Air Modeling Method and Results

D.1 AIR QUALITY MODELING OF FUGITIVE AIR EMISSIONS

Emissions of contaminants are predicted for future hypothetical construction activities at the Mechanicville site. Both particle and volatile emissions are estimated.

D.1.1 Fugitive Dust Emissions

The fugitive dust emission equations used for this analysis are based on empirical studies of surface mines and storage piles for various materials (Cowherd, 1985). These equations can be used to estimate the emissions of contaminants based on the measured chemical concentrations in the surface soil at the Mechanicville site.

The emissions predicted from these equations are for inhalable particles (PM_{10}) that have an aerodynamic diameter smaller than or equal to 10um. Inhalable particles can be retained by the body upon inhalation and contribute to inhalation exposure.

Contaminant emission rates were estimated from PM_{10} emission factors, the mass fraction of contaminant in the Mechanicville site soil, and the hypothetical exposed surface area of the contaminated soil. The contaminant emission rate (Q_{10}; g/sec) of particles 10 um and smaller was determined by the following equation:

$$Q_{10}\ (g/sec) = [\ f \times E_{10} \times A_c\ ] \times 10^{-6} \qquad (D\text{-}1)$$

where:

Q_{10} = contaminant PM_{10} emission rate (g/sec)

f = mass fraction of contaminant in PM_{10} emissions (mg contaminant/kg PM_{10})

E_{10} = PM_{10} emission rate (g PM_{10}/m^2-sec)

A_c = contaminated surface area (m^2)

10^{-6} = conversion factor for (mg contaminant/kg PM_{10}) to (g contaminant/g PM_{10})

The first step in estimating the emission rate (Q_{10}) from the contaminated surface area is to evaluate the sources of the particle emissions. For the Mechanicville site, the main source of particle emissions is wind erosion.

For estimating emissions from wind erosion for surface areas not covered by vegetation, two emission factor equations have been recommended by Cowherd et al. (1985). Selection of an equation depends on whether the contaminated site's surface material is classified as having a "limited reservoir" or an "unlimited reservoir" of erodible surface particles. Nonhomogeneous exposed surfaces that are crusted and include nonerodible elements are characterized as having a "limited reservoir" of erodible particles and require high threshold wind speeds for wind erosion. Exposed surfaces with "unlimited" erosion potential are those that do not form a crust and consist of finely divided particles (e.g., sandy agricultural soil). For the "unlimited reservoir" category, a lower threshold wind speed is necessary to entrain the contaminated soil. Based on field studies, a threshold friction velocity of 75 cm/sec is considered as the dividing line between the two classes of wind erosion.

Based on a relationship derived by Gillette (1980), the threshold friction velocity for wind erosion can be estimated from the mode of the grain-size distribution for soil samples from the site. Based on representative soil samples from the Mechanicville site, a threshold friction velocity less than 75.0 cm/sec was determined using the Gillette curve as presented in Cowherd et al. (1985). Therefore, the "unlimited reservoir" emission equation was used for the Mechanicville site.

For the utility repair scenario described in Section 5.0, Jordan calculated a conservative estimate of the PM_{10} emission rate (E_{10}) for the contaminated surface with "unlimited" erosion potential; an emission factor derived by Gillette (1981) based on field measurements of highly erodible soil was used. Cowherd (1985) presents a simplified form of this equation to represent the worst-case (short-term) emission rates. This equation is:

$$E_{10}\ (g/m^2\text{-sec}) = (1.0 \times 10^{-5})\ (1 - V)[U_{6\text{-hour}}]^3 \qquad \text{(D-2)}$$

where: V = fraction of contaminated surface with vegetative cover (equal to 0.0 for bare soil)

[$U_{6\text{-hour}}$] = expected maximum 6-hour mean wind speed (m/sec)

Based on local climatological data presented in Cowherd et al. (1985), the fastest mile [U^+] and mean wind speed [U] recorded for Albany, New York, are 21.4 m/sec and 4.0 m/sec, respectively. Because the Mechanicville site is located approximately 15 miles north of Albany, the Albany meteorological data were assumed to be representative of the Mechanicville site. As proposed by the World

Meteorological Organization to account for different averaging periods, the expected maximum 6-hour mean wind speed during the year can be estimated by the following equation:

$$[U_{6\text{-hour}}]\ (\text{m/sec}) = [U^{+}]\text{-}2.0 \qquad \text{(D-3)}$$

For the Mechanicville site, with all of the uncovered contaminated soil assumed to be bare (V = 0.0), worst-case hourly emission rates (E_{10}) due to soil erosion were calculated for the following two wind speed conditions:

Maximum Hourly Wind Speed: 19.4 m/sec

Most Probable Hourly Wind Speed: 4.0 m/sec

The particulate emission rates (E_{10}), per unit surface area, for the two wind speed cases were calculated to be:

Maximum 6-hour Wind Speed: $E_{10} = 7.30 \times 10^{-2}$ g/m^2-sec

Most Probable Wind Speed: $E_{10} = 6.40 \times 10^{-4}$ g/m^2-sec

A summary of the assumptions and input parameters used to estimate the fugitive dust emission rates due to unlimited soil erosion are given in Table D-1.

TABLE G-4-1

ASSUMPTIONS AND INPUT PARAMETERS
USED IN FUGITIVE DUST EMISSION RATE CALCULATIONS
MECHANICVILLE SITE

Wind Erosion Emissions

Erosion Potential:	Unlimited
Volume of Contaminated Soil Removed:	
Utility Repair Excavation: (Realistic Worst Case)	4,800 cubic feet
Utility Repair Excavation Case: (Most Probable Case)	1,200 cubic feet
Fraction of Contaminated Surface (V) with Vegetative Cover	0.00
Roughness Height (Zo):	5.0 cm

Wind Speed Range	Wind Speed [m/s]	E_{10c} [g/m^2 -s]
High Wind Speed:	19.4	8.00×10^{-5}
Mean Wind Speed:	4.0	9.73×10^{-7}

The surface area of contaminated soil was assumed to equal that of the soil pile. The volume of contaminated soil brought to the surface and piled at the site was estimated for the following two scenarios:

Utility Repair Excavation - Realistic Worst Case: 4,800 cubic feet

Utility Repair Excavation - Most Probable Case: 1,200 cubic feet

The exposed surface areas of the soil piles were estimated based on the assumption that the storage piles were shaped similar to a solid cone.

The actual contaminant emission rates (Q_{10}), in grams per second, were obtained by Equation D-1 for the two wind speed cases.

D.1.2 Volatilization Rates from Soils

The volatilization of contaminants through the soil is a complex process involving the mass transfer of volatiles from the soil particles into the air pores in the soil, mass transfer through the soil pore spaces, and mass transfer from the soil surface into the ambient air. Before estimating the volatilization rates of organic chemicals from the contaminated soil, several empirical models were evaluated. For each model, values for several input parameters were not directly available for Mechanicville and would have had to be estimated. The volatilization rates calculated by the different models for specific contaminants ranged over several orders of magnitude. Because of the

uncertainty of the applicability of these models for the Mechanicville site, it was decided that a more simplified but conservative approach would be used.

Based on the mean contaminant soil concentration measured at the Mechanicville site, the mass of the contaminant (grams) in the soil for the two soil volume cases previously discussed was determined. The contaminant emission rates due to volatilization from the surface soils were calculated for the following two cases:

Most Probable: 10 percent of VOC mass emitted over 20-day period

Realistic Worst: 100 percent of VOC mass emitted over 30-day period

For the two cases, the emission rates due to volatilization from the exposed soil are assumed to remain constant. For the contaminants measured in the Mechanicville soil, Table D-2 provides the mean soil concentration (mg/kg) and the 20-day and 30-day average emission rates (g/sec).

D.2 AIR QUALITY DISPERSION MODELS

Once contaminant emission rates for the different scenarios have been estimated, air quality modeling is used to estimate ambient air concentrations at selected distances from the Mechanicville site. Jordan modeled the emissions from the exposed soil surface area as area sources. Jordan assumed that no plume rise will occur, and that the contaminant emissions are mixed uniformly over a height equal to the height of the soil pile.

TABLE G-4-2

SOIL CONCENTRATIONS AND EMISSION RATES
FOR VOLATILIZATION FROM SURFACE SOILS
MECHANICVILLE SITE

ASSUMPTIONS:

MOST PROBABLE: 10% OF VOC MASS EMITTED OVER 20 DAYS
WORST CASE: 100% OF VOC MASS EMITTED OVER 30 DAYS

SOIL DENSITY: 1440 KG/M^3
SOIL VOLUME: MOST PROBABLE: 1200 CU. FT. WORST CASE: 4800 CU. FT.

		MOST PROBABLE		WORST CASE	
CONTAMINANT COMPOUND	MEAN SOIL CONC. (MG/KG)	MASS OF CONTAMINANT IN SOIL[a] (G)	20 DAY AVG. E[b] (G/S)	MASS OF CONTAMINANT IN SOIL (G)	30 DAY AVG. E (G/S)
Benzene	104	5.09E+03	2.94E-04	2.03E+04	7.85E-03
Toluene	151	7.38E+03	4.27E-04	2.95E+04	1.14E-02
Ethylbenzene	82.1	4.01E+03	2.32E-04	1.61E+04	6.20E-03
Styrene	150	7.34E+03	4.25E-04	2.93E+04	1.13E-02
Total Xylenes	306	1.50E+04	8.66E-04	5.99E+04	2.31E-02
Trimethylbenzene	26.7	1.31E+03	7.56E-05	5.22E+03	2.01E-03
Methylene Chloride	0.5	2.45E+01	1.42E-06	9.78E+01	3.77E-05

[a] Mass of contaminant in soil (g) = mean soil concentration $\left(\frac{\text{mg contaminant}}{\text{kg soil}}\right)$ x soil density $\left(\frac{\text{kg soil}}{m^3}\right)$ x soil volume (m^3)

[b] Average E(g/s) = $\frac{\text{mass of contaminant in soil (g)}}{20 \text{ days}} \times \frac{1 \text{ day}}{24 \text{ hour}} \times \frac{1 \text{ hour}}{60 \text{ min.}} \times \frac{1 \text{ min}}{60 \text{ sec.}}$

Jordan evaluated two air dispersion modeling approaches to determine which modeling approach was appropriate for the Mechanicville site. The first modeling approach involves a simple box model to estimate ambient concentrations due to emissions from an area source. The box model is based on conservation of mass equations, requires steady-state conditions, and is widely used in exposure studies where the receptors are on-site or very close to the exposed surface area. The box itself encloses the area of interest, bounded by the ground, with a height estimated by an assumed mixing layer. Mixing within the box is assumed to be complete. The width of the box is set equal to the width of the exposed soil area. The box is oriented so that its length lies in the direction of the wind. The box model is limited in its application to area sources with a surface width much larger than the distance to the receptor of interest.

For the Mechanicville site, predicted concentrations are of interest at receptors located on-site or within 750 feet of the exposed contaminated area. The size of the exposed contaminated soil piles for the Mechanicville site are relatively small, with the largest pile estimated to have a diameter of only 31 feet. Because the distance to the receptors of interest is greater than the width of the soil pile, the box model is not appropriate for the Mechanicville site. Therefore, another modeling approach was considered for determining the ambient contaminant concentrations due to fugitive emissions.

The second modeling approach follows the basic modeling procedures described in D. B. Turner's Workbook of Atmospheric Dispersion Estimates (Turner, 1970). These procedures are based on the basic Gaussian plume equation. For a ground-level source with no effective plume rise, the Gaussian equation reduces to a

simplified form that has been widely used in screening assessments. For the Mechanicville site, the emissions from the soil piles are assumed to be spread over the area of the pile. Following Turner's recommendations, Jordan modeled the area source emissions from the soil pile as if they originated from a virtual point source. The virtual point source approach creates a point source located at an appropriate distance upwind such that the horizontal dispersion at the soil pile is equal to the soil pile width. The horizontal dispersion downwind of the facility can then be simulated as if all the soil pile emissions were being emitted from the virtual point source. The distance used in the calculation of ambient concentrations is the total distance from the virtual point to the receptor.

The calculation of the ambient concentrations due to emissions from the soil piles is simplified by using the virtual source approximation. Further simplification is possible by assuming that the emissions due to soil erosion and volatilization are initially spread over the height of the soil pile. Having calculated the contaminant emission rate of particles 10 um and smaller (Q_{10c}), the ambient contaminant concentration can be estimated by the following equation:

$$C10 = Q_{10c} / [\ pi * sigma_y * (sigma_z + H_p) * U\ ] \quad (D\text{-}6)$$

where:

C10 = Contaminant air concentration (g/m^3)

Q_{10c} = Contaminated emission rate (g/sec)

$sigma_y$ = Horizontal dispersion coefficient (m) at distance X + Xv

$sigma_z$ = Vertical dispersion coefficient (m) at distance X

H_p = Height of soil pile (m)

U = Average wind speed (m/sec)

X_v = Virtual source distance (m)

X = Distance from edge of soil pile to receptor (m)

For the Mechanicville site evaluation, downwind receptors were placed 10, 100, and 750 feet from the edge of the soil pile. The initial virtual horizontal dispersion coefficient is estimated by dividing the width of the soil surface pile by 4.3. From extrapolation of the horizontal dispersion coefficient curve in Turner's workbook for D atmospheric stability class, the virtual source distance (X_v) was determined for two different soil volume cases:

Case Description	Exposed Soil Volume
Utility Repair Excavation - Realistic Worst	4,800 cubic feet
Utility Repair Excavation - Most Probable	1,200 cubic feet

Different wind speeds were used with Equation D-6 to represent realistic worst and most probable conditions at the Mechanicville site. To represent the most probable conditions, a wind speed of 4.0 m/sec with a D atmospheric stability class was assumed. To represent the worst case conditions, two wind speed values were assumed. To simulate realistic worst conditions from emissions due to the volatilization of contaminants in the soil pile, a wind speed of 2.0 m/sec was selected. Because fugitive emissions due to unlimited soil erosion increase with wind speed, a wind speed of 19.4 m/sec was selected to represent worst case particulate emissions.

Based on the assumptions used in this analysis, the ambient air quality concentrations calculated using Equation D-6 predict hourly values of contaminant concentrations. To relate these predictions to longer averaging time periods, conservative scaling factors recommended by USEPA (1977) were used to estimate longer duration exposure concentrations. The 1-hour average box model predictions were multiplied by 0.40 to obtain 24-hour average off-site concentrations, and by 0.70 to obtain 8-hour average on-site concentrations.

Table D-3 presents the ambient air concentrations due to fugitive dust emissions from soil erosion for the realistic worst case utility repair scenario. Table D-4 presents the contaminant ambient air concentrations for the analogous most probable case.

Based on the emission rates for volatilization from surface soil given in Table D-2, Table D-5 provides the chemical-specific average concentrations for the two contaminated soil volume cases (i.e., two utility repair scenarios). The ambient 1-hour average concentrations were calculated based on an assumed D atmospheric stability class and wind speed values of 2.0 and 4.0 m/sec. From the predicted 1-hour average concentrations, 8-hour and 24-hour average concentrations were calculated using the scaling factors given previously.

SITE SAFETY PLAN

A. GENERAL INFORMATION

SITE: Mechanicville

LOCATION: Mechanicville, New York

PLAN PREPARED BY: T. Plante DATE: 2/20/92

APPROVED BY: Meg MacJesock DATE: 2/25/92

OBJECTIVE(S): To maintain health and safety while collecting environmental characterization samples (soil/water) from a former coal gasification plant site. This plan covers activities to be performed under Task 5: Phase IIA Supplemental Remedial Investigations.

PROPOSED DATE OF INVESTIGATION: May 1992 through November 1992

BACKGROUND REVIEW: Complete: X Preliminary: ____

OVERALL HAZARD: Serious: ___ Moderate: X Low: X Unknown: ___

1.1 SCOPE AND PURPOSE

This Health and Safety Plan (HASP) was prepared in conformance with the ABB Environmental Services, Inc. (ABB-ES) Health and Safety Program, and is intended to meet the requirements found in 29 CFR 1910.120. As such, the HASP addresses all activities associated with field operations at the NYSEG, Mechanicville site. Compliance with this HASP is required of all ABB-ES personnel, contractor personnel, or third parties entering the site.

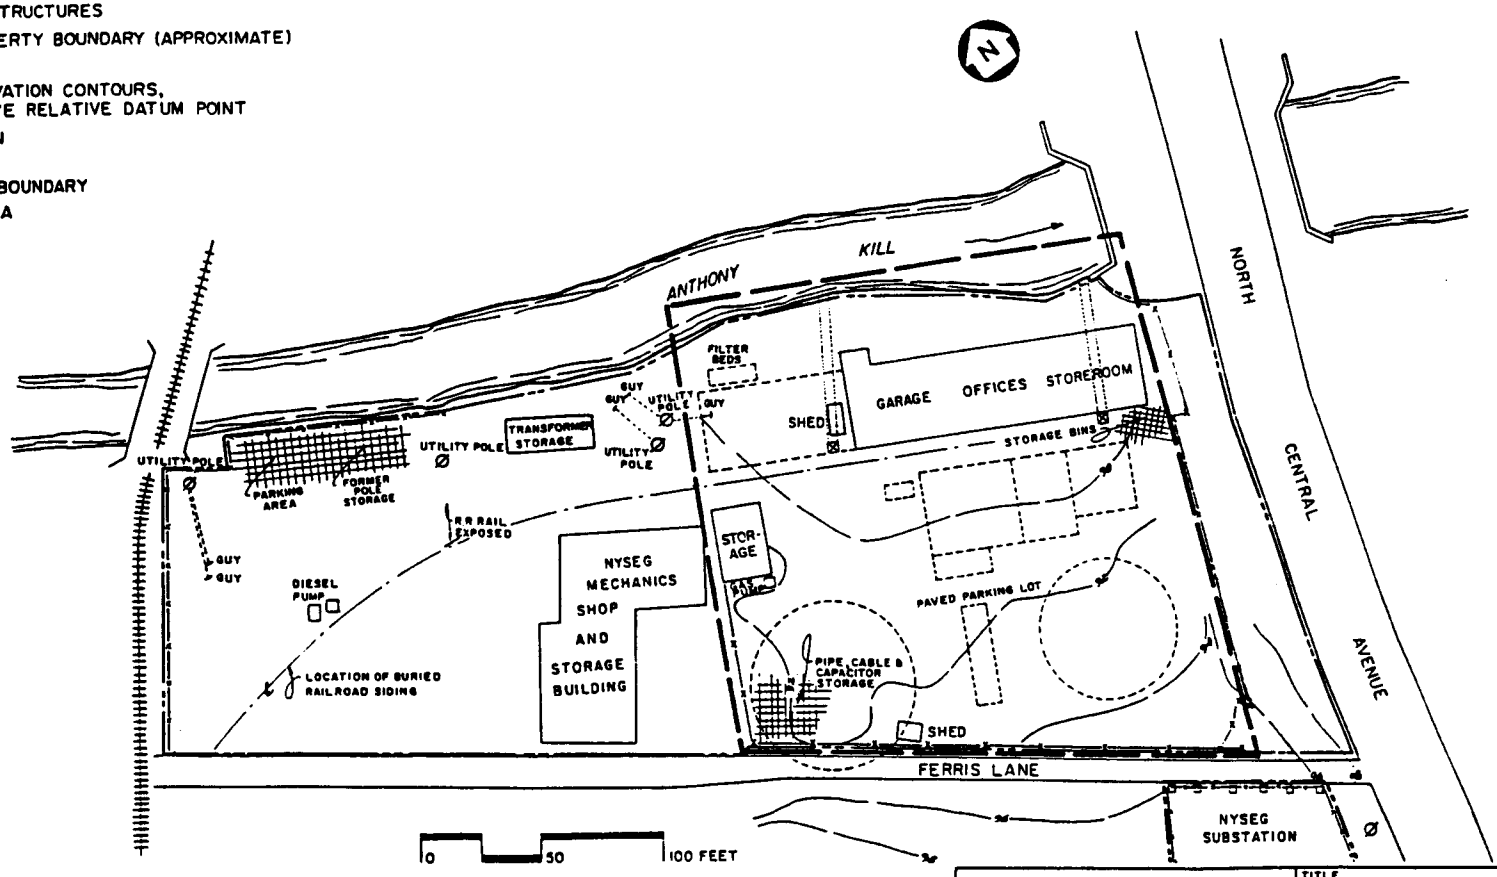
- measurement of water levels in wells, piezometers, and surface water; and
- collection of groundwater and seep water samples for analyses.

B. SITE/WASTE CHARACTERISTICS

WASTE TYPES(S): Liquid X Solid X Sludge ___ Gas ___

CHARACTERISTICS(S): Corrosive ___ Ignitable ? Radioactive ___

Volatile X Toxic X Reactive ? Unknown X Other (Name) ___



FACILITY DESCRIPTION:

The former Mechanicville manufactured gas plant (MGP) site is located in Mechanicville, New York along the Anthony Kill (a small tributary of the Hudson River). The site is a quarter-mile upstream of the Hudson River, on the western side of North Central Avenue. The site is bounded by the Anthony Kill on the north, North Central Avenue on the east, Ferris Lane on the south, and a lot presently owned by NYSEG on the west. A gas manufacturing plant was operated at the site by New York State Electric and Gas Corporation (NYSEG) and its predecessor companies from 1901 until 1955. Most of the structures utilized in the coal gas manufacturing operation were cleaned out and demolished at the time of closure in 1955. Two of the original gas plant structures are still standing on the site. These are: (1) a large building formerly used as a boiler house and a substation; and (2) a small building formerly used as an office. Between 1955 and 1990, NYSEG operated natural gas and electric service center. The site is currently unoccupied and is surrounded by a 6-foot high chain link fence on three sides and the Anthony Kill to the north. The site is being investigated because it was formerly used for coal gas manufacturing.

The present layout of the facility is shown in Figure 1. A more detailed facility description and site history is contained in Section 1.0 of the Phase II Remedial Investigation Report.

MECHANICVILLE SITE PLAN - 1987
MECHANICVILLE, NEW YORK

INVESTIGATION OF FORMER COAL GASIFICATION SITES

PROJECT NO. 4945-04

FIGURE 1

TABLE 1

CONTAMINANTS OF CONCERN
MECHANICVILLE SITE

CARCINOGENS	MEDIUM IN WHICH DETECTED
Carcinogenic PAHs[1]	Soil, Sediment
Benzene	Soil, Sediment, Indoor Air
NONCARCINOGENS	
Toluene	Soil, Indoor Air
Xylene	Soil
Ethyl Benzene	Soil, Sediment
Styrene	Soil
Noncarcinogenic PAHs[2]	Soil, Sediment
Cyanide	Soil, Sediment
Trimethylbenzene	Soil

Notes:

1 Include benzo(b)fluoranthene, benzo(k)fluoranthene, benzo(a)anthracene, benzo(a)pyrene, chrysene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene.

2 Include acenaphthene, acenaphthylene, anthracene, benzo(g,h,i)perylene, fluoranthene, fluorene, naphthalene, phenanthrene, pyrene, and 2-methylnaphthalene (sediment only).

TA

TOXICOLOGICAL PROPERTIES OF COMPOUNDS IDENTIFIED IN VARIOUS MEDIA MECHANICVILLE SITE

COMPOUND CLASS	MEDIA IDENTIFIED IN	SPECIFIC COMPOUNDS	TOXICOLOGICAL PROPERTIES[1]
Volatile Organic Compounds	Groundwater	Toluene, benzene, xylenes, ethylbenzene, trimethylbenzene, styrene	These aromatic compounds are absorbed readily through the respiratory and gastrointestinal (GI) tracts and can also be absorbed through the skin. Benzene has the potential to cause cancer. Depending on the dose received, the other compounds can exert toxic effects on the liver and kidneys; they can also act as central nervous system (CNS) depressants and respiratory irritants.
	Subsurface Soil	All of the above plus n-propylbenzene	
	Sediment	Toluene, benzene	
	Air	Toluene, benzene	
Semivolatile Compounds			
• PAHs	Groundwater	Acenaphthene, acenaphthylene, anthracene, benzofluoranthenes, benzo(g,h,i)perylene, benzo(a)anthracene, benzo(a)pyrene, chrysene, fluoranthene, fluorene, indeno(1,2,3-cd)pyrene, naphthalene, phenanthrene, pyrene	PAHs are a diverse group of compounds of varying toxicity. They are highly lipid-soluble and are absorbed through the GI and respiratory tracts, and to a lesser degree, through the skin. Many PAHs have been shown to be potentially carcinogenic. Other PAHs are thought to be noncarcinogenic; these include fluorene, anthracene, pyrene, naphthalene, phenanthrene, and fluoranthene. The acute toxicity and chronic toxicity of low level exposures are not well understood.
	Subsurface soil Sediment	All of the above plus dibenzo(a,h)anthracene	
• Phenolic compounds	Groundwater Subsurface soil Surface water	Total recoverable phenolics	Depending on the dose, these compounds can produce liver and kidney toxicity and CNS effects. They can act as respiratory and skin irritants.
Inorganic Compounds	Groundwater	Iron, zinc, cyanide, sulfate	Iron and zinc are essential nutrients. However, they can produce objectionable effects such as staining, bad taste, and GI irritation at high levels. Bioavailable cyanide can exert toxic effects on the liver, kidneys, CNS, and cardiovascular system at high levels. Sulfate is a natural constituents of groundwater which affects taste in high concentration (500 mg/ℓ).
	Subsurface soil	Iron, zinc, cyanide	
	Surface water	Iron, cyanide, sulfate	
	Sediment	Iron, zinc, sulfate	

1 In assessing the risks to public health and the environment posed by these chemicals, not only toxicological properties but also potential receptors and probable exposure conditions must be considered.

CHEMICAL TOXICITY OF COAL TAR CONSTITUENTS

CHEMICAL	APPROXIMATE ODOR THRESHOLD (PPM)	TLV (PPM)	PHYSICAL CHARACTERISTICS	DERMAL TOXICITY	REMARKS
Benzene	0.16	10	Aromatic odor	Local + + Systemic + + +	Poisoning occurs most commonly through inhalation; also penetrates through skin. Carcinogen.
Toluene	1	100 (skin)	Aromatic odor	Local + Systemic +	Penetrates through skin.
Xylenes	0.1-1	100	Aromatic odor		Moderate toxicity via inhalation and oral routes. Low dermal toxicity.
Naphthalene	0.01	10	Mothball odor	Local + + Systemic + +	Poisoning may occur through ingestion of large doses, inhalation, or skin absorption.
Phenolics	1	5 (skin)	Sweet, tarry odor		High toxicity via oral, dermal, and inhalation routes. Absorption from spilling phenolic solutions on the skin may be very rapid, and death results from collapse within 30 minutes to several hours.
Cresol	0.01	5	Sweet, tarry odor		Moderately toxic via inhalation and oral routes. Acts similarly to phenols, but less severe. Produces severe chemical burns and dermatitis.
Phenanthrene/Anthracene					
Ethylbenzene	0.1	100	Aromatic odor	Local + + Systemic + +	A skin irritant, and an allergen. Known carcinogen.
Pyridine	0.1	5 (skin)	Penetrating, sickening odor	Local + + Systemic +	Skin irritant.
Ammonia	1	25	Pungent, suffocating odor	Local + + +	A mild irritant to the skin. Mildly toxic via oral and inhalation routes.
Chrysene					Skin and eye irritant. Highly toxic via inhalation and oral routes.
Benzo(a)pyrene					Carcinogenic agent.
Cyanide compounds		5 (skin)	Faint almond odor		Suspected carcinogen. Toxic by inhalation.
Sulfide compounds Hydrogen sulfide		10	Rotten-egg odor		Cyanide compounds of sodium and potassium can affect the body if inhaled or in contact with eyes and skin or ingested. Sufficient cyanide may be absorbed through the skin to cause fatal poisoning. Cause softening and irritation of the skin. Hydrogen sulfide is extremely toxic.

nued

TABLE 3

CHEMICAL TOXICITY OF COAL TAR CONSTITUENTS

CHEMICAL	APPROXIMATE ODOR THRESHOLD (PPM)	TLV (PPM)	PHYSICAL CHARACTERISTICS	DERMAL TOXICITY	REMARKS
Coal Tar Pitch Volatiles		0.2 mg/m^3	Penetrating, sickening odor		
Arsenic and compounds		0.2 mg/m^3		Local +++ Systemic +++	
Polychlorinated biphenyl: PCB Arochlor 1242 $C_{12}H_7CL_3$ (approx.)	1	2	Colorless to dark brown liquid with mild hydrocarbon odor	Local ++ Systemic	Poisoning occurred most commonly through investigation or penetration of skin.
Archlor 1254 $C_6H_2C1_3C_6H_3C1_2$	0.5	1		Local ++	Symptoms: irritates eyes (discharge), skin acne-form, dermatitis, jaundice, dark urine. Target organ: liver, eyes, skin. First Aid: Swallow: Ipecac, vomit. Skin: soap wash (immed) Incompatibles: strong oxidizers.

