountered. This resulted in the DPE system operating for only two of the twelve months: April and May 2003. There was blockage within the air stripper, the air compressor lines were leaking, the transfer pump was leaking, and

the DPE pump was not functioning correctly. Repairs, including replacement of the DPE and ai stripper pumps was performed on February 25-26, 2004. Upon completion of these repairs, the system appeared to be up and running, however, the DPE system continued to go into high alarm phase. Additional investigation concerning this issue revealed the DPE float switch needed replacement. After completion of this last repair, the system has been operating smoothly.

During the two months the system was in operation, the DPE system operated at an average vacuum of 3.75 inches of mercury (Hg) as measured at the wellhead. The average airflov/ being extracted by the DPE system was approximately 33.7 CFM. During the two months the system was in operation the DPE system extracted 2,050 gallons of water at an average total VOC concentration of 1.43 ug/l. The average flow rate of extracted groundwater via the DPE for the three operational months is approximately  $2.37 \times 10^{-2}$  gallons per minute. Because the system was not operating upon arrival for 10 of the 12 operating months, the VOCs removed as a result of vapor extraction were calculated for the two operational months of April & May 2003. Calculations show a total mass of  $3.5 \times 10^{-6}$  pounds of VOCs removed as a result of the groundwater portion of the DPE system for the operational months of April (k May 2003. Total VOCs calculated to have been extracted as a result of the lifetime operation of the DPE system is 128.04 pounds, as illustrated in **Figure 3**.

Samples are collected monthly from GT-7S to track groundwater quality entering the DPE system. When compared to historical analytical data obtained in 2000 – 2001, 2001-2002 and 2002-2003, the analytical data for the time period of April 2003-March 2004 shows a continue 3 decrease in total VOC concentrations. For the reporting year 2000-2001, results ranged from a low of 10,390 ug/l (August 2000) to a high of 25,090 ug/l (February 2001). For the reporting period of 2001- 2002, results ranged from a low of 7 ug/l in September 2001 to a high of 12,883 in October 2001. For the period of April 2002-March 2003, results ranged from a low of 1 ug/l in March 2003 to a high of 6,763 ug/l in August 2002. Recent analytical data for the period of April 2003-March 2004 indicate a low of 1.0 ug/l in April 2003 to a high of 16.2 ug/l in October 2001. Recent analytical results are presented in **Table 6**; a summary of historical analytical data can be found on **Table 1**.

## Soil Vapor Extraction System •

Historical SVE data indicated asymptotic removal conditions had been reached in 1997; further VOC removal has not occurred since then. Therefore, the Soil Vapor Extraction System was shut down permanently in June 2003.

## Air Sparge System

The air sparge system was not operated during this reporting period.

## Off-Gas Treatment System

The effluent stacks were separated at the end of December 1993, per the approved air permit modification. Individual stack effluent concentrations were monitored monthly with a PID to document VOC levels emitted into the atmosphere. **Table 5** contains the monitoring results. Previous comparison of analytical data with the PID readings demonstrated that concentrations less than 1 ppmv with the PID are below discharge limits. Monitored readings for this current reporting period were all below measurable limits. Because all readings were below measurable limits, air samples were not required for laboratory analysis.

## Deep Groundwater Monitoring Well Analytical Data

As proposed in the Annual Status Report for 2002-2003, Shaw performed quarterly sampling cf deep groundwater monitoring wells MW-2D1 and MW-2D2 to verify the absence of impacts to deep groundwater located downgradient of the remediation system. Quarterly sampling was performed on these wells on November 20, 2003 and February 26, 2004. Analytical results ar  $\Rightarrow$  presented on Table 7. For well MW-2D1, total VOC concentrations were 3.0 ug/l for November 2003 and 7.8 ug/l for February 2004. Regarding well MW-2D2, analytical results were nor - detect for November 2003 and 3.9 ug/l for February 2004. There were no exceedances of th  $\Rightarrow$  NYS Groundwater Standards for any of the compounds detected. Quarterly sampling of thes  $\Rightarrow$  wells will continue during the next year.

## **Conclusions & Recommendations**

Through March 2003 the remedial system at this site had removed 577.14 pounds of VOCs from the subsurface (212.13 pounds through soil vapor extraction, 236.97 pounds through groundwater extraction, and 128.04 pounds from the DPE system at GT-7S). Figure 3 shows the cumulative VOC removal for the total system as well as the individual components. Due to several mechanical problems with various components of the system, the system was nor operational for 10 of the 12 months for this reporting period. Therefore, the VOC extraction total remains the same for the reporting period of April 2003-March 2004.

For the current reporting period, there has been no calculated removal of VOCs as a result of the groundwater treatment system. However, current available data continues to support the historical groundwater treatment data indicating that asymptotic removal conditions have been achieved utilizing current treatment equipment. Therefore, Shaw recommends discontinuing the operation of the groundwater treatment system.

Two rounds of quarterly sampling for deep wells MW-2D1 and MW-2D2 indicate the presence c f residual concentrations of VOCs in deep groundwater below State standards. The DPE system was repaired in February & March 2004, and has been functioning continuously since then. It is assumed that the continuous functioning of the DPE system will result in lower concentrations c f VOCs in the source area.

