Pemart Avenue former MGP Site (NYSDEC Site No. V00566)
Peekskill, New York
Voluntary Clean-up Agreement – Index No. D2-0003-02-08

Dear Mr. Miller:

Enclosed for the Department's review and approval are two paper copies and one electronic copy on CD of the Remedial Investigation Report for the Pemart Avenue Works former MGP and the associated former Electric Generating Plant, which collectively comprise the subject Site.

Please call me at (718) 204-4145 should you have any questions regarding this submittal.

Very truly yours,

Neil O'Halloran
Project Manager,
MGP Remediation Group
Environment, Health and Safety Department

1.0 Introduction

This Remedial Investigation (RI) report presents data and observations that were obtained during field investigations conducted at the former Pemart Avenue Works manufactured gas plant (MGP) and electric generation plant (EGP), collectively referred to as the Site, located in Peekskill, New York. The former Pemart Avenue properties were historically operated by predecessor companies to the Consolidated Edison Company of New York, Inc. (Con Edison). The investigation was conducted in accordance with Voluntary Cleanup Agreement (VCA) Index No. D2-0003-02-08 between Con Edison and the New York State Department of Environmental Conservation (NYSDEC).

1.1 Project Background

In 2002, Con Edison entered into a multi-site VCA with NYSDEC. Under this agreement, Con Edison is evaluating its former MGP sites, which included the Pemart Avenue Site, and, if necessary, remediate them. As an initial step of the site evaluation process, Con Edison conducted a site history investigation and prepared a Historical Investigation Report. The site history investigation was conducted to determine historical operations, ownership, uses, and conditions at the Site.

In July 2005 Con Edison prepared and submitted to NYSDEC a Site Characterization Study (SCS) Work Plan (Work Plan) (July 2005 – ENSR). The intent of the scope of work outlined in the Work Plan was to determine if residues from operations of the former plants and or any remnant structures of the former MGP and or EGP were present in the subsurface. The Work Plan was approved by NYSDEC and the New York State Department of Health (NYSDOH) in a letter dated August 24, 2005 and this initial phase of field investigation work commenced on August 16, 2005. Based on preliminary findings of MGP residues in subsurface soil during the SCS, Con Edison decided to expand the scope of work into a more extensive remedial investigation (RI), which required that the observed residues be delineated. A second phase of investigation was initiated in March 2006 and completed in June 2006. The results of the RI and the initial SCS activities are summarized herein.

1.2 Objectives of Field Investigation

The objectives of the SCS and RI were to

- determine the presence or absence of residues from the historical operations of the former MGP and EGP,
- delineate the horizontal and vertical extent of residues from the former MGP and EGP operations, if present, and
- determine if any structures related to the former Site operations were present in the subsurface.

1.3 Report Outline

Section 2 of this report outlines the field activities that were performed during the RI. Field observations, including the presence of former MGP structures and a description of the site hydrogeology, are discussed in Section 3. Analytical results of the soil and groundwater samples are presented in Section 4. Section 5 presents an exposure assessment including contaminant fate and transport. Section 6 provides a summary of findings and Section 7 presents conclusions based on the results of the investigation. References are provided in Section 8.

1.4 Site Description and Current Property Use

The former Pemart Avenue Site included an MGP and EGP and is located at approximately N 41° 17' 25.4" latitude and W 73° 55' 50.2" longitude between the Briarcliff-Peekskill Parkway (to the east) and the former New York Central Railroad Hudson Division (presently Metro-North) railroad tracks (to the west), see Figure 1-1. The former MGP and EGP that comprise the Site occupied properties on both sides of former Pemart Avenue, which is now North Water Street, north of the intersection of Main Street and Water Street. The Site covered approximately four acres, with approximately two acres on each side of former Pemart Avenue. In general, the Site is relatively level with the eastern portion of the Site sloping steeply from Pemart Avenue up to the Briarcliff-Peekskill Parkway to the east. This eastern area of the Site is characterized by heavily wooded steep-sloping bedrock outcrops. The western portion of the Site is relatively flat with a minor slope toward Peekskill Bay and the Hudson River to the west. Figure 1-2 provides a plan of the Site, which depicts the former and current features and Site boundaries, as described below.

Based on reviews of historical records, which included Sanborn Fire Insurance (Sanborn) Maps and other historical maps, the eastern portion of the Site contained four gas holders, two fuel oil tanks, and a battery house. The western portion of the Site contained the gas works building, the electrical generating plant building and transformers, two coal storage areas, a coal shed, and a coal conveyor. No other structures related to the former MGP or EGP were identified during the historical records review. It is noted that sometime after 1942, after operation of the MGP ceased in the 1930's, the gas plant area was used as a regulator station for distribution of natural gas. During these post-MGP operations, four high pressure gas storage tanks and a 575,000 cf Hortonsphere were constructed to provide additional storage capacity and to support management of pressure in the natural gas system.

The former MGP property is comprised of Tax Map 32.08, Tax Block 5, Lots 7 and 8 and Tax Block 8, Lots 1, 2, 3 (Figure 1-2), and the former EGP property is comprised of Tax Map 32.08, Tax Block 5, Lots 9 and 10, and Tax Block 8, Lot 4 (Figure 1-2). The historical Site information does not indicate any past Site operations on Tax Block 5, Lots 8 and 10. These two lots are characterized by steep bedrock topography and lack any evidence of past or current use or structures. These observations confirm that past operations were not conducted on these lots. No investigation activities were conducted on these two lots.

The Site is currently used for commercial and industrial purposes. The eastern portion of the Site contains an open gravel-covered area level with the street, the former battery house, the concrete foundation slab of the former 200,000 cubic foot (cf) above-ground gas holder, the retaining wall associated with the former 100,000 cf gas holder, and the concrete foundations of the former high pressure storage tanks. With the exception of the gravel-covered lot, the eastern portion of the Site is not used for any formal commercial or industrial operations. The gravel lot is used by a local landscaper for parking and for storage of materials.

At the time the field investigation was being implemented, the former gas production building and the former electric generating plant building were still present in the western portion of the Site. These buildings are currently occupied by various businesses (i.e., umbrella factory, millwork cabinetry making, and laboratory) and a homeless shelter. The southernmost parcel of the western portion of the Site is a City of Peekskill municipal parking lot. The only parcel of the Site currently owned by Con Edison is a small fenced vegetated yard between the former gas works building and the municipal parking lot. This parcel contains a small brick building that is attached to the former gas works building and a fenced vegetated yard and is not currently used.

The areas covered by the Site are contained within the City of Peekskill's Waterfront Redevelopment Area.

1.5 Adjoining Property Description

The Site is bound to the north and east by steep bedrock outcrops and vegetation. At the north end of North Water Street there is a small parking area with a single lane gravel access road that continues to the north. This gravel road provides limited access along the Hudson River. To the south are commercial businesses, including an automobile detailing facility, an office cleaning business, a restaurant, and a landscaping contractor facility. A municipal parking lot borders and overlaps the property to the south. The MTA Metro-North Railroad right-of-way (ROW) borders the property to the west and runs the length of the Site. The parcel of land west of the MTA ROW, west of the former MGP, is vacant and currently referred to as the Peekskill Landing Site. The Hudson River forms the western border of the MTA ROW and or Peekskill Landing properties.

Historic Sanborn Maps show that properties adjoining the Site have been used for a variety of industrial and commercial activities including: coal yards (W. H. Chase Coal and Lumber Yard), lumber yards (W. H. Chase Coal and Lumber Yard, N. Dain's Sons Co., and Chapman Brothers), stove manufacturers (Ely Ramsey Stove Manufacturer and Wm. M. Crane Co. Stove Works, which included an electroplating operation) and an unnamed Boat Builder.

1.6 Site History

A historical investigation was conducted for Con Edison by The RETEC Group, Inc. and summarized in a Historical Investigation Report (RETEC, 2002). The results of the historical investigation are summarized below.

1.6.1 Site Ownership

Prior to MGP and EGP operations at the Site, the property was used for a variety of industrial purposes including the Jones and Mead Enameled Holloware Works and Enameling Iron Works, a lime kiln, and the New York Emery Company. Immediately prior to the MGP and EGP use, the property was vacant.

The property on which the MGP was constructed was acquired by the Peekskill Gas Company in 1899 and the MGP began operations shortly thereafter. The MGP was operated by the Peekskill Gas Light Company (also under the name of Peekskill Lighting and Railroad Company, and Westchester Lighting Company) from 1899 to approximately 1931 when it was placed on standby service. The former EGP was operated from 1905 to around 1950 by Westchester Lighting Company.

The portion of the property formerly used for the MGP was sold in 1978, with the exception of a small parcel to the south that was retained by Con Edison for use as a gas regulator station. The former gas regulator facility has since been removed and a new regulator has been installed in a subsurface vault beneath the sidewalk along the west side of North Water Street.

1.6.2 Site Operations

The former MGP reportedly produced approximately 116 million cubic feet of gas during its approximately 32 years of operation. Gas was produced at the Site using the water gas or the Lowe process. After the plant operations ceased, a portion of the former MGP property was used for distribution of natural gas.

The 1900 Sanborn Map depicts the presence of the gas production building (including generator house, boiler house, storage, and purifying house) and a coal shed west of Pemart Avenue. Two iron gas holders, an oil tank, and a small building were located on the eastern side of Pemart Avenue. The gas holders included a

2-lift, 100,000 cf holder in the southeastern-most corner of the property and a 1-lift, 30,000 cf holder directly north of the 2-lift holder. The oil tank was a 25,000-gallon iron tank.

By 1905, a coal conveyor was constructed north of the MGP building. The conveyor was used to transfer coal from barges in the river to a storage pile between the former EGP and MGP. The vacant building on the east side of Pemart Avenue was used as a battery room. By 1923, a fuel oil tank had been constructed east of the electric plant on the east side of Pemart Avenue and transformers were located directly north of the electric plant. In 1924, another above-ground gas holder was constructed east of Pemart Avenue directly north of the battery house. A portion of the hillside was cleared to bedrock and leveled for the construction of the foundation for this 200,000 cf gas holder. This holder had an approximate diameter of 75 feet.

After MGP operations ceased in the 1930's, the gas plant area was used as a regulator station for distribution of natural gas. Sometime between 1942 and 1947, the 100,000 cf gas holder was dismantled. In 1947, a 60-foot diameter Hortonsphere spherical gas holder with a capacity of 575,000 cubic feet was constructed at the location of the former 100,000 cf gas holder. It is likely that the 30,000 cf holder was removed from the Site within the same timeframe, as it was no longer shown on the 1950 Sanborn Map. By 1950, four cylindrical high pressure gas storage tanks were installed on the hillside to the east of the Hortonsphere holder.

The 200,000 cubic foot gas holder was demolished in 1958 and the Hortonsphere, high-pressure storage tanks, and related equipment were removed in 1966. Additionally, the 1958 Sanborn Map shows that by 1958 the electric light and power house was not in use as an electric plant and that the building had been expanded to the north to its current footprint.

1.7 Previous Investigations

No sampling, prior to the SCS and RI, has been conducted at the Site.

However, environmental investigations have been performed on behalf of the City of Peekskill on the parcel of land west of the railroad tracks, referred to here as the Peekskill Landing Site. These investigations extended from the southern end of the RI investigation area further to the south. The results of the investigations are summarized in an RI prepared for that Site. Select results from the investigations have been reviewed in preparing this RI Report for the former Pemart Avenue MGP and EGP. The results generally show that subsurface soil and groundwater contain elevated concentrations of metals, semi-volatile organic compounds (SVOCs) and volatile organic compounds (VOCs) at similar concentrations, within an order of magnitude, as those detected at the Site. It is noted that in addition to compounds such as ethylbenzene, xylenes, naphthalene, polycyclic aromatic hydrocarbons (PAHs), arsenic, lead, and mercury, which typically may be associated with MGP residues, chlorinated solvents 1,1,1-tricholorethane and tetrachloroethene were also detected in soil at concentrations similar to those detected at the Site. These chlorinated solvent detections appear unrelated to the former MGP or EGP operations.

1.8 Environmental Setting

The following environmental setting information is summarized from the Historical Investigation Report (RETEC, 2002) and from published resources. The geologic, hydrogeologic, and hydrologic data obtained during the Site investigation activities is presented in Section 3 of this report.

1.8.1 Topography/Geology/Hydrogeology

Based on the 1969 United States Geological Survey (USGS) topographic map for the Peekskill, New York Quadrangle, the eastern portion of the Site slopes steeply to the west towards the Hudson River. The elevation decreases by approximately 50 feet from the Briarcliff Peekskill Roadway, which is at an elevation of

approximately 100 feet above mean sea level, to an elevation ranging from 45 to 65 feet above mean sea level at the eastern-most Site boundary (i.e., in the steep wooded area with bedrock outcrops). Land surface elevation decreases further by approximately 50 feet from the eastern-most Site boundary to the MTA ROW track bed, which is the western Site boundary. The track bed is approximately 6 to 8 feet above mean sea level.

Consistent with the westward-sloping topography, surface water, which is not captured by the storm drain system along North Water Street or which does not infiltrate the ground, flows to the southwest and may eventually enter Peekskill Bay of the Hudson River. The shoreline of the Hudson River is located approximately 70 feet west of the western boundary of the former EGP and approximately 180 feet west of the western boundary of the former MGP.