Notes:

TLV - Threshold Limit Value
\+ - Slight Hazard
++ - Moderate Hazard
+++ - Extreme Hazard

D. SITE SAFETY WORK PLAN

PERIMETER ESTABLISHMENT:

Map/Sketch Attached? Yes Site Secured? Partially
(6' perimeter fence)
Perimeter Identified? Yes Zone(s) of Contamination Identified? Some

PERSONNEL PROTECTION:

Level of Protection: A ___ B ___ C X D X - Modified

Anything above background in the breathing zone on the PID, monitor for benzene using the 0.5/a Draeger tube. If benzene levels exceed 1.0 ppm (note: using 1.0 instead of 0.5 ppm because tube also reads toluene and xylene), upgrade to Level C. If benzene levels are below 1.0 ppm, continue working at modified Level D until PID levels reach 25 ppm then upgrade to Level C. If PID levels near 50 ppm, monitor with benzene 5/b tube. If benzene levels exceed 50 ppm, upgrade to Level B. Otherwise, continue working at Level C until PID readings read over 100 ppm.

Level B required if:

- PID ≥ 1000, or
- Benzene ≥ 50 ppm

Level C required if:

- PID between 25 and 1000 ppm, and/or
- Benzene between 1 and 50 ppm

Modified Level D ok if:

- PID < 25 ppm, and
- Benzene < 1 ppm

SURVEILLANCE EQUIPMENT AND MATERIALS:

To the extent feasible, the presence of airborne contaminants will be evaluated through the use of direct-reading instrumentation. Information gathered will be used to ensure the adequacy of the levels of protection being employed at the site, and may be used as the basis for upgrading or downgrading levels of protection, at the discretion of the site HSO.

- ISD Dual Detector. This meter monitors for combustible gases and oxygen. It can be used to determine (1) if an area contains concentrations of combustible gases with readings in percentage of the lower explosive limit; and (2) the percentage of oxygen. This equipment will be calibrated in accordance with the manufacturer's instructions.

- HNU IS101 and Photovac TIP Photoionization Detector (PID). Like the OVA, the PID operates on the basis of ionization of the contaminant, which results in a meter deflection proportional to the concentration of the contaminant. In the PID, ionization is caused by a UV light source. The strength of the UV (measured in electron volts [eV]) determines which contaminants can be ionized. The HNU can use three different strength UV sources, including 9.6, 10.2, and 11.7 eV. Only the 10.2- and 11.7-eV probes are currently available for field use. The TIP operates using a UV light source of 10.6 eV. Calibration and maintenance will be performed in accordance with the manufacturer's instructions.

- Detector Tubes (MSA and Draeger). A colorimetric detector tube is a direct-reading instrument that consists of a glass tube impregnated with an indicating chemical, which is connected to a piston cylinder or bellows-type pump. A known volume of air is drawn through the glass tube. The contaminant in the air reacts with the indicator chemical, producing a stain the length of which is proportional to the contaminant's concentration. Care must be taken when using the detector tubes because reliability of the results depends on proper calibration, the degree of stability of the reacting chemical, and the ambient temperature. Interfering gases or vapors can also positively or negatively affect measured results. Calibration and maintenance will be performed in accordance with the manufacturer's instructions.

DECONTAMINATION PROCEDURES:

Equipment to be decontaminated during the project may include (1) drill rig, (2) tools, (3) monitoring equipment, (4) sample containers, and (5) truck or trailer. Drilling equipment will be steam-cleaned prior to arrival at the Mechanicville site, followed by on-site steam-cleaning with approved water upon site arrival and between boring/well sites. Prior to use on-site, all casings, augers, recirculation and water tanks, etc., will be devoid both inside and out of any asphaltic, bituminous, or other encrusting or coating materials, grease, grout, soil, etc.

To the extent practical, all steam cleaning shall be performed in an area that is on-site. All decontamination will be done by personnel in protective gear appropriate for the level of decontamination, as determined by the Health and Safety Officer. Decontamination areas will be lined with plastic. If heavy coal tar is present, equipment will be decontaminated in a lined, bermed pit, and decontamination fluids will be collected and drummed. All other decontamination fluids will be disposed of via percolation on-site.

The split-spoon sampler utilized during the subsurface soil sampling procedures will be decontaminated using a TSP/water rinse followed by a distilled water rinse. Loose material will be removed using a brush, prior to the split-spoon washing procedure.

Heavy coal tar material that cannot be removed from sampling equipment will be cleaned with kerosene, then a TSP/water rinse, followed by a distilled water rinse. Large drilling equipment (i.e., augers) will be cleaned with kerosene, then steam-cleaned.

Spoils from the borehole operation, to the extent possible, shall be placed back in the borehole directly above the bentonite grout seal. If a larger than expected quantity of concentrated wastes is encountered, NYSEG will be notified and the wastes will be separated and drummed for later disposal.

SITE ENTRY PROCEDURES:

The site itself will normally be divided into three zones: the majority of the work area will be considered the Exclusion Zone, with limited areas serving as the Support

Zone, and an area for decontamination called the Contamination Reduction Zone (CRZ).

Exclusion Zone

The Exclusion Zone isolates the area of contaminant generation and restricts (to the extent possible) the spread of contamination from active areas of the site to support areas and off-site locations. The Exclusion Zone is demarcated by the Hot Line (i.e., a tape line or physical barrier). Personnel entering the Exclusion Zone must (1) enter through the CRZ; (2) wear the prescribed level of protection (see Section 4.3.1); and (3) be otherwise authorized to enter the Exclusion Zone (see Section 1.3, 1.4, and 9.1). Any personnel, equipment, or materials exiting the Exclusion Zone will be considered contaminated. Personnel will be subject to decontamination; equipment and materials will either be subject to decontamination or containerized in uncontaminated devices.

Within the Exclusion Zone, specific locations or restricted areas (clearly marked or identified) will be established as necessary for particular locations or around specific site operations. In the case of well drilling or excavation operations, a restricted area will be established that includes a minimum 30-foot radius from the drill rig or excavation operation. Other restricted areas may include drum areas, active site areas, sources of combustible gases or air contaminants, or other dangerous areas as they are identified. Specific access for emergency services to areas of specific site operations will be established.

Contamination Reduction Zone

Moving out from the Exclusion Zone, starting at the Hot Line and continuing to the Contamination Control Line, is the CRZ. The CRZ is a transition zone between contaminated and uncontaminated areas of the site. When "hot" or contaminated personnel, equipment, or materials cross the Hot Line, they are assumed to be as "hot" or contaminated as they are going to be from site operations. Being subjected to the decontamination process, they become less contaminated; when they reach the Contamination Control Line, they are clean and can exit this zone without spreading contamination.

Within the CRZ is the Contamination Reduction Corridor (CRC), where materials necessary for full personnel and portable equipment decontamination are kept. A

separate facility will be established for heavy equipment decontamination. In addition, certain safety equipment (e.g., emergency eye wash, fire extinguisher, stretcher, and first aid kit) are staged in this zone.

Support Zone

The Support Zone is the outermost zone of the site, separated from the CRZ by the Contamination Control Line; it is considered a clean area. Movement of personnel and materials from this zone into the CRZ is generally unrestricted, except as required through access points controlled for administrative purposes. However, only uncontaminated/decontaminated personnel or materials may enter this zone from the CRZ.

The Support Zone contains the necessary support facilities (including personal hygiene facilities) for site operations. It also serves as the communications center and source of emergency assistance for operations in the Exclusion Zone and CRZ. A log of all persons entering the site will be maintained by the HSO, the field operations leader, or the site designee.

COMMUNICATIONS:

When radio communication is not used, the following air horn signals will be employed:

HELP	three short blasts	(. . .)
EVACUATION	three long blasts	(_ _ _)
ALL CLEAR	alternating long and short blasts	(_ . _ .)

ENGINEERING CONTROLS, WORK PRACTICES, AND PERSONAL PROTECTIVE EQUIPMENT

ENGINEERING CONTROLS:

No special engineering controls can be used at the Mechanicville site.

WORK PRACTICES:

Workers are expected to adhere to established safe work practices for their respective specialties (e.g., drilling, sampling collection, laboratory analysis, or construction). The need to exercise caution in the performance of specific work tasks is made more acute due to (1) weather conditions; (2) restricted mobility and reduced peripheral vision caused by the protective gear itself; (3) the need to maintain the integrity of the protective gear; and (4) the increased difficulty in communicating caused by respirators. Work at the site will be conducted according to established protocols and guidelines for the safety and health of all involved. Among the most important of these principles for working at a hazardous waste site are the following:

- In any unknown situation, always assume the worst conditions and plan responses accordingly.

- Use the buddy system. Under no conditions will any person be permitted to enter the Exclusion Zone alone. Establish and maintain communication. In addition to radio communications, it is advisable to develop a set of hand signals, because conditions may greatly impair verbal communications.

- Because no personal protective equipment is 100-percent effective, all personnel must minimize contact with excavated or contaminated materials. Plan work areas, decontamination areas, and procedures accordingly. Do not place equipment on drums or the ground. Do not sit on drums or other materials. Do not sit or kneel on the ground in the Exclusion Zone or CRZ. Avoid standing in or walking through puddles or stained soil.

- Smoking, eating, or drinking in the work area and before decontamination will not be allowed. Oral ingestion of contaminants is the second most likely means of introducing toxic substances into the body (inhalation is the first).

- Avoid heat and other work stresses related to wearing protective gear. Work breaks should be planned to prevent stress-related accidents or fatigue.

- To the extent feasible, handling of contaminated materials should be done remotely, particularly when drummed or other containerized hazardous waste materials are found on-site. Every effort should be made to identify the contents of containers found on-site before they are subject to material-handling applications.

- Personnel must be observant of not only one's own immediate surroundings, but also those of others. Everyone will be working under constraints; therefore, a team effort is needed to notice and warn of impending dangerous situations. Extra precautions are necessary when working near heavy equipment and while utilizing personal protective gear because vision, hearing, and communication can be restricted.

- Contact lenses are not allowed to be worn on-site; if corrosive or lachrymose substances enter the eyes, proper flushing is impeded.

- All facial hair that interferes with the face piece fit, must be removed prior to donning a respirator at all sites requiring Level C or B protection.

- Rigorous contingency planning and dissemination of plans to all personnel minimizes the impact of rapidly changing safety protocols in response to changing site conditions.

- Personnel must be aware that chemical contaminants may mimic or enhance symptoms of other illnesses or intoxication. Avoid excess use of alcohol or working while ill during field investigation assignments.

- The site leader, HSO, and sampling personnel will maintain project records in a bound notebook (e.g., daily activities, meetings, incidents, and data). Notebooks will remain on-site for the duration of the project so that replacement personnel may add information, thereby maintaining continuity. These notebooks and daily records will become part of the permanent project file.

Team Member	Responsibility
Dan Ostrye	Project Manager
Tom Plante+*	Site Manager
Bob Burger	Sampling Supervisor
Rick Allen	Geophysical Supervisor
Nathan Hagelin+*	Site Hydrogeologist
Nathan Hagelin+*	Site Health and Safety Officer

* First Aid Certified + CPR Certified

WORK LIMITATION: (Time of day, etc.)

Work will be conducted only during daylight hours. Sampling work undertaken during the winter will continue until winter conditions make efforts unproductive or inefficient, or the provisions of the cold weather operations plan are invoked.

TRAINING

Training is defined under the ABB Environmental Health and Safety Program, and all personnel entering potentially contaminated areas of this site must meet the requirements of 29 CFR 1910.120. Personnel without the required training will not be permitted in any area with potential for exposure to toxic substances or harmful physical agents (i.e., downrange).

MEDICAL SURVEILLANCE

All personnel entering potentially contaminated areas of this site will be medically qualified for site assignment through a medical surveillance program outlined in the ABB Environmental Health and Safety Program. Personnel who have not received

medical clearance will not be permitted in any area with potential for exposure to toxic substances or harmful physical agents (i.e., downrange).

EMERGENCY/CONTINGENCY PLAN

This section identifies the emergency contingency planning undertaken for operations at this site. Other sections provide further information to be used under emergency conditions.

PERSONNEL ROLES, LINES OF AUTHORITY, AND COMMUNICATION:

The site HSO is the primary authority for directing site operations under emergency conditions. All communications both on- and off-site will be directed through the HSO.

EVACUATION:

Withdrawal Upwind

The work party will continually note general wind directions while on-site. (A windsock may be set up near the work site for visual determinations.) When conditions warrant moving away from the work site, the crew will relocate upwind a distance of approximately 100 feet or farther, as indicated by site monitoring instruments. Donning an SCBA and a safety harness and line, the HSO and a member of the crew (the buddy system must be used) may return to the work site to determine if the condition noted was transient or persistent. If persistent, an alarm should be raised to notify on-site personnel of the situation and the need to leave the site or don an SCBA. An attempt to decrease emissions should be made only if greater respiratory protection is donned. The HSS and client will be notified of conditions. When site access is restricted, thus hindering escape, the crew may be instructed to evacuate the site rather than move upwind, especially if withdrawal upwind moves the crew away from escape routes.

Site Evacuation

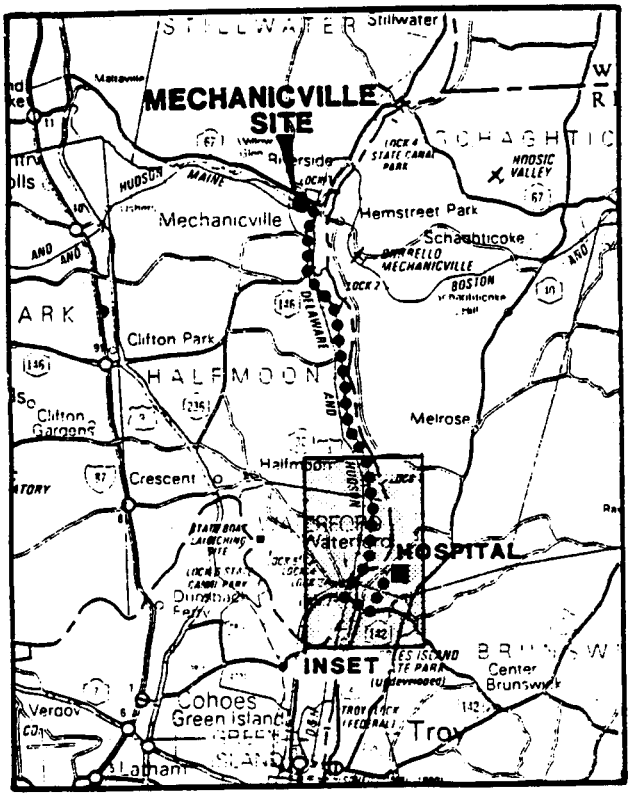
When conditions warrant site evacuation, the work party will proceed upwind of the work site and notify the security force, HSO, and field office of site conditions. If the decontamination area is upwind and greater than 500 feet from the work site, the

crew will pass quickly through decontamination to remove contaminated outer suits. If the hazard is toxic gas, respirators will be retained. The crew will proceed to the field office to assess the situation. If instrumentation indicates an acceptable condition, respirators may be removed. As more information is received from the field crew, it will be relayed to the appropriate agencies. The advisability and type of further response action will be coordinated and carried out by the HSO.

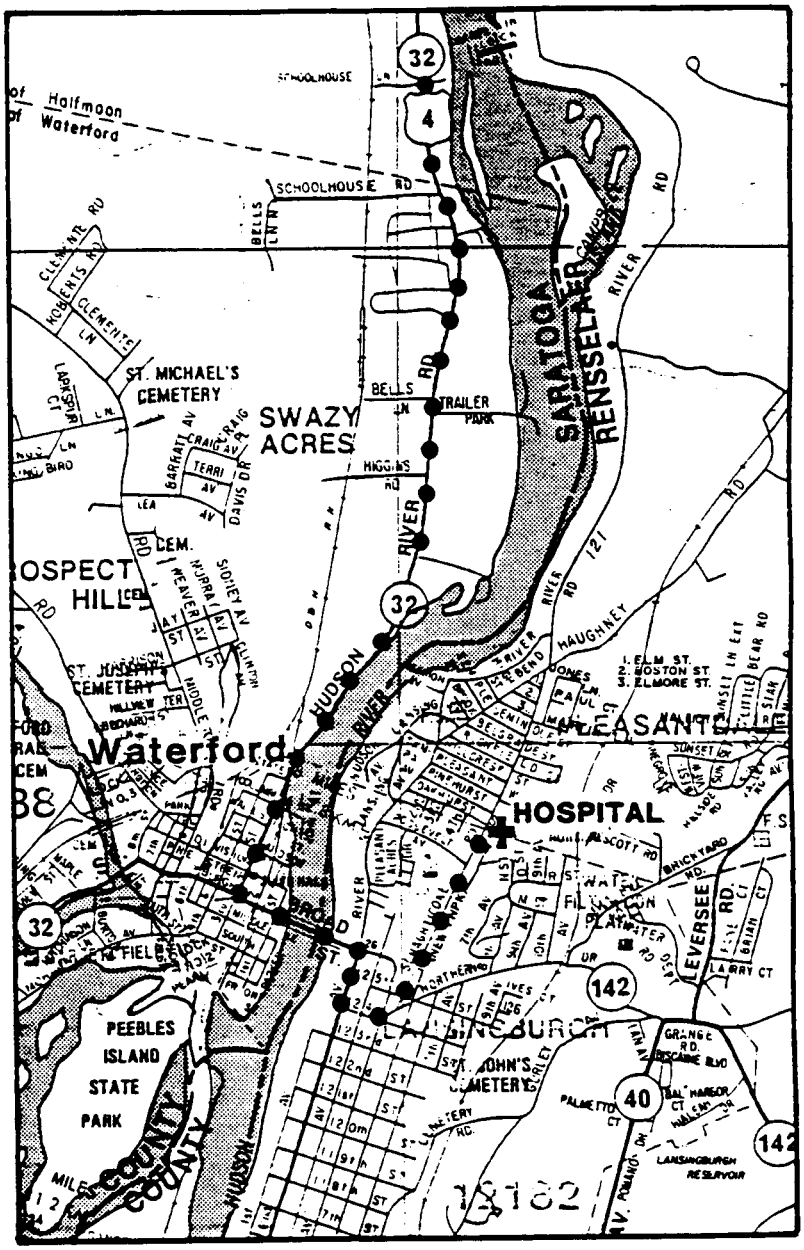
Evacuation of Surrounding Area

When the HSO determines that conditions warrant evacuation of downwind residences and commercial operations, local agencies will be notified and assistance requested. Designated on-site personnel will initiate evacuation of the immediate off-site area without delay.

EMERGENCY MEDICAL TREATMENT/FIRST AID:



First aid will be rendered to any person injured on-site, as appropriate. The injured person will then be transported to medical personnel for further examination and/or treatment. The preferred transport method is a professional emergency transportation service; however, when this is not readily available or would result in excessive delay, other transport is authorized. Under no circumstances will injured persons transport themselves to a medical facility for emergency treatment.



When an injury occurs in a downrange position, provisions for decontamination of the victim will be made. However, life-threatening conditions may preclude normal decontamination procedures. In such cases, arrangements will be made with the medical facility and transporter to provide for the situation.

F. EMERGENCY ROUTES

(Give road or other directions; attach map)

HOSPITAL: Exit site - Proceed south on North Central Avenue (Route 4). Follow Route 4 to Waterford, New York. Turn left onto the Waterford Bridge at 2nd Avenue (Broad St.). Bear right upon crossing the Hudson River and continue on 2nd Avenue. At the first light turn left onto 124th St. which runs into New Turnpike Road. Proceed east approximately one mile on New Turnpike Road and Leonard Hospital is on the right. (See Figure 2).

MONSANTO PRODUCT NAME

TRISODIUM PHOSPHATE CRYSTALLINE

MONSANTO COMPANY
800 N. LINDBERGH BLVD.
ST. LOUIS, MO 63167

Emergency Phone No.
(Call Collect)
314-694-1000

PRODUCT IDENTIFICATION

Synonyms:	TSP/C; Trisodium orthophosphate; Sodium phosphate, tribasic; Phosphoric acid, trisodium salt; Trisodium phosphate dodecahydrate
Chemical Formula:	$Na_3PO_4 \cdot 12H_2O \cdot 1/4\ NaOH$ (approximately)
CAS No.:	10101-89-0*
DOT Proper Shipping Name:	Sodium Phosphate, Tribasic (see NOTE below)
DOT Hazard Class/ I.D. No.:	ORM-E/NA9148
DOT Label(s):	Not Applicable
Hazardous Substance(s)/ RQ(s):	Yes/5,000 lbs.
U.S. Surface Freight Classification:	Trisodium Phosphate

Note: Bagged material is not regulated.

*Since hydrated materials could not be reported on the ~~TSCA Initial~~ Inventory List, Trisodium Phosphate Crystalline was reported as anhydrous with the CAS No. 7601-54-9.

WARNING STATEMENTS

DANGER!
CAUSES EYE BURNS
CAUSES SKIN IRRITATION

PRECAUTIONARY MEASURES

Do not get in eyes, on skin, on clothing.
Avoid breathing dust.
Keep container closed.
Use with adequate ventilation.
Wash thoroughly after handling.

EMERGENCY AND FIRST AID PROCEDURES

FIRST AID: IF IN EYES, immediately flush with plenty of water for at least 15 minutes. Call a physician.

IF ON SKIN, immediately flush with plenty of water. Remove contaminated clothing. Wash clothing before reuse.

OCCUPATIONAL CONTROL PROCEDURES

Eye Protection: Wear chemical safety goggles to prevent eye contact. Have eye baths immediatey available where eye contact can occur.

Skin Protection: Wear appropriate impervious gloves and protective clothing to prevent skin contact. Launder contaminated clothing and clean protective equipment before reuse.

Respiratory Protection: Use NIOSH approved equipment suitable for nuisance dust when airborne exposure is excessive. Consult respirator manufacturer to determine appropriate type equipment for given application.

Ventilation: Provide ventilation to minimize exposure. Local exhaust ventilation preferred.

Airborne Exposure Limits: Product: Trisodium phosphate dodecahydrate

Although no specific exposure limit has been established for this material, OSHA and ACGIH have established limits for nuisance dusts:

OSHA PEL/TWA: Total 15 mg/m^3; Respirable 5 mg/m^3
ACGIH TLV/TWA: Total 10 mg/m^3; Respirable 5 mg/m^3

Keep exposure below these limits.

FIRE PROTECTION INFORMATION

This material is not combustible.

REACTIVITY DATA

Materials to Avoid: Trisodium Phosphate Crystalline could be corrosive to aluminum surfaces because of high pH. Sealed containers should be kept free of water because of its corrosivity when wet.

Hazardous Decomposition Products: None.

Hazardous Polymerization: Does not occur..

PHYSIOLOGICAL EFFECTS SUMMARY

Oral LD_{50} (Rat): 6,500 mg/kg, Practically Nontoxic
Dermal LD_{50} (Rabbit): 7,940 mg/kg, Practically Nontoxic
Eye Irritation (Rabbit): (FHSA) Corrosive
Skin Irritation (Rabbit): (FHSA) 3.3 on a scale of 8.0, Moderately Irritating

PHYSICAL DATA

Appearance and Odor: White, crystalline, free-flowing granules or powder; odorless

pH (1% solution @ 25°C): 12.0

SPILL, LEAK & DISPOSAL INFORMATION

Waste Disposal: Dispose of in a landfill in accordance with all local, state and federal regulations.

Spill or Leakage Procedures: Sodium phosphate, tribasic, as currently defined, is *a hazardous substance* in the Comprehensive Environmental Response, Compensation and Liability Act of 1980 (Superfund) and in the current federal regulations 40 CFR, Part 116 (Section 311, Clean Water Act) with a reportable quantity of 5,000 pounds when released to the environment. Since federal, state and local laws may vary, consult your attorney or appropriate regulatory officials for information relating to spill reporting.

Sweep, scoop or vacuum up all spilled material, contaminated soil and other contaminated material and place in containers. If possible, complete cleanup on a dry basis. After all practical dry cleanup has been done, residual contamination can be flushed with plenty of water.

ADDITIONAL COMMENTS

Environmental Toxicity Information:

96-hr LC_{50} (Bluegill) : 440 mg/l, Practically Nontoxic
96-hr LC_{50} (Trout) : 260 mg/l, Practically Nontoxic

DATE: 8/1/83 **REVISED:** x **SUPERSEDES:** 5/78
MSDS NO.: 010101890

OILS, FUEL: NO. 1

OON

Common Synonyms	Watery liquid	Colorless	Kerosene odor
Kerosene Kerosine Range oil JP-1	Floats on water.		

Stop discharge if possible
Call fire department
Avoid contact with liquid
Isolate and remove discharged material
Notify local health and pollution control agencies

Fire

Combustible
Extinguish with dry chemical, foam or carbon dioxide
Water may be ineffective on fire
Cool exposed containers with water

Exposure

CALL FOR MEDICAL AID.
LIQUID
Irritating to skin and eyes.
Harmful if swallowed.
Remove contaminated clothing and shoes.
Flush affected areas with plenty of water.
IF IN EYES, hold eyelids open and flush with plenty of water.
IF SWALLOWED and victim is CONSCIOUS, have victim drink water or milk.
DO NOT INDUCE VOMITING.

Water Pollution

Dangerous to aquatic life in high concentrations.
Fouling to shorelines.
May be dangerous if it enters water intakes.
Notify local health and wildlife officials.
Notify operators of nearby water intakes.

1. RESPONSE TO DISCHARGE

(See Response Methods Handbook)
Mechanical containment
Should be removed
Chemical and physical treatment

2. LABEL

2.1 Category: None
2.2 Class: Not pertinent

3. CHEMICAL DESIGNATIONS

3.1 CG Compatibility Class: Miscellaneous Hydrocarbon Mixtures
3.2 Formula: Not applicable
3.3 IMO/UN Designation: 3.3/1223
3.4 DOT ID No.: 1223
3.5 CAS Registry No.: Data not available

4. OBSERVABLE CHARACTERISTICS

4.1 Physical State (as shipped): Liquid
4.2 Color: Colorless to light brown
4.3 Odor: Characteristic

5. HEALTH HAZARDS

5.1 Personal Protective Equipment: Protective gloves; goggles or face shield.
5.2 Symptoms Following Exposure: INGESTION causes irritation of gastrointestinal tract; pulmonary tract irritation secondary to exhalation of vapors. ASPIRATION causes severe lung irritation with coughing, gagging, dyspnea, substernal distress, and rapidly developing pulmonary edema, signs of bronchopneumonia and pneumonitis appear later; minimal central nervous system depression.
5.3 Treatment of Exposure: INGESTION: do NOT lavage or induce vomiting; call physician. ASPIRATION: enforce bed rest; administer oxygen; call physician. EYES: wash with plenty of water. SKIN: wipe off and wash with soap and water.
5.4 Threshold Limit Value: Data not available
5.5 Short Term Inhalation Limits: Data not available
5.6 Toxicity by Ingestion: Grade 1; LD_{50} = 5-15 g/kg
5.7 Late Toxicity: Data not available
5.8 Vapor (Gas) Irritant Characteristics: Vapors cause a slight smarting of the eyes or respiratory system if present in high concentrations. The effect is temporary.
5.9 Liquid or Solid Irritant Characteristics: Minimum hazard. If spilled on clothing and allowed to remain, may cause smarting and reddening of the skin.
5.10 Odor Threshold: 1 ppm
5.11 IDLH Value: Data not available

6. FIRE HAZARDS

6.1 Flash Point: 100°F C.C.
6.2 Flammable Limits in Air: 0.7%-5%
6.3 Fire Extinguishing Agents: Dry chemical, foam, carbon dioxide
6.4 Fire Extinguishing Agents Not to be Used: Water may be ineffective
6.5 Special Hazards of Combustion Products: Not pertinent
6.6 Behavior in Fire: Not pertinent
6.7 Ignition Temperature: 444°F
6.8 Electrical Hazard: Not pertinent
6.9 Burning Rate: 4 mm/min.