Operation of the DPE system, while demonstrated to have not been continuous over the currer t monitoring period, has resulted in the removal of 3.5 x10<sup>-6</sup> pounds of VOCs from the subsurface. Operation of the DPE system in the area of GT-7S appears to be decreasing the concentrations of VOCs surrounding GT-7S, as evidenced by decreasing concentrations of VOCs in monthly groundwater samples. Continued operation of the DPE also appears to be helping to decreas a VOC concentrations in RW-1S and RW-2S. RW-1S has shown VOC concentrations below method detection limits for five of the last twelve quarters; the remaining five quarters displayed a VOC concentrations ranging from 1 to 8 ug/l. Concentrations of VOCs in RW-2S have been below method detection limits for nine of the last twelve quarters. Concentrations in RW-1D displayed a decrease in total VOC concentration during the past year: in February 2003 a total VOC concentration of 196 ug/l was detected, whereas in September 2003 a total VOC concentration of 13 ug/l was reported.

Quarterly groundwater sampling was performed during this reporting period on June 4, September 30 and November 20, 2003 and February 26, 2004. GT-7S was also sample 1 monthly during the reporting period. **Table 6** shows analytical results from monthly groundwater samples collected from GT-7S. **Table 1** shows the tabulated data collected for all analytical results received for this period as well as historical analytical results.

The VOC concentrations in recovery wells have been declining since operation of the DPE system was initiated in June 2000. VOC concentrations in monitoring wells have also declined during the reporting period. GT-6S has shown a total VOC concentration below the method detection limit for 16 of the last 17 quarterly sample events. GT-3S has shown total VOC concentrations below method detection limits for the last eleven quarterly sample events. VEF - 4 has shown total VOC concentrations below 10 ug/l for the last thirteen sampling events.

6

2008

It is imperative that continuous operation of the DPE system on a year round basis be implemented to address the final "hot spot" in this area. Remediation of the area in the vicinity of GT-7S is the last step necessary prior to obtaining clean closure for this area of concern Based upon decreasing VOC concentrations across the site, we believe progress is continuing to be made in remediating the last area of concern in OU-1. Extensive repairs were made to the DPE system in February and March 2004. The DPE system is now operating continuously, and increased removal of VOCs from the subsurface is anticipated for the next reporting year. We will continue to track data as it becomes available and notify you at the earliest opportunity of any changes to this strategy.

If you have any questions concerning this site, please contact us at (845) 492-3100.

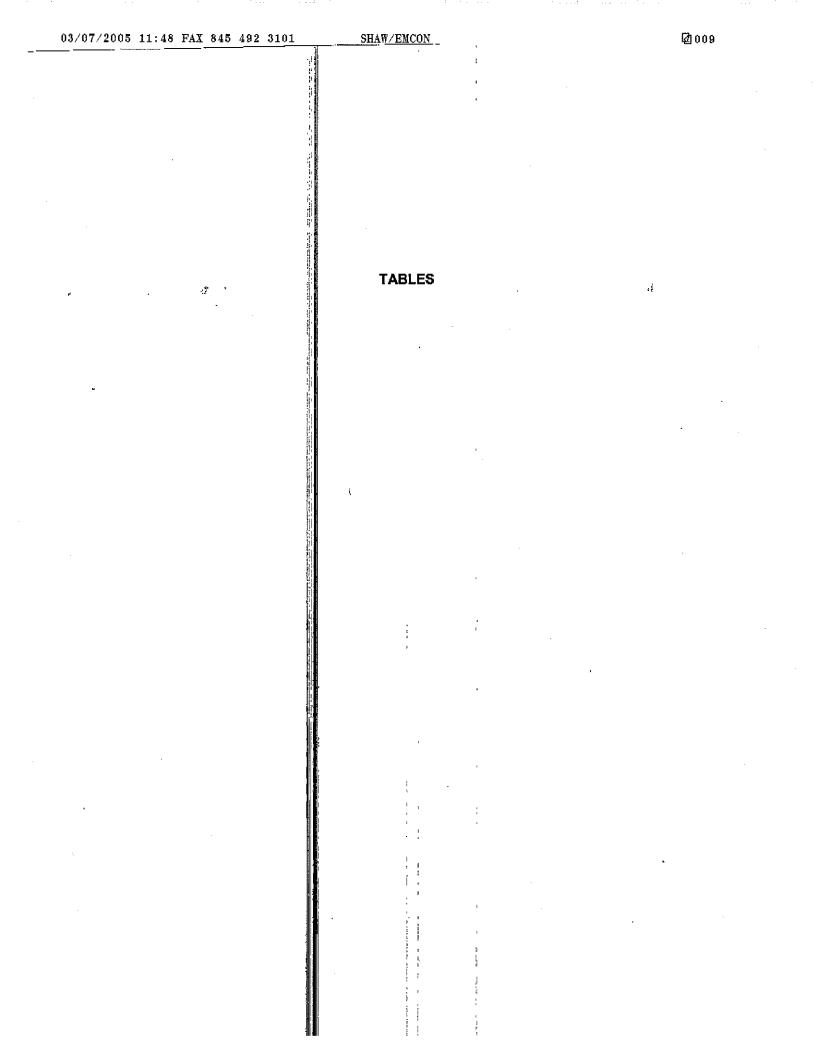

Sincerely,

Shaw Environmental, Inc.