The Surficial Geology Map of New York (Caldwell, 1989) indicates that surficial deposits are not present on Site. The ground surface is either bedrock or bedrock overlain by a thin (less than 3-feet thick) veneer of soil. However, as described in Section 3 of this report, this mapping does not properly reflect the Hudson River channel sediments that were deposited along its shores and on-lap the bedrock outcrops that comprised the paleo shoreline. These shoreline sediments comprise the area of the Site between the present-day shoreline and the bedrock outcrops and range up to 47.5 feet thick as were encountered at the Site during the investigation.

The Geologic Map of New York (Fisher, 1970, revised 1995) shows that the bedrock at the Site is metamorphic biotitic granitic gneiss of uncertain origin and Cambrian in age. The Site is located in the Manhattan Prong (RETEC, 2002). The Manhattan Prong, part of the Highlands Province, is a belt of ancient rock in southern New York, parts of Westchester County, and upland portions of southwestern Connecticut. The geology of the Highlands Province is characterized by complex patterns of folds, faults, and intrusions. The rocks have been subjected to several episodes of tectonic deformation, including stages of intense folding and metamorphism associated with the collision of ancient landmasses driven by plate tectonic forces. Following mountain building episodes during the Paleozoic, this region experienced extensive periods of gradual uplift and erosion lasting throughout Mesozoic and Cenozoic time (USGS website, http://3dparks.wr.usgs.gov/nyc/highlands/highlands.html, last accessed in September 2006).

Based on the local topography and proximity to the Hudson River, it was assumed in the Historical Investigation Report that the depth of shallow groundwater at the Site ranged from approximately 4 to 10 feet below ground surface and flows to the southwest towards the Hudson River. As discussed in Section 3, this RI generally confirms this assumption.

2.0 Field Investigation Scope of Work

This section describes the field activities that were performed during the RI. The field investigation was conducted in two phases from August to September 2005 and from March to June 2006, and included, exploratory test pit excavation, soil boring advancement, monitoring well installation in overburden and bedrock, and the collection of surface soil, subsurface soil, and groundwater for laboratory analysis. The two separate phases of field work were necessitated by delays in being granted access to the private properties that comprise the Site. All field activities were conducted in accordance with the Site Characterization Study Work Plan, Pemart Avenue Works Former MGP (Work Plan) (ENSR, 2005), Field Sampling Plan (FSP) (ENSR, 2005), Quality Assurance Project Plan (QAPP) (ENSR, 2005), and Health and Safety Plan (HASP) (ENSR, 2005).

Test pit, soil boring, monitoring well and surface soil sample locations are shown on Figure 2-1. Field records are presented in Appendix A and air monitoring data is presented in Appendix B. Table 2-1 provides a summary of the soil samples collected and Table 2-2 provides a summary of the groundwater samples collected. Analytical results for surface and subsurface soil samples are summarized in Tables 4-1 through 4-7, the groundwater analytical results are summarized in Tables 4-8 through 4-11, and total petroleum hydrocarbon (TPH) fingerprint analyses are summarized in Table 4-12. The soil and groundwater results are discussed in Section 4. A complete summary of analytical results is presented in Appendix C.

2.1 Utility Clearance

Prior to each phase of intrusive field activities, utility clearance was conducted to ensure the safety of field personnel and to confirm that planned investigation locations would not interfere with any existing overhead or subsurface utility lines. Utility clearance was conducted using Con Edison's Utility Clearance Process for Intrusive Activities and in accordance with Section 3.1 of the Work Plan. The underground utility clearance process included a New York State Department of Transportation (NYSDOT) Code 753 mark-out, review of available as-built utility maps, visual site inspection for the presence, or indications of the presence, of subsurface utilities, a utility mark-out using electromagnetic and geophysical techniques, and hand clearing and or vacuum extraction to approximately 5 feet below ground surface (bgs).

Geophysical prospecting surveys, including ground penetrating radar (GPR), were conducted at and within approximately 30 feet of planned investigation locations. These planned locations were reevaluated and/or offset if a subsurface anomaly was identified during these surveys. GPR was also used to assess the presence of the former MGP structures.

Once investigation locations were determined to be clear of subsurface utilities and or obstructions, the pavement and or concrete, when present, was broken up using a jackhammer and hand tools. The upper five feet of soil was then removed by vacuum excavation and or hand tools to confirm the absence of utilities. A similar procedure was followed inside buildings where utilities were cleared first by coring through the floor and then clearing with a hand auger and/or vacuum excavation to approximately 5 feet bgs.

Additional steps were taken within the MTA ROW because of the known presence of direct-buried train signal lines and three large (i.e., 12 to 24 inch-diameter) sanitary force mains. MTA personnel assisted in the location of its utilities within the MTA ROW. In addition, vacuum excavation was conducted in the vicinity of the sanitary force mains to visually confirm their depths and locations.

2.2 Community Air Monitoring

Community air monitoring was conducted during RI activities to provide a measure of protection for the downwind community (i.e., off-site receptors and on-site workers not directly involved with the RI work activities) from potential airborne constituent releases as a direct result of investigation activities. Air monitoring was conducted in general accordance with the community air monitoring plan (CAMP) developed by Con Edison, NYSDEC and New York State Department of Health (NYSDOH). The CAMP was designed as a proactive series of steps to monitor, prevent and, if necessary, mitigate potential fugitive emissions of VOCs and airborne particulates (dust) during intrusive activities that were planned during the RI. The specific procedures followed at the Site, including action levels, are summarized below and outlined in Section 3.2 of the Site Characterization Study Work Plan, Pemart Avenue Works Former MGP (ENSR, 2005).

During ground-intrusive activities (e.g., excavation of test pits, advancement of soil borings, and installation of monitoring wells), ambient total VOC and particulate concentrations (PM-10) were monitored continuously. Air quality was also monitored periodically during non-intrusive activities (e.g., surface soil and groundwater sampling). All monitoring data are provided on a compact disc in Appendix B.

VOCs in air were measured using a photoionization detector (PID) and dust was measured using a PM-10 particulate meter. One upwind and one downwind location adjacent to each work area were selected daily to monitor work onsite. Continuous measurements of total VOCs and PM-10 were reported as 15-minute averages. Air measurements were obtained over a period of 30 minutes prior to field activities each day to establish background levels of analytes in ambient air.

The action levels established for community air monitoring were not exceeded as a result of intrusive activities. Occasional exceedances of short duration were detected during the field investigation. In all such cases, the exceedances were directly attributed to nearby vehicular traffic (cars, trucks, and railroad cars) and routine operations at local commercial operations, such as spray application of varnish and paints related to furniture manufacturing. When exceedances were detected, the PID and PM-10 meters were closely monitored while the VOC and or particulate levels returned to below action levels and or to background levels.

2.3 Surface Soil Sampling

Surface soil samples were collected from locations across the Site to evaluate the potential influence of former Site operations on surface soil quality. Samples were spatially distributed in unpaved areas with sample locations biased toward areas which contained former MGP or EGP structures. Twelve surface soil samples (SS-1 through SS-12) were collected. Five of these locations (SS-8 through SS-12) are background locations (locations outside the former MGP and EGP operational areas).

Surface soil samples were collected using pre-cleaned stainless steel trowels and bowls. At each sample location, surface vegetation was removed and the sample was collected from within a square meter from a depth of 0- to 2-inches. Each sample was collected as a composite of five discrete samples, four from the corners and one from the center of the square-meter area. Soil at each location was visually classified for soil type, grain size, texture, moisture content, and visible evidence of staining or impacts using United Soil Classification System (USCS). The soil at each location consisted of dry, dark brown, sandy topsoil (loam). At seven of the twelve surface soil sample locations, debris, including glass fragments, plastic, gravel, clinker, brick fragments, or bottle caps, was encountered in the surface soil but not incorporated into the samples submitted to the laboratory. Debris was not present at locations SS-13 or SS-9 through SS-12.

2.4 Test Pit Excavations and Soil Sampling

Although not included in the Work Plan, five test pits (TP-1 through TP-5) were excavated in areas of the former MGP gas holders and fuel oil tank to determine the presence of historic MGP structures in the

subsurface and to determine the presence or absence of MGP-related wastes contained within these structures. Test pits were excavated by backhoe and were advanced to refusal (e.g., bedrock, structure, etc.) or to the water table at depths ranging from 0.5 feet to 5.5 feet. During test pit excavation, soil was visually classified for soil type, grain size, texture, moisture content, and visible evidence of impacts. In addition, soil was screened for VOCs by headspace analysis with a PID. The PID readings were recorded on the test pit logs, which are included in Appendix A.

Subsurface soil samples were collected from three of the five test pit locations (TP-2, TP-3, and TP-4). Soil samples were selected for collection based on PID screening and/or visible evidence of impact. Soil samples were not collected from TP-1 due to shallow refusal and TP-5 due to the presence of clean sand and gravel backfill.

Upon completion, the test pits were backfilled with the excavated soil. All soil excavated from the test pits was returned to the ground. No soil investigation derived waste (IDW) was generated during this activity.

2.5 Soil Boring Advancement and Subsurface Soil Sampling

Soil borings were advanced at 46 locations (SB-1 to SB-41 and MW-1A to MW-27) to characterize the nature of subsurface soil, evaluate the presence of MGP residuals and other constituents in soil, and for the installation of monitoring wells. In general, soil borings were advanced to the first semi-confining unit in the northern area of the Site where the former EGP was located. As no field evidence of impacts, such as odors, staining, elevated PID readings, non-aqueous phase liquid (NAPL), etc., were detected in this area of the Site, soil borings were not advanced below the upper semi-confining unit. In the southern area of the Site, where the former MGP was located, evidence of subsurface impacts was detected, and included elevated PID readings, odors and NAPL. Accordingly, many of the borings in the vicinity of the MGP were advanced to the lower semi-confining unit or bedrock. Soil borings SB-21, SB-25, and SB-26, which were located at or in the immediate vicinity of former gas holders, were advanced into bedrock and completed as bedrock monitoring wells, MW-1B, MW-13, and MW-9, respectively.

Soil borings were advanced using a variety of drilling techniques including hollow stem auger (HSA), direct push, drive and wash, wash rotary, hand augering, and rock coring. A majority of the soil borings were advanced via HSA drilling methods. At one location (SB-10), the drive and wash drilling technique was used to see if it would improve drilling efficiency and sample recovery. Significant improvements were not observed, so the HSA drilling method was used for subsequent borings. Soil borings with access difficulties for drilling equipment were advanced via direct push drilling techniques.

At nine locations (MW-5, MW-7, MW-8, SB-5/MW-2, SB-6/MW-3, SB-12/MW-25, SB-13/MW-24, SB-16/MW-26, and SB-38/MW-20), the borings were advanced deeper than the final monitoring well depth. At these locations, the borings were backfilled to the well depth prior to installation of the monitoring well.

Soil samples were collected at two soil boring and three manhole locations within the former EGP building. Boring SB-23 was cleared via hand auger to the water table in the southwestern corner of the building after a hole was cored through the concrete floor to allow access to the crawl space and soil beneath. A subfloor was not confirmed at the SB-23 location. Due to the unknown structural integrity of the floor above the crawl space, and the inherent safety concerns, a direct push rig was not mobilized to this location.

Boring SB-28 was advanced by direct push drilling techniques in the adjoining building north of the former EGP building. A hole was cored through the concrete floor to expose the underlying soil. No crawl space or subfloor were observed.

At three locations (MH-1 MH-2, and MH-3), the crawl space was accessed through manholes in the floor that were historically used during operation of the generating plant. Samples of accumulated soil above the

concrete subfloor were collected via hand auger or handheld direct push tools. Borings were not advanced through the subfloor at these locations.

One indoor soil boring (SB-41) was advanced within the former MGP building using handheld direct push tools.

Soil samples were collected during boring advancement and from the three manhole locations. During HSA and drive and wash drilling, soil samples were collected using a 2-inch diameter split spoon sampler. Soil samples were collected using a 3-inch diameter 4-foot or 5-foot long macro core sampler lined with a clean disposable acetate sleeve during direct push drilling. A closed-piston sampler was used beneath the water table in order to obtain discrete (intact) soil samples from each sample interval.

At each location, a soil sample was collected from within the upper five feet of the soil borings and from the base of the soil boring. If visual impacts or elevated PID readings were observed, two additional samples were collected. One sample was collected from a 6 to 12-inch interval from the zone with the highest PID reading or that exhibited the strongest physical evidence of impact (e.g., NAPL, staining, sheen, odor) and one soil sample was collected from below this zone to define the vertical extent of impacts at that location. If no impacts were detected a sample was collected from directly above the water table. Select soil samples containing heavy impacts were analyzed for fingerprint. Table 2-1 provides a summary of collected samples, sample depths, sample identifications, and analytical parameters.

Soil samples were visually classified for soil type, grain size, texture, moisture content, following the USCS and for visible evidence of impacts. In addition, the soil samples were screened for total VOCs in soil headspace using a PID. PID readings are recorded on the boring logs, which are included in Appendix A.

Upon completion, borings not completed as monitoring wells were backfilled with grout dispensed through a tremie pipe. Hydrated bentonite pellets were used at three borings (SB-15, SB-35, and SB-30) in the MTA ROW and in one boring (SB-20) between the MTA ROW and the Hudson River because of limited access and availability of water.