NOTES

BENZENE

BNZ

Common Synonyms	Watery liquid Colorless Gasoline-like odor
Benzol Benzole	Floats on water. Flammable. Irritating vapor is produced. Freezing point is 42°F.

Avoid contact with liquid and vapor. Keep people away.
Wear goggles and self-contained breathing apparatus.
Shut off ignition sources and call fire department.
Stop discharge if possible.
Stay upwind and use water spray to knock down vapor.
Isolate and remove discharged material.
Notify local health and pollution control agencies.

Fire	FLAMMABLE Flashback along vapor trail may occur. Vapor may explode if ignited in an enclosed area. Wear goggles and self-contained breathing apparatus. Extinguish with dry chemical, foam, or carbon dioxide. Water may be ineffective on fire. Cool exposed containers with water.
Exposure	CALL FOR MEDICAL AID **VAPOR** Irritating to eyes, nose and throat. If inhaled, will cause headache, difficult breathing, or loss of consciousness. Move to fresh air. If breathing has stopped, give artificial respiration. If breathing is difficult, give oxygen. **LIQUID** Irritating to skin and eyes. Harmful if swallowed. Remove contaminated clothing and shoes. Flush affected areas with plenty of water. IF IN EYES, hold eyelids open and flush with plenty of water. IF SWALLOWED and victim is CONSCIOUS, have victim drink water or milk.
Water Pollution	HARMFUL TO AQUATIC LIFE IN VERY LOW CONCENTRATIONS May be dangerous if it enters water intakes. Notify local health and wildlife officials. Notify operators of nearby water intakes.

1. RESPONSE TO DISCHARGE

(See Response Methods Handbook)

Issue warning-high flammability.
Restrict access.

2. LABEL

2.1 Category: Flammable liquid
2.2 Class: 3

3. CHEMICAL DESIGNATIONS

3.1 CG Compatibility Class: Aromatic Hydrocarbon
3.2 Formula: C_6H_6
3.3 IMO/UN Designation: 3.2/1114
3.4 DOT ID No.: 1114
3.5 CAS Registry No.: 71-43-2

4. OBSERVABLE CHARACTERISTICS

4.1 Physical State (as shipped): Liquid
4.2 Color: Colorless
4.3 Odor: Aromatic; rather pleasant aromatic odor, characteristic odor

5. HEALTH HAZARDS

5.1 Personal Protective Equipment: Hydrocarbon vapor canister, supplied air or a hose mask; hydrocarbon-insoluble rubber or plastic gloves, chemical goggles or face splash shield; hydrocarbon-insoluble apron such as neoprene.
5.2 Symptoms Following Exposure: Dizziness, excitation, pallor, followed by flushing, weakness, headache, breathlessness, chest constriction. Coma and possible death.
5.3 Treatment of Exposure: SKIN: flush with water followed by soap and water; remove contaminated clothing and wash skin. EYES: flush with plenty of water until irritation subsides. INHALATION: remove from exposure immediately. Call a physician. IF breathing is irregular or stopped, start resuscitation, administer oxygen.
5.4 Threshold Limit Value: 10-ppm 1 ppm
5.5 Short Term Inhalation Limits: 75 ppm for 30 min
5.6 Toxicity by Ingestion: Grade 3; LD_{50} = 50 to 500 mg/kg
5.7 Late Toxicity: Leukemia
5.8 Vapor (Gas) Irritant Characteristics: If present in high concentrations, vapors may cause irritation of eyes or respiratory system. The effect is temporary.
5.9 Liquid or Solid Irritant Characteristics: Minimum hazard. If spilled on clothing and allowed to remain, may cause smarting and reddening of the skin.
5.10 Odor Threshold: 4.68 ppm
5.11 IDLH Value: 2,000 ppm

6. FIRE HAZARDS

6.1 Flash Point: 12°F C.C.
6.2 Flammable Limits in Air: 1.3%-7.9%
6.3 Fire Extinguishing Agents: Dry chemical, foam, or carbon dioxide
6.4 Fire Extinguishing Agents Not to be Used: Water may be ineffective
6.5 Special Hazards of Combustion Products: Not pertinent
6.6 Behavior in Fire: Vapor is heavier than air and may travel considerable distance to a source of ignition and flash back
6.7 Ignition Temperature: 1097°F
6.8 Electrical Hazard: Class I, Group D
6.9 Burning Rate: 6.0 mm/min
6.10 Adiabatic Flame Temperature: Data not available
6.11 Stoichiometric Air to Fuel Ratio: Data not available
6.12 Flame Temperature: Data not available

7. CHEMICAL REACTIVITY

7.1 Reactivity With Water: No reaction
7.2 Reactivity with Common Materials: No reaction
7.3 Stability During Transport: Stable

12.27 Reid Vapor Pressure: 3.22 psa

NOTES

ETHYLBENZENE

ETB

Common Synonyms	Liquid	Colorless	Sweet gasoline-like odor
Phenylethane EB	Floats on water. Flammable, irritating vapor is produced		

Avoid contact with liquid and vapor. Keep people away.
Wear goggles, self-contained breathing apparatus, and rubber overclothing (including gloves).
Shut off ignition sources and call fire department.
Stop discharge if possible.
Stay upwind and use water spray to "knock down" vapor.
Isolate and remove discharged material.
Notify local health and pollution control agencies.

Fire

FLAMMABLE.
Flashback along vapor trail may occur.
Vapor may explode if ignited in an enclosed area.
Wear goggles, self-contained breathing apparatus, and rubber overclothing (including gloves).
Extinguish with dry chemical, foam, or carbon dioxide.
Water may be ineffective on fire.
Cool exposed containers with water.

Exposure

CALL FOR MEDICAL AID.

VAPOR
Irritating to eyes, nose and throat.
If inhaled, will cause dizziness or difficult breathing.
Move to fresh air.
If breathing has stopped, give artificial respiration.
If breathing is difficult, give oxygen.

LIQUID
Will burn skin and eyes.
Harmful if swallowed.
Remove contaminated clothing and shoes.
Flush affected areas with plenty of water.
IF IN EYES, hold eyelids open and flush with plenty of water.
IF SWALLOWED and victim is CONSCIOUS, have victim drink water or milk.
DO NOT INDUCE VOMITING.

Water Pollution

HARMFUL TO AQUATIC LIFE IN VERY LOW CONCENTRATIONS.
Fouling to shoreline.
May be dangerous if it enters water intakes.

Notify local health and wildlife officials.
Notify operators of nearby water intakes.

1. RESPONSE TO DISCHARGE

(See Response Methods Handbook)

Mechanical containment.
Should be removed.
Chemical and physical treatment.

2. LABEL

2.1 Category: Flammable liquid
2.2 Class: 3

3. CHEMICAL DESIGNATIONS

3.1 CG Compatibility Class: Aromatic hydrocarbon
3.2 Formula: $C_6H_5CH_2CH_3$
3.3 IMO/UN Designation: 3.3/1175
3.4 DOT ID No.: 1175
3.5 CAS Registry No.: 100-41-4

4. OBSERVABLE CHARACTERISTICS

4.1 Physical State (as shipped): Liquid
4.2 Color: Colorless
4.3 Odor: Aromatic

5. HEALTH HAZARDS

5.1 Personal Protective Equipment: Self-contained breathing apparatus; safety goggles.
5.2 Symptoms Following Exposure: Inhalation may cause irritation of nose, dizziness, depression. Moderate irritation of eye with corneal injury possible. Irritates skin and may cause blisters.
5.3 Treatment of Exposure: INHALATION: if ill effects occur, remove victim to fresh air, keep him warm and quiet, and get medical help promptly; if breathing stops, give artificial respiration. INGESTION: induce vomiting only upon physician's approval; material in lung may cause chemical pneumonitis. SKIN AND EYES: promptly flush with plenty of water (15 min. for eyes) and get medical attention; remove and wash contaminated clothing before reuse.
5.4 Threshold Limit Value: 100 ppm
5.5 Short Term Inhalation Limits: 200 ppm for 30 min.
5.6 Toxicity by Ingestion: Grade 2; LD_{50} = 0.5 to 5 g/kg (rat)
5.7 Late Toxicity: Data not available
5.8 Vapor (Gas) Irritant Characteristics: Vapors cause moderate irritation such that personnel will find high concentrations unpleasant. The effect is temporary.
5.9 Liquid or Solid Irritant Characteristics: Causes smarting of the skin and first-degree burns on short exposure; may cause secondary burns on long exposure.
5.10 Odor Threshold: 140 ppm
5.11 IDLH Value: 2,000 ppm

6. FIRE HAZARDS

6.1 Flash Point: 60°F O.C., 59°F C.C.
6.2 Flammable Limits in Air: 1.0%-6.7%
6.3 Fire Extinguishing Agents: Foam (most effective); water fog, carbon dioxide or dry chemical
6.4 Fire Extinguishing Agents Not to be Used: Not pertinent
6.5 Special Hazards of Combustion Products: Irritating vapors are generated when heated.
6.6 Behavior in Fire: Vapor is heavier than air and may travel considerable distance to the source of ignition and flash back.
6.7 Ignition Temperature: 860°F
6.8 Electrical Hazard: Not pertinent
6.9 Burning Rate: 5.8 mm/min
6.10 Adiabatic Flame Temperature: Data Not Available

STYRENE

STY

Common Synonyms	Watery liquid	Colorless to light yellow	Sweet pleasant odor
Styrol Vinylbenzene Phenylethylene Styrolene	Floats on water. Flammable, irritating vapor is produced.		

Avoid contact with liquid and vapor. Keep people away.
Wear chemical protective suit with self-contained breathing apparatus.
Stop discharge if possible.
Call fire department.
Isolate and remove discharged material.
Notify local health and pollution control agencies.

Fire

FLAMMABLE.
CONTAINERS MAY EXPLODE IN FIRE.
Flashback along vapor trail may occur.
Vapor may explode if ignited in an enclosed area.
Wear chemical protective suit with self-contained breathing apparatus.
Combat fires from safe distance or protected location.
Extinguish with dry chemical, foam, or carbon dioxide.
Water may be ineffective on fire.
Cool exposed containers with water.

Exposure

CALL FOR MEDICAL AID.

VAPOR
Irritating to eyes, nose and throat.
If inhaled, will cause dizziness or loss of consciousness.
Move to fresh air.
If breathing has stopped, give artificial respiration.
If breathing is difficult, give oxygen.

LIQUID
Will burn skin and eyes.
Harmful if swallowed.
Remove contaminated clothing and shoes.
Flush affected areas with plenty of water.
IF IN EYES, hold eyelids open and flush with plenty of water.
IF SWALLOWED and victim is CONSCIOUS, have victim drink water or milk.
DO NOT INDUCE VOMITING.

Water Pollution

HARMFUL TO AQUATIC LIFE IN VERY LOW CONCENTRATIONS.
Fouling to shoreline.
May be dangerous if it enters water intakes.

Notify local health and wildlife officials.
Notify operators of nearby water intakes.

1. RESPONSE TO DISCHARGE

(See Response Methods Handbook)

Issue warning-air contaminant
Mechanical containment
Should be removed
Chemical and physical treatment

2. LABEL

2.1 Category: Flammable liquid
2.2 Class: 3

3. CHEMICAL DESIGNATIONS

3.1 CG Compatibility Class: Olefin
3.2 Formula: $C_6H_5CH=CH_2$
3.3 IMO/UN Designation: 3.3/2055
3.4 DOT ID No.: 2055
3.5 CAS Registry No.: 100-42-5

4. OBSERVABLE CHARACTERISTICS

4.1 Physical State (as shipped): Liquid
4.2 Color: Colorless
4.3 Odor: Sweet at low concentrations; characteristic pungent; sharp; disagreeable

5. HEALTH HAZARDS

5.1 Personal Protective Equipment: Air-supplied mask or approved canister; rubber or plastic gloves; boots; goggles or face shield.
5.2 Symptoms Following Exposure: Moderate irritation of eyes and skin. High vapor concentrations cause dizziness, drunkenness, and anesthesia.
5.3 Treatment of Exposure: INHALATION: remove to fresh air; keep warm and quiet; use artificial respiration if needed. INGESTION: do NOT induce vomiting; call physician; no known antidote. SKIN OR EYE CONTACT: flush with plenty of water; for eyes get medical attention.
5.4 Threshold Limit Value: 50 ppm
5.5 Short Term Inhalation Limits: 100 ppm for 30 min.
5.6 Toxicity by Ingestion: Grade 2; LD_{50} = 0.5 to 5 g/kg
5.7 Late Toxicity: Data not available
5.8 Vapor (Gas) Irritant Characteristics: Vapors cause moderate irritation such that personnel will find high concentrations unpleasant. The effect is temporary.
5.9 Liquid or Solid Irritant Characteristics: Causes smarting of the skin and first-degree burns on short exposure; may cause secondary burns on long exposure.
5.10 Odor Threshold: 0.148 ppm
5.11 IDLH Value: 5,000 ppm

6. FIRE HAZARDS

6.1 Flash Point: 83°F O.C., 88°F C.C.
6.2 Flammable Limits in Air: 1.1%-6.1%
6.3 Fire Extinguishing Agents: Water fog, foam, carbon dioxide, or dry chemical
6.4 Fire Extinguishing Agents Not to be Used: Water may be ineffective
6.5 Special Hazards of Combustion Products: Not pertinent
6.6 Behavior in Fire: Vapor is heavier than air and may travel considerable distance to a source of ignition and flash back. At elevated temperatures such as in fire conditions, polymerization may take place which may lead to container explosion.
6.7 Ignition Temperature: 914°F
6.8 Electrical Hazard: Class I, Group D
6.9 Burning Rate: 5.2 mm/min

TOLUENE

TOL

Common Synonyms	Watery liquid	Colorless	Pleasant odor
Toluol Methylbenzene Methylbenzol	Floats on water. Flammable, irritating vapor is produced.		

Stop discharge if possible. Keep people away.
Shut off ignition sources and call fire department.
Stay upwind and use water spray to "knock down" vapor.
Avoid contact with liquid and vapor.
Isolate and remove discharged material.
Notify local health and pollution control agencies.

Fire

FLAMMABLE.
Flashback along vapor trail may occur.
Vapor may explode if ignited in an enclosed area.
Wear goggles and self-contained breathing apparatus.
Extinguish with dry chemical, foam, or carbon dioxide.
Water may be ineffective on fire.
Cool exposed containers with water.

Exposure

CALL FOR MEDICAL AID.

VAPOR
Irritating to eyes, nose and throat.
If inhaled, will cause nausea, vomiting, headache, dizziness, difficult breathing, or loss of consciousness.
Move to fresh air.
If breathing has stopped, give artificial respiration.
If breathing difficult, give oxygen.

LIQUID
Irritating to skin and eyes.
If swallowed, will cause nausea, vomiting or loss of consciousness.
Remove contaminated clothing and shoes.
Flush affected areas with plenty of water.
IF IN EYES, hold eyelids open and flush with plenty of water.
IF SWALLOWED and victim is CONSCIOUS, have victim drink water or milk.
DO NOT INDUCE VOMITING.

Water Pollution

Dangerous to aquatic life in high concentrations.
Fouling to shoreline.
May be dangerous if it enters water intakes.

Notify local health and wildlife officials.
Notify operators of nearby water intakes.

1. RESPONSE TO DISCHARGE

(See Response Methods Handbook)

Issue warning-high flammability
Evacuate area

2. LABEL

2.1 Category: Flammable liquid
2.2 Class: 3

3. CHEMICAL DESIGNATIONS

3.1 CG Compatibility Class: Aromatic Hydrocarbon
3.2 Formula: $C_6H_5CH_3$
3.3 IMO/UN Designation: 3.2/1294
3.4 DOT ID No.: 1294
3.5 CAS Registry No.: 108-88-3

4. OBSERVABLE CHARACTERISTICS

4.1 Physical State (as shipped): Liquid
4.2 Color: Colorless
4.3 Odor: Pungent, aromatic, benzene-like; distinct, pleasant

5. HEALTH HAZARDS

5.1 Personal Protective Equipment: Air-supplied mask; goggles or face shield; plastic gloves.
5.2 Symptoms Following Exposure: Vapors irritate eyes and upper respiratory tract; cause dizziness, headache, anesthesia, respiratory arrest. Liquid irritates eyes and causes drying of skin. If aspirated, causes coughing, gagging, distress, and rapidly developing pulmonary edema. If ingested causes vomiting, griping, diarrhea, depressed respiration.
5.3 Treatment of Exposure: INHALATION: remove to fresh air, give artificial respiration and oxygen if needed; call a doctor. INGESTION: do NOT induce vomiting; call a doctor. EYES: flush with water for at least 15 min. SKIN: wipe off, wash with soap and water.
5.4 Threshold Limit Value: 100 ppm
5.5 Short Term Inhalation Limits: 600 ppm for 30 min.
5.6 Toxicity by Ingestion: Grade 2; LD_{50} = 0.5 to 5 g/kg
5.7 Late Toxicity: Kidney and liver damage may follow ingestion.
5.8 Vapor (Gas) Irritant Characteristics: Vapors cause a slight smarting of the eyes or respiratory system if present in high concentrations. The effect is temporary.
5.9 Liquid or Solid Irritant Characteristics: Minimum hazard. If spilled on clothing and allowed to remain, may cause smarting and reddening of the skin.
5.10 Odor Threshold: 0.17 ppm
5.11 IDLH Value: 2,000 ppm

6. FIRE HAZARDS

6.1 Flash Point: 40°F C.C., 55°F O.C.
6.2 Flammable Limits in Air: 1.27%-7%
6.3 Fire Extinguishing Agents: Carbon dioxide or dry chemical for small fires, ordinary foam for large fires
6.4 Fire Extinguishing Agents Not to be Used: Water may be ineffective
6.5 Special Hazards of Combustion Products: Not pertinent
6.6 Behavior in Fire: Vapor is heavier than air and may travel a considerable distance to a source of ignition and flash back.
6.7 Ignition Temperature: 997°F
6.8 Electrical Hazard: Class I, Group D
6.9 Burning Rate: 5.7 mm/min
6.10 Adiabatic Flame Temperature: Data not available

(Continued)

7. CHEMICAL REACTIVITY

7.1 Reactivity With Water: No reaction
7.2 Reactivity with Common Materials: No reaction
7.3 Stability During Transport: Stable
7.4 Neutralizing Agents for Acids and Caustics: Not pertinent
7.5 Polymerization: Not pertinent
7.6 Inhibitor of Polymerization: Not pertinent
7.7 Molar Ratio (Reactant to Product): Data not available
7.8 Reactivity Group: 32

8. WATER POLLUTION

8.1 Aquatic Toxicity: 1180 mg/l/96 hr/sunfish/TL_m/fresh water
8.2 Waterfowl Toxicity: Data not available
8.3 Biological Oxygen Demand (BOD): 0%, 5 days; 38% (theor), 8 days
8.4 Food Chain Concentration Potential: None

9. SHIPPING INFORMATION

9.1 Grades of Purity: Research, reagent, nitration-all 99.8 + %; industrial: contains 94 + %, with 5% xylene and small amounts of benzene and nonaromatic hydrocarbons; 80/120: less pure than industrial.
9.2 Storage Temperature: Ambient
9.3 Inert Atmosphere: No requirement
9.4 Venting: Open (flame arrester) or pressure-vacuum

NOTES

COAL TAR PITCH VOLATILES

CAS: 8007-45-2

TLV-TWA. 0.2 mg/m³, as Benzene Soluble Fraction
Appendix A1a — Recognized Human Carcinogen

The pitch of coal tar is the black or dark brown amorphous residue that remains after the redistillation process. The volatiles contain a large quantity of lower molecular weight polycyclic hydrocarbons.[1,2] As these hydrocarbons (naphthalene, fluorene, anthracene, acridine, phenanthrene) sublime into the air and there is an increase of benzo(a)pyrene (BaP or 3,4-benzpyrene) and other higher weight polycyclic hydrocarbons in the tar and in the fumes. Polycyclic hydrocarbons, known to be carcinogenic, are of this large molecular type.

Coal tar is used as a base for coatings and paints, for roofing and paving, and as a binder for carbon electrodes.

Doll[4] found that deaths from cancer of the lungs and pleura of retired gas-workers is approximately two times the expected rate.

Coal tar pitch polluted air is characterized by large amounts of phenanthrene, anthracene, pyrene, and carbazole. Coal tar pitch contains approximately 10% polycyclic hydrocarbons, and three different samples analyzed by Sawicki *et al*[1] gave a concentration of 1.4% BaP alone.

Samples collected in urban and nonurban sites[1,2] contained a range of 2.4-410 μg BaP/g of particulate (38-2600 μg BaP/g of benzene fraction or 0.11-61 μg/1000 m³ of air) in the former locations and 0.15-51 μg BaP/g of particulate (9.3-730 μg BaP/g of benzene soluble fraction or 0.01-1.9 μg BaP/1000 m³ of air) in the latter[3] during a three-month period, January through March.

Falk *et al*[5,6] pointed out that the amount of BaP in the air was greater than one would expect on the basis of comparative quantitative emissions of other hydrocarbons. The composition of the hydrocarbons varies with time and distance, suggesting differences in stability of the compounds. The authors conclude that chrysene, 1,12-benzperylene, coronene, and BaP are stable, and phenanthrene, an "unidentified hydrocarbon" and anthranthrene are most readily destroyed, usually within 48 hours. Intermediate stability is demonstrated by pyrene (58% recovery in 48 hours) and fluoranthrene (80% recovery in 48 hours).

Stability of polycyclic hydrocarbons was also studied by Commins and Lawther.[11] They point out that the temperature applied to sinter the filter used to collect the sample altered the apparent stability for BaP. They concluded that the filter should never be subjected to temperatures above 100°C; no loss of BaP was found after heating 100 μg BaP on a sintered disc in a sealed tube at 100°C for seven hours.

In further experiments, Kotin *et al*[8] painted the interscapular area of C57 black mice three times weekly with benzene extracts of natural smog. First tumors appeared 465 days following the initial application.

Fairhall[12] stated that fumes of dust from native asphalt do not present a substantial health hazard in comparison with coal tar fume or dust, citing the work of Hueper[13] and Davies.[14] Hueper[15] also pointed out that, as a rule, a minimal time of exposure of one to five years is required to develop occupational cancer. Similarly, occupational cancers often develop many years after exposure to carcinogens has ceased. Simmers[16] concluded that the degree of change noted in the lungs of rats breathing air contaminated with aromatic polycyclic hydrocarbons is dose-dependent.

In its criteria document for coal tar products, NIOSH cites papers dealing primarily with coke oven and aluminum potroom workers.[17] A study of aluminum industry potroom workers[18] showed an increase in lung cancer mortality. A paper on this industry in the Soviet Union associates such an increase with concentrations of tarry substances between 27 and 2130 mg/m³, while the BaP levels were between 0.6 and 56 μg/m³.[19] High respiratory mortality among coke oven workers in Great Britain was reported.[20] Kidney as well as lung cancer was relatively prevalent among American coke-oven workers exposed 5 years or more.[21]

Animal studies indicating that lung and kidney tumors were caused by exposure to coal tar aerosols were also cited.

The occupational exposure standard recommended by NIOSH was 0.1 mg/m³ for the cyclohexane extractable fraction.[17] A 1977 summary, however, gives 0.2 mg/m³ as the NIOSH recommendation for coal tar pitch volatiles.[22]

In the absence of more definitive information on the identity of the components of coal tar pitch aerosols responsible for carcinogenic effects, a TLV based on the benzene (or other suitable solvent) soluble fraction appears to be the most practical compromise. If the concentration of aerosols from coal tar, on this basis, is maintained below 0.2 mg/m³, any increase in the incidence of lung and other tumors, due to occupational exposure, should be minimal.

OSHA POSTER

JOB SAFETY & HEALTH PROTECTION

The Occupational Safety and Health Act of 1970 provides job safety and health protection for workers by promoting safe and healthful working conditions throughout the Nation. Requirements of the Act include the following:

Employers

All employers must furnish to employees employment and a place of employment free from recognized hazards that are causing or are likely to cause death or serious harm to employees. Employers must comply with occupational safety and health standards issued under the Act.

Employees

Employees must comply with all occupational safety and health standards, rules, regulations and orders issued under the Act that apply to their own actions and conduct on the job.

The Occupational Safety and Health Administration (OSHA) of the U.S. Department of Labor has the primary responsibility for administering the Act. OSHA issues occupational safety and health standards, and its Compliance Safety and Health Officers conduct jobsite inspections to help ensure compliance with the Act.

Inspection

The Act requires that a representative of the employer and a representative authorized by the employees be given an opportunity to accompany the OSHA inspector for the purpose of aiding the inspection.

Where there is no authorized employee representative, the OSHA Compliance Officer must consult with a reasonable number of employees concerning safety and health conditions in the workplace.

Complaint

Employees or their representatives have the right to file a complaint with the nearest OSHA office requesting an inspection if they believe unsafe or unhealthful conditions exist in their workplace. OSHA will withhold, on request, names of employees complaining.

The Act provides that employees may not be discharged or discriminated against in any way for filing safety and health complaints or for otherwise exercising their rights under the Act.

Employees who believe they have been discriminated against may file a complaint with their nearest OSHA office within 30 days of the alleged discrimination.

Citation

If upon inspection OSHA believes an employer has violated the Act, a citation alleging such violations will be issued to the employer. Each citation will specify a time period within which the alleged violation must be corrected.

The OSHA citation must be prominently displayed at or near the place of alleged violation for three days, or until it is corrected, whichever is later, to warn employees of dangers that may exist there.

Proposed Penalty

The Act provides for mandatory penalties against employers of up to $1,000 for each serious violation and for optional penalties of up to $1,000 for each nonserious violation. Penalties of up to $1,000 per day may be proposed for failure to correct violations within the proposed time period. Also, any employer who willfully or repeatedly violates the Act may be assessed penalties of up to $10,000 for each such violation.

Criminal penalties are also provided for in the Act. Any willful violation resulting in death of an employee, upon conviction, is punishable by a fine of not more than $10,000, or by imprisonment for not more than six months, or by both. Conviction of an employer after a first conviction doubles these maximum penalties.

Voluntary Activity

While providing penalties for violations, the Act also encourages efforts by labor and management, before an OSHA inspection, to reduce workplace hazards voluntarily and to develop and improve safety and health programs in all workplaces and industries. OSHA's Voluntary Protection Programs recognize outstanding efforts of this nature.

Such voluntary action should initially focus on the identification and elimination of hazards that could cause death, injury, or illness to employees and supervisors. There are many public and private organizations that can provide information and assistance in this effort, if requested. Also, your local OSHA office can provide considerable help and advice on solving safety and health problems or can refer you to other sources for help such as training.

Consultation

Free consultative assistance, without citation or penalty, is available to employers, on request, through OSHA supported programs in most State departments of labor or health.

[illegible] OFFICE

COLD WEATHER OPERATIONS

COLD WEATHER OPERATIONS

I. INTRODUCTION

Cold weather often causes problems for personnel working outside. There are several types of cold weather injuries which can occur, even at temperatures above freezing. As temperatures drop below freezing, the potential for these injuries increases dramatically, as does the potential for equipment failure. Because of the considerable danger to personnel, outdoor work should be suspended if the ambient temperature drops below O° F (-18° C) or if the windchill factor drops below -29° F (-34° C). This level represents a guideline which should be used as an action level unless the HSO determines and documents otherwise.

Snow and ice add additional risks to personnel and operations. Reduced visibility, increased potential for falling injuries, reduced on-site mobility, and the increase in time required to access the site (or off-site support services) are some of the problems posed by snow and ice.

In view of the above, it is critical that the Site Safety Officer establish site specific safety and operating protocols, and that all on-site personnel be made aware of the risks from the recognition of, and the treatment of cold weather injuries.