Rebecca A. Ferguson, CPG Project Manager

## **1.0 INTRODUCTION**

Roux Associates, Inc. (Roux Associates) has prepared this status report on behalf of Pawling Corporation for the June 2006 through December 2006 monitoring period of the groundwater pumping and treatment and dual phase extraction (DPE) systems at 157 Charles Colman Boulevard, Pawling, New York (Site) (Figure 1). The monitoring period activities included groundwater sampling, and laboratory analysis, as well as operation and maintenance (O&M) of the groundwater treatment and DPE systems.

This report provides a brief description of the Site background information, a description of the operation and maintenance (O&M) activities and methodologies, a discussion of the groundwater analytical results, as well as the O&M of the groundwater treatment and DPE systems.

## 2.0 SITE BACKGROUND

The following sections provide the background information regarding the Site, including a brief summary of previous investigations, and description of the groundwater treatment and DPE systems installed at the Site.

## 2.1 Site Background

The New York State Department of Environmental Conservation (NYSDEC) issued a Consent Order Case #3-1498/8712 to Pawling Corporation on February 24, 1988. This Consent Order alleged that non-contact cooling water discharged to the Swamp River through SPDES Permit #NY-000-4616 contained copper, zinc, and organic solvents. The NYSDEC also contended that storm water runoff from Pawling Corporation property (Site), containing copper, lead, and iron in concentrations exceeding State groundwater discharge limits, discharged into the groundwater via a dry well.

## 2.2 Previous Investigations

The NYSDEC Consent Order required Pawling Corporation to perform a groundwater investigation to identify the extent and source of the groundwater contamination. A summary of the findings of this investigation are presented in a report titled "Ground Water Investigation, Pawling Corporation, Pawling, New York" dated September 2, 1988 (GTI, 1988). Further delineation of potential upgradient sources was recommended as the final work step in the preliminary groundwater investigation.

Borings into the overburden and bedrock at the Site were conducted in June of 1988. Monitoring locations were placed adjacent and downgradient to the suspected contaminant sources. Several of these borings were completed as monitoring wells and were gauged and sampled in June 1988. Groundwater samples were also collected from production wells on the Site. Water and sediment samples from the stream were also collected during this monitoring well sampling event. Some of the results exceeded the NYSDEC Ambient Water-Quality Standards and Guidance Values (AWQSGVs) for toluene and 1,1,1-trichloroethene (1,1,1-TCA).

The objectives of this initial groundwater study included:

- Delineation of the concentration and extent of metal and solvent contamination in the groundwater;
- Determination of upgradient source potential impact to the Site;
- Evaluation of pathways of contaminant migration; and
- Obtaining information required for Site remediation design.

The initial groundwater study met most of these objectives; however, an additional upgradient well couplet was installed to determine if off-site sources were contributing to the groundwater contamination observed on the Site. This study also indicated that the groundwater at the facility had a north-northwesterly flow direction.

The groundwater quality information collected from the Site monitoring and production wells in June 1988 indicated generally low levels of volatile organic compounds (VOCs) across the Site, with high levels in the vicinity of MW-2S, MW-2D1 and MW-2D2. The locations of the monitoring wells are shown on Figure 2. Toluene and chlorinated compounds (i.e., tetrachloroethene [PCE]) comprised the VOCs that were detected. The area determined to have the most contamination was an area suspected of trenching and burning. Solvents were alleged to have been burned in these trenches in the late 1960s.

#### 2.3 Description of Groundwater Treatment System

A work plan was submitted to the NYSDEC entitled "Work Plan for Subsurface Remedial Design and Implementation, Pawling Corporation", dated May 25, 1989 (GTI, 1989). This work plan was approved by the NYSDEC. The results of this work plan were utilized to select and design a remedial system for this Site. An engineering report, "Remedial System Design, Pawling Corporation", dated February 26, 1991 (GTI, 1991), was prepared and submitted to the NYSDEC. The plan was approved by the NYSDEC on June 17, 1991. The approved groundwater treatment system consisted of groundwater extraction wells, low-profile air stripper followed by liquid phase granular activated carbon (LPGAC), air sparging, soil vapor extraction (SVE) and vapor phase granular activated carbon (VPGAC) for off-gas treatment.

The final groundwater treatment system consisted of the following components:

- One air sparge point (SP-1);
- Five combined air sparge/SVE points (VP-1 through VP-5) plus one existing monitoring well (GT-2/VP-6);
- Two overburden recovery wells (RW-1S and RW-2S);
- One bedrock recovery well (RW-1D) (presently not a pumping well); and
- Two bedrock monitoring wells (MW-2D1 and MW-2D2).

Monitoring points were also installed to monitor the effectiveness of the remedial system. The monitoring points installed consisted of two monitoring wells (GT-6S and GT-7S) and one nested vapor probe (NVP-1). Figure 2 shows the locations of the groundwater treatment system, recovery and monitoring wells.