All soil cuttings and other IDW were placed in clean Department of Transportation (DOT)-approved 55-gallon drums, sealed, and labeled for temporary storage on site, prior to disposal off site (see Section 2.11).

2.6 Monitoring Well Installation

Groundwater monitoring wells were installed primarily to assess groundwater quality, but in some instances were installed to solely gauge the nature and extent of NAPL. Gauging of the fluid levels in the wells was also conducted to evaluate tidal influences and evaluate groundwater flow direction and gradient. Monitoring wells were installed in each of three primary aquifer zones present at the site, which were shallow (water table), intermediate, and bedrock. Throughout this section, all sampling locations are referenced by the monitoring well designation only. For example, SB-5/MW-2 is discussed as MW-2. Construction details are provided on the monitoring well construction logs located in Appendix A. Monitoring well locations are shown on Figure 2-1.

Twenty-three monitoring wells were installed in the shallow zone, or first water-bearing unit encountered (i.e., water table aquifer). As described in Section 3.2, this zone is comprised of the fill unit and the upper sand unit. All but one of the shallow wells (MW-5) were screened across the water table with approximately 2 feet of screen above the water table. In general, the bottoms of these screens were installed to the top of the first semi-confining unit and the lengths of the well screens vary based on the depth to the first semi-confining unit. Seventeen of the shallow zone wells were located in areas where NAPL was observed or suspected and included the installation of a 1- to 2-foot sump to collect dense non-aqueous phase liquid (DNAPL), if present, and to collect any fine suspended sediments that settle out of the water column.

One shallow zone well, MW-5, was screened from 8 to 13 feet bgs at the bottom of the shallow zone, but not across the water table. This well was paired with shallow zone well MW-12, which was screened across the water table to a depth of 8 feet bgs. These paired wells were installed to independently monitor for the presence of light non-aqueous phase liquid (LNAPL) at MW-12 and DNAPL at MW-5.

Two monitoring wells (MW-17 and MW-18) were installed as intermediate zone wells. As described in Section 3.2, these wells were screened in a sand lens that was encountered within the upper silt/clay unit (first semi-confining unit) in the southern half of the site. At the intermediate depth wells, the augers were advanced approximately three feet into the first semi-confining unit, a 4-inch diameter permanent outer steel casing was installed to one foot below the bottom of the auger and grouted in place as the augers were removed. After the grout was allowed to set, the boring was advanced through the upper semi-confining unit to the target depth using the drive and wash drilling method. The 4-inch diameter steel casing was installed to prevent the potential migration of impacted materials and or DNAPL from the shallow zone into intermediate sand. The intermediate depth wells were constructed using a 10 foot-long screen, with the top of the screen at a depth of approximately 1.5 to 2 feet below the bottom of the steel casing or approximately 20 to 30 feet bgs.

Three bedrock monitoring wells (MW-1B, MW-9, and MW-13) were installed at the Site immediately downgradient of the subsurface remnant gas holder foundations. The bedrock monitoring wells were installed through 4-inch steel casings grouted into bedrock to prevent the migration of DNAPL and or impacted materials from the shallow zone, if any, into bedrock monitoring wells. These wells were constructed by advancing a boring to the top of bedrock using HSA drilling methods and then advancing one foot into bedrock using wash rotary drilling methods. After this initial drilling, a steel casing was set into the bedrock 'socket' and tremie grouted into place. After the grout had set for at least 24 hours, the borings were advanced into bedrock using a 2.875-inch diameter rock core barrel. The bedrock wells were constructed with 10 feet of well screen that was generally positioned below the bottom of the steel casing to bottom of screen depths ranging between 14.5 and 29.5 feet bgs.

The monitoring wells were constructed of 1-inch or 2-inch internal diameter flush-jointed Schedule 40 poly vinyl chloride (PVC) riser pipe with a 0.10-inch slot well screen and a locking well cap. All of the wells were constructed as 2-inch diameter PVC casing and screen, except wells MW-9, MW-20, MW-21, and MW-22, which were installed in the City of Peekskill parcels located west of the MTA ROW and the Hudson River. These wells were constructed as 1-inch diameter wells. At all wells, a sand pack was placed in the borehole annulus to a level of approximately two feet above the top of the well screen followed by a two-foot thick bentonite seal. The remainder of the borehole annulus was backfilled to one foot bgs with cement-bentonite grout via a tremie pipe or by hydrated bentonite pellets. All but five of the wells were completed with a one-foot square concrete pad at grade and a flush-mounted road box. The five wells installed west of the train tracks (MW-15, MW-19, MW-20, MW-21, and MW-22) were completed above grade with locking protective steel casings.

Monitoring wells were left undisturbed for a minimum of 24 hours after installation to ensure that the cement/bentonite grout had set. Prior to development, the static water level and well depth was measured using an electronic oil/water interface probe. Wells where DNAPL was detected were developed in a manner to minimize the potential of smearing NAPL over the well screen. Development was performed by surging and pumping using a Waterra™ hand pump and/or a submersible Whale pump and was considered complete when the discharging water looked relatively clear and/or after a minimum of three, and a maximum of ten, well volumes had been removed from the well.

Water removed during development and other IDW was contained in clean DOT-approved 55-gallon drums, sealed, and labeled for temporary storage on site, prior to disposal off site (see Section 2.11).

2.7 Groundwater Sampling

Groundwater samples were collected from monitoring wells using low-flow purging and sampling procedures according to the NYSDEC Draft DER-10 Technical Guidance for Site Investigation and Remediation (December 2002) and the USEPA Region I Standard Operating Procedure (SOP) titled "Low Stress Purging and Sampling Procedure for the Collection of Groundwater Samples from Monitoring Wells," Revision 2, July 1996. Groundwater was not sampled from wells that exhibited evidence of NAPL.

Each well was purged prior to sampling. Groundwater was pumped through a multi-parameter water quality meter equipped with a flow-through cell. The following parameters were measured along with water level drawdown, flow rate, and purge volume: pH, conductivity, temperature, dissolved oxygen (DO), and oxidation reduction potential (ORP). Water quality parameter measurements were recorded approximately every 5 minutes for the first 20 minutes of sampling, and every 15 minutes thereafter, until a minimum of three system volumes (capacity of the pump, tubing and flow-through cell) were purged and parameters stabilized.

Immediately following purging, groundwater samples were collected and placed into the appropriately preserved sample containers. All groundwater samples were submitted for chemical analyses as discussed in Section 2.12. Results are provided and discussed in Section 4 and a summary of groundwater samples is provided in Table 2-2. Low-flow groundwater sample collection record are provided in Appendix A and a full summary of analytical results is included in Appendix C.

In addition to collecting groundwater samples from monitoring wells, grab groundwater samples were collected during the advancement of two soil borings (SB-16 and SB-30). The grab groundwater samples were collected during direct push drilling by extending a temporary 5-foot long, 1-inch diameter PVC well screen through a temporary direct push casing. The sample at SB-16 was collected across the 31 to 36-foot interval using a peristaltic pump. The sample at SB-30 was collected across the 30 to 35-foot interval using a Waterra™ inertial lift pump as the peristaltic pump was unable to lift the turbid water from this depth. These grab groundwater samples were very turbid and were collected without a sand pack and without a good seal with overlying formations despite having installed a temporary casing into the upper silt/clay unit prior to advancing the boring with a closed-piston (i.e. discrete) sampler. Therefore, these samples are likely not representative of groundwater in the deep zones sampled. The analytical results of these grab samples are not included in Section 4 tables, but are included in the full analytical results in Appendix C.

Water removed during groundwater sampling and other IDW was contained in clean DOT-approved 55-gallon drums, sealed, and labeled for temporary storage on site, prior to disposal off site (see Section 2.11).

2.8 Fluid Level Monitoring

Fluid level monitoring (LNAPL, DNAPL, and water level) was conducted to evaluate groundwater flow and the presence or absence of NAPL. Fluid levels were measured using an electronic oil/water interface probe accurate to within 0.01 feet. These measurements were recorded from the surveyed measuring point of the well (i.e., the highest point of the top of the PVC riser). In addition, water level and total well depth measurements in each of the monitoring wells were recorded immediately prior to purging the wells for groundwater sampling. The results of the fluid level monitoring are discussed in Section 3.

2.9 Tidal Survey

A tidal survey was conducted over a 48-hour period from May 3 to 5, 2006. The objective of the tidal survey was to evaluate the influence of tidal fluctuations in the Hudson River on groundwater levels at the Site. The tidal survey entailed measuring water levels in four monitoring wells (MW-13, MW-14, MW-16, and MW-18) and in the Hudson River piezometer (see Figure 2-1) continuously over a 48-hour period using pressure

transducers. The tidal survey locations (one bedrock well, two shallow wells, and one intermediate well) were selected to monitor the tidal influence on groundwater at the Site; both vertically and horizontally. Each transducer was set at a predetermined depth below the top of casing, which was surveyed at each location, so that the water level measurements could be converted into elevation measurements.

In-Situ™ Mini Troll Pro pressure transducers were used to measure and log the water levels. These transducers measure water levels by recording the pressure of the water column above the transducer. The transducers have an internal program that stores the data and converts the pressure readings into depth-to-water measurements. Following completion of the tidal survey, the data was downloaded and evaluated.

A summary of the well depths and distance from the Hudson River is presented in Table 2-3. The tidal survey results are presented in Appendix D and discussed in Section 3.2.7.

2.10 Site Survey

The RI sampling locations (i.e., test pits, surface soil locations, soil borings, and monitoring wells) were surveyed by GEOD, a licensed, New York State surveyor. The horizontal coordinates and vertical elevations were measured for each sampling point. At each well, the top of PVC well casing and ground surface (i.e., road box rim) elevations were also surveyed. All vertical measurements were recorded relative to the 1988 USGS National Geodetic Vertical Datum (NGVD), and all horizontal measurements were surveyed in New York State Plane coordinates using the 1983 North American Datum (NAD83).

Sampling locations MH-1, MH-2, MH-3, SB-28, SB-41, SS-10, SS-11, and SS-12 were not surveyed during the site-wide survey due to their inaccessibility at that time. These sampling locations are approximated on figures in this report.

2.11 Waste Management

IDW generated during the RI field investigation included soil cuttings, debris from borings (e.g., concrete and bricks), concrete cores from the interior soil borings, drive and wash drilling water, decontamination water, monitoring well development and purge water, used personal protective equipment (PPE), used polyethylene sheeting, and used disposable sampling equipment. All IDW was containerized in clean 55-gallon DOT-approved drums, characterized, transported by Clean Venture – Cycle Chem, and disposed as non-hazardous waste at GROWS Landfill in Falls Township, PA, a licensed waste management facility.

2.12 Sample Analysis

All samples, except the samples analyzed for gas chromatograph/flame ionization detector (GC/FID) fingerprint analyses, were submitted to Columbia Analytical Services (CAS) in Rochester, NY, for chemical analysis. The GC/FID fingerprint samples were submitted to META Environmental (META) in Watertown, MA. CAS provided the analytical results in paper and electronic format. The paper format was provided as NYSDEC Analytical Services Protocol (ASP) Category B deliverables. META provided the results of their analysis in paper report format. The electronically formatted data was loaded into the Site database. The analyses performed, by media, are presented in Table 2-4.

A Data Usability Summary assessment was performed to determine the usability of the data collected during the RI for the purpose of assessing soil and groundwater quality, delineating impacted media, and evaluating potential risks associated with the chemicals detected. The results of the data assessment are summarized in the Data Usability Summary Report (DUSR), which was prepared in accordance with the NYSDEC Guidance for Development of Data Usability Summary Reports (NYSDEC 2001). Usability was evaluated by reviewing the data following USEPA Region 2 Data Validation Standard Operating Procedures (SOPs) as guidance.

Where necessary, the Region 2 SOPs were modified to incorporate project-specific or method-specific criteria. Data qualifiers were applied consistent with the Region 2 guidance. All elements reviewed in preparing the DUSR were consistent with those specified in the NYSDEC guidance (NYSDEC, 2001). The DUSR is provided on a compact disc as Appendix F.

Based on the results of the data usability assessment, as described in detail in the DUSR (Appendix F), it is concluded that the majority of the dataset are valid as reported and may be used for assessment and decision-making purposes. Selected data points (e.g., lead in surface soil) were rejected (R) or qualified as non-detect (U), estimated (J), or estimated non-detect results (UJ) based on certain quality control nonconformances, all of which are described in the DUSR.

3.0 Field Investigation Results

This section summarizes the field observations made during the RI, including the Site geology and hydrogeology and field evidence of potential soil and groundwater impacts. Based on these observations, the apparently impacted soil is delineated and a summary of the apparent source areas are identified.

3.1 Site Geology

Five test pits and 51 soil borings, including 17 soil borings (primarily in the southern portion of the site) to bedrock, were excavated to evaluate environmental conditions and characterize the geology beneath the Site (see Figure 2-1). The Site is located in a narrow (110 to 250 feet wide) isolated piece of land situated between Peekskill Bay on the Hudson River to the west and steeply sloping bedrock cliffs to the east. The Site is underlain by glaciofluvial sediments deposited in the Hudson River Valley along Peekskill Bay. These sediments range in thickness from 4.5 feet and 43.5 feet and consist primarily of silt with interbedded layers of sand, clay, and peat. Due to the nature of the environments in which sediments were deposited, the sediment layers vary in thickness and are not continuous across the Site. The geology is depicted in four cross sections, Figures 3-1 through 3-4, and described in detail below.