II. COLD WEATHER INJURIES

There are two basic categories of cold weather injuries; local and systemic.

A. Local Cold Injuries

Local cold injuries are those injuries which affect specific areas of the body (e.g., fingers, ear, toes) and include the more commonly recognized cold weather injuries described below.

1. Chilblains is a condition that can result from prolonged exposure of bare skin to temperatures in the low sixties (°F) or below. This condition generally occurs in the extremities, and is a chronic injury of the skin and peripheral

capillary circulation. Covering and protecting the skin from prolonged exposure to the cold is the best method of preventing and treating chilblains.

2. Frostbite is the freezing of some part of the body as a result of exposure to very low temperatures. Frostbite can affect hands, feet, ears, and exposed parts of the face. It occurs when ice crystals form in the fluid in cells of the skin and tissue. As long as blood circulation remains good, frostbite will not occur. Frostbite is a constant hazard in sub- zero weather, especially where there are strong winds.

There are three stages of frostbite. Classification depends upon the amount of tissue damage. Severity can range from incipient frostbite (frostnip), which affects the skin, to superficial frostbite, which involves the skin and the tissues immediately beneath it, to deep frostbite, a much more serious injury with damage that may affect deeper tissue and even bone.

a. Symptoms

Symptoms for each of the three stages of frostbite include:

Frostnip
Skin first turns red, later becomes pale or waxy white.
May be tingling, stinging, or aching or uncomfortable sensation of coldness, followed by numbness, or it may be unnoticed by person.

Superficial Frostbite
Skin is white or gray-white and waxy in appearance.
Skin is firm to touch, does not move easily.
Tissue beneath the skin is soft and resilient.
Lack of sensation in the area.

Deep Frostbite
Tissues are pale, cold, solid.
Usually affects hands and feet.
Blisters and swelling may occur.

b. Emergency Treatment of Frostbite

Frostnip is easily reversed in the field by the application of body heat. Apply body heat before the affected area becomes numb. Thaw frozen spots immediately. Do not rub affected areas.

If frostnip affects your fingers and hands, place them against the skin of your chest or in your armpits. To warm your face, hold a mitten or scarf over the lower part of your face and breathe into it.

Superficial Frostbite usually responds to the application of body heat. If it does not or if it resembles the early stages of deep frostbite, treat the condition as though it were.

Deep Frostbite
If possible remove person to a heated shelter to avoid further frostbite.

Remove all constricting items (boots, gloves, socks) from area of injury if it can be done without danger of further frostbite.

RAPID REWARMING WILL MINIMIZE TISSUE LOSS.

Warm extremities in a carefully-controlled warm water bath (104°F to 106°F) until tips of the fingers or toes turn pink and feeling is restored.

If a water bath is not available, use ALTERNATE METHODS;

Apply wet packs (100°F to 112°F) to the person's body.

Gently wrap frostbitten area in blankets or other warm material.

DO NOT attempt to thaw by exercising the affected parts or heating them in front of an open fire, heat lamps, radiator or a stove. The person may have lost sensation in the parts and may receive a heat injury as a result.

DO NOT use snow to thaw frostbite.

DO NOT rub, massage or use pressure on the affected areas.

Watch to see if CPR is necessary.

Continue Care:

Keep frostbitten parts elevated if possible.

Give victim warm drinks such as tea, coffee, or soup.

DO NOT GIVE ALCOHOLIC BEVERAGES.

Have victim exercise fingers or toes as soon as they are warmed.

Do NOT allow a person with frostbitten feet to walk. It may cause additional damage.

c. Medical Treatment of Frostbite

Frostnip usually does not require medical care.

Superficial Frostbite. Blisters may require medical care.

Deep Frostbite. EARLY MEDICAL TREATMENT IS URGENT! Get the victim to medical care at once.

d. Prevention of Frostbite

It is far easier to prevent or to stop frostbite in earlier stages than to thaw and take care of badly frozen flesh:

Wear enough clothing to protect yourself against cold and wind.

Wear warm gloves and boots.

Pull a scarf or jacket flap over the lower part of your face or a hood tightly around your face.

Exercise face, fingers and toes from time to time to keep them warm and to detect any areas that may have become numb.

Crew members should watch each other closely for signs of frostbite, especially on the face.

3. Immersion foot (formerly called trench foot) is a cold injury resulting from prolonged exposure to temperatures near freezing, especially when standing or walking in wet or swampy ground.

a. Symptoms

In the early stages the feet and toes are pale, feet are cold, numb, stiff. Walking is difficult. If preventive action is not taken, feet will swell and ache. In extreme cases, irreversible damage to the tissues of the foot or leg may result.

b. Emergency Treatment of Immersion Foot

Feet should be handled very gently. Do not rub or massage.

If necessary, clean feet carefully with soap and water, then dry and elevate them and expose them to warm but not hot air.

c. Prevention of Immersion Foot

Because early stages of immersion foot are not painful, you must be constantly alert to prevent this condition.

Check feet often when working in wet cold.

Keep your feet dry by wearing waterproof foot gear and by avoiding standing in wet areas.

Since perspiration trapped inside waterproof boots or heavy footgear can contribute to immersion foot symptoms, change your socks frequently.

Dry your feet as soon as possible if they get wet. Warm them with your hands. Use foot powder and put on dry socks.

If you cannot change wet boots and socks, exercise your feet frequently by wriggling your toes and moving your ankles. Never wear tight boots.

B. Systemic Cold Injuries

Systemic injuries are those that affect the entire body system. Severe general body cooling is known as systemic hypothermia, and can occur at temperatures well above freezing. Hypothermia is the progressive lowering of body temperature accompanied by rapid, progressive mental and physical collapse. Subnormal temperature within the central body can be fatal. A large percentage of wilderness deaths are the result of hypothermia.

Hypothermia is caused by exposure to cold and it is aggravated by moisture, cold winds, fatigue, hunger, and inadequate clothing or shelter. Excessive perspiration from strenuous exercise followed by too rapid cooling can lead to hypothermia.

Hypothermia usually occurs between the temperatures of 30-50°F, temperatures which most people believe are not dangerous. Crew members should be alert for symptoms of hypothermia, especially when temperatures are dropping rapidly or when they must work in rain, snow or ice.

Hypothermia may occur on land or following submersion in even moderately cold water, 65°F or below. Death in cold water may seem to be from drowning but it is usually the result of hypothermia.

On land, hypothermia may take up to a full day or more of exposure to develop. If the cold conditions are extremely severe, however, death may occur within a few hours of the first symptoms.

In water, skin and nearby tissues chill very fast. Within even 10 to 15 minutes, the temperature of the heart and brain may drop. When core (internal body) temperature reaches 90°F, unconsciousness may occur. In water, when the body temperature

drops to 80°F, heart failure is the usual cause of death. A person may drown as a result of losing the use of arms and legs or by becoming unconscious.

a. Symptoms

In the early stages of hypothermia, the body begins to lose heat faster than it can produce it and makes efforts to stay warm by shivering. When the body can no longer generate heat fast enough to overcome heat loss and the energy reserves of the body are becoming exhausted, a second stage begins; the body temperature begins to drop. This affects the ability of the brain to make judgments and also results in loss of muscular control.

As the body temperature drops, hypothermia symptoms become increasingly severe:

SYMPTOMS OF HYPOTHERMIA	APPROX. CORE TEMPS.
Person is conscious, alert. May have shivering that becomes uncontrollable as core temperature nears 95°F. Respirations increase at first.	Above 95°F
Person is conscious but disoriented, apathetic. Shivering present but diminishes as temperature drops. Below 92°F respiratory rate gradually diminishes, pupils begin to dilate.	95-90°F
Person is semi-conscious. Shivering replaced by muscular rigidity. Pupils fully dilated at about 86°F.	90-86°F
Unconscious, diminished respirations.	Below 86°F
Barely detectable or nondetectable respirations.	Below 80°F

b. Emergency Treatment of Hypothermia

In very mild cases of hypothermia, dry clothing and shelter may be all that is needed.

Move victim to shelter and warmth as rapidly as possible.

Gently remove all wet clothing (so victim does not expend energy warming and drying wet clothing) and replace it with dry.

Give the person something warm to drink. Do not give alcoholic beverages.

ALL OTHER CASES SHOULD BE CONSIDERED MEDICAL EMERGENCIES.

PROVIDE EXTERNAL HEAT ANY WAY POSSIBLE!

A WARM BATH with the water kept between 105°F and 110°F is the most effective way of warming a victim of hypothermia. (NEVER put an UNCONSCIOUS VICTIM in a bathtub.)

If it is not possible to give the person a warm bath, use an ALTERNATIVE METHOD:

Wrap warm moist towels (or other fabric) around the victim's head, neck, sides, groin. As the packs cool, rewarm them by adding warm water (about 105°F). (Check the temperature of the water with your elbow or the inside of your arm. Water should be warm but not hot).

Or, if you are at an remote outdoor location and cannot use any of the other methods:

Make a "human sandwich" by placing the unclothed victim in a sleeping bag (or between blankets) with two other undressed persons to provide body-to-body heat transfer. THIS WILL SAVE LIVES. Additional sleeping bags or blankets can be placed over and under the sleeping bag.

Do NOT wrap a hypothermia victim in a blanket without an auxiliary source of heat unless it is to protect against any further heat loss before treatment can begin.

Do NOT leave the person in a sleeping bag without extra heat in order to go for help unless there is no other alternative.

Continue treatment:

Give warm liquids and nourishing food if the person is conscious.

Check the person for symptoms of frostbite and if necessary, give treatment for frostbite.

Handle the patient gently and do not allow him to walk. Exertion can circulate cold stagnant blood from extremities to the central body and cause "after-drop", in which the patient's core temperature may drop below the level which will sustain life. (Alcohol also contributes to after-drop.)

c. Medical Care for Hypothermia

HYPOTHERMIA IS A SEVERE EMERGENCY. GET MEDICAL TREATMENT AS SOON AS POSSIBLE. Even persons with mild hypothermia should see a doctor.

d. Prevention of Hypothermia

Never go into the field in cold weather without wearing adequate clothing and taking a complete change of warm clothes and one or two pairs of extra socks (in plastic bags).

Wear or carry a windproof, water-resistant outer jacket. In rain or snow, wear adequate rain gear.

Stay dry. If your clothing becomes wet from perspiration, rain, snow or immersion in water, change it as soon as possible.

If you start to shiver in a prolonged or violent way, seek shelter at once. Shivering produces heat but uses up energy. Shivering violently may be an early sign of hypothermia.

Avoid accidental immersion in water. Practice boat safety and learn cold water survival techniques if your field work involves activities where you could fall into the water.

If you do fall into water (and are not very close to shore), remain quiet with your head out of water or climb onto the boat or any other object that will support you and keep you up out of the water.

C. Safety/First Aid Equipment

In view of the causes, results, and appropriate treatment of cold weather injuries discussed above, the following items should be included as safety equipment during cold weather operations.

Extra clothing for all personnel
Blankets/sleeping bag
High energy food, and drinking water supply
Toboggan
Tow ropes

In extreme cold conditions, the following safety items should also be included:

Electric blanket
Portable emergency generator (with fuel, oil, and cords)
Space heater and fuel

III. GENERAL WINTER OPERATIONS

Cold weather conditions can severely affect winter operations. The Site Manager and Site Safety Officer must plan work schedules and project tasks accordingly.

A. Preliminary Assessment

If you will be working outdoors in cold weather, assess the local weather conditions through the news media (radio, television, newspapers) in order to know the amount of preparation you will need to make. Carefully consider such questions as:

What are the typical wind and weather conditions for the period in which you will be sampling?

Are the areas in which you will work sheltered or open to the wind?

Is there a place nearby for periodic warming breaks? Can you obtain or heat warm food and beverages there? Is there a source of drinking water?

Are there ways to minimize the length of time that crew members will have to work outdoors in the cold?

If you use a vehicle for a warming area or will use a heater in a closed room, how can you insure there is adequate ventilation to prevent carbon monoxide poisoning?

B. Scheduling

Try to schedule work in the least severe weather.

Plan to rotate crew members to keep cold exposures short.

Allow sufficient time for frequent warming breaks.

Remember that workers in heavy clothing may need more time to complete tasks and may become fatigued more easily.

Be aware that you may have to discontinue operations if winds increase or the temperature drops.

Remember that winter days are short. Scheduling should allow time for taking care of equipment and supplies before nightfall when it is more difficult to gauge terrain and when temperatures are likely to drop.

C. Site Access

Snow and ice could make travel on site access roads impossible, or treacherous at best. Personnel should not be allowed to work on-site if conditions severely hamper the arrival or departure of emergency vehicles. An otherwise minor injury could

result in a major medical emergency if the route to off-site medical facilities is blocked by snow, ice, etc.

If conditions warrant, the following provisions should be made:

1. Snow removal/plowing services for site access roads should be secured.

2. A dependable four wheel drive vehicle should be immediately available on-site to transport injured to off-site medical facilities.

3. Sleeping bags, blankets, food supply, and water should be kept on-site in the event a sudden storm requires personnel to remain on-site overnight.

The HSO must decide when weather conditions make site access unsafe, and must stop work until conditions improve.

D. Equipment and Supplies

You should obtain equipment and supplies that will help prevent cold stress and that will help in the treatment of cold stress disorders.

Take a reliable ambient temperature thermometer, a wind gauge and a wind chill chart.

If the site is very windy, try to provide means of shielding workers from the wind.

If you are working at a distance from stores, carry extra food and water since hunger and dehydration contribute to cold stress. Try to take a means of providing hot food and beverages if one is not available nearby.

Provide emergency communication equipment for use between ground crews and those working in the cold, at heights, or in remote locations.

Very close attention must be paid to the effects of cold weather on field equipment. Many types of batteries can be severely affected by cold resulting in disabled radios, air monitoring equipment, sampling pumps, and vehicles. A supply of fresh batteries, sufficient number of charging units, and a set of automotive jumper cables should be maintained on-site.

The electronics in many field instruments such as PI meters, LEL meters and oxygen meters can also be adversely affected by the cold. Manufacturers literature must be consulted for operating ranges.

If at all possible, monitoring well sampling tasks should not be scheduled during cold weather. These tasks generally require the use of (relatively delicate) pumps; long, uninsulated stretches of tubing; and significant quantities of decontamination solutions. Unless considerable effort is expended to prevent pumps, hoses, decontamination solutions, and sample containers from freezing, attempting to sample monitoring wells in cold weather may be counter-productive. Portable shelters should be considered if cold weather sampling is necessary.

IV. CONCLUSIONS

Safe cold weather operations require considerable planning on the part of the Site Manager and Site Safety Officer.

Weather conditions and forecasts must be watched closely, and on-site activities and procedures modified accordingly.

On-site personnel must be made aware of the hazards of cold weather, and the symptoms and treatment of cold weather injuries.

A sufficient number of warm-up breaks must be provided to on-site personnel.

Enclosed, heated decontamination facilities may be required.

Additional time must be allotted in the morning to check out and warm-up field equipment. Additional time must also be allotted for the end of the day to drain hoses and pumps, pack and secure equipment, and plan the next day's activities based upon up-to-date weather forecasts.

SITE DESCRIPTION

Site: Mechanicville Site ID: ME

Street: Corner of North Central Avenue and Ferris Lane.

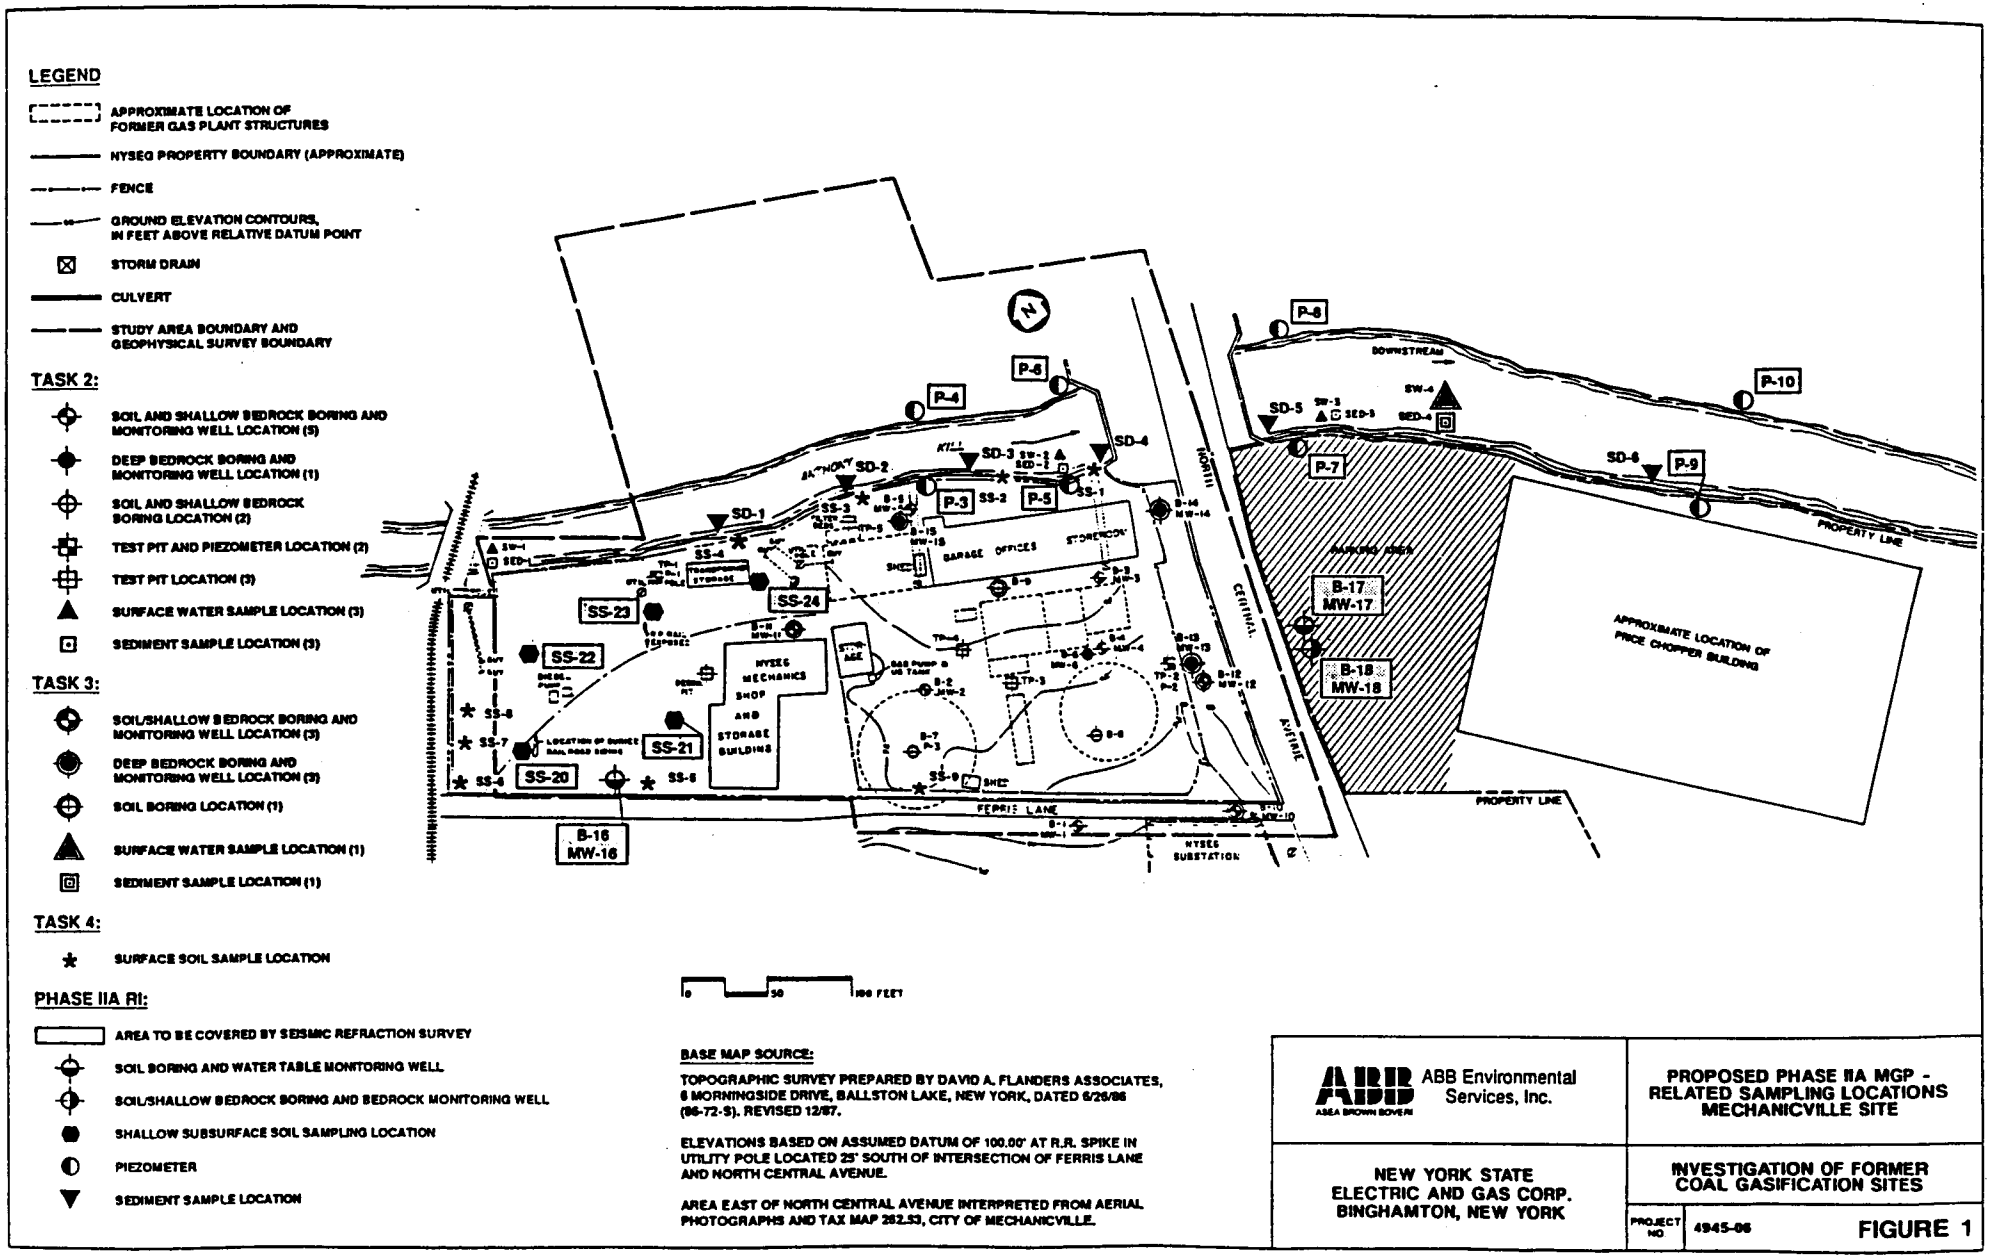
City: Mechanicville County: Saratoga State: New York

Site Owners: New York State Electric and Gas Corp. (NYSEG)

Phone No: (518) 664-7371

Address: Park Plaza, Mechanicville, New York 12118

Purpose of Study: To expand our understanding of the nature and distribution of environmental contamination resulting from past use of the site for coal gasification and electrical equipment storage. Also, to gather hydrogeologic data to further define site hydrogeology and chemical migration pathways. This is the fifth phase of a phased investigation.



SUMMARY OF INVESTIGATION

The objective of this Phase IIA Supplemental Remedial Investigation is to gain a greater understanding of the site which will address comments and recommendations offered by the New York State Department of Environmental Conservation (NYSDEC). The work plan specifically focuses on assessing site soils for PCB contamination, further investigation west of the site to assess soil and groundwater quality, and installation of soil borings, monitoring wells, piezometers and seepage

meters downgradient of the site to assess off-site migration of site-related contaminants. The investigation includes the following activities:

- geophysical survey of the area directly east of the site to delineate the bedrock surface and locate the bedrock trough;
- installation of one upgradient shallow monitoring well;
- installation of one shallow and one bedrock monitoring well pair downgradient of the site;
- possible installation of one to two additional monitoring wells downgradient if visible evidence of contamination is found in the first pair;
- collection of subsurface boring soil samples inside and outside the boundary of the site;
- possible installation of additional soil borings if initial downgradient borings show visible evidence of soil contamination;
- shallow subsurface soil sampling within the site boundary;
- installation of piezometers along the Anthony Kill adjacent to and downgradient of the site;
- sediment sampling and UV/IR screening of samples;
- installation of seepage meters along the banks of the Anthony Kill adjacent to and downstream of the site;
- measurement of water levels in wells, piezometers, and surface water; and
- collection of groundwater and seep water samples for analyses.

The Phase IIA Supplemental Remedial Investigation is summarized below and sampling locations are shown in Figures 1 and 2. Detailed sampling procedures and

quality assurance objectives are for the activities to be undertaken during this field investigation are contained in the NYSEG contract QAPP (Jordan, 1986). A summary of these activities and any changes or additions are noted below.

weight impact (sledge hammer) or small buried charges of explosives. If explosives are used, shotholes are usually prepared with a driven rod (not excavated) so as to insure good ground coupling. Th explosives are tightly tamped and the depths and amount of explosives used are noted.

Seismograms are obtained using a portable signal enhancement seismograph which records the wave arrivals from the energy source along the seismic spread, acquiring separate data for each geophone position. Timing lines are provided across the entire recording allowing direct reading of wave arrivals to an accuracy of one millisecond. The signal enhancement capability refers to the ability of the instrument to record the seismic waves from several impacts (or explosions), add them electronically,a nd retain this data in its internal digital memory for later processing and interpretation. The enhanced signal improves data quality and greatly facilitates interpretation.

Generally, several recordings are obtained along each seismic spread; seismograms are generated with the energy source at each end, and others may be obtained by energy generation in the middle, and at other positions along an individual seismic spread as necessary.

Continuous profiling is accomplished by having an end shotpoint of one seismic spread coincident with an end or intermediate position shot point of the succeeding spread. The length of each spread is determined by the required depth of penetration. Seismic spreads of varying lengths can be used in a study; the deeper the required penetration, the longer the spread must be.

Interpretation

The data are interpreted by first accurately measuring the individual transit times at each geophone position, then constructing a graph of these times versus their distance from the energy source. The geophysicist then determines by inspection of the time-distance graphs the number of subsurface seismic layers present. Straight line segments of best fit are drawn onto the graph, each layer being represented by a line of different slope. The inverse of the slope of each line is the (apparent) velocity value for each layer. The distance from the origin (or energy source) of the "crossover point" between two layers is proportional to the thickness of the overlying layer.

The identification of various materials can be made with a knowledge of seismic velocity values based on other engineering studies, and on correlations with various test borings taken near seismic lines. The results of seismic refractions will be used to place the downgradient borings/monitoring wells in the bedrock trough and/or the interpreted groundwater migration pathway (if different then any bedrock trough identified) and will be included in the Phase IIA Supplemental RI Report.

2.0 SUBSURFACE EXPLORATIONS

The Phase IIA Supplemental RI drilling program will consist of a minimum of three borings with an additional five optional borings depending on if visible evidence of contamination is found in the initial downgradient borings. Boring B-16 will be drilled to approximately 10 feet bgs (to bedrock), B-17 and B-18 will be advanced to bedrock (approximately 30 feet bgs). Boring B-18 will be advanced an additional 15 feet into bedrock. Monitoring wells will be installed in these borings and two of the optional borings downgradient of the site (if borings are completed). Split-spoon samples will be screened for coal tar residues by visual observation and odor, and for volatile compounds by use of a portable HNU or Photovac TIP photoionization detector. All borings not completed as monitoring wells will be grouted to the surface.