A complete groundwater gauging round was performed on March 9, 1992 prior to remedial system start-up to document the initial Site conditions. The overall Site overburden and bedrock groundwater flow directions were similar to that of previous gauging and indicated flow to the north toward Swamp River. The groundwater treatment system began operation on March 11, 1992. The SVE system was permanently shutdown in June 2003. The total VOCs removed by the SVE system is approximately 215 pounds. The air sparge system was not operated during this monitoring period. Historical performance monitoring data for the groundwater treatment system is presented in Appendix A.

#### 2.3.1 DPE System

A temporary DPE system was installed in GT-7S in August of 1995 because it was thought that it would enhance remediation at the Site. The DPE system consists of a high-vacuum blower connected to GT-7S. The high-vacuum blower pulls groundwater into a knockout tank. The groundwater is then pumped from the knockout tank to the existing low profile air stripper for treatment. The temporary system ran from August 1995 until November 1995 and again the following summer. In November of 1998, a permanent installation of the DPE System was completed. Except for temporary shutdown periods due to mechanical difficulties, the DPE system has been in operation since November 1998.

#### 3.0 GROUNDWATER TREATMENT SYSTEM MONITORING

Groundwater treatment system O&M visits during the monitoring period between June 2006 and December 2006 were performed on June 22, June 26, July 6, August 8, September 8, October 11, November 22, and December 27, 2006. The O&M visits consisted of performing routine maintenance activities of the groundwater treatment system and recording pertinent data. There were mechanical problems observed in October 2006 with the operation of the air compressor that powers the pneumatic groundwater extraction pumps in recovery wells RW-1S and RW-2S. As a result, no groundwater has been pumped from RW-1S and RW-2S since October 2006. As will be discussed below, it is recommended that the operation of the recovery wells be discontinued.

Groundwater samples were collected from RW-1S and RW-2S during the June and October 2006 quarterly sampling rounds and analyzed for VOCs. The sampling results for RW-1S and RW-2S are presented in Appendix B and summarized in Table 1. The concentrations in RW-1S were non-detect except for tetrachloroethene (PCE) at a concentration of 2.0 micrograms per liter ( $\mu$ g/L) in June 2006. The VOC concentrations in RW-1S have been non-detect since February 2004. RW-2S has also shown VOC concentrations below method detection limits since August 2004. The concentrations in RW-2S were non-detect except for trichloroethene (TCE) at a concentration of 1.4  $\mu$ g/L in October 2006.

Effluent samples were collected from the groundwater treatment system by Pawling Corporation to track the performance of the groundwater treatment system to ensure that the discharge from the system is within allowable levels. As reported to Roux Associates by Pawling Corporation, concentrations of all system effluent samples collected have been below the SPDES discharge limit as summarized in Table 2.

The groundwater treatment system has been in operation since March of 1992. Historical performance monitoring data for the groundwater treatment system is presented in Appendix A. No significant concentrations have been removed by the groundwater treatment system since the autumn of 1997. The total amount of VOCs removed by the groundwater treatment system is approximately 240 pounds. This data indicates that the groundwater treatment system has been

successful in removing the majority of VOCs from the groundwater within the zone of influence for pumping wells RW-1S and RW-2S.

#### **3.1 DPE System Monitoring**

The DPE system has been running continuously since June 2006. The total amount of groundwater removed during operation of the DPE system from June 2006 to December 2006 is approximately 16,000 gallons. Previously, the DPE system operated intermittently due to constant system mechanical failures.

The continued operation of the DPE system appears to be helping to decrease the toluene concentration in GT-7S. The concentration of toluene was 2,100  $\mu$ g/L in October 2004. With the system up and running, the toluene concentrations have been non-detect over this reporting period. The total amount of VOCs removed by the DPE system is approximately 130 pounds. The groundwater sampling results from GT-7S are presented in Appendix B and summarized in Table 3.

#### 4.0 QUARTERLY GROUNDWATER MONITORING

Quarterly groundwater monitoring was performed on June 7, 2006 and October 2, 2006 during this reporting period. The quarterly groundwater monitoring is discussed below.

#### 4.1 Water-Level Measurements

During the quarterly monitoring events, water-level measurements were performed in the overburden and bedrock monitoring wells using an electronic water interface probe. All water-level measurements were recorded in the field notebook.

Groundwater occurs at a depth ranging from 5.31 feet to 9.06 feet below land surface (bls) as measured in the monitoring wells at the Site (Table 4). The estimated overall overburden and bedrock groundwater flow direction is toward the Swamp River.

#### 4.2 Quarterly Groundwater Sampling

Quarterly groundwater samples were collected from three overburden monitoring wells VEP-4, GT-3S, GT-6S, and bedrock monitoring wells RW-1D, MW-2D1, and MW-2D2 on June 7, 2006 and October 2, 2006.

Prior to sampling, a minimum of three well-casing volumes of water was purged from each monitoring well. After purging was completed, each well was sampled using a new, clean disposable bailer and rope. The samples were transferred from the bailers directly into preserved laboratory-supplied sample bottles, which were then sealed, labeled with the well designation, and immediately placed in an ice-filled cooler for shipment to the laboratory. The samples were shipped via overnight delivery service, under chain of custody procedures, to Pawling's contract laboratory, Adirondack Environmental Services, Inc., in Albany, New York. All purge water was containerized in 55-gallon capacity drums and pumped through the groundwater treatment system.