3.1.1 Fill Unit

The fill is the uppermost unit and is present across the Site to varying depths of approximately 3 to 20 bgs. The fill is generally organically rich and in various areas of the Site, included silt, sand, gravel and various debris (e.g., glass, wire, bottle caps, plastic, clinker, coal fragments, wood fragments, concrete, steel plates, brick fragments, etc.). The water table was generally observed within the fill unit.

3.1.2 Upper Sand Unit

The upper sand unit was encountered beneath the fill unit in southern portions of the Site (see Figure 3-1 and Figure 3-3). This unit extends to the upper silt/clay unit and ranges in thickness between 2 and 18 feet, with the top of the unit encountered from 4 to 13 feet bgs and the bottom of the unit encountered between 15 and 30 feet bgs. The upper sand unit is absent in the eastern portion of the site and the fill unit extends to the next underlying unit. This upper sand unit is primarily composed of fine to medium-grained sand. Some silt, coarse sand and/or fine gravel were also observed, although they were less prevalent.

3.1.3 Upper Silt/Clay Unit

The upper silt/clay unit is present beneath most of the Site; however, it was not observed in a small area in the eastern portion of the Site where the overburden pinches out against the adjacent bedrock outcrops. This unit ranges in thickness between 1 foot and 20 feet, with the top of the unit observed from 7 to 22 feet bgs. The bottom of the upper silt/clay unit was observed between 15 and 43 feet bgs. This unit is variable both horizontally across the Site and vertically within specific borings and ranged from a sandy silt unit to a silty clay unit to alternating clay and silt, and contains gravel in some locations.

Within this silt/clay unit are lenses of peat and sand. The sand lenses form a somewhat continuous unit referred to in this report as the intermediate sand unit. Two peat lenses were observed at three soil boring locations. SB-11 and SB-16 appear to extend into one peat area and MW-8 appears to pass through a second peat area (see Figure 3-1). The peat lenses range in thickness from 4 to 8.5 feet, with the top of the lenses observed between 22.5 and 25 feet bgs. A sand lens and a gravel lens also appear within this unit (see

Figure 3-4); the sand lens is approximately 7 feet thick and occurred at 17 feet bgs at MW-7 and the gravel lens is approximately 1 foot thick and appeared at 24 feet bgs at SB-8.

3.1.4 Lower Sand Unit

The lower sand unit was observed throughout the Site. This sand unit appears to begin between approximately 10 feet bgs (see Figure 3-3) and 31 feet bgs (see Figure 3-4). It varies in thickness from 1 foot (see Figures 3-1 and 3-2) to 7 feet (see Figure 3-1). This sand unit is generally composed of fine to coarse-grained sand. It is not known if this unit is continuous through the northern portion of the Site, since drilling in this area extended only to the upper silt/clay unit. However, this unit was observed in most borings completed in the rest of the Site, with the exception of one location (SB-8), where it was absent (see Figure 3-4).

3.1.5 Lower Silt/Clay Unit

The lower silt/clay unit was encountered beneath the lower sand unit, except in the eastern portion of the Site near the 200,000 cf gas holder (see Figure 3-2), where the lower sand unit was underlain by weathered bedrock and the northern portion of the Site where drilling extended only to the upper silt/clay unit. The lower silt/clay unit ranged in thickness from 2 to 10 feet (see Figures 3-1, 3-3, and 3-4), with the top of the unit observed between 24 and 40 feet bgs and the bottom between 30 and 43.5 feet bgs. This unit ranges from a silty sand with clay, to a clayey silt, to a clay.

3.1.6 Bedrock

Bedrock is present in outcrops in the eastern portion of the Site and was encountered beneath the Site at depths ranging between 5 and 47.5 feet bgs. A weathered bedrock zone was observed above solid bedrock across most of the Site. Where present, the weathered bedrock ranged in thickness between 2.5 and 10 feet, but it may not have been fully penetrated at all locations. In the eastern portion of the Site, a thick weathered bedrock and or talus zone (larger rock fragments along the bedrock slope below ground) was observed above competent bedrock. This area of thick weathered bedrock is the only area of the Site where the upper silt/clay unit was not observed.

Three soil borings in the eastern portion of the Site were advanced into bedrock and rock cores were collected. The thickness of the weathered bedrock unit at these locations ranged from 6 to 10 feet. The top of a competent bedrock unit was observed from 12 to 25 feet bgs.

Based on the rock cores, bedrock at the Site is micaceous dark grey gneiss, with light grey felsic bands. Consistent with the tectonic history (summarized in Section 1.8.1), fractures were common in all three cores. Some of the fracture planes were mineralized with pyrite/pyrohitite.

3.2 Site Hydrogeology

The Site is located along the eastern margin of a steep-sided bedrock valley that contains the Hudson River. The bedrock valley wall that makes up the eastern side of the Site isolates the glaciofluvial sediments that underlie the Site. To the west of the Site is Peekskill Bay on the Hudson River.

Recharge to the groundwater system at the Site is from three sources. The first source is run off from the elevated areas to the east running along the bedrock surface. Some of this runoff is channeled into storm drains that drain the Site. A second source of recharge to the groundwater system is infiltration of precipitation on the Site. A third potential source of recharge, and a likely lesser source, is groundwater seeping from bedrock fractures either as springs above the land surface or as direct flow to the aquifer system.

The Site is relatively flat, so significant overland surface runoff is not likely. However, the areas of former MGP and EGP operations are generally paved or covered by buildings and precipitation in these areas may be drained from the Site through storm drains.

As described below (Section 3.2.1), groundwater at the Site flows from the east towards the Hudson River. A tidal survey performed at the Site (see Section 3.2.7) during the RI shows that groundwater levels in all hydraulic units monitored (shallow, intermediate, and bedrock) are influenced by tidal fluctuations in the river.

The aquifer system beneath the site consists of an upper (water table) aquifer separated by an intermediate low permeability aquitard (i.e., upper silt/clay unit), and a lower aquifer, which is generally separated from the bedrock aquifer by a deeper low permeability unit (i.e., the lower silt/clay unit). These hydraulic units are described below.

3.2.1 Upper Aquifer

The first hydraulic unit beneath the Site is the upper aquifer and includes the fill and upper sand units. This unit ranges in thickness between 0 feet (where bedrock outcrops) and 30 feet (SB-12). The water table was encountered in this unit at depths ranging between approximately 3 and 8 feet bgs. A round of water level measurements in wells completed in the upper aquifer, referred to in this report as shallow wells, was completed on May 2 and 3, 2006. No significant precipitation event occurred during water level measurements. These measurements were used to construct a groundwater flow map for the water table (Figure 3-5). This water table map shows that groundwater flow in the upper aquifer is west towards the Hudson River.

3.2.2 Semi-Confining Unit (Upper Silt/Clay Unit)

The second hydraulic unit observed at the Site is the semi-confining unit and includes the upper silt/clay unit. This semi-confining unit was observed in borings across the Site, except in the eastern portion of the Site, and ranged in thickness between 0 feet (where bedrock outcrops) and 20 feet (SB-10).

3.2.3 Intermediate Sand Aquifer

Within the upper silt/clay unit there are lenses of sand that form what is referred to in this report as the intermediate sand aquifer. This aquifer was observed in the southern portion of the Site. Where present, the intermediate sand aquifer was about 7 feet thick and occurred at 17 feet bgs. Two monitoring wells (MW-17 and MW-18) were screened in this aquifer and are referred to as intermediate depth wells.

Water level measurements from MW-17 and MW-18 show significantly different piezometric elevations, at one location the piezometric surface in this unit is above (piezometric elevation of 3.27 feet relative to mean sea level [ft rmsl]) the water table observed in the shallow aquifer and at one location it is below (piezometric elevation of -0.11 ft rmsl) the water table. Piezometric fluctuations produced by tidal fluctuations (as observed during the tidal survey) are not likely to account for these relatively large differences in water level elevations.

3.2.4 Lower Sand Aquifer

The semi-confined lower sand aquifer is separated from the upper aquifer and intermediate sand aquifer by the upper silt/clay unit and is either directly in contact with weathered bedrock below (see Figure 3-2) or is underlain by a silt/clay unit. Although the upper silt/clay unit is somewhat heterogeneous and contains sand and gravel in some locations, analytical results (see Section 4) generally indicate that communication between the upper sand aquifer and the intermediate and lower sand aquifers is not occurring through the upper silt/clay unit. However, at the northeast portion of the site, bedrock is overlain by weathered bedrock which may provide a path for groundwater migration between the aquifers in that area.

Groundwater monitoring wells were not completed in the lower sand aquifer, so there is no information on the potentiometric surface or direction of groundwater flow in this lower aquifer unit.

3.2.5 Lower Silt/Clay Unit

A lower silt/clay semi-confining unit was observed below the lower sand aquifer and above bedrock over most, but not all of the Site where borings were advanced to bedrock. Where present, this unit ranged up to 5 feet in thickness.

3.2.6 Bedrock/Weathered Bedrock Unit

Bedrock is observed at the Site in outcrops along the eastern portion of the Site (i.e., the parcels east of North Water Street.) It was also encountered in borings at depths ranging between 5 (SB-21) and 47.5 feet bgs (SB-(MW-8). When encountered in the subsurface, the bedrock was overlain by a weathered bedrock zone. When penetrated, the weathered zone ranged in thickness between 2.5 and 10 feet.

Three monitoring wells (MW-1B, MW-9, and MW-13) were completed in competent bedrock in the eastern portion of the Site. The bedrock is micaceous dark gray gneiss and groundwater flow is through fractures. The groundwater levels in these three monitoring wells ranged between approximately 6.5 and 7.5 feet bgs. The groundwater elevations in two of these wells are above the elevations in the shallow aquifer wells and below in one of the bedrock wells. The one bedrock monitoring well (MW-1B) with a groundwater elevation below the shallow aquifer wells is the shallowest of the three bedrock monitoring wells.

3.2.7 Tidal Survey

As described in Section 2, a tidal survey was performed to evaluate the potential influence of tidal fluctuations on groundwater beneath the Site. This survey included a piezometer installed approximately 15 feet into the Hudson River beyond the low tide line, two shallow monitoring wells (MW-14 and MW-16), one intermediate depth monitoring well (MW-18), and one bedrock monitoring well (MW-13). Graphs of the water levels observed during the tidal survey over time are included as Figure 3-6 and the tidal survey water level data is provided in Appendix D.

During the 48-hour period of the tidal survey, the Hudson River water level transitioned through four tidal cycles with a tidal range of approximately 3.75 feet. Water levels in shallow monitoring wells MW-14 and MW-16, which are located 216 and 72 feet, respectively, from the Hudson River, were both influenced by tidal fluctuations. The tidal effect was greatest closest to the river in MW-16 where fluctuations in water level were approximately 80% of that in the river and least in MW-14 (furthest from the River) where only approximately 12% of the tidal changes of the river were detected. This decline in tidal related water level fluctuation with distance from the River is typical of hydraulic units in contact with tidal surface water bodies and shows the declining influence of the tidal fluctuations with distance from the tidal water body.

The tidal survey included one intermediate depth well, MW-18, located 210 feet from the Hudson River. This well also shows fluctuation in piezometric surface in response to River level fluctuations with 16 percent of the fluctuation observed in the River and approximately the same level of fluctuation as observed in the shallow monitoring well (MW-14) located approximately the same distance from the River.

One bedrock monitoring well, MW-13, was included in the tidal survey. This well also shows water level fluctuations in response to river level fluctuations. MW-13 is located 282 feet from the Hudson River. This well shows 8 percent of the fluctuation observed in the River.

The tidal survey shows that the three hydraulic units surveyed, shallow, intermediate, and bedrock, all experience fluctuation in water levels in response to tidal fluctuations in the Hudson River. The survey shows that the magnitude of water level changes decline with distance from the river and that wells in different

hydraulic units at about the same distance from the river have approximately the same magnitude of tidal influence. These results indicate that all the hydraulic units monitored are hydraulically connected to the Hudson River.

3.3 Investigation Results for Potential Source Areas

Site field activities included the investigation of all known potential historic source areas (e.g., gas holders, fuel oil storage tanks, coal storage areas, and operations buildings) associated with the former MGP and EGP operations to evaluate if these structures were still present and if they were potential past or current sources of constituents to the environment. Based on field observations, it was determined that remnants of former MGP and EGP structures are present above grade or in the subsurface and that subsurface soil associated with several of these structures exhibited evidence of contamination.

3.3.1 Former MGP Features

According to the Historical Investigation Report (RETEC, 2002), the following features were associated with the MGP operations at the Site.

- Former MGP Building (generating house, boiler house, storage, and purifying house)
- 200,000 cf Gas Holder
- 100,000 cf Gas Holder
- 30,000 cf Gas Holder
- 25,000 gallon Fuel Oil Tank
- Coal Shed and Coal Pile Area

Aside from the former MGP building and the remnant foundation of the gas holders and fuel oil tank, all of the features listed above have been removed from the Site. The MGP building appeared to be structurally sound and its internal partition walls are consistent with the original partitions when the gas plant was operating. No equipment and/or structures associated with MGP operations were observed inside the former MGP building during the field investigation. The former MGP building is currently used as a wood working shop, a laboratory, and as office space.