All borings completed to the bedrock surface (except B-18) will be drilled by using 4.25-inch inner diameter (ID) hollow-stem augers with continuous 3-inch outer diameter (OD) split-spoon sampling. B-18 will not be sampled since it is adjacent to B-17. Boring B-18 will be advanced 15 feet into bedrock by NX-coring. Core samples will be taken continuously. For boring B-18, the double-cased drilling technique will be used since it is anticipated that a confining silty-sand layer potentially overlain by coal tar will be encountered 1 to 2 feet above the bedrock surface as observed in borings B-12 and B-13 completed during Task 3. Potable water will be used for drilling and will be analyzed for volatile organic analytes (VOAs), semivolatile organic analytes (SVOAs), inorganics and total cyanide. Drilling methods are described in the NYSEG contract QAPP (Jordan, 1986c).

A minimum of one soil sample will be collected from each boring, preferably from the screened interval, and submitted to the NYSEG laboratory for analyses. These soil samples will be analyzed for VOAs, SVOAs, reactive cyanide and reactive sulfide, and inorganics. Analyses are summarized in Table 1, and documentation and

Notes:

1. A minimum of one sample from each boring sampled will be submitted for laboratory analysis from the contaminated area or the well screen depth or both if different.
2. Analytes include Fe, Zn, Al, Cd, Sb, Co, Cu, Mn, Ni, Pb, Cr, and total amenable, and ferro-ferric cyanide. ASP Superfund CLP analytical methods will be used.
3. Filtered/unfiltered applicable to groundwater samples for metals.
4. ASP denotes NYSDEC Analytical Services Protocol, December 1991 revision.
5. All data validation performed according to USEPA protocol. 10% of samples will be subject to full validation, 90% to blank validation.
6. Samples from MW-22 and MW-23 behind Price Chopper will only be collected if these wells are deemed necessary and installed. Therefore, they are not included in this table.
7. Five seep meter/surface water samples will be collected. Surface water samples will be taken inplace of seepage meter samples where seepage meters prove ineffective.
8. All existing monitoring wells are to utilize NYSDEC ASP 91-1 for VOAs. All proposed wells (i.e., MW-16, MW-17, MW-18, MW-22 and MW-23) are to utilize NYSDEC ASP 91-4.
9. All PCB analyses will be performed using USEPA Method 8080 by NYSEG laboratories or NYSDOH ELAP-CLP certified laboratories.

data quality levels are also indicated in Table 1. All samples will be submitted to, and analyzed by a laboratory certified by NYSDOH for ELAP-CLP category. Information from split-spoon samples will be logged according to procedures outlined in the NYSEG contract QAPP (Jordan, 1986).

Maintaining proper records is an important aspect of soil sample taking. At the time samples are obtained, the following must be recorded by the sampler:

- sample site location (e.g., grid coordinates baseline station and offset, or the location plotted on a map or aerial photograph)
- sample type and depth
- soil description
- date and time of sampling
- project and sample designations
- sampler identification
- analyses requested

For laboratory samples, the sampler must initiate chain-of-custody (COC) procedures and describe the sample site in adequate detail to allow the analytical results to be properly interpreted and, if necessary, to allow collection of additional samples form the same sample location. Jordan uses standardized record forms to expedite this process and ensure uniformity of records. The sampling protocols and recordkeeping requirements for the types of samples described in the following pages vary according to the sampling techniques. Additional requirements may also be established on a site-specific basis.

The entire soil sampling process is designed and conducted in a manner that provides properly documented samples suitable for the intended analyses.

3.0 SHALLOW SUBSURFACE EXPLORATION

A total of six (five plus one duplicate) shallow subsurface soil samples will be collected west of the site (SS-20 through SS-24) as shown in Figure 1. The rationale for these samples is to evaluate whether chemicals from reported disposal of spent oxide wastes and wood chips are present on this area of the NYSEG property and to assess their impact. Samples will be collected with a stainless steel trowel or spoon or a spade from 0 to 12 inches below the pavement (or bgs if unpaved) and composited. Samples will be submitted to NYSEG for laboratory analysis of reactive cyanide and reactive sulfide.

A total of 27 shallow subsurface samples (SS-25 through SS-48 plus three duplicates) will be collected from the six electrical equipment storage areas shown on Figure 2. Each storage area will be subdivided into four equal-sized areas. Four samples will be collected from each sub-area from the 3- to 12-inch depth interval and composited, resulting in four composite samples for PCB analysis from each storage area. The sample grid spacing is illustrated in Table 2. Additional samples will be collected at locations other than the six storage areas if visible evidence of oil stains is encountered. Samples will be collected with a stainless steel trowel or spoon or a spade. Samples will be submitted to the NYSEG laboratory for PCB analysis (NYSDEC ASP 91-3).

Information from shallow subsurface soil samples will be logged according to procedures outlined in the NYSEG contract QAPP (Jordan, 1986). Soil sample recordkeeping described in the previous section also applies here. Figure 3 is an example surface soil sampling record.

4.0 MONITORING WELL/PIEZOMETER INSTALLATION

This program will further characterize the distribution of the groundwater chemical plume downgradient of the site (MW-17, MW-18, and possibly MW-21 and MW-22) and to provide additional upgradient groundwater quality information (MW-16). The monitoring wells will be constructed of 2-inch OD stainless steel construction. The final location of the downgradient wells will be based on a review of current on-site groundwater level measurements, the seismic refraction survey, and property access. These wells will also serve to better define the groundwater flow direction downgradient of the site. The monitoring well pair, MW-17/MW-18, will also be

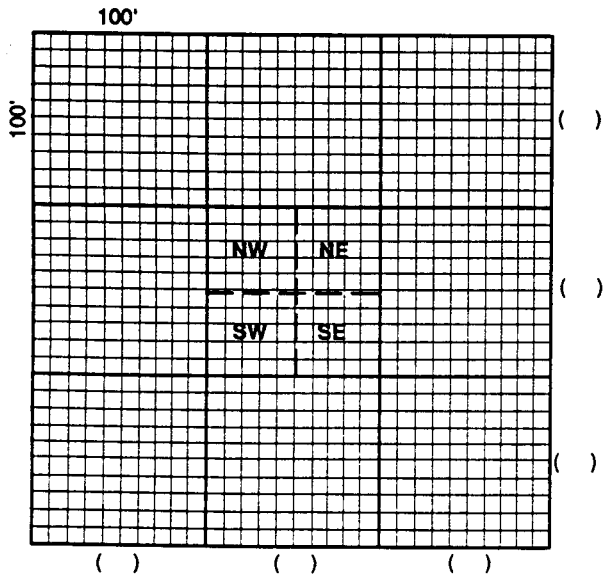
useful in determining the presence of vertical gradients between the bedrock and the overburden. Proposed locations of the wells are shown in Figure 1. Permission from private property owners will be necessary to install all off-site wells and piezometers as they are currently located.

In addition to the monitoring well installations, eight 1-inch PVC piezometers (P-3 through P-10) will be installed with a hand auger or hand driven into the ground to a depth of no greater than five feet along both banks of the Anthony Kill as shown in Figure 1. Well point piezometers will serve as groundwater level measurement points to be incorporated into the shallow groundwater flow contour maps for the Mechanicville site and, in conjunction with measured surface water elevations, used to indicate discharging or recharging conditions. This will enable better evaluation of shallow groundwater flow directions, gradients, and velocities from the site to these areas. These piezometers, in conjunction with water level data from the overburden/bedrock monitoring well pair MW-15/MW-5, will also indicate determine the presence of vertical gradients along the Anthony Kill, adjacent to the site.



In general, monitoring wells and piezometers will be installed according to NYSEG procedures for monitoring wells and piezometers at former coal gasification plant sites (NYSEG, 1989). All substitutions, alterations and/or deviations from these procedures will require NYSDEC approval in advance. Based on previous site information, it is anticipated that well screens will be stainless steel, 10-slot (0.010 inch screen), with silica sand filter pack. The sand will be No. 0 Morie sand, with the uppermost six inches of the sand pack being No. 00 Morie sand, a finer material. A monitoring well installation report, including individual well construction details, will be prepared. In the shallow wells, the well screen and sand pack will be positioned to monitor the upper 10 feet of groundwater. The deep well will monitor the zone approximately 20 to 30 feet below the ground surface. Monitoring well installation details for the shallow and deep wells are shown in Figures 3 and 4, respectively. The borehole above (and below as necessary, including any sediment trap) the screened zone is sealed with dry bentonite pellets to preclude preferential vertical groundwater flow along the well annulus. The space between the bentonite seal and the surface seal will be filled with cement/bentonite grout (94 lbs cement per 3 to 5 lbs bentonite) regardless of whether or not contamination is encountered in the fill soil. Any deviations from the installation details specified in this QAPP must be approved by both NYSEG and NYSDEC.

FIGURE 3
SURFACE SOIL SAMPLING RECORD
PROGRAM QUALITY ASSURANCE PROJECT PLAN

The preferred well development technique will be the surge (or surge-block) technique. During this development technique, in-situ well water is forced out, and pulled into, the well screen. This technique will draw silt-sized material entrained within the sand filter pack during well installation into the well. The accumulated silt within the well can then be periodically removed by bailing or pumping the well. The advantage of this development technique is that it will generate less water than continuous pumping development or air-lift development and it effectively removes fine-grained sediments surrounding the well screen. If this technique is not effective, the pumping or air-lift methods will be used as alternates. The development water generated will be pumped into closed-top 55-gallon drums and transported to the site. The development water will be allowed to infiltrate into an on-site groundwater recharge pit. The area as a recharge pit will be covered with clean soil when it is no longer needed in accordance with NYSDEC TAGM "Disposal of Contaminated Groundwater Generated During Remedial Investigations".

As part of this task, rising-head permeability tests will be conducted on all new wells to determine the horizontal hydraulic conductivities of the geologic strata being monitored. Rising-head tests will be performed by temporarily depressing the water level in the wells, using compressed air or a slug, and recording time and water level recovery using an in-situ Hermit data logger and pressure transducer or water level indicator.

5.0 WATER LEVEL MEASUREMENTS

Water level measurements will be taken at all monitoring wells and piezometers associated with the site with an electronic water level meter using the top of the riser pipe as the reference datum. Elevations of top of risers will be surveyed subsequent to installation. Surface water elevations will be established in reference to adjacent piezometers. Water level measurement procedures are outlined in the NYSEG contract QAPP (Jordan, 1986). Duplicate keys for all wells will be provided to NYSDEC at the completion of the field investigation.

6.0 GROUNDWATER SAMPLING AND ANALYSIS

The well installation program will be followed by one round of groundwater sampling of all wells. Dedicated stainless steel bailers will be installed in all existing site monitoring wells, and monitoring wells will be sampled according to the procedures

outlined in the NYSEG contract QAPP (Jordan, 1986), with the exception of the volume of water to be purged to reach turbidity goals.

Prior to obtaining a groundwater sample from a well, at least four to ten bore volumes of water must be pumped or bailed from a well of high yielding formation. Conversely, if the yield is low, the well may be purged of all its water, then sampling commenced as soon as the well recovers. The bore is the hole in which the stainless steel pipe stands, and volume is calculated from $(pi)(d^2)(h)/4$, where pi = 3.14,d = diameter of borehole, and h = height of water column from the bottom of the well to the surface of water in the well. Four to ten volumes are required to minimize turbidity and to obtain a representative sample; the turbidity goal is 50 NTUs or less. This holds for high yielding wells. For wells that can be totally evacuated by the four to ten (or less) bore volumes one total evacuation of the well will be sufficient.

Wells should be pumped or bailed dry. If this cannot be accomplished, the water level in the well should be monitored while pumping or bailing until the level has "stabilized". When this occurs, most if not all of the water being removed is coming from the aquifer. Temperature, specific conductance, and pH of the water should be monitored; when these factors "stabilize", it is probable that little or no water is coming from casing storage.

Purge water from monitoring will be drummed and transported to the site. Here it will be passed through granular activated carbon canisters and discharged in an on-site groundwater recharge pit.

In developing and extracting samples wells, the Division will require that dedicated tubes, hoses (rubber or tygon is unacceptable), and bailers, including line and other sampling equipment, must be provided for each well. Groundwater elevation equipment and other non-dedicated equipment will be decontaminated. Decontamination procedures are described in Section 9.0.

Groundwater sample analyses and data quality objectives are summarized in Table 1; all samples from monitoring rounds will be submitted to NYSEG laboratories, and may be subcontracted to the following New York State certified laboratories: Galson Laboratories in Syracuse, New York; Friend Laboratories in Waverly, Pennsylvania; and UPSTATE in Syracuse, New York. Any laboratory used to NYSEG must be certified by NYSDOH for ELAP-CLP category.

Groundwater samples will be analyzed in the field for turbidity temperature, pH, and conductivity and sent to a laboratory for analysis of volatile organics (NYSDEC ASP 91-1), semivolatile organics (NYSDEC ASP 91-2), inorganics, and turbidity. Table 1 details the sample analysis parameters. Groundwater sample collected-data will be recorded on a data record such as Figure 4.

7.0 SEDIMENT SAMPLING/SCREENING

The sediment sampling and screening will be conducted on samples collected from the southern bank of the Anthony Kill, adjacent to and downstream of the site. Sample locations will be determined in the field through visual observation of the stream bank conditions (i.e., stained sediments, flowing seeps, stressed vegetation) and evaluation of the hydrogeology of the site incorporating the additional wells and piezometers. A minimum of seven sediment samples (SD-1 through SD-6 plus one duplicate) will be collected for laboratory analysis of volatile organics (NYSDEC ASP 91-1), semivolatile organics (NYSDEC ASP 91-2), inorganics, total organic carbon, reactive cyanide (USEPA Method 9010) and reactive sulfide (USEPA Method 9030). Approximate locations are shown in Figure 1. Sediment sampling and field screening will be used to locate seepage meter investigation areas by identifying areas of the stream bank containing site-related chemicals. The sediment sampling rationale is contained in Table 8-2.

Sediment samples will be collected using stainless steel spoons or trowels, teflon or glass coring tubes in shallow surface water, and gravity cores in deeper waters as outlined in the NYSEG contract QAPP (Jordan, 1986). Samples will be collected at two to three depth intervals at each location (where sediment depth is sufficient) to profile potential discharge zones. If no sediment deposits are available, sampling will be collected from the submersed interface of the bedrock and the streambank overburden. Sediment sample data will be recorded on data sheets such as Figure 5.

All sediment samples will be examined in the field for visual signs of contamination and screened using a PID meter. Sediment samples collected will also be screened for the presence of PAH and TPH using the UV fluorescence and IR spectroscopy screening methods.

The UV fluorescence screening procedure involves the extraction of a soil sample in an organic solvent and comparison of the fluorescence of the extract to the

NOTES/SKETCH

FIGURE 5
SURFACE WATER/SEDIMENT SAMPLE DATA RECORD
PROGRAM QUALITY ASSURANCE PROJECT PLAN

fluorescence of a known standard which can be either a specific PAH or a mixture of PAH. Since many other extractable organics, including naturally occurring compounds, also fluoresce; this screening can produce false positive results. However, the absence of fluorescent matter in a sample generally confirms the absence of medium to high levels of manufactured gas plant contaminants. The degree to which false positives are encountered is related to subsequent site uses, presence of natural lignite in soils, and vegetation.

The IR screening procedure is an adaptation of the laboratory procedure for measuring TPH. The adaptations are primarily related to sample volumes and extraction protocols which result in reduced analytical times. The results of TPH screening are more variable than laboratory results but provide useful data, especially where elevated levels (i.e., greater than 250 parts per million) are encountered.

These screening results will be used to select which sediment samples will be submitted for laboratory analysis.

8.0 SEEPAGE METER INSTALLATION/SAMPLING

The purpose of the seepage meter investigation is to empirically measure seepage rates of site-derived groundwater into the Anthony Kill and determine the chemical quality of seep water both adjacent to and downgradient of the site. Discharge rates determined through the seepage meters will be compared against Darcy's Law calculated estimates.

Seepage meters will be installed at approximately three locations adjacent to and two locations downstream of the site. The exact location and number of seepage meters actually installed will be determined by visual observation of the stream bank for stained sediments or flowing seeps and field screening of sediment samples for TPHs and PAHs.

Design specifications and interpretative methods for the data collected from the seepage meters are contained in Appendix A of this QAPP. A brief description of seepage meter construction follows.

Seepage meters are constructed of 55-gallon, steel drums, cut in half along the horizontal plane. A 3/8-inch ID section of threaded pipe is fitted through the end

of the drum with rubber washers and two nuts on either side of the drum end. The nuts are tightened to create a water-tight seal around the pipe, and each drum is checked for leaks.

A rubber hose is then fitted to the pipe, the other end of which is connected to a plastic bladder bag obtained from a medical supplier. The bag is equipped with a one-way valve on the drum end of the bag, and a flip valve for emptying tat the other end of the bag. The drum and bag are then fully submersed in water and pressed firmly into the stream bottom. Because the drums have neutral buoyancy, they must be anchored. To ensure no disturbance or movement, a wooden stake is driven adjacent to each drum, and a 3-inch-thick cinder block is slipped over the stake, to rest on top of and secure the drum. The bag is then submersed under water with a sinker. This completes the seepage meter installation; each stake is marked to identify the meter.

Flow into the meter through the stream bed is measured by closing the flip valve on the bag and allowing the bag to fill for several hours or days. The volume of seepage water collected in the bag over a measured time interval provides a groundwater seepage rate into the Anthony Kill for the area covered by the seepage meter. Seepage water will also collected and submitted for laboratory chemical analyses for volatile organics (NYSDEC ASP 91-4), semivolatile organics (NYSDEC ASP 91-2), and inorganics (see Table 1).

9.0 DECONTAMINATION PROCEDURES

Equipment to be decontaminated during the project may include (1) drill rig and drilling equipment; (2) truck or trailer; (3) tools; (4) monitoring equipment; and (5) sample containers. The drill rig and drilling equipment will be steam cleaned prior to arrival at the Mechanicville site, followed by on-site steam cleaning with water upon arrival, between boring/well sites, and after all work is complete at the site. The truck and trailer and assorted tools (i.e., pipe wrenches for breaking drill rods) will also be steam cleaned prior to leaving the site. Prior to use on-site, all casings, augers, recirculation and water tanks, etc., will be devoid, both inside and out, of any asphaltic, bituminous, or other encrusting or coating materials, grease, grout, soil, etc.

To the extent practical, all steam cleaning shall be performed in an area that is on-site. All decontamination will be performed by personnel in protective gear appropriate for the level of contamination, as determined by the Health and Safety Officer. All decontamination fluids will be disposed of via on-site percolation.

The split-spoon sampler(s) used during the subsurface soil sampling procedures will be decontaminated between samples and after final use, using a Liquinox/water rinse followed by a distilled water rinse. Loose material will be removed using a brush, prior to the split-spoon washing procedure.

Heavy coal tar material that cannot be removed from sampling equipment (i.e., hand/power augers for shallow subsurface samplers, may be cleaned with hexane, then a Liquinox/water rinse, followed by a distilled water rinse. Large equipment coated with heavy coal tar material (i.e., drilling augers) will be steam-cleaned.

Soil cuttings from the soil borings and monitoring well installation will be placed into 55-gallon drums, labeled, covered, and stored within the site property boundaries pending subsequent testing for hazardous waste characteristics and disposal by NYSEG in accordance with NYSEG TAGM "Disposal of Drill Cuttings". Wash water generated by the double-cased drilling method will be transported to the site, and after settling of solids, the supernate will be allowed to infiltrate into an on-site groundwater recharge pit. The area as a recharge pit will be covered with clean soil when it is no longer needed in accordance with NYSEC TAGM "Disposal of Contaminated Groundwater Generated During Remedial Investigations".

10.0 DATA QUALITY OBJECTIVES (DQOS)

DQOs are based on the premise that different data uses require different quality data. Data quality refers to a degree of certainty with respect to precision, accuracy, reproducibility, completeness, and comparability. DQOs are qualitative and quantitative statements specifying the quality of data required to support RI/FS activities, such as including site screening, site characterization, and risk assessment, and to support engineering alterative evaluation and selection decisions.

Two levels of data quality, USEPA Level III and Level IV (USEPA, 1988; USEPA, 1989), are needed for the soil and groundwater samples submitted for analyses. These data quality objective levels are in accordance with the NYSDEC ASP. The

specific DQO levels for each individual sample are shown in Table 1. All samples undergoing ASP analyses will have Level IV data quality; all other samples will have Level III data quality. Level III allows the use of non-contract laboratory program (CLP) methods, but requires that the analytical methods be accepted by USEPA; the data is typically used for risk assessment, site characterization, alternative evaluation, and engineering design. This level of data quality is considered sufficient for the majority of the soil and water samples collected from this site; these samples are being used primarily to further characterize and define the limits of coal gasification process-related contaminants, to select and implement a remedial action.

Level IV requires CLP methods and CLP data packages; the data is used for risk assessment, alternative evaluation and engineering design for sites that are near heavily populated areas, or are likely to undergo litigation. Samples analyzed and documented to this level of data quality are being used primarily to confirm the presence of contaminants in sensitive areas (i.e., upgradient and downgradient, off-site monitoring wells) with a high degree of precision and accuracy. For Level IV validation, 10% of the samples will undergo full validation and 90% will undergo blank validation only.

The analytical laboratory (i.e., NYSEG or NYSEG subcontractor) must analyze matrix spikes (MS) and matrix spike duplicates (MSD) sufficient for determining analytical precision and accuracy for specified methods and requested levels of data quality. Frequency of MS and MSD analyses will be five percent for each matrix. Field, sampler, and trip blanks and field duplicates will be collected as described in the NYSEG contract QAPP (Jordan, 1986).

ABB Environmental will provide third-party validation and review of analytical results, in accordance with NYSDEC and USEPA protocol. The validation of analytical measurements consists of a systematic process of reviewing data to provide assurance that the data are adequate for their intended use.

Performance verification will be done for all data. During performance verification, the Chain-of-Custody and Analytical Request Forms (ARFs) are reviewed for completeness and accuracy. Method blank corrections will also be made to the data based on field, sampler, trip, and laboratory blank results.

In addition to the activities associated with Level III data validation, Level IV data validation requires more thorough quality control (QC) review of analytical methods

and laboratory Quality Assurance/Quality Control (QA/QC) documentation. Full validation Level IV will be performed for 10% sample and includes reviewing measurement system calibration and calibration verification, quality control activities, field sample data records and chain-of-custody, and intermediate calculations, as well as certifying the process.

See Table 1 for Sample Analysis Plan.

SAMPLE IDENTIFICATION

The standard method for sample identification used by ABB-ES for NYSEG former coal gasification plant sites includes the following codes:

Type of Sample	Code
Monitoring Well	MW
Groundwater Seep	GS
Surface Water	SW
Borehole	B
Test Pit	TP
Sediment	SD
Air	A
Duplicate	DUP
Trip Blank	TB
Filtration Blank	FB
Sampler Blank	SB
Tar Well	TW

The digits following the sample type code denote the number of the sample round (if more than one set of samples will be collected) and the number assigned to the sample point. For example, the groundwater sample collected from monitoring well Number 1 on the first sampling round would be MW-101 and the sample collected from that well on the second round would be MW-201. When more than one sample will be collected at the same point, as with boreholes, sample numbers are also assigned. The first sample from Boring 1 would be B-1(S1), the second sample B-1(S2), and so on. Sampling round numbers are not needed for boring samples because they are collected only once.

For this project, ABB will also use a sample identification code developed by NYSEG for direct use with NYSEG's computerized data recording system. Each sample will be assigned a thirteen-digit alpha-numeric code comprised of the following elements:

Element	Number of Digits
Site	2
Source of sample	1
Relative location (x)	1
Location of sample	2

Year of well installation (applies to groundwater samples only)	2
Sample point	2
Slash	1
Sample number	1
Round number	1
	13

The specific codes to be used in this investigation for each element are presented in the attached table. This table contains only a small portion of the coding system developed by NYSEG.

Abstract

Basic principles of physical hydrogeology and the nature of the hydrologic interactions between groundwater and surface water can be convincingly demonstrated in the field using two inexpensive and easily-constructed devices known as the miniature piezometer and the seepage meter. These instruments have been successfully used during a hydrogeology field course at the University of Waterloo and have been adopted as a routine teaching aid. Seepage meters and miniature piezometers are inserted in the sediment of shallow areas in lakes, estuaries, or streams. In a matter of a few hours, the devices can be installed, monitored, and removed. Information on the direction and rate of groundwater flow can be obtained. Hydraulic conductivity can be measured using several types of tests. Samples of the groundwater can be collected and, with field measurements of parameters such as specific conductance, dissolved oxygen, pH, and chloride, comparisons between groundwater and surface water quality can be made. Student investigations can include the identification of groundwater inflow or outflow areas in lakes, streams, or estuaries, measurement of the spatial and temporal variations in seepage flux through bottom sediments, and identification of zones of subsurface pollutant migration into surface waters. A day of equipment preparation and a preliminary site visit are prerequisites to the student field activities. Materials for a seepage meter and a miniature piezometer can be acquired for less than 25 dollars.

Key Words: education, hydrogeology, groundwater, limnology, hydrology, water quality, contaminant, seepage, field exercise, lake, stream, estuary.

Introduction

This paper describes the use of two simple inexpensive devices that enable students to measure the flow of groundwater and to demonstrate for themselves some of the basic principles of hydrogeology. A half-day field trip to a shallow body of surface water, preferably with a sandy bottom, makes it possible for students to acquire data that can serve as an impressive indication of the dynamic nature of groundwater flow in a natural setting. The methods are rapid and direct and provide information that cannot otherwise be obtained even if expensive drilling equipment is available. The exercise involves the use of seepage meters to measure groundwater flow rates and the use of manually-installed miniature piezometers to measure hydraulic head (groundwater potential) and hydraulic conductivity. These methods have been used during field experiments in a groundwater hydrology course at the University of Waterloo and as a means of investigating groundwater-flow conditions in lake- and streambeds. The devices are also being used in current research projects, including thesis studies by undergraduate and graduate students.

The basic elements of groundwater flow are related through the Darcy equation,

$$Q = A \frac{dh}{dl} K.$$

Q is the flux of groundwater (volume/unit time), A is the area through which flow occurs, dh/dl is the hydraulic gradient (the change in hydraulic head over a distance along the line of flow (unitless)) and K is the hydraulic conductivity of the material (usually expressed as cm/s). Hydraulic head is a measure of the energy per unit weight of the groundwater. Textbooks on hydrogeology such as Todd (1959), Davis and De Weist (1966) and Domenico (1972) present more detailed discussions of the Darcy equation and its significance in groundwater studies.

Figure 1 shows schematic illustrations of groundwater flow near lakes, in lake bottoms, and in stream bottoms. The flow systems are represented by isopotential lines (contour lines of hydraulic head) and arrows showing the direction of groundwater flow. In lake bottoms and streambeds groundwater flow is upward, downward, or horizontal but is rarely non-existent. The direction and rate of flow is dependant on the physiography, texture and stratigraphy of the subsurface materials. Locally, the flow in streambeds and lake bottoms can vary dramatically, thus providing a variety of observational conditions within a single study area.

The two devices described below provide information on the flow net and on the flux and velocity of water moving along the flow lines at and near the interface. The seepage meter and the minipiezometer also provide a means of sampling the water that is either leaving or entering the groundwater zone beneath the lake or stream. This can often serve to demonstrate the influence

of groundwater on surface-water quality. In some cases it is possible to demonstrate that pollutants are fed to lakes or streams by groundwater seepage.

Miniature Piezometers

Piezometers are used to measure the hydraulic head in geologic materials that are saturated under positive pressure. They consist of pipes with slotted tips or well points on the end. Piezometers are normally installed in boreholes drilled by power auger, wash-boring, rotary drill or cable-tool equipment. Piezometers installed at depths between several meters and many tens of meters below ground surface have been used routinely by hydrogeologists and soil engineers for several decades. The miniature piezometer (mini-piezometer) is a similar device but is smaller in size and is installed manually.