#### 4.3 Groundwater Analytical Methods and Results

The groundwater samples were analyzed for VOCs using United States Environmental Protection Agency (USEPA) Method E601/E602/8260B. The results for the overburden and

bedrock monitoring wells are provided in Tables 5 and 6, respectively. The laboratory analytical data is provided in Appendix B.

The overburden monitoring wells GT-3S and GT-6S were non-detect for VOCs in this reporting period and have been non-detect since December 2003. The TCE concentrations in VEP-4 ranged from 2.3  $\mu$ g/L to 3.2  $\mu$ g/L during this reporting period, which are below the NYSDEC AWQSGVs.

The results for bedrock monitoring wells MW-2D1 and MW-2D2 indicate vinyl chloride (VC) and cis1,2-dichloroethene (DCE) have been detected at concentrations above the NYSDEC AWQSGVs in this reporting period. The DCE concentration was 14  $\mu$ g/L and the VC concentration was 85.0  $\mu$ g/L in MW-2D1. The results for bedrock monitoring well RW-1D also indicate VC and DCE were detected at concentrations above the NYSDEC AWQSGVs in this reporting period. The DCE concentrations above the NYSDEC AWQSGVs in this reporting period. The DCE concentrations above the NYSDEC AWQSGVs in this reporting period. The DCE concentration was 6.0  $\mu$ g/L and the VC concentration was 26.0  $\mu$ g/L in RW-1D in the October 2006 sampling round.

#### 5.0 CONCLUSIONS AND RECOMMENDATIONS

The following summary regarding groundwater conditions at the Site is based on the results of the quarterly groundwater sampling and laboratory analysis, and groundwater and DPE system performance monitoring performed during the reporting period.

- The VOC concentrations continue to be non-detect and/or less than the NYSDEC AWQSGVs in overburden wells RW-1S and RW-2S. The current and historical data continues to indicate that asymptotic removal rates (i.e., no additional VOC removal) have been achieved with the current groundwater treatment system.
- VOCs were non-detect in overburden wells GT-3S and GT-6S during the reporting period and have been non-detect since December 2003. TCE and DCE were detected in VEP-4 but at concentrations less than the NYSDEC AWQSGVs during this reporting period. The low VOC concentrations in the shallow monitoring wells also indicate that the groundwater treatment system has reached asymptotic levels.
- The continued operation of the DPE system in the area of GT-7S appears to be decreasing the concentrations of VOCs surrounding GT-7S. The toluene concentration in GT-7S has decreased from a concentration of 2,100 µg/L in October 2004 to non-detect from the June 7, 2006 sampling round to the November 22, 2006 sampling round. As discussed above, the VOC concentrations in the shallow monitoring wells GT-3S, GT-6S, VEP-4 and the recovery wells RW-1S and RW-2S continue to be non-detect or less than the NYSDEC AWQSGVs. This may be attributable to the continued operation of the DPE system.
- DCE and VC concentrations exceeding the NYSDEC AWQSGVs were detected in the bedrock monitoring wells RW-1D, MW-2D1, and MW-2D2. Minor detections of DCE and VC above the NYSDEC AWQSGVs have been found in RW-1D since December 2003. The presence of DCE demonstrates that some biologically mediated reductive dechlorination of PCE and TCE is occurring, since DCE is breakdown product of PCE and TCE. The presence of VC also indicates that natural degradation is occurring at the Site.

#### Recommendations

Based on the information presented in this status report, Roux Associates recommends:

- Groundwater monitoring and sampling activities should continue on a semi-annual basis.
- Groundwater treatment and DPE systems will continue to be monitored on a monthly basis.
- Continue with natural attenuation monitoring for the bedrock monitoring wells; the bedrock monitoring wells will continue to be monitored on quarterly basis.
- The recovery wells RW-1S and RW-2S should remain off as the groundwater concentrations remain below the NYSDEC AWQSGVs.

• The groundwater treatment system will continue to operate to treat the groundwater from the DPE system. The DPE system at GT-7S should continue to operate in the next reporting period.

If you should have any questions regarding the contents of this status report, please contact either of the undersigned.

Respectfully submitted,

ROUX ASSOCIATES, INC.

Mr. James Schreyer New York State Department of Environmental Conservation 21 South Putt Corners New Paltz, New York 12561

Re: Summary of Investigation – Soil Vapor Intrusion Study Pawling Corporation, Pawling, New York NYSDEC Site# 314002

Dear Mr. Schreyer:

On behalf of Pawling Corporation ("Pawling"), Roux Associates, Inc. ("Roux Associates") has prepared the following Summary of Investigation for a soil vapor intrusion study associated with the Pawling facility at 157 Charles Colman Boulevard, Pawling, New York (the "Site"). The soil vapor intrusion study was conducted on March 6, 2009 in accordance with Roux Associates' December 16, 2008 Scope of Work for Soil Vapor Intrusion Study ("Scope of Work") as approved by the New York State Department of Environmental Conservation ("NYSDEC") and New York State Department of Health ("NYSDOH") on January 9, 2009.

#### Scope of Work

In accordance with the Scope of Work, Roux Associates collected three samples at the locations summarized below and shown in the attached figure (Figure 1):

- One indoor air sample (AS-101) from the marketing closet;
- One outdoor ambient air sample (AS-102); and
- One sub-slab soil vapor sample (SV-103) collected from beneath the floor in the marketing closet.