The foundation of the 200,000 cf gas holder is still present aboveground to the north of the battery house. The foundation is a massive concrete and brick structure that is 75 feet in diameter and approximately 20 feet tall on its western perimeter. No evidence of coal tar was detected on the remnant foundation, the bedrock, or in soil surrounding the holder foundation.

The foundations of the former 30,000 cf and 100,000 cf gas holders, 25,000 gallon fuel oil tank, and of a former pulsation tank were determined to be present in the subsurface between 0.5 and 5.5 feet bgs on the former MGP parcel east of North Water Street.

Results of the site investigation activities indicate that subsurface soil beneath and downgradient of the former MGP operations is impacted with MGP residue, including sheen, coal tar, and MGP odor. Site cross sections shown in Figures 3-1 through 3-4 show the vertical extent and Figure 3-7 shows the horizontal extent of MGP and non-MGP impacts in the subsurface. The MGP-related impacts are primarily present in the fill unit and extend into the top of the upper silt/clay semi-confining unit, the top of which was encountered between 7 and 22 feet bgs. There was no visual or olfactory indication of impact (sheen, odor, or NAPL) or elevated PID readings, below the upper semi-confining unit.

Localized occurrences of MGP-related impacts were detected in overburden above the bedrock in the eastern-most portion of the former gas plant in the vicinity of the former gas holders. The upper silt/clay unit is absent from this area as this is where the sediments lap onto the bedrock valley walls. A weathered bedrock zone was noted in this location. No evidence of NAPL was detected in bedrock at these locations.

Based on these observations, it appears that the likely historical sources of MGP residue in the environment were the 100,000 cf and 30,000 cf gas holders. There is no direct evidence that the former MGP building or the 200,000 cf gas holder were also historical sources of MGP residue to the environment; however, more NAPL was observed downgradient than upgradient of the former MGP building. This apparent increase in coal tar NAPL downgradient from the former MGP building is potentially due to the fact that top of the upper silt/clay semi-confining layer dips downward in the direction of the Hudson River and the overlying fill layer is thicker in this direction. This geologic configuration would allow a thicker accumulation of NAPL above the silt/clay semi-confining layer downgradient of the former MGP building. The building appears to be structurally sound and it does not appear that either the building or the remnant bases of the gas holders are ongoing sources of NAPL or MGP constituents to the environment.

Evidence of petroleum-related impacts to subsurface soil was observed co-mingled with the MGP-related impacts to the environment in the vicinity of the former MGP operations. Field evidence was limited to a petroleum-like odor; however, fingerprint results from META, as discussed in Section 4.2, indicate the presence of weathered fuel oil and an unidentified light oil-like material mixed with, but unrelated to the coal tar. Based on the location, it appears that the 25,000 gallon fuel oil tank was the likely historical source of the petroleum impacts. The distribution of petroleum-related impacts along the axis of the former Pemart Avenue indicates the potential of migration along utilities located in the street.

Test pit excavation activities identified the horizontal limits of the fuel oil tank including the base and the remains of the steel tank bottom. Field observations indicated that there appears to be a void below the metal tank remains, but the tank bottom was not disturbed during investigation activities.

The coal shed and coal pile areas are no longer present at the Site. No evidence of coal or ash material was observed at SB-29 which was advanced within the former coal pile area. Ash was observed in the upper 5 feet of boring SB-30 which was advanced in the vicinity of the former coal shed. A significant volume of ash was observed in nearly all of the borings advanced along, or within close proximity to the MTA ROW. A significant layer of ash material was also observed in SB-11 which was advanced within the vicinity of the former coal conveyor; however, this location is also along the MTA ROW. The exact source, or source(s), of this ash material is not known; however the potential sources include the coal conveyor from the former EGP operations and the coal shed.

3.3.2 Former Electric Generating Plant (EGP) Features

According to the Historical Investigation Report (RETEC, 2002), the following features were associated with EGP operations at the Site.

- Former EGP Building
- Battery House
- Fuel Oil Tank and Building
- Transformer Area
- Coal Conveyor

Aside from the former EGP building and the battery house, all of the features listed above have been removed from the Site. The EGP building appeared to be structurally sound and was determined to have been

constructed with a sub-slab crawl space under the original portion of the building. Observations at SB-28 did not reveal the presence of a crawl space beneath the adjoining building to the north. Four manholes that allow direct access to the crawl space were observed in the ground floor of the EGP. In addition, numerous cables and/or pipes extend beneath the slab floor of the EGP building and appear to extend through the concrete floor of the EGP. These cables and/or pipes were covered by metal caps on the top-side of the floor surface. Based on these observations, the crawl space appears to have been designed to allow access to the utilities that extended from the electric generators and transmission components (e.g., transformers, etc.) for maintenance, etc. No equipment and/or structures associated with EGP operations were observed inside the former EGP building during the field investigation. The former EGP building and the adjoining building to the north are currently used as wood working shops, an umbrella factory, and a homeless shelter.

In general, no visual impact (odor, sheen, or NAPL) or elevated PID readings were observed upgradient, adjacent to the north, underneath, or downgradient of the former EGP building. Co-mingled MGP-like and petroleum-like odor and NAPL were observed in subsurface soil adjacent to, south, and downgradient of the former EGP building. These impacts appear to be attributable to the former MGP and not the former EGP operations. Non-MGP related NAPL was observed in the soils in the crawl space. No MGP-like odor was observed in the soils of the crawl space. A soil sample from the crawl space was submitted for fingerprinting analysis. The results of these analyses are presented in Section 4.

No evidence of the former fuel oil tank, which had been located at the north end of the former Pemart Avenue, or the nearby building were found on site. Similarly, no physical evidence of petroleum-related impact (e.g., NAPL, sheen, odor, or elevated PID readings) was observed in borings and monitoring wells located downgradient of the historical locations of these structures.

The former transformer area, abutting the original footprint of the EGP building, is currently enclosed by the adjoining building north of the former EGP. No equipment and/or associated structures associated with the transformers were observed in the former transformer area. Additionally, no evidence of a sub-floor or physical evidence of petroleum-related impact (NAPL, sheen, odor, or elevated PID readings) were observed in the former transformer area during drilling activities.

Other than the petroleum-related NAPL in the crawl space soils, these observations indicate that the former EGP building, fuel oil tank, and transformers, are not historical or current sources of constituents to the environment. The source of the petroleum-related NAPL in the crawl space soils is not known. The former transformer area is currently used by the wood working shop for automobile and commodities storage.

The former Battery House is still present at the Site. It is currently boarded-up and locked. This building was not identified as a structure that would typically release constituents to the environment, so no detailed investigation specific to this area of the Site was performed. It is anticipated that the battery house was used for the storage of lead acid batteries and accordingly it is likely that the only constituents stored and or used in this facility would have included lead and acids. Lead batteries also may have included small amounts (4 percent or less) of other inorganic constituents including calcium, copper, silver, antimony, arsenic, or tin. Lead concentrations above the NYSDEC RSCO of 37 mg/kg were detected ranging from 58 to 135 mg/kg in borings SB-7, SB-24, and MW-5, located downgradient and within 90 feet of the battery house. Lead at 460 mg/kg was also detected in SB-21 located 18 feet north of the battery house. These lead concentrations cannot be directly attributed to the battery house as these borings are also located in close proximity to the former coal conveyor where coal, coal ash have been observed. Additionally, groundwater samples in the area did not exhibit sub-neutral pH.

The coal conveyor was located south of the former EGP building and was oriented east to west between the former EGP and MGP buildings, across the railroad tracks, and into the Hudson River. This structure is no longer present at the Site, but borings SB-24(1) and SB-24(2) (two unsuccessful boring attempts) encountered shallow obstructions that might be the footer of this conveyor, or bedrock highs. A layer of ash material was observed in the upper 5 to 7 feet of nearly all borings advanced along the MTA ROW. The exact source(s), of

this ash material is not known; however potential sources related to the former MGP and EGP include the former coal shed, coal conveyor, and coal pile areas.

3.4 Off-Site Areas

Adjacent off-site areas south and west (downgradient) of the former MGP were investigated in order to complete delineation of impacts that appear to originate at the Site.

The area to the south is currently used as a paved City of Peekskill municipal parking lot. Soil borings SB-34 and SB-36 and monitoring well MW-14 were installed in this area (Figure 2-1). No physical evidence of MGP or petroleum-related impacts (e.g., odor, sheen, NAPL or elevated PID readings) was detected in subsurface soil and or groundwater at these locations, so the RI was not expanded further south.

A total of seven soil borings (SB-20, SB-32, SB-33, SB-37, SB-38, SB-39, and SB-40) and six monitoring wells (MW-15, MW-16, MW-19, MW-20, MW-21, and MW-22) were completed in the parcels west (downgradient) of the former MGP between the MTA ROW and the Hudson River. Physical evidence of MGP residue (e.g., odor, sheen, NAPL or elevated PID readings) and/or petroleum-related NAPL was detected in subsurface soil and or groundwater at these locations, with the exception of the southern-most soil borings/monitoring wells SB-37/MW-19 and SB-40/MW-22 (Figure 3-7).

3.5 Groundwater Quality Parameters

Water quality parameters (pH, conductivity, temperature, dissolved oxygen (DO), oxidation reduction potential (ORP), salinity, total dissolved solids (TDS), and turbidity were measured in the field during well purging prior to collection of groundwater samples. The water quality parameter measurements are summarized in Table 3-2.

Based on the water quality parameter measurements, groundwater at the Site is generally characterized as having a circum-neutral pH, mildly reducing (low ORP), and slightly high salinity and conductivity (especially in the vicinity of the river). The range of ORP is typical for groundwater containing abundant organic matter, such as peat, and organic contamination (e.g., coal tar). The mildly elevated salinity and conductivity may reflect mixing of the groundwater with the brackish surface water of the Hudson River. Notable exceptions to these overall characteristics is the relatively high pH measured in groundwater samples MW-1B (11.2 standard units [S.U.]) and MW-5 (9.87 S.U.). No obvious source for these elevated pH measurements was observed in the subsurface soil encountered during drilling.

3.6 Limits of Observed Impacts

No staining or odors were observed in any of the surface soil samples or within the upper 1-foot of Site soil boring or monitoring well locations.

Coal tar residue, which included sheen, staining and NAPL was limited to the upper aquifer in areas at and downgradient from the former MGP structures. These MGP-related impacts were generally detected in discrete intervals that typically corresponded to higher-permeability lithologies (i.e., sand lenses) or accumulated in the material above the low permeability upper clay semi-confining unit. Figure 3-7 shows the approximate limits of residual impacts in subsurface soil of the upper aquifer. The locations of the transects for cross sections A-A', B-B', C-C', and D-D' are depicted on Figure 2-1 and the corresponding cross sections are shown on Figures 3-1 through 3-4. NAPL partially penetrates the upper-most portions of the upper silt/clay semi-confining unit including the peat lenses to depths of 20 feet bgs. NAPL and impacted material was not observed below the upper-most portions of the upper silt/clay unit or in the lower sand unit, lower silt/clay unit, weathered bedrock, or in bedrock.

3.7 Summary of Field Observations

This section provides a summary of the RI field observations.

- The Site covers approximately four acres, with approximately two acres on each side of the former Pemart Avenue. With the exception of the steep eastern-most portions of the site, it is generally flat with a gentle slope towards the Hudson River located to the west of the Site.
- The geology at the Site consists of silt with interbedded layers of sand, clay, and peat deposited along the eastern edge of the Hudson River Valley and overlying weathered bedrock and bedrock. The valley wall that occupies the eastern portion of the MGP and EGP Sites is steep and the bedrock is composed of micaceous dark grey gneiss, with light grey felsic bands.
- Groundwater flows from east to west across the Site and ultimately discharges to the Hudson River. Steep bedrock outcrops to the north and east hydrogeologically isolate the unconsolidated aquifer system at the Site. Based on the steep bedrock topography, observed groundwater seeps indicating an upward hydraulic gradient, and variations in water elevations in deep groundwater monitoring wells installed during the RI, which also generally indicate an upward hydraulic gradient, it appears that groundwater may discharge from bedrock fractures into the unconsolidated aquifer system present beneath the Site. Other than this discharge, the bedrock appears to be isolated from the unconsolidated aquifer system by weather bedrock and the upper silt/clay unit.
- Structures associated with the former MGP are present at the Site. Above-grade former MGP structures include the gas works building, the concrete foundation for the 200,000 cf gas holder, and the retaining wall associated with the 100,000 cf gas holder. Subsurface structures present are the foundations of the 100,000 cf and 30,000 cf gas holders, and the 25,000 gallon fuel oil tank.
- Structures associated with the EGP, including the electric generation building, the battery house, and the former transformer area are present at the site.
- Field evidence of MGP residues, which included odors, elevated total VOCs in soil headspace, staining, sheen and coal tar NAPL, were detected in the subsurface soil and groundwater associated with the 100,000 cf and 30,000 cf gas holders and were present above and into the top of the low permeability upper silt/clay unit. NAPL partially penetrates the upper-most portions of the upper silt/clay unit, which forms a semi-confining unit at the Site. Collectively, these impacts encompass an area that includes most of the former MGP, the southern portion of the EGP, and extend offsite to the west beneath the adjacent MTA ROW and onto the undeveloped former industrial properties between MTA ROW and the River.
- No field evidence of contamination related to operations of the former EGP was detected. However, evidence of an non-descript petroleum-like oil was detected in soils collected from the crawl space beneath the EGP.
- The scope of the RI was expanded to include off-Site areas to the west towards the Hudson River and to the south until the visual limits of contamination had been delineated.