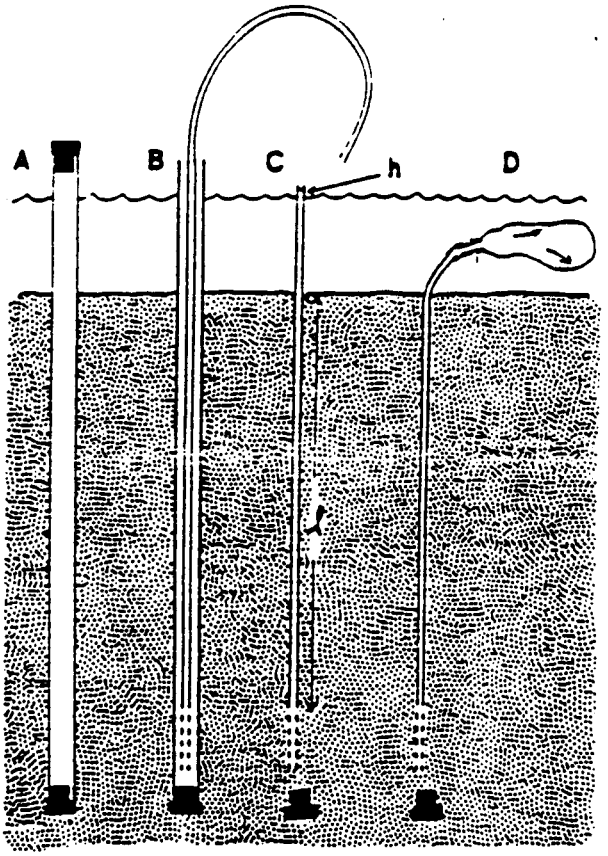

Fig. 2. — General features and method of installation of a mini-piezometer. A, casing driven into the sediment; B, plastic tube with screened tip inserted in the casing; C, plastic tube is a piezometer and indicates differential head (h) with respect to the surface water; D, plastic bag attached to the piezometer collects sediment-porewater. (See text for details)

Figure 2 shows the general features and method of installation of the mini-piezometer. The piezometer consists of a 0.31 cm ID translucent polyethylene tube (approximately $0.12/m) with a perforated tip wrapped with 0.2 mm nylon mesh netting or fiberglass cloth. The netting protects the tip from influx of sediment. The piezometer is installed using a 1.7 cm ID steel pipe that is driven into the bed by hammer or vibrator. The casing pipe is loosely fitted with 1.4 cm (5/8 inch) lag bolts at each end. When the steel pipe is driven to the desired depth the plastic tube is inserted and held in place as the pipe is pulled out. The bottom lag bolt remains in the sediment near the piezometer tip. Raised above the water level, the translucent tube shows the head differential with respect to the surface water.

Small differences in hydraulic head relative to the surface water are measured using a manometer that overcomes the difficulties of observing head differences that are slightly above or below the level of the surface water. The principle of the apparatus is indicated in figure 3A which shows how the difference in head between the piezometer and the surface water may be elevated and measured accurately. The equipment needed to measure this differential head in mini-piezometers is shown in figure 3B. The meter stick is attached to a rod and installed vertically next to the piezometer. The apparatus is prepared for use by blowing water out of the tygon tube using a rubber suction bulb. The bulb is squeezed and released slowly allowing water to rise to a static level. The

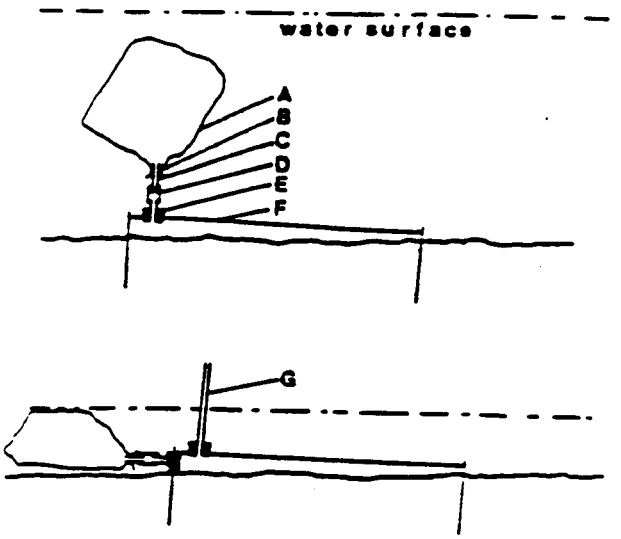

Fig. 4 — Full section view of seepage meter showing proper placement in the sediment. A, 4 liter, 0.017 mm membrane plastic Baggies Alligator bag (open end was heat sealed); B, rubber-band wrap; C, 0.64 cm inside diameter, 5 cm long, polyethylene tube; D, 0.79 cm inside diameter, 4.5 cm long, amber-latex tube; F, 15 cm x 57 cm diameter epoxy-coated cylinder (end-section of a steel drum); G, 0.64 cm inside diameter, polyethylene tube long enough to reach above the surface water.

levels in the two tubes are compared to be sure no bubbles of air are causing different heads in the two tubes. One end of the tube is then attached to the piezometer tube and the other is left in the overlying water. When the water levels in the two tubes reach static levels, the differential head, Δh, is read on the meter stick. The vertical hydraulic gradient is $\Delta h/\Delta 1$, where $\Delta 1$ is the depth of the piezometer screen below the sediment-water interface.

To measure the hydraulic conductivity of the sediment adjacent to the piezometer tip, two types of tests can be conducted, a falling head test and a constant head test. For the falling head test the piezometer tube is extended vertically above the surface-water level and then filled with water to a condition of overflow. The overflow condition is discontinued at a time that is recorded as t initial. The rate at which the water level in the tube declines is then recorded. This can be facilitated by taking stop-watch readings of times at which the water level passes marked intervals on the tube. If the hydraulic conductivity is very high, the rate of water-level fall will be very rapid. Increased accuracy can be obtained if the fall distance is lengthened by extending the tube a couple meters above the surface-water level or by feeding water to the piezometer from a larger diameter reservoir with marked intervals. A constant head test can be performed by placing a known volume of water in a plastic bag attached to the submerged tube. The hydraulic head in the submerged bag is the level of the stream or lake level. The change in volume of water in the bag over a recorded time interval is measured. Example results and calculation procedures are summarized in Table 1. The derivations of the equations used in this analysis were first presented by Hvorslev (1951) and have been summarized by Lambe and Whitman (1969). The constant head and falling head formulas are based on significantly different assumptions. Comparison of hydraulic conductivities determined by these two methods can be an interesting endeavor.

Where the hydraulic gradient is downward, groundwater from the piezometer can be collected using a suction bulb or hand-operated vacuum pump connected to a bottle. Where the gradient is upward samples can be obtained by simply letting water discharge from the piezometer tube. Where the gradient is weak or the material poorly conductive, the screened area of the piezometer tip must be increased and suction must be applied to obtain water samples.

Seepage Meters

Seepage flux between the groundwater and the overlying surface water can be measured directly by covering an area of sediment with an open-bottomed container and then measuring the time and change of water volume in a bag connected to the container (Lee 1977). Two of these devices, known as seepage meters (Fig. 4), can be made by cutting 15-cm-long, end-sections from a 0.208 m^3 (55 gallon) metal drum. Seepage meters can detect flux as low as 0.001 cm^3/m^2 s (about 0.1 mm/day) if the bag is left connected for a day or longer. In water over 20 cm deep, a single tube through the top of the seepage meter serves both as a vent for any gas released from the sediment and as a connection for the measuring bag. In shallow water an additional outlet tube on the side of the seepage meter permits the bag to be submerged as it must be to maintain the same piezometric head in the seepage meter and in the surface water.

In use, the seepage meter is pushed slowly into the sediment and tilted slightly so that the vent will function properly (Fig. 4). Unless the sediment surface is soft or irregular, it is often unnecessary to push the seepage meter more than 8 cm into the sediment to obtain an adequate seal. The stopper with tube is then twisted into cylinder hole. Where flow is upward, it is unnecessary to

Piezometer observations

Piezometer number: P1 Depth of screen below sediment: 1 m

Time	Δh,mm	Gradient Δh/1	Elapsed time, min	Volume change, cm³
1630	35	.035	—	—
1650	33	.033	—	—
1739	36	.036	—	—
1705-1723	—	—	18	+12

Hydraulic conductivity calculation: Assuming a case G screen (Hvorslev 1951),

$$K_h = \frac{q \ln [(mL/D) + (1 + (mL/D)^2]^{-.5}}{2 \pi L H_c}$$

, where

D = diameter, intake, sample (cm)
L = length, inake, sample (cm)
H_c = constant piezometric head (cm)
q = flow of water (cm³/s)
t = time (s)
m = transformation ratio, $(K_h/K_v)^{-.5}$ assumed to equal 1*
ln = 2.3 $\log_{10}$.

Therefore K_h =

$$\frac{(12 \text{ cm}^3/1080 \text{ s}) \text{ LN } [(10 \text{ cm}/.31 \text{ cm}) + (1 + (10 \text{ cm}/.31 \text{ cm})^2)^{-.5}]}{2 \pi (10 \text{ cm})(3.5 \text{ cm})}$$

$= 2.1 \times 10^{-4}$ cm/s

Seepage meter observations

Seepage meter number: SM 1
Depth of water: 0.2m
Sediment type: sand and organic matter

Time	Volume change, cm³	Elapsed time, min	Seepage flux, μm/s	Hydraulic conductivity, cm/s
1630-1648	+126	18	+.450	1.3×10^{-3}
1650-1736	+355	46	+.496	1.5×10^{-3}
1739-1752	+ 94	13	+.485	1.2×10^{-3}

Seepage flux calculation:

$$Q, \mu m/s = \frac{(\text{volume change, cm}^3)\ 0.0643}{(\text{elapsed time, min})}$$

$$= \frac{(126)\ 0.0643}{18} = 0.450\ \mu m/s$$

Hydraulic conductivity calculation:
From the Darcy equation K = v/S, where
v = Darcy velocity
S = hydraulic gradient, Δh/Δ1
K = hydraulic conductivity

Therefore $K = \frac{0.450\ \mu m/s}{0.035} = 1.3 \times 10^{-3}$ cm/s

* The effect of this assumption is small (e.g. If m = 10, $K_h = 2.7 \times 10^{-4}$ cm/s; If m = 1000, $K_h = 3.9 \times 10^{-4}$ cm/s.

before connecting it to the seepage meter.

The Darcy velocity, v, (volume per unit area per unit time) is calculated from the relation 0.0643V ÷ t = v, where V is the volume of water (cm³) entering or leaving the bag, and t is the elapsed time (min). The Darcy velocity is expressed as micrometers per second (1 μm/s = 8.64 cm/day). The factor 0.0643 converts units of time, volume, anc area covered by a seepage meter (0.255 m²) to equivalent units of velocity (μm/s) or seepage flux (cm³/m² s). The average linear interstitial velocity is equal to the Darcy velocity divided by the porosity of the sediment. For most sandy sediments, porosities are in the range of 0.3 to 0.4 (expressed as a fraction).

Student Activities

Students from the University of Waterloc used these techniques to investigate the migration of tritium-contaminatec groundwater to a small lake and stream in an experimental watershed at the Chalk River Nuclear Laboratories in eastern Ontario. To minimize the number of pieces of equipment required, this exercise was combined with stream-flow metering so the students could rotate from one activity to the other. Each student installed a piezometer and a seepage meter and measured piezometric head during seepage-measurement intervals ranging from 10 to 45 minutes. Because of the difficulty of removing deeper casings by hand, most students elected to emplace their piezometer 0.6 to 1 m into the sediment. Each student conducted a constant head test to determine the hydraulic conductivity of material near the piezometer screen, and then removed the seepage meter so that subsequent students could install the equipment themselves.

The study sites met the following selection criteria:
Wave height less than 0.3 m;
Current speed less than 0.2 m/s;
Firm sand with very little gravel and cobble; and
Water depth 0.1 to 0.6 m.

Preliminary measurements were made to be sure the students coulc install the equipment and find seepage rates high enough to complete the exercise in 2 to 3 hours. Because seepage rates are generally highest near the shore, as illustrated in figure 1B, and because shoreline areas were accessible by wading, students worked within 10 m of the shoreline.

Data collected by one student and some sample calculations are shown in Table 1. Piezometric head and seepage rate generally decreased with distance from the lakeshore but seepage rates were quite variable in the streambec. Current effects probably accounted for the variability of replicate seepage measurements in the stream. Streambed heterogeneity probably caused variability between points. No zones of downward seepage were found in either the lake or the stream.

Direct measurements of seepage flux, made by the students, showed that groundwater flowed into the lake along the northern shore. A pore-water constituent (in this case tritiated water) indicated that this seepage water is contaminated by tritium, contained in waste waters pumped into disposal pits locatec about 800 m north of the lakeshore. The use of seepage meters and mini-piezometers thus enabled the students within a very short time to draw conclusions with regard to the occurrence and source of contaminants entering the lake. Analysis of water from mini-piezometers in the nearby streambed

showed no tritium contamination despite the presence of considerable tritium in the stream itself.

The dynamic nature of the groundwater regime was demonstrated in a visibly impressive manner by filling of the measuring bag attached to the seepage meter. All but 2 of 14 piezometers functioned properly as indicated by raising and lowering the piezometer tube and watching the water level fall or rise to a static level and by the constant-head response tests. Failure to obtain responsive piezometers was due to lifting of the piezometer tube while pulling the casing out of the sediment and consequent loss of the nylon-mesh screen.

We anticipate that a similar approach could be used by others to teach general principles of hydrogeology. This exercise could be included as a part of an introductory course in hydrogeology. It could also be used in hydrology, limnology, geomorphology or sedimentology courses. It could serve as a springboard for student projects designed to determine the importance of the groundwater component to the water budget of a lake or pond, to identify contaminant migration from groundwater to surface waters, to study the effects of seepage flux on sediment chemistry, or to study the role of groundwater in fluvial erosion and deposition. Because these topics have only recently begun to receive research attention, this work offers an opportunity and a freshness which is attractive to students.

Planning the Field Exercise

Sandy shores of gravel-quarry ponds, lakes, reservoirs, and estuaries are ideal sites for these exercises, but the importance of making preliminary measurements to identify suitable sites cannot be overemphasized. Seepage rates must be high enough so that volume changes of at least 50 cm^3 can occur in the measuring bag in 1-2 hours. The sediment should not contain rocks which will bend piezometer drive-casings. Strong wave action and currents interfere with accurate measurements of seepage, although piezometers would probably not be affected adversely. Mud bottoms may not have sufficient flow to permit flux measurement in 1-2 hours.

In estuaries, where tidal fluctuations induce seepage flux through sediment, it may be helpful to consult tide tables before planning a field exercise. At low tide, the highest rates of upward seepage and the strongest upward gradients occur (Lee 1977), and it is easier to install seepage meters at this time. Estimates of net seepage flux will require measurement through an entire tidal cycle.

In streams where surface-water velocity is low and especially in sandy areas, these methods can be used successfully. In other stream environments, however, it may be difficult to find suitable demonstration sites. Downward seepage in streams may be induced where permeability or depth of gravel increases in the direction of streamflow or where the longitudinal bed profile is concave (Vaux 1968). These factors, heterogeneity and current, make data from streambeds more difficult to interpret than comparable data from quieter waters.

water flow systems around lakes (Born et al. 1974) and estuaries are poorly documented.

The usual approach for obtaining estimates of groundwater-surface water interaction is to install observation wells on land near the shore or in the water basin. The wells are then used to obtain measurements of the distribution of the hydraulic head and estimates of permeability. This is generally unsatisfactory because it is seldom feasible to estimate permeability by less than an order of magnitude and because surface-groundwater interaction is often controlled at or very near the sediment–water interface.

I thank J. K. Neel for guidance in the initial phases of this work. J. K. Neel, Q. L. Gehle, J. A. Cherry, and L. S. Clayton provided comments. Work space and equipment were provided by the staff of the Lake Sallie Fisheries Station, Minnesota Department of Conservation, and by the Department of Geology, Virginia Polytechnic Institute and State University. Part of this work appeared in my M.S. thesis (University of North Dakota).

Groundwater seeping into standing surface waters can be collected by covering an area of lakebed with a bottomless cylinder vented to a deflated plastic bag (Fig. 1). The cylinder is turned slowly (≈1 cm s^{-1}), open-end down, into the sediment until its top is about 2 cm above the sediment surface. The vent hole is elevated slightly so that any gas from the sediment may freely escape. The cylinder is marked and left for several days to allow benthic organisms to escape (although preliminary measurements can be started immediately). Then a stopper with tube is inserted into the cylinder hole.

To collect a sample, a deflated plastic bag is connected to the tube and left for a specified time or until it contains 0.5–3 liters. Where surface water seeps *into* the sediment, the plastic bag is filled with a known amount of water before it is connected to the tube. Macroscopic seepage velocity is determined as

$$v = \frac{1.075\ V}{t},$$

where V is liters of water entering (+ value) or leaving (− value) the bag, t is hours of elapsed time, and v is seepage velocity (+ is upward, − is downward) expressed as micrometers per second. The factor 1.075 converts units of volume, time, and area covered by the cylinder (0.255 m^2) to equivalent units of velocity ($\mu m\ s^{-1}$) or seepage flux ($ml\ m^{-2}\ s^{-1}$). The macroscopic seepage velocity should not be confused with the average interstitial velocity, which is equal to 100 times the seepage velocity divided by the percent porosity of the sediment.

Most problems in measuring seepage are due to improper placement of the cylinder. If the cylinder is not positioned with its hole near the highest point, gas from the sediment accumulates and reduces seepage. Measurements are also reduced if the cylinder lid presses against the lakebed. If the cylinder is pushed too rapidly into the sediment, blowouts can cause erratic results. In areas where sediment accumulates, the vent hole should be extended with a short length of pipe. Plugging from algal growth may necessitate periodic examination and cleaning of the vent tube. About 5 ml of water unavoidably enter the plastic bag during

connection. A lightweight, steel fence-picket notched to hook the lower edge of the cylinder, helps in removal of the cylinder. It is easier to find the cylinders if the tops are painted white. Material for constructing each seepage meter costs $4 to $9 (in 1976) if two cylinders are cut from one 55-gallon (208 liter) drum.

The method will probably find its greatest application where surface waters lie in high to moderately permeable material. Without modifications, it is not designed for use in the turbulent water of the surf zone or in rapidly flowing rivers. In fine, low permeability sediments, groundwater velocity may be too low to measure with this technique, or flow may be restricted to discrete springs or leaks.

The principle of the method described here was first used to measure water losses from irrigation canals (Israelsen and Reeve 1944). Other methods (Bower and Rice 1968; Warnick 1951; Zuber 1970) have also been suggested to measure flow into or away from surface waters, but all involve substantial cost and none is appropriate for sample collection.

Laboratory-scale tests were designed to see if the seepage meter gave an accurate measure of groundwater flow over the velocity range encountered in the field. A rectangular test tank 1.3 m deep and 1.26 × 2.66 m in area held a bed of sand (0.5–0.125-mm-diameter granules, 4% silt and clay) 0.76 m deep. A permeable plate supported the sand 10 cm above the bottom of the tank. Upward or downward seepage through the sandbed was controlled with a variable-head tank connected to the water beneath the permeable plate. An overflow pipe kept 0.40 m of water over the sandbed. The seepage flux through the sand was controlled by the difference in the piezometric head measured by two tubes, one open to the water beneath the permeable plate and one open to the water above the sand. Measurements of seepage flux were made at several hydraulic gradients ranging from −0.071 to 0.097.

Reproducibility of velocity measurements was evaluated at Lake Sallie, Minnesota. Two seepage meters were placed 0.15 m apart. Simultaneous measurements were made during 3 consecutive days and at longer intervals over 2 months. The water surface elevations were recorded for Lake Sallie and nearby Muskrat Lake, 50 m away and 1.6 m higher.

A site near the Duke Marine Lab (Beaufort, North Carolina) was selected for additional tests because there was a recording tide gauge operated by the National Oceanic and Atmospheric Administration. About 30 m southwest of the tide gauge, three seepage meters were placed 0.65 m apart on a line perpendicular to shore in water about 0.4 m deep at mean low tide. The sediment was composed of sand and pieces of shells. Seepage flux was measured during 53–79-min intervals over a complete tidal cycle. When the tide was above mean sea level, measurements were started with 1 liter of water in the bag to permit detection of seepage into the sediment.

For evaluation of the seepage meter as a groundwater collection device, a site was selected in an area of fairly uniform groundwater discharge at Lake Sallie. Wells were installed to intercept water before it reached the lake, and seepage meters were placed in the lake adjacent to these wells to collect entering seepage (Fig. 2). Wells, driven 1.72 to 2.11 m into the water table, were sampled 8 times during 108 days. Only small amounts of water (0.6 liter) and soil (20 to 30 g) were removed at each sampling.

Water samples were either frozen and analyzed several weeks later or stored at 0° to 5°C and analyzed within 48 h. Ammonia, nitrite, and nitrate nitrogen, and soluble orthophosphate were determined according to *Standard methods* (Am. Public Health Assoc. 1965, 1971). Specific conductivity was measured at 20°C with a conductivity bridge. Chloride was determined with a specific-ion electrode. Samples were analyzed for total phosphate by a persulfate procedure (Dominick 1971). Filtration through medium-grade filter

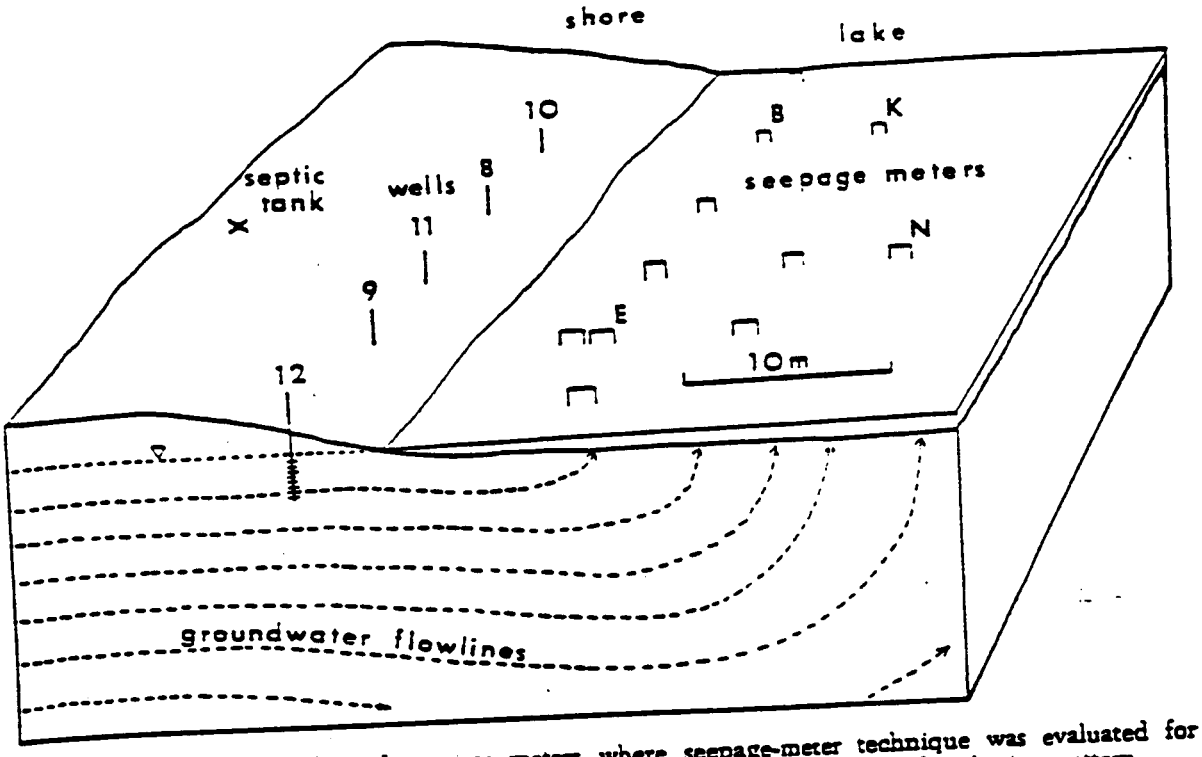

Fig. 2. Position of wells and seepage meters where seepage-meter technique was evaluated for collection of groundwater for chemical analysis. Flow lines show seepage distribution pattern.

paper (Sargent 501 or equivalent) preceded analyses for orthophosphate, nitrite, and nitrate.

Regression coefficients for the relation of velocity and hydraulic gradient in the experimental tank ranged from 0.995 to 0.994. Results for a representative seepage meter are shown in Fig. 3. Slopes for the regression lines for seepage at different locations in the test tank differed slightly (16 to 22 for upward seepage and 9.1 to 20 for downward seepage) probably due to heterogeneity in the test tank. However for any particular location in the tank, the slopes of the regression lines were significantly higher (at $p = 0.05$) for upward than for downward seepage. A 2–3-mm layer of fine clay particles accumulated at the surface of the sediment and these particles may have controlled permeability by impeding downward seepage more than upward seepage.

Results of the experiments on simultaneous measurement of seepage velocity showed that velocity for the two seepage meters always differed by about 0.1 μm s^{-1} and ranged from 0.596–0.854 μm s^{-1} over the 2-month period (Fig. 4). Variation in seepage velocity over time was not significantly correlated with changes in the relative elevation of nearby Muskrat Lake and Lake Sallie (Fig. 4). Changes in atmospheric pressure may have caused variations in velocity by changing the permeability of the sediment (Christiansen 1944; Peck 1960). Small variations in velocity were reproduced with closely placed seepage meters.

Measurements of velocity and water surface elevation during a tidal cycle at Beaufort, North Carolina, are presented in Fig. 5. Seepage velocity, measured with three seepage meters, was significantly correlated with water surface elevation ($R = 0.853$, $n = 32$). Seepage *into* the sediment (groundwater recharge) was detected in only 2 of 32 measurements. The close agreement of the three seepage meters over the tidal cycle showed that the technique gave reproducible results.

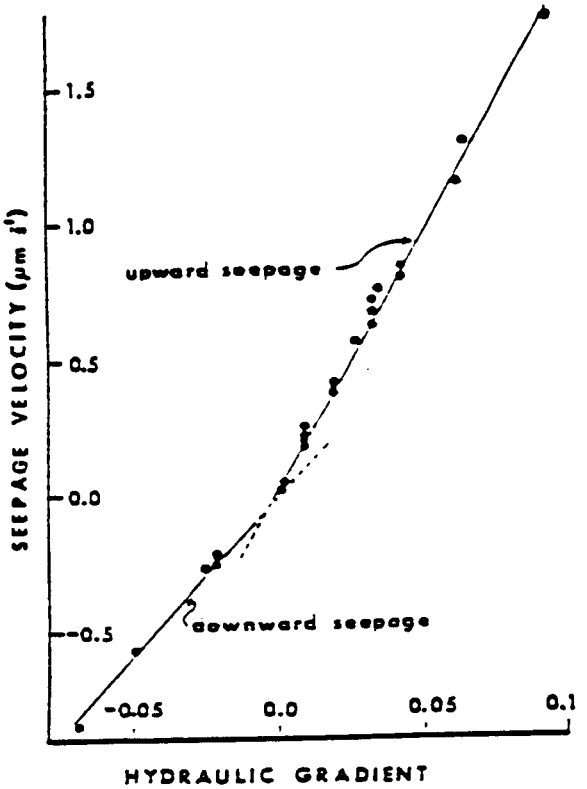

Fig. 3. Relation of hydraulic gradient and velocity measured with seepage meter in experimental tank. For upward seepage: velocity = (19.07 ± 0.32) gradient + (0.0220 ± 0.0012), R = 0.996, n = 29. For downward seepage: velocity = −(11.68 ± 0.94) gradient − (0.0028 ± 0.0110), R = 0.984, n = 7.

Along an 800-m segment of Lake Sallie shoreline, seepage measurements were made 5–160 m from shore. Near the midpoint of this section of shoreline, a site was selected for evaluation of the seepage meter as a groundwater collection device. At this site there was about 10 m of clean sand and gravel below the water table; the sand and gravel was underlain by a thick, relatively impermeable, clay layer (USGS well records, M.S. McBride personal communication).