Soil vapor and air samples were sent to Test America of South Burlington, Vermont, an Environmental Laboratory Approval Program ("ELAP") certified laboratory and analyzed for volatile organic compounds ("VOCs") using USEPA method TO-15.

#### March 2008 Sampling

On March 6, 2009, three samples were collected concurrently: one indoor ambient air sample (AS-101), one outdoor ambient air sample (AS-102), and one sub-slab soil vapor sample (SV-103). Air sample AS-101 and soil vapor sample SV-103 were collected from a storage room (referred to by Pawling staff as the "marketing closet") located between

Mr. James Schreyer December 3, 2009 Page 2

the shipping area, maintenance shop, and stockroom offices. This room is approximately 10 feet by 12 feet and is located 40 feet from the front of the building. The room has doors that are typically closed and has a former floor drain that is filled with concrete. This area was selected due to its proximity to the source area, potential intrusion pathways along the former floor drain piping, and limited air circulation due to the closed doors (worst case scenario). Outdoor ambient air sample AS-102 was collected outside a pedestrian doorway between the main building and the treatment building approximately 150 feet away from the marketing closet. This location was selected due to its access and as it was protected from the vehicular traffic of the shipping area. The sampling locations were shown to and discussed with you during the sampling event. Sampling locations are shown on Figure 1.

Prior to sample collection, a product inventory of potential chemical interferences and the NYSDOH Indoor Air Survey, which included recording occupancy and describing the location and operational conditions of the building's HVAC system, were completed. A copy of the completed NYSDOH Indoor Air Survey is included as Attachment 1. There were no potential sources of VOCs observed in the area of any sample. Monitoring of the ambient air in the sampling locations as well as adjacent spaces was conducted during sampling with a photoionization detector. Concentration ranges detected during this monitoring are shown on Figure 2. As discussed above, the marketing closet had a former floor drain that was sealed with concrete. The only active utility egresses observed during the building inspection were located in the bathrooms (Figure 1).

Soil vapor sample point SV-103 was installed by drilling a one-inch diameter hole to a depth of six inches beneath the concrete floor. The floor in the marketing closet was measured to be seven inches thick and appeared to be in good condition. A six-inch long stainless steel screen was installed to zero to six inches beneath the concrete slab and connected to an inert sampling tube from the screen to a three-way stopcock at the surface. The annular space around the screen was filled with sand and the annular space between the tubing and the concrete was filled with clay. Additional tubing was connected from the second stopcock port to a vacuum pump and from the third stopcock port to a pre-evacuated six-liter Summa canister.

The stopcock and network of tubing was covered with an enclosure that was filled with helium. The soil vapor sampling point was purged of approximately three tubing volumes using the vacuum pump calibrated to 0.19 L/min. The helium concentration in the enclosure fluctuated near 27 percent (27,000 parts per million "ppm") during purging with 100 to 125 ppm of helium measured from the pump discharge (background measured at 125 ppm).

Following purging, the valve leading to the pump was closed and the valve on the Summa canister was opened. The Summa canister was equipped with a laboratory calibrated flow-controlling regulator that collected the soil vapor sample over a four-hour period.

Mr. James Schreyer December 3, 2009 Page 3

flow-controlling regulator that collected the soil vapor sample over a four-hour period. Samples were collected concurrently between approximately 11:00 A.M. and 3:00 P.M. During sample collection, the building's heating system was operating under normal conditions.

#### Results

Analytical results for VOCs in soil vapor and ambient air are presented in Attachment 2, summarized in Table 1, and discussed below. A data usability summary report ("DUSR") is being prepared and will be submitted to NYSDEC under separate cover. Analytical results for samples collected during this soil vapor intrusion study were evaluated using Air Guideline Values and decision matrices presented in the NYSDOH's October 2006 "Guidance for Evaluating Soil Vapor Intrusion in the State of New York" ("Guidance").

Analytical results reported 19 VOCs detected in sub-slab soil vapor, 15 VOCs detected in indoor air, and 6 VOCs detected in outdoor air. Of these detections, there were only 8 VOCs that were detected in both the subslab and indoor air samples. The NYSDOH Guidance includes Air Guideline Values for three VOCs: methylene chloride, tetrachloroethene ("PCE"), and trichloroethene ("TCE"). There were no concentrations of these VOCs detected above their respective NYSDOH Air Guideline Values in any sample.

The NYSDOH Guidance includes decision matrices for four VOCs: carbon tetrachloride, PCE, 1,1,1-trichloroethane ("111-TCA"), and TCE. These decision matrices compare concentrations of indoor air and sub-slab soil vapor to assist in making decisions when soil vapor may be entering buildings. Concentrations of PCE, TCE, carbon tetrachloride, and 1,1,1-trichloroethane ("111-TCA") detected in sub-slab soil vapor, indoor air, and ambient air as well as the NYSDOH recommended action as determined by the NYSDOH decision matrices are summarized in the table below.