4.0 Analytical Results

This section summarizes the laboratory analytical results of surface soil, subsurface soil, groundwater, and NAPL (including Fingerprint and TPH) samples collected as part of the RI. Summaries of detected constituents by media are presented in Tables 4-1 through 4-3 (surface soil), Tables 4-4 through 4-7 (subsurface soil), Tables 4-8 through 4-11 (groundwater), and Table 4-12 (TPH fingerprint in soil) with complete analytical summary tables included in Appendix C (on CD). Fingerprint analytical data packages are included in Appendix E (on CD). The results of the data usability assessment are presented in the Data Usability Summary Report (DUSR) in Appendix F (on CD).

Soil sample analytical results were compared to NYSDEC Recommended Soil Cleanup Objectives (RSCOs), which are either presented in, or were determined following procedures presented in, Technical and Administrative Memorandum (TAGM) #4046 (NYSDEC, 1994). Groundwater samples were compared to NYSDEC Water Quality Standards. Water Quality Criteria (WQC) were obtained from the Division of Water Technical and Operational Guidance Series (1.1.1) Ambient Water Quality Standards and Guidance Values and Groundwater Effluent Limitations (NYSDEC, 1998), an errata data sheet dated January 1999 (NYSDEC, 1999), and an April 2000 Addendum (NYSDEC, 2000).

4.1 Surface Soil Results

A total of 12 soil samples and associated Quality Assurance/Quality Control (QA/QC) samples were collected from surface soil locations during the Site investigation activities. Five of these locations (SS-8 through SS-12) are background locations (locations outside the former MGP and EGP operational areas). The surface soil analytical results are summarized in Tables 4-1 through 4-3 and are shown on Figures 4-1 and 4-2. As per the Work Plan, surface soil samples were not analyzed for VOCs.

4.1.1 Semi-Volatile Organic Compounds

SVOCs were detected in all twelve surface soil samples (see Table 4-1). A total of 20 SVOCs were detected in at least one sample. The SVOCs detected were primarily PAHs. Out of the 20 SVOCs detected, 17 were PAHs and 3 were non-PAH SVOCs: dibenzofuran, carbazole, and bis(2-ethylhexyl) phthalate. Of the SVOCs detected, only 1 non-PAH, dibenzofuran, and 12 PAHs were detected at concentrations above their respective RSCOs. Dibenzofuran was detected at a concentration above its RSCO at only one location, SS-7. Dibenzofuran was not detected in any of the other surface soil samples. SS-7 is also the only location where the PAHs anthracene, fluoranthene, naphthalene, phenanthrene, and pyrene were detected. This location, therefore, has a significantly different SVOC signature than the other sample locations.

Comparison of the analytical data for SVOCs detected in surface soil from the five background samples (SS-8 through SS-12) to the data for the remaining seven surface soil samples (i.e., non-background samples) SS-1 through SS-7 shows that except for samples SS-5, SS-6, and SS-7, the non-background samples contained similar compounds and concentrations of PAHs to those in the background locations. Samples SS-6 and SS-7 were collected along the western boundary of the EGP in the MTA ROW and SS-5 was collected from near the northwest corner of the gas works building (see Figure 4-1). Potential sources of PAHs for these samples may be from operations of trains along the MTA ROW, operation of the aboveground fuel oil storage tank adjacent to these respective sample locations, or car and truck exhaust from traffic on North Water Street. The sources of SVOCs in surface soils, therefore, are likely not attributable to MGP or EGP operations.

4.1.2 Inorganics

As shown in Table 4-2, each of the 23 inorganic constituents was detected in one or more of the 12 surface soil samples. The concentrations of inorganic constituents were compared to the RSCOs. TAGM 4046 allows the use of background concentrations for inorganic constituents. Five surface soil samples were collected at background locations, so the RSCOs for inorganic constituents were selected using the following procedure:

- For constituents listed in TAGM 4046 as site background (SB), the highest detected concentration in the background samples was selected as the RSCO. The background data set was reviewed for outliers and if the concentration in one sample greatly exceeded the concentrations in the other samples, the highest concentration of the other samples (i.e., the non-outliers) was selected as the RSCO.
- For constituents with a default values (D) listed in TAGM 4046, the higher of the background value or the default value listed in TAGM 4046 was selected as the RSCO.
- For mercury, TAGM 4046 lists a value of 0.1 mg/kg and does not allow the use of a background value. The background value for mercury at the Pemart Site is 0.31 mg/kg.

One or more of the detected constituents were detected above RSCOs in 10 of the 12 surface soil samples. Concentrations of antimony, arsenic, barium, cadmium, calcium, chromium (total), copper, iron, mercury, nickel, selenium, silver, and zinc were detected above the RSCOs in at least one surface soil sample.

Based on the random distribution and concentrations of inorganics in surface soil in the vicinity of the former MGP and EGP sites, as shown on Figure 4-2, it is concluded that they were deposited from airborne sources (e.g., from the foundry, EGP, car and truck exhaust, and/or other historical industrial operations), runoff from the roadway (e.g., Briarcliff Peekskill Roadway), and/or from operation of the trains along the MTA ROW that form the western boundary of both the MGP and EGP. It is further noted that all of the metals detected are naturally occurring and are significant components of both the soil and bedrock.

Cyanide was detected at low concentrations in two of the twelve surface soil samples (SS-1 and SS-5) near the former MGP area at concentrations of 5.40 mg/kg and 1.77 mg/kg, respectively.

Based on the data validation, it was determined that the analytical results for lead in the surface soil samples were unusable. This conclusion was based on the finding that the laboratory QA analysis for the percent recovery of lead from the matrix spike (MS) sample for the batch of surface soil samples was outside the acceptable range (i.e., greater than 200%). This means that the lead data, as reported by the analytical laboratory, may be artificially biased high, and are unreliable. These data were rejected and are not included in Table 4-2.

4.1.3 Polychlorinated Biphenyls

One PCB, Aroclor 1260, was detected in surface soil sample SS-6 at a concentration of 240 µg/kg, which is well below the RSCO for PCBs of 1,000 µg/kg. No PCBs were detected in the other surface soil sample (SS-7) that was analyzed for PCBs. The detected PCB results are presented in Table 4-3.

4.2 Subsurface Soil Results

A total of 136 subsurface soil samples and associated QA/QC samples were collected from 50 sampling locations during the RI. The results of these analyses are provided in Tables 4-4 through 4-7 and are shown on Figures 4-3 through 4-5.

4.2.1 Volatile Organic Compounds

A total of 30 VOCs were detected in at least one subsurface soil sample (see Table 4-4). Of the VOCs detected, 16 were chlorinated VOCs, which are not related to MGP or EGP operations. The concentrations of 5 of the 16 chlorinated VOCs, 1,1,1-trichloroethane, 1,1-dichloroethane, tetrachloroethene, trichloroethene, and vinyl chloride, exceeded their respective RSCOs in one or more samples. A majority of the chlorinated VOCs detected at elevated concentrations were present in the soils collected from the floor of the crawl space beneath the EGP and downgradient of the EGP.

The concentrations of 5 of the 14 non-chlorinated VOCs detected, namely benzene, toluene, ethylbenzene, and the xylenes (collectively referred to as BTEX) and acetone exceeded their respective RSCOs in at least one sample. BTEX compounds were detected in 81 of the 136 soil samples. Total BTEX concentrations ranged from 0.3 µg/kg to 4,260,000 µg/kg. One or more BTEX compounds were detected above their respective RSCOs in fourteen subsurface soil samples. These elevated BTEX concentrations in subsurface soil were only detected in the vicinity of the former MGP, which exhibited physical evidence of MGP-residues or petroleum-residues, such as odor, staining, NAPL, and or elevated PID readings. No BTEX compounds were detected above RSCOs in borings associated with the former EGP. Most elevated BTEX concentrations were detected at or below 9 ft bgs and above the upper silt/clay unit. The highest BTEX concentration was detected at 2 to 3 feet bgs between the former 30,000 cf and 100,000 cf gas holders. It is noted that the presence of methyl tert-butyl ether (MTBE), a gasoline additive, and isopropylbenzene, a component of refined fuels, such as diesel fuel, fuel oils, gasoline, etc., confirms that petroleum is an additional source of BTEX and other VOCs at the Site.

Total VOC concentrations in subsurface soil exceeded the RSCO for total VOCs of 10 µg/kg in 112 samples collected from 48 locations. Concentrations of total VOCs ranged from 12 µg/kg to 4,483,000 µg/kg. In approximately half of these samples, the elevated concentrations of total VOCs were constituted almost exclusively of chlorinated VOCs. The remaining samples with elevated total VOCs contained primarily BTEX and isopropylbenzene and some chlorinated VOCs.

4.2.2 Semi-Volatile Organic Compounds

At total of 30 SVOCs were detected at least once in 108 of the 135 subsurface soil samples collected during the RI. The SVOCs detected most frequently were PAHs. In addition to PAHs, the SVOCs 1,1-biphenyl; 2,4-dimethylphenol; 2-methylphenol; 4-methylphenol (p-cresol); acetophenone; benzaldehyde; bis(2-ethylhexyl) phthalate; carbazole; dibenzofuran; di-n-butyl phthalate; di-n-octyl phthalate; and phenol were also detected.

The concentrations of one or more of the PAHs detected exceeded their respective RSCOs in 98 subsurface soil samples. The samples that contained elevated PAHs concentrations typically also exhibited physical evidence of MGP-residues or petroleum, such as odor, staining, NAPL, and/or elevated PID readings. In addition to PAHs, four other SVOCs, dibenzofuran, 2-methylphenol, 4-methylphenol, and phenol, were detected in subsurface soil samples at concentrations that exceeded their respective RSCOs. Elevated dibenzofuran concentrations were detected in five subsurface soil samples collected in the vicinity of the former MGP generating house. The other three non-PAHs (2-methylphenol, 4-methylphenol, and phenol) were detected above their respective RSCOs in only one sample from soil boring SB-22/MW-10, which is the northern-most sample location and furthest from both the former EGP and MGP operating areas. The source for the phenol and substituted phenols is not known.

Total detected SVOC concentrations ranged from 45 µg/kg to 52,630,000 µg/kg. The highest concentration was detected at 2 to 3 feet bgs at soil boring SB-25 at a location between the former 30,000 cf and 100,000 cf gas holders. In general, the SVOC concentrations above the RSCO for total SVOCs of 500,000 µg/kg, were detected in subsurface soils collected from soil borings located in the vicinity of the former gas holders, gas house and downgradient from the former gas works. Additionally, at most, but not all locations, the higher

concentrations of total PAHs were detected in shallow samples between approximately 5 and 11 feet bgs and above the upper silt/clay unit. Subsurface soil samples collected within the upper portions (approximately the top seven feet or less) of this upper silt/clay unit had significantly lower concentrations of SVOCs than the shallower samples.

4.2.3 Inorganics

All inorganics (a total of 23 inorganics were included in the inorganic analyte list) and total cyanide were detected in at least one of the 134 subsurface soil samples collected. The RSCOs established for surface soils were used for subsurface soils with the addition of 400 mg/kg as the RSCO for lead, based on the US EPA Residential standard. Twenty of these inorganics, specifically aluminum, antimony, arsenic, barium, beryllium, cadmium, calcium, chromium, cobalt, copper, iron, lead, magnesium, mercury, nickel, selenium, silver, thallium, vanadium, and zinc, were detected at concentrations above their respective RSCOs. All but 25 of the samples had at least one constituent detected above a RSCO. The concentrations of metals that exceeded their respective RSCOs were detected in shallow subsurface soil samples comprised of fill materials (a variety of materials including coal, coal ash, and debris) and in deeper native subsurface soils. Inorganic RSCO exceedances were also observed in subsurface soils below the fill material that did not exhibit any evidence of contamination (e.g., odor or staining, NAPL, elevated VOCs or SVOCs concentrations, etc.). Although the inorganics detected may be related to MGP residues, they also are naturally-occurring common components of soil and bedrock, therefore, their presence is attributed to both natural and anthropogenic sources.

Cyanide was detected in 17 subsurface soil samples generally in the upper 5 feet bgs. The maximum detection, 38.2 mg/kg, was detected in soil sample SB-18 (2-2.5 ft bgs), which was located to the north of the site in the former EGP. There is no RSCO for cyanide.

4.2.4 Polychlorinated Biphenyls

A total of 32 subsurface soil samples were analyzed for PCBs. These samples were collected in the vicinity of the EGP. The analytical results show that Aroclor 1260 was detected in three samples, MH-3, MW-5, and SB-23. Concentrations of Aroclor 1260 in these samples ranged from 58 µg/kg (MH-3 at 5-6 feet ft bgs) to 140 µg/kg (SB-23 at 3.3-3.5 ft bgs). These concentrations are all well below the RSCO for PCBs of 1,000 µg/kg. Sample MH-3 (5-6 ft bgs) was collected from the crawl space beneath the EGP and sample SB-23 (3.3-3.5 ft bgs) was collected beneath the EGP. Aroclor 1260 was detected at MW-5, located immediately downgradient (south) of the EGP, at 21 to 23 ft bgs at 110 µg/kg, but was non detect at 39 µg/kg in the duplicate sample collected at this location and depth. PCBs were not detected in any other samples. The source of PCBs is not known.