A flow net (Fig. 6) was drawn assuming isotropic-homogeneous conditions, relatively low permeability of the underlying clay compared to the sand and gravel, and predominantly horizontal flow in the sand and gravel around the lake. The flow net showed that seepage velocity decreased exponentially with distance from shore and

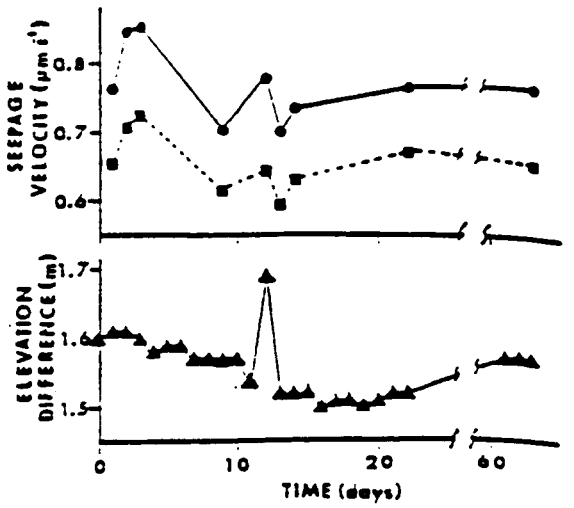

Fig. 4. Seepage velocity measurements from two seepage meters set 0.15 m apart, and relative elevations of lakes Sallie and Muskrat.

that shallow groundwater was discharged nearshore, deeper groundwater farther from shore.

Seepage measurements along the shoreline showed that nearshore discharge was rapid (0.3–0.8 μm s^{-1}) and that velocity did decline approximately exponentially

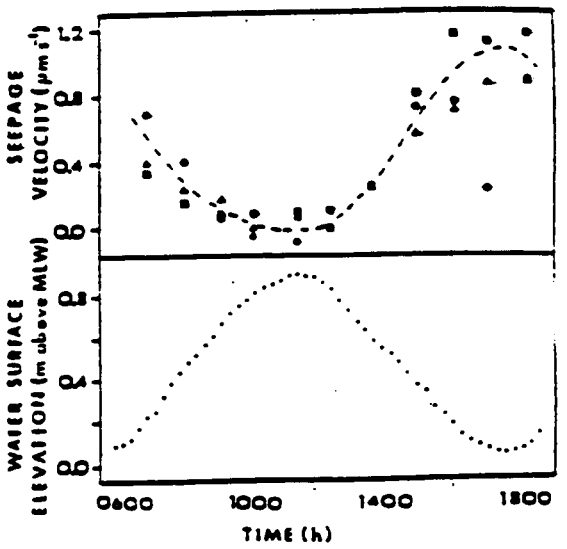

Fig. 5. Seepage velocity and water surface elevation during tidal cycle at Beaufort, North Carolina, 16 May 1975. Symbols (▲, ●, ■) denote different seepage meters. Water surface elevation data was obtained from NOAA tide gauge located at study site.

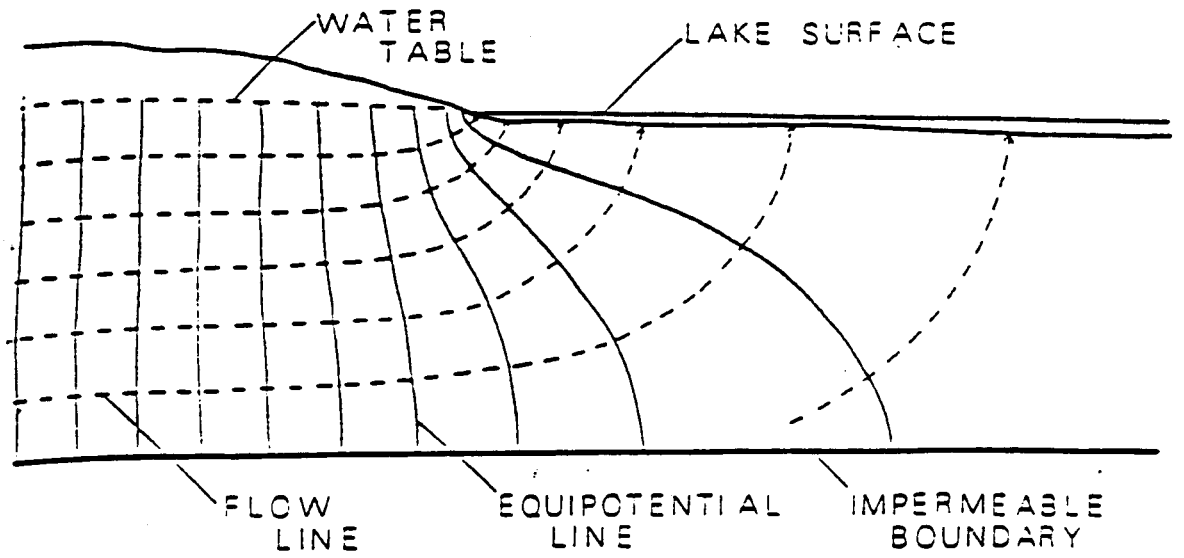

Fig. 6. Theoretical flow net showing distribution of groundwater discharge into Lake Sallie.

with distance from shore (Fig. 7). Substantial seepage influx occurred 60–80 m from shore, whereas the flow net showed high rates of flow to only about 15 m from shore. Seepage distribution would be skewed lakeward in this way if the horizontal to vertical permeability ratio were about 1 : 18 (Cedergren 1968), a common feature of glacial outwash terrain (Weeks 1969). McBride and Pfannkuch (1975) have also discussed the distribution of groundwater flow into lakes.

Seepage influx at the site adjacent to the wells ranged from 0.4–0.8 μm s^{-1}. Water collected from the seepage meters initially contained high and varying concentrations of orthophosphate (0.21–1.15 mg liter^{-1}) which eventually stabilized in the range 0.02–0.30 mg liter^{-1}, the average concentration being 0.15 (Fig. 8). Ammonia concentrations in the water collected from the seepage meters were also high initially, but there was a steady decline over a 2-month period. Ammonia levels dropped below 0.25 mg liter^{-1} after 900 liters of groundwater passed through the seepage meters. An exception, seepage meter E, consistently yielded water containing over

* This column shows the volume of water which flowed through the seepage meter before the sample was collected. The average flow during the preceding months was used to calculate this number.

+ This number, for a sample collected in 1972, was calculated using the autumn flow rate.

2.0 mg $liter^{-1}$ NH_3-N even after 4,000 liters of groundwater and 9 months had passed. However, the phosphate concentration in seepage meter E was not higher than that of the other meters at this site (Table 2). Wells 9 and 11 (Fig. 2), located lakeward of a septic tank, had the highest specific conductivity and the highest concentration of orthophosphate, nitrate nitrogen, and chloride (Table 2). Average orthophosphate concentration of water from the other wells (8, 10, and 12) was in the same range as the orthophosphate concentration of water from the seepage meters.

Some evidence indicated that a high nitrate zone capped the water table. The seepage inflow 7 m from shore (B and E, Fig. 2) contained from 8.8–16 mg $liter^{-1}$ NO_3-N, but in groundwater discharged 12 m and 17 m from shore, nitrate concentrations were <0.005 mg $liter^{-1}$ N. Average nitrate concentrations in the shallow wells near the lakeshore ranged from 8.78–31.8 mg $liter^{-1}$ N (Table 2). Monthly samples from a well 57 m from the edge of the lake contained 1.57–0.34 mg $liter^{-1}$ NO_3-N at the surface of the water table, but when the well was driven 0.5 m deeper, nitrate levels fell to <0.012. It is not uncommon to find high nitrate concentrations in shallow groundwater near the water table (Behnke 1975).

Lake water contained less phosphate, less inorganic nitrogen, lower conductivity, and higher chloride than the seepage water (Table 2). Seepage water contained about the same amount of orthophosphate and about the same conductivity as the well water not affected by the septic tank.

The inexpensive seepage meter was used on moderately permeable sediment of lakes and estuaries to measure seepage velocities ranging from −0.1–2.58 $\mu m\ s^{-1}$. Where seepage is upward, the seepage meter yields a sample of water which can be used for chemical analysis.

For the velocity range encountered in the field, a linear relation was observed between measured seepage velocity and an experimentally controlled hydraulic gradient. Changes in the rate and direction of seepage flux during a tidal cycle were correlated with changes in the water surface elevation of an estuary. Closely placed seepage meters gave reproducible results.

Velocity and chemistry of seepage inflow to Lake Sallie thus concurred with results predicted by the theoretical flow net: shallow groundwater discharged nearshore contained high concentrations of nitrate, whereas deeper groundwater, discharged farther from shore, contained very little nitrate; nearshore seepage was rapid and declined with distance from shore. Where groundwater discharge was relatively rapid (0.4–0.8 $\mu m\ s^{-1}$), water collected with the seepage meter became chemically consistent after about 4 months and was chemically similar to water from wells located along the same flow path.

CITIZEN PARTICIPATION PLAN

CITIZEN PARTICIPATION PLAN

1.0 Introduction to the Plan

The New York State Electric and Gas Corporation (NYSEG) is committed to a citizen participation program as part of its responsibilities for the clean-up of the Mechanicville Central Avenue former manufactured gas plant (MGP) site. Citizen participation promotes public understanding of the remedial investigation process, and proposed remedial activities that are planned for the site. This plan provides an opportunity for the public to express their concerns and have input into the investigation and remedial actions that are being planned for the site.

2.0 Basic Site Information

Former MGP sites are being investigated by NYSEG because by-products of the gas production process may be present on site. These by-products, predominantly coal tars, have the potential to adversely effect human health and/or the environment.

The Mechanicville Central Avenue former manufactured gas plant produced coal gas, a predecessor to natural gas, from 1901 to 1955. Coal gas was produced by heating coal under low oxygen conditions in brick ovens. The gas was then cooled and cleaned for impurities. Coal tars, coal ash, and gas purifier waste were by-products generated on-site. The majority of coal tar generated on-site was collected and sold to tar refineries. However, previous investigations of the site identified that coal tars are present on the site in the subsurface soils. These coal tars have the potential to migrate and impact groundwater.

The site is currently listed on the New York Registry of Inactive Hazardous Waste Sites. The site is classified by the New York Department of Environmental Conservation (NYSDEC) as Classification 2; a site posing a significant threat to the public health or the environment--action required. NYSEG disagrees with NYSDEC's determination as no health or environmental threat has been identified in previous studies. However, NYSEG does agree that remedial actions are necessary for the site because coal tars and impacted groundwater are migrating into the Anthony Kill adjacent to the site.

3.0 Project Description

In 1986, NYSEG contracted an independent environmental consultant, E.C. Jordan Co. (Jordan) to conduct a multi-phase environmental investigation of the site. NYSEG conducted this investigation on a voluntary basis. The investigation included performing testpits, soil and bedrock borings, monitoring well installation, sampling and chemical analysis of soil, groundwater, Anthony Kill surface water and sediments, and indoor air. All analytical work was performed using generally accepted sampling protocols at New York State certified laboratories. Coal tars were found in several subsurface structures and also found in the subsurface soils. In 1990, Jordan concluded that the coal tar was impacting the quality of the local groundwater and seeping into the Anthony Kill. The impacted groundwater was also discharging into the Anthony Kill.

Jordan's Risk Assessment of the site concluded that the site did not pose a significant risk to public health nor was there a significant environmental risk to the Anthony Kill. These conclusions were based on the surface water and sediment samples taken from the Anthony Kill, and modeling of the discharges to the Anthony Kill. Although no significant risks were identified, NYSEG proposed plans to conduct a feasibility study to eliminate the discharge of coal tars to the Anthony Kill. These plans were proposed to the NYSDEC in the Fall of 1991. NYSDEC Region 5 staff responded to NYSEG's proposal by requesting NYSEG to resubmit the site investigation reports in a format that is consistent with NYSDEC guidelines. NYSDEC also identified several areas where additional study were warranted.

To address NYSDECs concerns, NYSEG contracted ABB Environmental Services, Inc. (ABB-ES) formerly the E.C. Jordan Co., to conduct a Phase IIA supplemental investigation. The Phase IIA Work Plan focuses on assessing surface soils for PCB oil contamination and installing additional soil borings and monitoring wells, and piezometers downgradient of the site. Additional groundwater samples will be collected from the new and existing monitoring wells. Seep samples and additional sediment samples will also be taken from the Anthony Kill. Several locations have been identified where NYSEG had historically stored electrical equipment. These areas will undergo soil sampling for PCB contamination.

Upon analysis of the samples from the Phase IIA investigation sampling points, a Feasibility Study will be performed to identify remedial actions that will address

the discharge of coal tar, and coal tar constituents, into the Anthony Kill. In the event that PCBs are detected in shallow subsurface soil samples, the need for remediation will be evaluated based on state and federal requirements.

NYSEG anticipates conducting the Phase IIA field investigation activities in May of 1992. A Draft Final Report will be available for public review in November 1992. This schedule is dependent on NYSDEC approval of the Phase IIA Work Plan by March 27, 1992.

6.0 Identification of Document Repository

Mechanicville District Public Library
15 South Main Street
Mechanicville, New York 12118
(518) 664-4646

7.0 Description of Specific Citizen Participation Activities

Upon NYSDEC review, notice of development of the Phase IIA Workplan will be made to all contacts listed in Section 4.0 A copy of the final work plan will be kept at the designated repository. The workplan will be presented at a public meeting after final approval by NYSDEC. A minimum two week advance notice of the public meeting will be provided to the contact list. Site RI/FS updates will be submitted to the contact list every six to twelve months until the Phase IIA work is complete. When the Phase IIA work is completed, the final draft report will be submitted to NYSDEC and two copies will be forwarded to the repository identified in Section 6.0.

Although utility work adjacent to the site and sediment exposure was considered in the health assessment, to address NYSDEC concerns over possible exposure to site related chemicals at adjacent facilities, NYSEG will contact all abutters and public utilities which may conduct intrusive work adjacent to the site. For any planned intrusive activities, NYSEG will provide an assessment of the potential exposure risk and provide guidance on developing health and safety procedures.

It is anticipated that a Proposed Remedial Action Plan (PRAP) will be written after the approval of the Phase IIA report. The PRAP identifies the problems and the recommended remedial actions that are necessary for the site. The PRAP also identifies all the options that were evaluated to remediate the site and provides justification for the remedial action that was chosen. NYSEG staff will take the lead to setup a public meeting to present the results of the Phase IIA report and the PRAP with a two week minimum advance notice. A 30-day public review period will follow and NYSEG will address issues and concerns raised during the public review process. The final Remedial Action Plan (RAP) will include response to any issues raised during the review period. The two copies of the final version of the RAP will be sent to the repository.

8.0 Glossary of Key Terms and Major Program Elements

NOTE: The first eight definitions represent major elements of the remedial process. They are presented in the order in which they occur, rather than in alphabetical order, to provide a context to aid in their definition.

Site Placed on Registry of Inactive Hazardous Waste Sites - Each inactive site known or suspected of containing hazardous waste must be included in the Registry. Therefore, all sites which state or county environmental or public health agencies identify as known or suspected to have received hazardous waste should be listed in the Registry as they are identified. When possible, the Department carries out an initial evaluation of the site before listing.

Phase I Site Investigation - Preliminary characterizations of hazardous substances present at a site; estimates pathways by which pollutants might be migrating away from the original site of disposal; identifies population or resources which might be affected by pollutants from a site; observes how the disposal area was used or operated; and gathers information regarding who might be responsible for wastes at a site. Involves a search of records from all agencies known to be involved with a site, interviews with site owners, employees and local residents to gather pertinent information about a site. Information gathered is summarized in a Phase I report.

After a Phase I investigation, DEC may choose to initiate an emergency response; to nominate the site for the National Priorities List; or, where additional information is needed to determine site significance, to conduct further (Phase II) investigation.

Phase II Site Investigation - Ordered by DEC when additional information is still needed after completion of Phase I to properly classify the site. A Phase II investigation is not sufficiently detailed to determine the full extent of the contamination, to evaluate remedial alternatives, or to prepare a conceptual design for construction. Information gathered is summarized in a Phase II report and is used to arrive at a final hazard ranking score and to classify the site.

Remedial Investigation (RI) - A process to determine the nature and extent of contamination by collecting data and analyzing the site. It includes sampling and monitoring, as necessary, and includes the gathering of sufficient information to determine the necessity for, and proposed extent of, a remedial program for the site.

Feasibility Study (FS) - A process for developing, evaluating and selecting remedial actions, using data gathered during the remedial investigation to: define the objectives of the remedial program for the site and broadly develop remedial action alternatives; perform an initial screening of these alternatives; and perform a detailed analysis of a limited number of alternative which remain after the initial screening stage.

Remedial Design - Once a remedial action has been selected, technical drawings and specifications for remedial construction at a site are developed as specified in the final RI/FS report. Design documents are used to bid and construct the chosen remedial actions. Remedial design is prepared by consulting engineers with experience in inactive hazardous waste disposal site remedial actions.

Construction - DEC selects contractors and supervises construction work to carry out the designed remedial alternative. Construction may be as straightforward as excavation of contaminated soil with disposal at a permitted hazardous waste facility. On the other hand, it may involve drum sampling and identification, complete encapsulation, leachate collection, storage and treatment, groundwater management, or other technologies. Construction costs may vary from several thousand dollars to many millions of dollars, depending on the size of the site, the soil, groundwater and other conditions and the nature of the wastes.

Monitoring/Maintenance - Denotes post-closure activities to insure continued effectiveness of the remedial actions. Typical monitoring/maintenance activities include quarterly inspection by an engineering technician; measurement of level of water in monitoring wells; or collection of ground water and surface water samples and analysis for factors showing the condition of water, presence of toxic substances, or other indicators of possible pollution from the site. Monitoring/maintenance may be required indefinitely at many sites.

Consent Order - A legal and enforceable negotiated agreement between the Department and responsible parties where responsible parties agree to undertake investigation and cleanup or pay for the costs of investigation and cleanup work at a site. The order includes a description of the remedial actions to be undertaken at the site and a schedule for implemented.

Contract - A legal document signed by a contractor and the Department to carry out specific site remediation projects.

Contractor - A person or firm hired to furnish materials or perform services especially in construction projects.

Delisting - Removal of a site from the state Registry based on study which shows the site does not contain hazardous wastes.

Potentially Responsible Party Lead Site - An inactive hazardous waste site at which those legally liable for the site have accepted responsibility for investigating problems at the site, and for developing and implementing the site's remedial program. PRP's include: those who owned the site during the time wastes were placed, current owners, past and present operators of the site, and those who generated the wastes placed at the site. Remedial programs developed and implemented by PRP's generally result from an enforcement action taken by the State and the costs of the remedial program are generally borne by the PRP.

Ranking System - The United States Environmental Protection Agency uses a hazard ranking system (HRS) to assign numerical scores to each inactive hazardous waste site. The scores express the relative risk or danger from the site.

Responsible Parties - Individuals, companies (e.g., site owners, operators, transporters or generators of hazardous waste) responsible for or contributed to the contamination problems at a hazardous waste site. PRP is a potential responsible party.

Site Classification - The Department assigns sites to classifications established by state law, as follows:

- Classification 1 - A site causing or presenting an imminent danger of causing irreversible or irreparable damage to the pubic health or environment--immediate action required.

- Classification 2 - A site posing a significant threat to the public health or environment--action required.

- Classification 2a - A temporary classification for a site known or suspected to contain hazardous waste. Most likely the site will require a Phase I and Phase II investigation to obtain more information. Based on the results, the site then would be reclassified or removed from the state Registry if found not to contain hazardous wastes.

- Classification 3 - A site which has hazardous waste confirmed, but not a significant threat to the public health or environment--action may be deferred.

- Classification 4 - A site which has been properly closed--requires continued management.

- Classification 5 - A site which has been properly closed, with no evidence of present or potential adverse impact--no further action required.

State-Lead Site - An inactive hazardous waste site at which the Department has responsibility for investigating problems at the site and for developing and implementing the site's remedial program. The Department uses money available from the State Superfund and the Environmental Quality bond Act of 1986 to pay for these activities. The Department has direct control and responsibility for the remedial program.

1.0 INTRODUCTION

This Phase IIA Supplemental Remedial Investigation (RI) and Feasibility Study (FS) Report was prepared by ABB Environmental Services, Inc. (ABB-ES) for the New York State Electric and Gas Corporation (NYSEG) under Contract No. 85-159. It presents a summary of previous investigations and the findings of the Phase IIA Supplemental RI conducted at the Mechanicville Central Avenue Site (the site), Mechanicville, New York. In addition, this report presents the results of the FS completed to evaluate potential remedial measures that may be warranted to address certain environmental conditions encountered at the site.

1.1 BACKGROUND

In 1986 NYSEG initiated field investigation activities at the former coal gasification site at Mechanicville to assess the potential presence of residual by-products and wastes associated with former gas manufacturing activities at the facility. The investigation activities were conducted as four separate tasks completed during the period between 1986 and 1990. The results of the individual investigation activities were consolidated into a summary document entitled, "Investigation of the Former Coal Gasification Site at Mechanicville, New York; Phase II Remedial Investigation Report and Work Plan for Phase IIA Supplemental Remedial Investigation and Feasibility Study" (Phase II RI Report) which was submitted to the New York State Department of Environmental Conservation (NYSDEC) in June 1992.

In February 1993, NYSEG entered into an Order on Consent - Index #A5-0276-91-10 (the Order) with NYSDEC relative to the Mechanicville Site. The goal of the Order was to develop and implement a Phase IIA Supplemental RI and Feasibility Study (FS) which address health and environmental hazards and potential hazards attributable to the site. Work plans detailing the technical approach and specific supplemental investigation and feasibility study activities required in the Order were included in the Phase II RI Report. The work plan components of this report and modifications required pursuant to comments provided by NYSDEC in correspondence to NYSEG dated July 2, 1992, constitute the Work Plan as incorporated into the Order.

Field work activities associated with the Supplemental Investigation were conducted by ABB Environmental Services, Inc. between May 1993 and July 1993. The FS was conducted subsequent to receipt and evaluation the Phase IIA Supplemental RI data. The scope of the NYSDEC approved "focused" FS was modified to address comments provided by the NYSDEC project manager in a letter to NYSEG dated April 3, 1993. Specifically, the Work Plan was modified to address additional environmental media which were not initially included in the FS work plan.

This Phase IIA Supplemental Remedial Investigation and Feasibility Study Report presents and discusses the data collected from Phase IIA Supplemental field activities as they relate to the current understanding of site conditions developed from previous investigations of the site. The results of the FS are presented and discussed in the context of the requirements of the Order to address any presence of potential threat to the public health or environment posed by the presence of residual by-products and wastes associated with former site operations and any threatened release of such residual materials at or from the site.

1.2 Summary of Phase IIA Supplemental RI Field Work Activities

The following activities were completed during the Phase IIA Supplemental RI field program:

- the collection, field characterization, and laboratory analyses of twenty-four (24) surface soil samples;
- the installation of four (4) seepage meters in the Anthony Kill, the measurement of seepage rates, and collection and laboratory analyses of seepage samples;
- the collection, field characterization, instrumental screening, and laboratory analyses of six (6) sediment samples from the Anthony Kill;
- the completion of three (3) soil borings and the collection and laboratory analysis of two (2) subsurface soil samples;
- the installation of three (3) groundwater monitoring wells and the collection and laboratory analysis of one (1) round of groundwater samples from selected groundwater monitoring wells;
- the performance of in situ hydraulic permeability testing of zones in which new monitoring wells were screened;

- the measurement of water levels in selected overburden and bedrock monitoring wells to evaluate the direction of groundwater flow; and

- the completion of an expanded topographic survey.

1.3 REPORT ORGANIZATION

This RI report contains the following sections:

- Background (Section 2.0)
- Previous Investigations (Section 3.0)
- Summary of Phase IIA Supplemental RI Field Work (Section 4.0)
- Site Topography, Geology, and Hydrogeology (Section 5.0)
- Field and Laboratory Data (Section 6.0)
- Summary of Findings (Section 7.0)
- Conclusions and Recommendations of the Phase IIA Supplemental RI (Section 8.0)
- Feasibility Study Introduction (Section 9.0)
- Identification of Standards, Criteria, and Guidelines (Section 10.0)
- Identification and Screening of Technologies (Section 11.0)
- Development of Remedial Alternatives (Section 12.0)
- Initial Screening of Mechanicville Site Alternatives (Section 13.0)
- Detailed Analysis of Remedial Action Alternatives (Section 14.0)
- Comparative Analysis of Alternatives (Section 15.0)
- Recommendations of Remedial Action (Section 16.0)

The *Background Section* contains information concerning, among other things, site setting, site history, regional geology and regional hydrogeology. The *Previous Investigations Section* summarizes previous investigations conducted at the site. The summary of *Remedial Investigation Field Work Activities Section* contains a description of the Phase IIA Supplemental RI field work activities conducted at the site. The *Site Topography, Geology and Hydrogeology Section* presents ABB-ES' interpretations of geologic and hydrogeologic data collected during RI field work activities. The *Field and Laboratory Data Section* presents field characterization and laboratory analytical data collected during the Phase IIA Supplemental RI field work activities. The *Summary of Findings Section* summarizes the geologic and hydrogeologic data as well as the field characterization and laboratory analytical data relative to environmental conditions at the site. The *Conclusions and Recommendations Section* presents conclusions from the RI and presents recommendations for potential remedial activities at the site to be considered in the FS.

The *Feasibility Introduction* discusses the purpose and scope of this FS. *Identification of Standards, Criteria, and Guidelines* summarizes federal, state, and local SCGs and includes development of remedial objectives that apply to this site. *Identification and Screening of Technologies* focuses on technologies for controlling migration of overburden groundwater and coal tar at the site. *Development of Remedial Alternatives* assembles alternatives with different combinations of technologies based on observations and site features. *Initial Screening of Mechanicville Site Alternatives* uses criteria of implementation, effectiveness, and cost to screen assembled alternatives. *Detailed Analysis of Remedial Action Alternatives* focuses on the three alternatives that emerged from alternatives screening. *Comparative Analysis* of Alternatives compares advantages and disadvantages of each of the three alternatives, relative to one another, with regard

to evaluation criteria. This analysis is the basis for *Recommendations of Remedial Action*.

2.0 BACKGROUND

2.1 SITE SETTING

The site is located in the City of Mechanicville, Saratoga County, New York (see Figure 2-1). The site is bordered on the east by North Central Avenue (formerly Champlain Canal), on the south by Ferris Lane, on the west by a railroad right-of-way, and on the north by the Anthony Kill. Current site conditions are depicted in Figure 2-2.

Saratoga County is in the Valley and Ridge physiographic province of east-central New York (Heath, et al., 1963; Waller, et al., n.d.). The Hudson River forms the northeastern and eastern boundaries of Saratoga County; the Mohawk River, the largest tributary to the Hudson River, forms the southeastern boundary.

The nearest surface water body is the Anthony Kill, a small tributary to the Hudson River at Mechanicville, that borders the northern boundary of the site approximately 1,500 feet upstream from its confluence with the Hudson River.

2.2 HISTORY AND OPERATIONS

2.2.1 Description of Manufactured Gas Plant (MGP) Operations

The water gas process was used at the Mechanicville site to manufacture gas. According to available information, both the blue gas and carbureted water gas manufacturing processes were used during plant operations (USWAG, 1984). Prior to the 1950s, the blue gas process was used, after which the plant converted to the carbureted water gas process. The site plan circa 1910 is shown in Figure 2-3. The site plan circa 1951 is shown in Figure 2-4.

Blue gas was produced by passing steam over incandescent coke and recovering the released gases. Because the steam lowered the temperature of the fuel bed, air blasts were needed periodically to restore the temperature. Using the blue gas process involved alternating cycles of steam injection and air blasts (See Figure 2-3).

The carbureted water gas process was developed to raise the heat content (British thermal units [Btu]) of the gas. In this process, blue gas passes through a carburetor where a spray of oil is injected into the gas streams and subsequently thermally cracked in a superheater (USWAG, 1984). Hydrocarbon gases, such as methane and ethane, were formed in the superheater adding to the Btu content of the gas.

The oil used in the carbureted water gas process was stored in three (3) aboveground tanks underneath a platform supporting the oxide house. A

fourth aboveground tank (10,000 gallons) was located between the two gas holders as shown in Figure 2-4.

At the Mechanicville facility, gas flowed from the gas house to the purifier house to the relief holder, and to the larger distribution holder. All piping was underground (Elvins, 1986; McBride, et al., 1986). This flow path differs from the typical water gas plant where gas was stored in the relief holder prior to being purified. The oxide house apparently stored fresh and/or spent oxide material used to purify the gas.