Analyte	Soil- Vapor	Indoor Air	Outdoor Air	NYSDOH Recommended Action
Carbon Tetrachloride	ND	ND	ND	No Action
Tetrachloroethene	8.1	4.2	ND	Identify Sources / Reduce Exposure
1,1,1-Trichloroethane	ND	1.2	ND	Identify Sources / Reduce Exposure
Trichloroethene	ND	ND	ND	No Action

#### Summary of NYSDOH Decision Matrix VOCs

ND - not detected; concentrations reported in micrograms per cubic meter ( $\mu g/m^3$ )

Mr. James Schreyer December 3, 2009 Page 4

#### Discussion

A soil vapor intrusion study was requested by the NYSDEC to evaluate the potential for groundwater to act as a source of VOCs to soil vapor and subsequent exposure of the building.

Pawling has not used chlorinated solvents at the Site since the early 1990's. Following previously reported Site Investigation and Alternative Analysis, Pawling has treated groundwater containing VOCs including PCE, TCE, cis-1,2-dichloroethene ("cis-12-DCE"), and vinyl chloride at the Site between 1992 and March 2009. Active groundwater remediation ceased in March 2009 following several monitoring periods that demonstrated only low level residual VOC concentrations.

Analytical data suggests that the low level residual VOCs in groundwater beneath the Site contribute a *de minimus* amount of VOCs to soil vapor. As an example, PCE was detected in groundwater in May 2009 at a concentration of 2.6 micrograms per liter (" $\mu$ g/L") and in soil vapor in March 2009 at a concentration of 8.1  $\mu$ g/m<sup>3</sup>. There were no other VOCs detected in both groundwater and soil vapor.

Chlorinated solvents were detected in indoor air but at very low concentrations. Despite the indoor air being in a potential worst case scenario location (limited air flow, former utility egress, close to former source area) there were no VOCs that exceeded the NYSDOH Air Guidance Values.

#### Recommendations

Based on the analytical results of the soil vapor intrusion study, no additional soil vapor investigation is recommended at this time.

If you have any questions concerning this Summary of Investigation report, please do not hesitate to contact me.

Sincerely,

ROVX ASSOCIATE IN(

Michael Roux Principal Hydrogeologist

Sewage Disposal: Public Sewer Septic Tank Leach Field Dry	Well Other: SVE .
10. RELOCATION INFORMATION (for oil spill residential emergency)	
a. Provide reasons why relocation is recommended:	
b. Residents choose to: remain in home relocate to friends/family	relocate to hotel/motel
c. Responsibility for costs associated with reimbursement explained?	Y/N
d. Relocation package provided and explained to residents?	Y/N

· . . . .

#### **11. FLOOR PLANS**

Draw a plan view sketch of the basement and first floor of the building. Indicate air sampling locations, possible indoor air pollution sources and PID meter readings. If the building does not have a basement, please note.

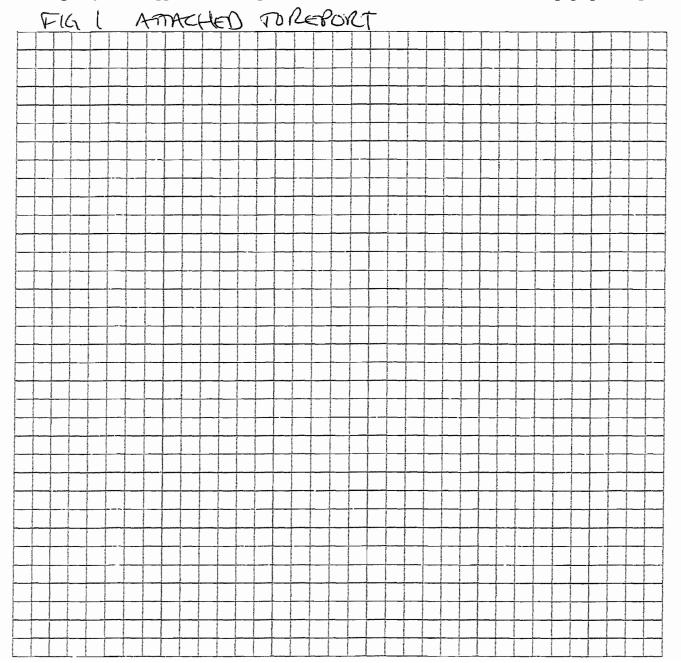

# **12. OUTDOOR PLOT**

Draw a sketch of the area surrounding the building being sampled. If applicable, provide information on spill locations, potential air contamination sources (industries, gas stations, repair shops, landfills, etc.), outdoor air sampling location(s) and PID meter readings.

Also indicate compass direction, wind direction and speed during sampling, the locations of the well and septic system, if applicable, and a qualifying statement to help locate the site on a topographic map.

#### **13. PRODUCT INVENTORY FORM**

Make & Model of field instrument used:

List specific products found in the residence that have the potential to affect indoor air quality.

TestAmerica Laboratories, Inc.

March 23, 2009

Mr. Michael Roux Roux Associates 209 Shafter Street Islandia, NY 11749

Re: Laboratory Project No. 29000 Case: 29000; SDG: NY130524

Dear Mr. Roux:

Enclosed are the analytical results for the samples that were received by TestAmerica Burlington on March 9<sup>th</sup>, 2009. Laboratory identification numbers were assigned, and designated as follows:

Lab ID	Client	Sample	Sample
	<u>Sample ID</u>	<u>Date</u>	<u>Matrix</u>
	Received: 03/09/09 ETR No:	130524	
787647	AS-101	03/05/09	AIR
787648	AS-102	03/05/09	AIR
787649	SV-103	03/05/09	AIR

Documentation of the condition of the samples at the time of their receipt and any exception to the laboratory's Sample Acceptance Policy is documented in the Sample Handling section of this submittal.