4.3 Groundwater Analytical Results

A total of 23 groundwater samples including QA/QC samples were collected from 21 monitoring wells installed during the RI. These 21 monitoring wells include 16 shallow monitoring wells, 2 intermediate depth monitoring wells, and 3 bedrock monitoring wells. Groundwater samples were not collected from six monitoring wells (MW-2, MW-3, MW-4, MW-7, SB-32/MW-5, and SB-11/MW-27) where evidence of NAPL was detected. The groundwater analytical results are provided in Tables 4-8 through 4-11 and are shown on Figures 4-6 through 4-8.

4.3.1 Volatile Organic Compounds

A total of 23 VOCs, including 11 chlorinated VOCs, were detected in at least one of the 21 groundwater samples. The concentrations of 9 VOCs exceeded their respective WQC in at least one sample. The non-

chlorinated VOCs detected at elevated concentrations were BTEX, which are the potentially MGP-related VOCs. At least one BTEX compound was detected in groundwater at six of the monitoring wells; three shallow monitoring wells (MW-5, MW-6, and MW-12), one intermediate monitoring well (MW-17), and two bedrock monitoring wells (MW-1B and MW-9). These detections were all in the vicinity of and downgradient from the 30,000 cf and 200,000 cf gas holders and the 25,000 gallon fuel oil tank. Total BTEX concentrations ranged from 0.8 µg/l to 747.4 µg/l. One or more BTEX compounds were detected at concentrations above the WQC in three shallow monitoring wells (MW-5, MW-6, and MW-12) and one bedrock monitoring well (MW-9).

Seven non-chlorinated VOCs (2-butanone, carbon disulfide, cyclohexane, isopropylbenzene, MTBE, methylcyclohexane, and styrene), not including BTEX discussed above, were detected in groundwater samples and only one of these non-chlorinated VOCs (MTBE) was detected above the WQC. MTBE, a gasoline additive, was detected in a total of five monitoring wells, three located along the MTA ROW (SB-14/MW-23, SB-12/MW-25, and SB-13/MW-24), one at the north end of North Water Street (SB-22/MW-10), and one in the municipal parking lot in the southern portion of the site (MW-8). None of the MTBE detections coincided with the BTEX detections. MTBE was detected above the WQC in shallow monitoring well SB-14/MW-23.

Concentrations of 5 of the 10 detected chlorinated VOCs exceeded their respective NYSDEC WQC. Elevated concentrations of chlorinated VOCs were only detected in groundwater samples collected from shallow wells. Chlorinated VOCs were not detected above WQC in the intermediate or bedrock monitoring wells. As previously noted, chlorinated VOCs are not related to MGP or EGP operations. The 10 chlorinated VOCs detected are: 1,1,1-trichloroethane; 1,1-dichloroethane; 1,1-dichloroethene; chloroethane; chloroform; chloromethane; cis-1,2-dichloroethene; trans-1,2-dichloroethene; trichloroethene, and vinyl chloride.

4.3.2 Semi-Volatile Organic Compounds

A total of 15 SVOCs were detected at least once in 9 of the 21 monitoring wells sampled including 6 shallow wells, 1 intermediate well, and 2 bedrock wells. The SVOCs detected included 1,1-biphenyl; 4-methylphenol (p-cresol); acetophenone; bis(2-ethylhexyl)phthalate; dibenzofuran; phenol; and PAHs. The PAHs were detected most frequently.

The concentrations of phenol and two PAHs (acenaphthene and naphthalene) exceeded the WQC in one or more wells. WQC were exceeded in five monitoring wells including four shallow wells (MW-5, MW-6, MW-8, and MW-12) and one bedrock well (MW-9). Total PAH concentrations ranged from 2.3 µg/l to 2,736 µg/l.

4.3.3 Inorganics

A total of 20 of the 24 inorganic constituents analyzed for in groundwater samples (aluminum, arsenic, barium, cadmium, calcium, chromium, cobalt, copper, cyanide, iron, lead, magnesium, manganese, mercury, nickel, potassium, sodium, thallium, vanadium, zinc) were detected in at least one of the 21 monitoring wells sampled. The constituents antimony, beryllium, selenium, and silver were not detected in any of the groundwater samples. Only six inorganic constituents were detected above their respective WQC in one or more of the groundwater samples: iron, lead, magnesium, manganese, sodium, and thallium. The exceedances of WQC were observed in shallow, intermediate, and bedrock wells, and similar to subsurface soils, the occurrence of these exceedances may be attributed to both natural and anthropogenic sources. Most wells had elevated turbidity when sampled and, therefore, the groundwater samples contained naturally occurring inorganics associated with this turbidity. The presence of sodium above the WQC in all the shallow wells and in some of the intermediate and bedrock monitoring wells may reflect the brackish nature of the Hudson River influencing the groundwater quality at the Site.

Cyanide, a potential MGP-related constituent, was detected in 3 of the 21 monitoring wells, MW-1A (0.0185 mg/l), MW-23 (0.0189 mg/l), and MW-24 (0.0155 mg/l). However, at each of these locations, the

cyanide concentration was below the WQC. Groundwater samples from 17 monitoring wells were also analyzed for amenable cyanide (ACN), which was not detected in any of the samples.

Groundwater samples were collected from two monitoring wells (MW-5 and SB-21/MW-1B) with slightly elevated to elevated pH (9.87 and 11.2) and were analyzed for alkalinity as well as chloride and sulfate anions. The results are included in Table 4-11. The locations with elevated to slightly elevated pH are not locations where relatively elevated concentrations of calcium were observed. The typical source of elevated pH at MGP sites is the use of calcium hydroxide (lime). The absence of a correlation between calcium and pH at the Site indicates that calcium hydroxide may not be the source of the elevated pH.

4.3.4 Polychlorinated Biphenyls

Groundwater samples from 21 monitoring wells were submitted for PCB analysis. PCBs were not detected in any of these samples.

4.4 NAPL Results (Fingerprint and TPH Analysis)

Coal tar and/or petroleum-related NAPL was detected in 22 soil borings (SB-7, SB-8, SB-9, SB-10, SB-11, SB-16, SB-20, SB-25, SB-29, SB-32, SB-33, SB-41, SB-5/MW-2, SB-6/MW-3, MW-4, MW-5, MW-6, MW-7, MW-12, MH-1, MH-2, and MH-3). Eleven of the locations contained evidence of coal tar NAPL (i.e., SB-7, SB-8, SB-9, SB-10, SB-20, SB-25, SB-29, SB-41, SB-6/MW-3, MW-6, and MW-7); four of the locations contained evidence of petroleum-related NAPL (i.e., SB-16, MH-1, MH-2, and MH-3); and seven of the locations contained evidence of both coal tar NAPL and petroleum-related NAPL (i.e., SB-11, SB-32, SB-33, SB-5/MW-2, MW-4, MW-5, and MW-12).

Nine samples containing NAPL were submitted to META for extended PAH scan and GC/FID fingerprint analyses. The laboratory analytical reports from META are included in Appendix E. One sample that contained evidence of petroleum-related NAPL, MH-1(5-6), was also submitted to CAS for Total Petroleum Hydrocarbon (TPH) fingerprint (product identification) analysis. The results of the CAS analyses are summarized in Table 4-12. The fingerprint results for the various NAPL types detected are summarized below.

In general, the META analytical results indicated that both petrogenic materials (a material produced from unburned petroleum products such as fuel oil, diesel, fuel, gasoline, lubricating oils, etc.) and/or pyrogenic materials (a material produced under intense heat during burning) were detected. Both petrogenic and pyrogenic materials may be produced by the coal gasification process. Petrogenic materials include coal, crude oil, and derivatives such as gasoline, fuel oils, and asphalt.

Coal Tar NAPL - Coal tar NAPL was detected in samples from 11 soil boring locations (i.e., SB-7, SB-8, SB-9, SB-10, SB-20, SB-25, SB-29, SB-41, SB-6/MW-3, MW-6, and MW-7). Three samples from these locations, SB-25 (7), SB-6/MW-3 (4.5-5), and SB-6/MW-3 (5-6) were submitted to META for analysis. The META results indicate that the SB-25 and SB-6/MW-3 (4.5-5) soil samples contained pyrogenic materials from a relatively low temperature process and are similar to some carbureted water gas tars such as a gas plant in META's library. The META results for the SB-6/MW-3 (5-6) sample indicate that it is a petrogenic material consistent with severely weathered heavy fuel oil.

Petroleum-Related NAPL – Petroleum-related NAPL was detected in subsurface soil samples from five locations (i.e., SB-6/MW-3, SB-16, MH-1, MH-2, and MH-3). Two samples, MH-1 (5-6) and SB-6 (5-6), were submitted to META for analysis. The MH-1 (5-6) sample was also submitted to CAS for TPH fingerprint analysis. Sample MH-1 was collected from soils in the crawl space under the former EGP building. The META results indicate that the sample is a petrogenic material and it appears to be a mixture of two or more high molecular weight lubricating oils, such as motor oil, cutting oil, or gear oil. The CAS TPH fingerprint

results show that diesel range organics (DRO) were detected at a concentration of 20,000,000 µg/kg. The META results for the SB-6 sample (collected in the same boring as MW-3) indicate that it is a petrogenic material consistent with severely weathered heavy fuel oil. Based on the extent of petroleum-related NAPL, as shown on Figure 3-7, it appears that the former fuel oil tank located on the former MGP property is the likely source of this petroleum-related NAPL. The distribution of this NAPL north and south along the former Pemart Avenue also indicates that the migration of the petroleum-related NAPL was likely along utility trenches.

Mixed NAPL - Coal tar NAPL and petroleum-related NAPL were detected in subsurface soil samples from seven locations (i.e., SB-11, SB-32, SB-33, SB-5/MW-2, MW-4, MW-5, and MW-12). Five samples from these locations, SB-5/MW-2 (5.5), SB-5/MW-2 (4.5-5), MW-5 (5), MW-5 (9-11), and SB-32 (17-19), were submitted to META for analysis. The META results indicate that the sample from MW-5 (5) is a petrogenic material, the samples from SB-5/MW-2 (4.5-5), MW-5 (9-11), and SB-32 (17-19) are pyrogenic materials, and the sample SB-5/MW-2 (5.5) is a mixture of petrogenic and pyrogenic materials. Four of these samples (SB-5/MW-2 (4.5-5), SB-5/MW-2 (5.5), MW-5 (9-11), and SB-32 (17-19)) have the characteristics of tars from a low temperature process such as the water gas process. Two of these four samples, MW-2 (4.5-5) and SB-5 (5.5), also may have the characteristics of weathered heavy fuel oil or residual oil. In addition, the characteristics of the NAPL in subsurface soil sample MW-2 (4.4-5) is consistent with those for weathered fuel oil. This sample also has an unidentified light oil-like material which appears to be mixed with, but unrelated to the tar-like material. These samples were taken downgradient of the former 25,000-gallon fuel oil tank and the 30,000 cf gas holder, respectively, and support the conclusion that the impacts detected in these samples represent a mixture of residues from these two potential sources.

4.5 Analytical Results Summary

This section provides a summary of the analytical results.

- SVOCs and inorganics were detected in surface soils collected from across the Site at concentrations above RSCOs. It is noted that similar levels of these analytes were also detected in background surface soil samples. The occurrence of these analytes at the concentrations detected appears to be attributable primarily to the input from airborne deposition from various historical industrial operations in this area of Peekskill and runoff of surface water from the Briarcliff-Peekskill Parkway.
- VOCs and SVOCs were detected in subsurface soils and groundwater at concentrations above RSCOs and WQC in areas of the Site where field evidence of MGP impacts was also detected. Inorganics were also detected in subsurface soils and groundwater at concentrations above RSCOs and WQC. The inorganic exceedances of RSCOs and WQC are not consistent with the VOC and SVOC exceedances and, therefore, indicate that the inorganics may be attributed to both natural and anthropogenic sources.
- Sodium was present above the WQC in all the shallow wells and some of the intermediate and bedrock monitoring wells and may reflect the brackish nature of the Hudson River impacting the water quality of the groundwater at the Site.
- NAPL was found primarily at shallow depths. It penetrates only the upper-most portions of the upper silt/clay unit. It was not observed below the upper-most portions of the upper silt/clay unit or in the lower sand unit, lower silt/clay unit, weathered bedrock, or in bedrock.
- The NAPL fingerprint analytical results indicate that both petrogenic materials and/or pyrogenic materials were detected. In general, the NAPL samples have the characteristics of tars from a low temperature process such as the water gas process and/or of weathered heavy fuel oil or residual oil.
- Evidence of an unknown petroleum product was detected in the soils found in the EGP crawl space. Based on fingerprint analysis, this material appeared to be a light oil and is not attributable to former operations of either the EGP or MGP.
- PCBs were not detected in any soil or groundwater sample above the applicable standards.