#### EPA Method TO-15 – Volatile Organics:

Manual integration of quantitation peaks was performed where necessary. Documentation of each manual integration was provided in the supportive documentation.

Any reference within this report to Severn Trent Laboratories, Inc. or STL, should be understood to refer to TestAmerica Laboratories, Inc. (formerly known as Severn Trent Laboratories, Inc.) The analytical results associated with the samples presented in this test report were generated under a quality system that adheres to requirements specified in the NELAC standard. Release of the data in this test report and any associated electronic deliverables is authorized by the Laboratory Director's designee as verified by the following signature.

THE LEADER IN ENVIRONMENTAL TESTING

If there are any questions regarding this submittal, please contact me at 802 660-1990.

Sincerely,

on feitent

Ron Pentkowski Project Manager

Re: Groundwater Sampling Results Pawling Corporation, Pawling, New York Site No. 314002

Dear Ms. Hackett:

On behalf of Pawling Corporation ("Pawling"), Roux Associates, Inc. ("Roux Associates") has prepared this summary of groundwater sampling conducted at the Pawling facility in Pawling, New York (the "Site"). Groundwater sampling was conducted on May 25, 2011 in accordance with a May 10, 2011 letter from Pawling to the New York State Department of Environmental Conservation ("NYSDEC").

# Scope of Work

Groundwater samples were collected from three monitoring wells, GT-6S, GT-7S, and RW-ID using low flow sampling procedures. Each sample was submitted to Adirondack Environmental Services, Inc. of Albany, New York and analyzed for the following volatile organic compounds ("VOCs"): toluene; trichloroethene; tetrachloroethene; 1,1,1-trichloroethane; vinyl chloride; cis-1,2-dichloroethene, and trans-1,2-dichloroethene.

# Results

Laboratory analytical results are included as Attachment 1 and summarized below and in Table 1. In addition, Table 1 summarizes historical groundwater data collected from the three monitoring wells between 2007 and 2011.

Four of the seven VOCs analyzed were detected in at least one of the three monitoring wells. There were no VOCs detected in monitoring well GT-6S.

Trichloroethene and cis-1,2-dichloroethene were detected in monitoring well GT-7S at concentrations above their respective NYSDEC Ambient Water Quality Standards and Guidance Values ("AWQSGVs"). Concentrations of these two VOCs have decreased from the previous sampling event in October 2009.

Ms. Robin Hackett June 28, 2011 Page 2

Two degradation products, vinyl chloride and cis-1,2-dichloroethene, were detected in monitoring well RW-1D at concentrations above their respective AWQSGVs. Concentrations of these two VOCs have increased from the previous sampling event in October 2009, but still remain below concentrations observed in the well in 2007.

# Recommendations

As previously discussed, Pawling seeks to get permanent delisting of the facility. Based on the analytical results of the May 2011 sampling event and to achieve the goal of delisting the facility, Roux Associates requests that the NYSDEC reclassifies the Site to a Class 4 Inactive Hazardous Waste Site. Furthermore, we propose to prepare a Site Management Plan describing two additional rounds of groundwater sampling (similar to the May 2001 event) to be conducted every fifth quarter (August 2012 and November 2013).

We appreciate your help in achieving a final closure of this project. Feel free to contact Mr. John Rickert of Pawling at 845-855-1000 or Roux Associates at 631-232-2600 should you have any questions.

Sincerely,

ROUX ASSOCIATES, INC.

Glenn Netuschil, P.E. Senior Engineer

Michael Roux Principal Hydrogeologist

Site Management Plan

# **APPENDIX D**

**Electronic Database** 

# **Appendix D**

# Information Included in Electronic Database

Site Summary:

A Site Management Plan ("SMP") was prepared for the Pawling Engineered Products ("Pawling") facility located at 157 Charles Colman Boulevard in Pawling, New York (the "Site") at the request of the New York State Department of Environmental Conservation ("NYSDEC") in order to proceed with a reclassification of the Site (Site # 314002) from a Class 2 Inactive Hazardous Waste Site to a Class 4 Inactive Hazardous Waste Site.

Pawling operated several remedial systems at the Site from March 1992 to March 2009 to address an area of impacted soil and groundwater that resulted from historic releases associated with a waste burning trench at the Site. Following completion of the remedial work, some contamination was left in the subsurface at this Site, which is hereafter referred to as "residual contamination." The SMP was prepared to manage residual contamination at the Site until the Declaration of Covenants and Restrictions (Appendix A) is extinguished, and it defines Site-specific implementation procedures as required by the Declaration of Covenants and Restrictions.

<u>Current Site Owner:</u> Pawling Engineered Products 157 Charles Colman Boulevard Pawling, New York

<u>Site Location:</u> 157 Charles Colman Boulevard Pawling, New York

# Current Status of Site Remedial Activity:

Remedial action at the Site has been completed and groundwater at the Site is currently being monitored on a periodic basis.