Notes
ug/kg - micrograms per kilogram
RQL - Reported Quantitation Limit
J - Reported analytical value is estimated
U - Constituent not detected above RQL.
UJ - Constituent not detected above estimated RQL.
Bolded values are detections.
Shaded are detections above the NYSDEC Recommended Soil Cleanup objective

Total SVOCs (including PAHs)			**61800**	**431900**					

Notes
ug/kg - micrograms per kilogram
RQL - Reported Quantitation Limit
J - Reported analytical value is estimated
U - Constituent not detected above RQL.
UJ - Constituent not detected above estimated RQL.
R - Rejected
Bolded values are detections.
Shaded are detections above the NYSDEC Recommended Soil Cleanup objective
[1] Sample collected at original MW-2 location. MW-2 was moved and completed across the street at the SB-5 location.
[2] Sample collected at original MW-3 location. MW-3 was moved and completed directly across the street at the SB-6 location.

Notes
mg/kg - milligrams per kilogram
RQL - Reported Quantitation Limit
J - Reported analytical value is estimated
U - Constituent not detected above RQL.
UJ - Constituent not detected above estimated RQL.
Bolded values are detections.
Shaded are detections above the Recommended Soil Cleanup objective
(D) Based on NYSDEC TAGM 4046 Criteria.
(SB) Based on Site Background.
(EPA) EPA residential lead standard.

Notes
ug/l- micrograms per liter
RQL - Reported Quantitation Limit
J - Reported analytical value is estimated
U - Constituent not detected above RQL.
UJ - Constituent not detected above estimated RQL.
R - Rejected
NA - Not Available
Bolded values are detections.
Shaded are detections above the NYSDEC Water Quality Standard
* Grab groundwater sample collected during boring advancement.

Table 4-10
Summary of Detected Inorganic Constituents in Groundwater
Pemart Avenue Works Former MGP and EGP - Remedial Investigation
Consolidated Edison, Peekskill, New York

Table 4-11
Summary of Detected Alkalinity Constituents in Groundwater
Pemart Avenue Works Former MGP and EGP - Remedial Investigation
Consolidated Edison, Peekskill, New York

Chemical Name - mg/l	Location ID Sample Date Sample ID Unit	MW-5 5/4/2006 MW-5 Shallow	SB-21/MW-1B 5/3/2006 MW-1B Bedrock
Alkalinity, Total as CaCO3		**148**	**46.7**
Bicarbonate Alkalinity as CaCO3		**119**	2.00 U
Carbonate Alkalinity as CaCO3		**29.0**	**36.7**
Hydroxide Alkalinity as CaCO3		2.00 U	**10.0**
Phenolphthlein Alkalinity		**15.0**	**28.3**
Anions			
Chloride		**240**	**209**
Sulfate as SO_4		**3.58**	**22.5**

Notes
mg/l - milligrams per liter
RQL - Reported Quantitation Limit
U - Constituent not detected above RQL.
Bolded values are detections.

Table 4-12
Summary of Detected TPH Fingerprint Constituents in Subsurface Soil
Pemart Avenue Works Former MGP and EGP - Remedial Investigation
Consolidated Edison, Peekskill, New York

Location ID:	MH-1
Sample Date:	5/2/06
Sample ID:	SB27(5-6)
Depth Interval:	5 - 6
Chemical Name - mg/kg	
KEROSENE	2,700,000 U
Fuel Oil No. 6	2,700,000 U
Fuel Oil No. 4	2,700,000 U
Fuel Oil No. 2	2,700,000 U
Diesel Range Organics (DRO)	**20,000,000**

Notes
mg/kg - micrograms per kilogram
RQL - Reported Quanitation Limit
U - Constituent not detected above RQL.
Bolded values are detections.

RCRA METALS AND CYANIDE DETECTED IN GROUNDWATER (ug/l) REMEDIAL INVESTIGATION

PEMART AVENUE FORMER MGP
PEEKSKILL, NEW YORK

Project Number: 01869-116-0400
Date: 12/06
Scale: 1" = 30'

Figure Number: 4-8

Sheet Number: 1

J:\Ind_Service\Project Files\ConEd 1869\Pemart Ave MGP\GIS\Projects\Metals_in_groundwater_rev.mxd

5.0 Exposure Assessment

This section presents the results of an assessment of potential existing and future exposure risks relative to current site conditions that may have resulted from operations of the former Pemart Avenue MGP and EGP. The qualitative exposure assessment was performed in accordance with the steps outlined in the NYSDEC Draft Technical Guidance for Site Investigation and Remediation (DER-10).

5.1 Potentially Exposed Populations

As described in other sections of this RI, the former Pemart Avenue Site is currently used for commercial purposes. Surrounding the Site to the north and east are steep bedrock outcrops and vegetation, to the southeast are commercial businesses and a parking lot, to the northwest is a small parking area, and to the southwest is the MTA ROW, beyond which is the undeveloped property that was formerly used for heavy industry including a foundry. The property is currently either covered by buildings, pavement, vegetated areas, or ballast associated with the MTA ROW.

It is Con Edison's understanding that the City of Peekskill's future redevelopment plans for the Peekskill waterfront, which includes the former Site, will entail demolition of the existing structures and construction of new buildings for residential and commercial purposes.

Currently, human populations that may potentially be exposed to impacted soil and groundwater at the Site include on-site workers, recreational users, part-time residents (homeless shelter), and construction and utility workers. In the future, construction and/or municipal workers may also be potentially exposed during routine maintenance, service utility lines, and/or future redevelopment activities at the Site. In addition, future recreational users and on-site residents may be potentially exposed.

5.2 Exposure Pathways

The potential exposure pathways described below were identified based on the current and future uses of the Site uses summarized above:

Surface Soils – Access to surface soil at the Site by on-site workers, recreational users, and residents is generally unrestricted. However, with the exception of the unpaved parking lot, the majority of surface soil on the parcels along the east-side of North Water Street (former Pemart Avenue) is located on the steep and heavily vegetated hillside. The surface soils present on the unpaved lot on this side of the North Water Street are primarily imported and do not represent a potential risk. The majority of the parcels that comprise the Site west of North Water Street are covered by buildings and other structures, with minimal exposed or accessible surface soil. PAHs and inorganics were detected in the surface soils at concentrations above RSCOs. The PAHs are below background at all but three locations located adjacent to the MTA ROW. The inorganics may be due to urban background, emissions from the former EGP, and/or from historical non-MGP or EGP activities (e.g., historic foundry) in the area.

Subsurface Soils – Construction and utility workers may potentially contact subsurface soils. Other receptors are unlikely to directly contact subsurface soils that locally contain elevated concentrations of VOCs, SVOCs and/or inorganics, as well as coal tar and petroleum-related NAPL.

Groundwater – Groundwater in the area of the Site is not used for drinking water due to the low volumes of water produced by the water table aquifer and its generally brackish character. Based on the low recharge rates during groundwater sampling and the relatively small overall volume of the water table aquifer, it would not likely produce a significant quantity of water for drinking water purposes. Classification of the groundwater as brackish, and therefore not potable, is based on the relatively high concentrations of dissolved anions and

cations, as reflected by moderate to high specific conductivity of the water measured in the field during groundwater sampling and the elevated sodium concentrations measured during laboratory analysis of groundwater samples. In keeping with the limited groundwater use, direct contact would likely only occur during activities that require excavation that extend below the top of the water table, such as utility upgrade and/or maintenance and construction-related activities.

Indoor Air – In accordance with the Work Plan, indoor air sampling was not performed. It is noted, however, that the City of Peekskill's future redevelopment plans include demolishing all existing buildings and related structures on the Site and surrounding properties. It is noted that all existing structures are constructed as slab-on-grade and that this construction typically entails installation of a coarse aggregate layer prior to installing the slab. It is anticipated that any VOCs that migrate from soil and/or groundwater would likely travel along the coarse layer and be significantly diluted with ambient outdoor air. Additionally, several of the commercial operations currently in the Site buildings (e.g., furniture finishing) use materials that contain significant volumes of volatile compounds (e.g., paints, solvents, varnishes, etc.) that will impact indoor air quality. The potential for indoor air impacts will be considered when evaluating potential remedies for the Site.

5.3 Contaminant Fate and Transport

MGP related constituents, including NAPL, are present at the former Pemart Avenue Site. Chlorinated VOCs were detected in the soils in the crawl space of the EGP and other samples associated with the EGP. Inorganics were detected in soil and groundwater samples associated with both the former MGP and EGP. PCBs were not detected in any media above RSCOs or WQC.

NAPL was observed in the shallow aquifer at the former gas holders and downgradient areas to the west. NAPL and dissolved phase migration in the shallow aquifer is a potential transport mechanism at the Site. Groundwater at the Site discharges to the Hudson River, which is located downgradient of the Site.

Dissolved phase constituents were not detected in intermediate depth groundwater samples at concentrations above WQC (except iron, manganese, and sodium). Migration of constituents in this intermediate depth zone is not considered a significant pathway.

Exceedances of WQC were observed in one of the bedrock monitoring wells. Bedrock groundwater is not used in this area and is brackish, so it is not likely to be used for drinking water in the future. Bedrock groundwater flow to the overburden aquifer is a potential migration pathway, but based on the bedrock groundwater concentrations and likely small quantity of bedrock groundwater flow, it is anticipated to be significantly less of a migration pathway than the overburden aquifer. Bedrock groundwater flows to the west and provides recharge to the overburden aquifer system and to the Hudson River. Other than this discharge, the bedrock appears to be isolated from the unconsolidated aquifer system by weather bedrock and the upper silt/clay unit.

6.0 Summary of Findings

This section provides a summary of the RI findings.

- The site covers approximately four acres, with approximately two acres on each side of North Water Street (formerly Pemart Avenue).
- The geology at the Site consists of sand, silt, peat and clay layers overlying weathered bedrock and a micaceous dark grey gneiss competent bedrock.
- Groundwater flows from east to west across the Site and ultimately discharges to the Hudson River. Steep bedrock outcrops to the north and east hydrogeologically isolate the unconsolidated aquifer system at the Site. Based on the steep bedrock topography, observed groundwater seeps indicating an upward hydraulic gradient, and variations in water elevations in deep groundwater monitoring wells installed during the RI, which also generally indicate an upward hydraulic gradient, it appears that groundwater may discharge from bedrock fractures into the unconsolidated aquifer system present beneath the Site. Other than this discharge, the bedrock appears to be isolated from the unconsolidated aquifer system by weathed bedrock and the upper silt/clay unit.
- Structures associated with the former MGP and EGP are present at the Site.
- Field evidence of MGP residues, which included odors, staining, sheen and coal tar DNAPL, were detected in the subsurface soil and groundwater associated with the former 100,000 cf and 30,000 cf gas holders and gas generating building. These residuals partially penetrate the upper-most portions of the upper silt/clay semi-confining unit including the peat lenses to depths of 20 feet bgs. NAPL and impacted material was not observed below the upper-most portions of the upper silt/clay unit or in the lower sand unit, lower silt/clay unit, weathered bedrock, or in bedrock. Collectively, impacts at the Site encompass an area that includes most of the former MGP, the southern portion of the EGP, and extends offsite to the west beneath the adjacent MTA ROW and onto the undeveloped former industrial properties between the tracks and the river.
- No field evidence of contamination related to operations of the former EGP was detected. However, a non-descript petroleum-like oil was locally detected in soils collected from the crawl space beneath the EGP. Based on fingerprint analysis, this material appeared to be a light oil and is not attributable to former operations of either the EGP or MGP.
- SVOCs and inorganics were detected in surface soils collected from across the Site at concentrations above RSCOs. The occurrence of these analytes at the concentrations detected appears to be attributable primarily to the input from airborne deposition from various historical industrial operations in this area of Peekskill and runoff of surface water from the Briarcliff-Peekskill Parkway.
- VOCs and SVOCs were detected in subsurface soils and groundwater at concentrations above RSCOs and WQC in areas of the Site where field evidence of MGP impacts was also detected. Inorganics were also detected in subsurface soils and groundwater at concentrations above RSCOs and WQC. The inorganic exceedances of RSCOs and WQC may be attributed to both natural and anthropogenic sources.
- Sodium was present above the WQC in all the shallow wells and some of the intermediate and bedrock monitoring wells and may reflect influence of the brackish Hudson River water on groundwater quality at the Site.
- The NAPL fingerprint analytical results indicate that both petrogenic materials and/or pyrogenic materials were detected. In general, the DNAPL samples have the characteristics of tars from a low temperature process such as the water gas process and/or of weathered heavy fuel oil or residual oil. Conversely, LNAPL appears to be primarily related to diesel range organics (DRO), which would include fuel oil and diesel fuel.
- PCBs were not detected in any soil or groundwater above the applicable standards.

7.0 Conclusions and Recommendations

This section provides the RI conclusions:

- An extensive RI has been completed that characterizes the nature and extent of constituents related to the former MGP and EGP operations at the Site. No further land-based characterization is recommended at this time. However, as part of the remedial selection and planning process, additional remedy-specific data and information may be necessary (e.g., soil gas sampling, geotechnical data, etc.).
- Characterization of the Site was expanded until the upland limits of impacts were delineated. Based on the results of the upland investigation, it is recommended that soils and sediments that comprise the Hudson River channel be investigated in order to evaluate the presence or absence of MGP residues downgradient from the Site.
- In accordance with the Work Plan, indoor air sampling was not performed. It is noted however, that the City of Peekskill's future redevelopment plans include demolishing all existing buildings and related structures on the Site. The potential for indoor air impacts will be considered when evaluating potential remedies for the Site. Since the existing buildings will be demolished, no indoor air or soil gas sampling is recommended at this time.