By-products generated at the Mechanicville gas plant included: ash and condensate from the gas house; wood chips from the purifier house; coal tar; light oils; and tar/oil water emulsions. Information documenting the management of manufactured materials and by-product/wastes generated at the site have not been located. However, it was common practice to dispose of ash and spent oxide material on-site (USWAG, 1984).

According to NYSEG employees, the following methods of disposal were employed:

- The ash and clinkers (noncombusted material) were shoveled out of the generator at night and spread in the area between the relief holder and Ferris Lane.

- The condensate from the water gas purification process was treated in the tar dehydrator (tar separator). The oil was used for fuel and

the water piped through a series of filter beds located behind the coal storage building. These filter beds consisted of wood troughs (approximately ten (10) feet by six (6) feet, and four (4) feet deep) set in the ground and filled with coke. Baffles directed the flow through the coke and discharged the water into the Anthony Kill. The oily coke in the beds was collected periodically and burned in the gas house.

- Wood chips treated with iron oxide were used to remove cyanide and hydrogen sulfide from the gas in the purifier house. When free sulfur accumulated to approximately 50 percent of the mass, much of the iron was tied up in iron sulfide and ferrocyanides, and the spent wood chips were replaced by fresh ones. The plant employed several disposal methods for the spent wood chips: (1) incinerated by the City of Mechanicville from 1951 to 1955; (2) piled along the road until someone came and hauled them away; and (3) spread on the lot just west of the active plant area (NYSEG n.d. and E.C. Jordan Co. 1986).

- Residual coal tar condensed out of the purified gas and mixed with water in the bottom of the relief holder. The mixture was periodically pumped into a truck and hauled off-site.

2.2.2 History and Operation

Founded in 1900, the Halfmoon Light, Heat & Power Co. began gas manufacturing operations in 1901. The layout of the gas plant, circa 1910, is depicted in Figure 2-3. (Sheehan, n.d.). The plant was expanded in 1911 to include a larger water gas holder and distribution gas holder.

In 1924, the Halfmoon Light, Heat & Power Co. was acquired by the Associated Gas and Electric System. Four years later, in 1928, the Associated Gas and Electric System was incorporated into NYSEG (Sheehan, n.d.). The site contained the following facilities/structures as of 1951:

- purifier house
- tar dehydrator
- storage and tool house
- relief gas holder (40,000 cubic feet)
- distribution gas holder (100,000 cubic feet)
- boiler room
- substation
- coal storage area
- filter beds
- transformer platform
- gas regulator building
- radiator shop.

The plant layout in 1951 is depicted in Figure 2-4. Coal gas production continued at the site until 1955 (Elvins, 1986).

From 1955 to 1990, NYSEG operated a natural gas and electric service center until the center was relocated to Halfmoon, New York. During the service center's 1955-1990 occupation, electrical equipment, including new and used transformers, regulators and capacitors, was stored on site. Prior to the late 1970s, the transformers were stored on two wooden platforms. One platform was located on the south border of the site, along Ferris Lane; the other platform was located above the filter beds, east of the former boiler room/substation building. After removal of the platforms, the transformers were relocated to an area by the banks of Anthony Kill. Because of oil staining, the top 8 to 12 inches of soil beneath this transformer storage area were removed by NYSEG in August 1984. Twelve (12) drums of excavated soil were hauled to an approved disposal facility and the excavated area was backfilled with gravel.

Upon routine inspection, minor oil stains were identified at several other locations. A 12- by 24-foot area, located approximately 25 feet west of the former filter beds, was excavated to depth of 2 feet. The excavated soils were then disposed of under the assumption they contained polychlorinated biphenyls (PCBs). Following the excavation, five (5) samples were collected for laboratory analysis. One sample in the center of the excavation area contained 1.0 part per million (ppm) of the PCB Aroclor-1248. The excavation was then lined with plastic and backfilled with clean soil to the original grade.

NYSEG purchased the 0.25-acre lot adjacent to the site on the corner of Ferris Lane and North Central Street in 1924 (Bevis, 1986). The lot remained empty until the 1950s when NYSEG built the existing electrical substation. NYSEG also owns the property west of the site. NYSEG purchased the land between the railroad tracks and the Anthony Kill in 1952, and the land between the railroad tracks and Ferris Lane in 1987.

Recent environmental activities at the site included the removal of one (1) 3,000-gallon gasoline tank. One (1) 3000-gallon diesel tank was decommissioned in place. The tank removal was performed in 1991. Hope Oatman, New York State Department of Environmental Conservation (NYSDEC) Region 5 Division of Environmental Quality, was present to verify that the tanks were properly addressed and did not leak.

In October 1992, the building that formerly housed the boiler room and electric generating equipment was demolished leaving the foundation in place.

The site is currently unoccupied and serves as a garage and supply storage/maintenance shop. The site is bordered by a 6-foot chain-link fence on the east, south, and west perimeters and by the Anthony Kill to the north.

2.3 REGIONAL GEOLOGY AND HYDROGEOLOGY

Regional geologic and hydrogeologic descriptions are based on a review of available literature, regional geologic and hydrogeologic maps, and data gathered in Tasks 1, 2, and 3.

2.3.1 Regional Geology

Saratoga County is located within the Hudson River Valley. The geomorphology is predominantly glacial. Soils in this region include gravelly sands, ablation tills (deposited during the Laurentide Ice sheet), stratified silt and clay deposits, and silty shale (weathered bedrock). Overburden soils range from 0 to 50 feet in thickness. The near-surface strata may have been altered by cultural activities such as farming and urban development.

The bedrock topography in Saratoga County is part of a regional preglacial drainage system that was glacially scoured to form U-shaped valleys. The most prominent surficial bedrock feature is a buried tributary known locally as the Colonie channel which traverses the Clifton Park area in a north-south direction, approximately 4 miles southwest of the site. Within the U-shaped channel is a narrow V-shaped inner gorge that in some places has been cut to sea level.

The Mechanicville area is predominantly underlain by interbedded shales and sandstone. Regionally, the principal bedrock formations consist of tightly folded, faulted and jointed Ordovician shales including the Normanskill Shale, Snake Hill Formation, Canajoharie Shale, and the Schenectady Formation. These formations

are primarily composed of blue-black to grey shales that range in total thickness from 100 to 1,000 feet. Older crystalline rocks (e.g. quartzite, gneiss, and schist) outcrop approximately 12 miles northwest of the site. These formations dip to the east and become overlain by sandstones, carbonates, and the shales described above.

The site is underlain by thinly bedded blue-grey Ordovician shales. The upper 10 feet is highly fractured with increased competency with depth. The shale bedrock beneath the site is approximately 100 to 400 feet thick.

2.3.2 Regional Hydrogeology

In the Mechanicville area, the regional groundwater flow is to the east, toward the Hudson River. Fine-grained stratified clay and silt deposits underlie relatively extensive areas in the eastern part of Saratoga County including the City of Mechanicville. The clay and silt is, for all practical purposes, impermeable and will not yield water in usable quantities (less than 10 gallons per minute (gpm)). Sand and gravel deposits are also common in the eastern region of the county. The saturated thickness of these soil deposits range from 0 to 100 feet. (Health, et. al., 1963).

Only one of the 18 high-use aquifers designated for public water supply by the New York State Department of Health is located in Saratoga County. This aquifer, referred to as the Colonie channel aquifer, consists of a series of the sand and gravel deposits primarily located within the village of Clifton Park, 4 miles southwest of the Mechanicville site. The Colonie channel aquifer consists of

discontinuous sand and gravel deposits that are confined in most places by a thick sequence of lacustrine silt and clay. Several public water supply systems tap the Colonie channel aquifer. Production wells in this aquifer have yields in excess of 500 gpm. Overlying the lacustrine silt and clay is a veneer of lake and dune sands that form a surficial aquifer. This aquifer is hydraulically connected to the lower confined aquifer through ice-contact deposits, such as kames or kame deltas, that are exposed at the land surface. These deposits act as recharge areas for the underlying confined aquifer. (Reynolds, R.J. 1983).

The overburden deposits underlying the Mechanicville site are generally less than 30 feet thick and are composed of silts and clays as well as highly weathered silty shale. The permeability of these deposits is low, ranging from $2.2x10^{-5}$ to $1.9x10^{-4}$ centimeters per second (cm/sec) or 0.06 to 0.54 feet per day (ft/day). Due to grain size and low permeability, the overburden deposits at the site are likely to be associated with the impermeable silts and clays described above. The groundwater at the Mechanicville site is not hydraulically connected to the Colonie channel aquifer.

Regionally, groundwater within the bedrock flows along planes influenced by bedding, cleavage, faults and/or joints. As the weight of the overlying bedrock and soils increases with depth, the interstitial spaces between joints and fractures decrease. On average, groundwater flow velocities in bedrock also decrease with depth.

Several natural springs that produce highly mineralized water are present in the dolomite formations in Saratoga Springs, approximately 9 miles north of

Mechanicville. The flow at these springs appears to be controlled by the Saratoga fault, which trends approximately north-south. The fault plane runs approximately 5 miles to the northwest of the Mechanicville site. East of the fault, dolomite is overlain by shale preventing upward seepage of the water. Opposite to dolomite, to the west of the fault, lies crystalline bedrock which acts as an impermeable barrier. Groundwater flowing in the dolomite is forced up to the surface along the fault plane, creating Saratoga Springs.

Bedrock groundwater is extracted primarily from wells installed in the carbonate formations (dolomites and limestones). These formations outcrop in the Glens Falls area and underlie the shales to the south. In 1963, twenty-five (25) wells installed in the carbonate reported yields ranging from 1 to 300 gpm. The average yield was 30 gpm. 110 wells installed in the Ordovician shales produce an average yield of 10 gpm.

Based on boring data collected during Tasks 1 through 4, Ordovician shales underlie the Mechanicville site and outcrop along the norther border of the site, forming the banks of the Anthony Kill. Both the overburden and the bedrock at the site have been documented to produce low yields (approximately 10 gpm), with the nearest primary aquifer 4 miles to the southwest (upgradient). The closest domestic wells are located nearly 1 mile southwest (i.e., upgradient) of the site in the Town of Halfmoon. According to available information, there are no active industrial wells in the Mechanicville area.

3.0 PREVIOUS INVESTIGATIONS

This section presents a summary of the previous investigations performed to complete the RI at the Mechanicville site. Sub-tasks performed during Task 1 (The Preliminary Site Evaluation), Task 2 (The Initial Field Investigation Program), Task 3 (The Expanded Problem Definition Program), and Task 4 (The Risk Assessment) are described in Subsections 3.1 through 3.4. A summary of the results is presented in Section 3.5, followed by conclusions and recommendations pertaining to the site and future investigations.

3.1 TASK 1 PRELIMINARY SITE EVALUATION

The Task 1 Preliminary Site Evaluation was conducted in 1986 to develop an understanding of the site's history, environmental setting, and current conditions. The field work activities included a detailed site reconnaissance, interviews, file searches, and a geophysical survey.

The geophysical survey was conducted within the two parking lots of the NYSEG facility on North Central Avenue. The survey area was approximately one (1) acre in size. The ground-penetrating radar (GPR), terrain conductivity profiling (also referred to as electromagnetic profiling), and seismic refraction surveys were conducted along the traverse lines indicated on Figures 3-1 and 3-2.

3.2 TASK 2 INITIAL FIELD INVESTIGATION PROGRAM

The Task 2 Initial Field Investigation Program was conducted during the period of 1986 to 1987. The purpose of the program was to investigate the presence of manufactured gas plant (MGP)-associated wastes at the Mechanicville site. Field activities included the completion of test pits and soil borings; installation of monitoring wells; sampling of air, soils, groundwater, surface water, and sediments; laboratory analyses; and completion of a preliminary land use investigation.

The primary objectives of Task 2 were problem identification, preliminary risk assessment, and preliminary in-house engineering determinations. The following field activities were performed:

- Excavated five test pits for characterization of the subsurface geology of the site; installed piezometers in two (2) of the test pits to obtain groundwater elevation data; collected six (6) soil samples for laboratory chemical analyses.

- Drilled eight (8) soil borings and collected eight (8) soil samples for laboratory analyses; installed six (6) monitoring wells and one (1) piezometer.

- Performed in situ permeability tests at all wells and obtained five (5) rounds of groundwater elevation data from monitoring wells and piezometers.

- Collected quarterly groundwater samples from six (6) monitoring wells for laboratory analyses.

- Collected quarterly surface water and sediment samples at three (3) locations along the Anthony Kill for laboratory analyses.

- Conducted a topographic survey to identify surficial features and exploration locations.

- Conducted a preliminary land use survey within a half-mile radius of the site.

- Performed a preliminary assessment of the potential health and environmental risks posed by chemical constituents found at the site, and identified remedial alternatives to control the effects and risks.

- Identified additional data requirements and proposed a Task 3 program to obtain the necessary data.

The detailed scope of work and analytical results for Task 2 were described in the Task 2 Report for the Mechanicville site, submitted to NYSEG in April 1986.

3.3 TASK 3 EXPANDED PROBLEM DEFINITION PROGRAM

The Task 3 Expanded Problem Definition Program was conducted during the period of 1987 through 1989. Task 3 was designed to (1) confirm analytical results of the Task 2 investigation, (2) obtain further data on chemical distribution in soil and shallow bedrock at the site, (3) further investigate the potential for chemical migration in groundwater, (4) assess the air quality within the buildings on the site, and (5) identify potential chemical receptors and potential sensitive land users.

Task 3 consisted of the following subtasks:

- Performed a ground penetrating radar (GPR) survey adjacent to the site on the northern side of the Anthony Kill to extend the area of bedrock contouring.

- Excavated four (4) shallow and three (3) deep borings drilled for further site characterization, including the collection and laboratory analyses of soil samples and characterization of bedrock.

- Installed six (6) monitoring wells and collected two (2) rounds of groundwater samples for laboratory analysis and two (2) rounds of water level measurements.

- Performed in situ permeability tests of overburden materials in which monitoring wells were screened. Packer pressure tests were conducted in the deep bedrock wells.

- Updated the topographic survey to include all Task 3 explorations.

- Collected air quality samples at three (3) indoor locations and one background location at the property line fence to assess volatilized contaminants.

- Evaluated and interpreted geologic, hydrogeologic, and chemical data to provide an understanding of site conditions.

- Identified potential receptors of site-derived chemicals.

- Developed a proposed outline for a Task 4 program to assess risks on-site and at the site boundaries.

A detailed discussion of the scope of work and analytical results were presented in the Phase II Remedial Investigation Report submitted to NYSEG in June 1992.

3.4 TASK 4 RISK ASSESSMENT

The scope of the Task 4 Risk Assessment was developed based on information obtained during Tasks 1 through 3. The Risk Assessment was designed to

(1) identify and assess the potential risk associated with exposure to the chemicals present on-site, and (2) evaluate the need for and develop, if necessary, the scope for Conceptual Design (Task 5).

The subtasks completed as part of the Task 4 Risk Assessment included the following:

- Reviewed and summarized the Tasks 2 and 3 field investigation findings on the distribution of chemicals present on-site.

- Selected the contaminants of concern identified on-site that represent potential hazards at the site.

- Identified the possible pathways of exposure and potentially exposed populations at and near the site.

- Identified the potential hazards associated with exposure to the contaminants of concern including acute and chronic toxic effects of the compounds.

- Identified the dose/response data used to quantitatively assess risk (e.g., U.S. Environmental Protection Agency [USEPA] cancer potency factors and reference doses).

- Compared the environmental concentrations of chemicals on-site to existing state and federal health-based criteria and standards.

- Characterized the human health and environmental risks associated with exposure to site-related chemicals.

- Established the Target Clean-up Levels (TCLs) to protect against future potential exposure to contaminants of concern.

- Evaluated the need for a conceptual Remedial Design (Task 5).

The Baseline Risk Assessment is presented in Section 6.0 of the Phase II Remedial Investigation Report submitted to NYSEG in June 1993. A summary of the results and conclusions are presented in Subsections 3.5 and 3.6 of this report.

3.5 SUMMARY

Site Setting, History

The Task 1 report identified potential environmental problems in soils, groundwater, surface water and air. From the site reconnaissance, interviews, and file reviews, it was concluded that:

- Land use in the vicinity of the site is both residential and commercial. Day-care centers, schools, recreational areas, nursing homes, and elderly housing projects are located within a half-mile radius of the Mechanicville site.

- Coal gas was produced at the site for fifty-four (54) years, from 1901 to 1955;

- Coal tar residues accumulated in the base of the relief gas holder;

- Condensate from the water gas process was treated in a tar dehydrator and filter bed system before being discharged into the Anthony Kill;

- Residual ash from the gas generator was reportedly stored on the site before removal by various users;

- Wood chips and oxide wastes from the purifying house were hauled off-site for final disposal. Some spent chips may have been spread on the lot west of the active plant area.

Geology, Hydrogeology

The findings of the field investigations and analytical programs conducted during Task 1, Task 2, Task 3, and Task 4 at the site are summarized as follows:

- The shallow geology consists of 8 to 25 feet of heterogeneous fill deposits including a silty sand and gravel, a clayey silt and fractured shale, and a silty shale, all overlying fractured shale bedrock.

- The water table is approximately 5 to 10 feet below ground surface (bgs). Groundwater movement is principally within the silty shale and underlying bedrock fractures which are prevalent in the upper 10 feet of bedrock.

- Regional groundwater flow is west to east across the site, toward the Hudson River. Locally, groundwater flows to the north-northeast, discharging to the Anthony Kill.

Figure 3-3 shows sampling locations by task.

3.5.1 Nature and Extent of Contamination

Surface Soil

No PCBs were detected in any of the collected surface soil samples. This includes sample SS-5, which was obtained next to the PCB waste-oil drums. Additionally, no volatile organic compounds (VOCs) were detected in samples SS-1 through SS-5. A trace of bromomethane was detected in sample SS-3, but at a concentration below the detection limit for that sample. In addition, this compound was not detected in the duplicate sample, SS-3A. Cyanide was detected in two (2) surface soil samples, SS-1 and SS-3A (no cyanide was detected in the replicate sample SS-3) at 1.8 and 1.9 ppm, respectively. Both samples were collected from the area behind the garage offices and storeroom building, along the upper bank of the Anthony Kill. Several polycyclic aromatic hydrocarbons (PAHs) were detected in samples SS-1 through SS-4, including the duplicate

sample. Concentrations of total PAHs ranged from 9.1 to 71 ppm. No PAHs were detected in sample SS-5. Bis(2-ethylhexyl)phthalate (BEHP) was found in insignificant concentrations in two samples plus the duplicate sample. Although this compound is a common laboratory contaminant, no BEHP was detected in the laboratory blank; therefore, this compound is considered to be present in the surface soil. One other semi-volatile organic compound (SVOC), di-n-butyl phthalate, was detected in several samples. However, this is also a common laboratory contaminant and was found in the laboratory blank at similar concentrations. Therefore, this compound was not considered to be present in surface soils at the site.

Subsurface Soil

Analyses of subsurface soil samples from the field investigation program showed the presence of coal tar and MGP-related compounds (i.e., VOCs, PAHs, and cyanide) near the former relief gas holder, purifier and oxide houses, and filter beds. The highest levels of VOCs and PAHs were detected in samples collected at or near these sites. The highest levels of VOCs (3,800 and 3,410 ppm) were observed in samples collected from B-8 (at depths of 13.5 to 15.5 feet and 15.5 to 17.5 feet), which is located beneath the foundation of the former gas relief holder. The highest levels of PAHs were observed in samples obtained from B-8 (5,440 ppm), TP-5 (8,500 ppm; adjacent to the filter beds), and B-3 (9,310 ppm in the vicinity of the former purifier and oxide houses). Deep soil samples (deeper than 15 feet) contained lower levels of organics than the samples collected from shallow soils.

Iron levels ranged from 18,000 to 35,000 ppm. The lower concentrations were in the deeper fine silty sand. Higher levels were seen in shallow fill samples. Zinc levels generally ranged from 32 to 390 ppm, except for one Task 2 sample (B-5/S-1), which contained 1,600 ppm.

Cyanide was detected in three (3) subsurface soil samples at levels ranging from 1 to 3.2 ppm. These samples were collected in the vicinity of the former purifier and oxide houses. The concentration of cyanide in this area is most likely due to spillage during cleaning of the purifier house (Wilson and Stevens, 1981).

Phenolic compounds were found in four (4) soil boring samples at depths of 4 to 11 feet. Concentrations ranged from 0.74 to 3.6 ppm. These samples were collected in the vicinity of the former filter beds and the former gas and purifier houses. Phenolics are widely distributed in the environment due to both natural (i.e., vegetative decomposition) and man-made processes. Tars and wastewaters at coal gas plants are a source of phenolics; however, the tars produced by water gas plants such as the one at Mechanicville usually contain only negligible amounts of phenolics.

Groundwater

Cyanide was detected in all wells except MW-11. The highest levels of total cyanide (0.58 to 0.8 ppm) were observed at MW-12 during Task 3. During Task 2, a maximum level of 0.42 ppm was reported at MW-3. Well MW-12 is located downgradient from the former relief gas holder while MW-3 is downgradient from the former purifier/oxide structures.

Volatile aromatic compounds, a subset of VOCs, were detected consistently in all wells except MW-1, MW-2, and MW-11. MW-1, MW-10, and MW-11 are located upgradient of the former coal gasification plant. MW-2 is downgradient from the former distribution gas holder, but soils data from B-2 and B-7 suggest little or no contamination in this area. Concentrations in the bedrock wells (MW-6, MW-13, MW-14, and MW-15) were generally greater than those detected in the shallow wells. Other VOCs, including 1,1,1-trichloroethane, 1,1-dichloroethane, and trichloroethylene were detected in several samples. These compounds show no spatial pattern of occurrence (i.e. shallow versus deep, upgradient versus downgradient) and are not typically associated with MGP-associated wastes. They are not believed to be site-derived (E.C. Jordan Co., 1989; GRI, 1987).

PAHs were observed in at least one (1) sample from all wells except MW-1, MW-2, and MW-11. The average concentrations of all the samples collected at each well ranged from nondetectable (at MW-1, MW-2, and MW-11) to 0.75 parts per billion (ppb) at MW-12. The maximum levels of 1500 and 1564 ppb were observed at wells MW-12 and MW-5, respectively. The distribution of PAHs in the groundwater is similar to the distribution in the soil, indicating that contaminated soil is associated with PAHs in the groundwater.

The groundwater sampling data indicate that the detected PAHs are particulate in nature, rather than dissolved species. Some measured concentrations greatly exceed the solubility of PAHs in water. The solubility of PAHs ranges from 0.50 ppb for dibenzo(a,h)anthracene to 620 ppb for indeno(1,2,3-cd)pyrene. Thus, the groundwater concentrations must not be indicative of dissolved PAH concentrations. This conclusion is consistent with the sampling protocol, because

groundwater samples for organics are not filtered prior to analysis for organic contamination.

Dissolved iron was present in at least one (1) sample from every well. Wells MW-1, MW-2, MW-10, and MW-11, considered to provide the most representative background concentrations, contained concentrations ranging from 0.04 to 1.4 ppb. The wells with the highest concentrations of dissolved iron were MW-3, MW-4, MW-5, MW-6, and MW-12. These were the same wells with the highest concentrations of PAHs.

Dissolved zinc was detected at least once in every well. Samples from MW-4 and MW-5 contained unusually high levels (0.52 to 1.09 ppb). Samples from other wells showed fairly uniform concentrations (0.01 to 0.11 ppb). This uniformity suggests that zinc is a natural constituent of site groundwater which has not been elevated by site activities (E.C. Jordan Co., 1989).

Total recoverable phenolics were detected in all wells. The maximum concentration in shallow wells was 17 ppb while the maximum concentration in deep wells was 0.3 ppb.

Surface Water

No volatile aromatics were detected in any surface water samples. PAHs were detected once at the location adjacent to the site at a concentration of 0.105 ppb. Other organics detected during Task 2 included methylene chloride (upstream), acetone (adjacent), and BEHP (all locations). These compounds were found at

concentrations less than 0.1 ppb. They were also found in some sampler and trip blanks. During Task 3, BEHP was found upstream on both sampling occasions at concentrations less than 0.5 ppb; it was not found adjacent or downstream of the site. These three contaminants (methylene chloride, acetone, and BEHP), when present at low concentrations, are common laboratory contaminants. It is unlikely that they are derived from the site (GRI, 1987).

Iron was found at all four locations at levels ranging from 0.2 to 1.8 ppb. The highest concentration was found adjacent to the site. Zinc was detected in at least one (1) sample from three (3) locations; only the downstream sample collected during Task 3 had no detectable zinc. Concentrations ranged from 0.01 to 0.03 ppb. Phenolics were detected in at least one (1) sample from all locations except the upstream and adjacent locations sampled during Task 3. Cyanide was not detected in any of the Task 3 samples. It was detected in at least one (1) sample in each Task 2 location.

Sediment

Three VOCs were detected in the sediments. During Task 2, Round 3 sampling, benzene and toluene were found at a concentration of 0.07 ppm, adjacent to and downstream from the site. During Task 3, ethylbenzene was detected at a level of 0.087 ppm adjacent to the site, along with a trace concentration of benzene. These contaminants are associated with coal tar wastes as well as petroleum products and industrial chemicals.

Analysis of Task 2 and Task 3 sediment samples indicated that PAH concentrations adjacent to the site are elevated compared to upstream and downstream sampling locations. Sampling location SD-2 contained trace levels up to 75.8 ppm of total PAHs during Task 2 sampling, and trace levels to 5.1 ppm during Task 3 sampling.

Concentrations of iron and zinc were fairly consistent in the four (4) locations. Iron concentrations ranged from 7,100 to 33,100 ppm, while zinc concentrations ranged from 25 to 100 ppm. Cyanide compounds were not detected in any Task 2 samples, while in Task 3 a cyanide level of 1.3 ppm was detected adjacent to the site. Phenolics were detected in Task 2 Round 4 samples at all three (3) locations at comparable levels (1.8 to 6.1 ppm). During Task 3, phenolic levels ranged from 0.68 to 2.3 ppm.

Indoor Air

The results of the indoor air program revealed low levels of benzene and toluene at most sampling locations. The only exception was benzene, which was not being detected in the background sample. Ethyl benzene and xylenes were below analytical detection limits for all samples.

The highest indoor levels of toluene and benzene were found in the storeroom. A possible source of benzene in the storeroom may be a forklift used in this area. Although the engine was not running during the sampling period, it is possible that residual gasoline vapors had volatilized into the air. Toluene was detected in the background sample at higher levels than two (2) of the indoor samples. It was

highest in the garage. It is possible that the sample was affected by vehicle use in the area.

Contaminants of Concern

No contaminants of concern were chosen for surface water or groundwater. This is because there was no indication of site-related surface water contamination, based on the Task 2 and 3 surface water sampling results. Also, groundwater is not a current source of drinking water nor does it represent a potential source for the future. Therefore, ABB-ES' evaluation of the risks associated with groundwater consumption is limited to a comparison of the concentrations found to groundwater or drinking water standards.

Chemicals were selected as contaminants of concern in subsurface soil, sediment, and indoor air based upon their concentrations, frequency of detection, and toxicologic properties. All chemicals detected in surface soil samples SS-1 through SS-4 were chosen as contaminants of concern for this medium. All the contaminants of concern are associated with coal gasification activities.

Both carcinogenic and noncarcinogenic PAHs were detected at a high frequency and magnitude. Of the sixteen (16) PAHs detected at the site, seven (7) have been classified as potential human carcinogens and were selected as contaminants of concern: benzo(b)fluoranthene, benzo(k)fluoranthene, benzo(a)anthracene, benzo(a)pyrene, chrysene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene. In addition, several PAHs were chosen as contaminants of concern to represent the noncarcinogenic hazards of PAHs: naphthalene, pyrene, acenaphthene,

acenaphthylene, phenanthrene, fluoranthene, fluorene; anthracene, 2-methylnaphthalene, and benzo(g,h,i)perylene.

Although iron and zinc were found in all samples, they were not selected because they are of such low toxicity. In addition, levels in soil were similar to background levels at the site, while levels in sediment were within an average background range. Other compounds such as acetone, BEHP, butylbenzyl phthalate, di-n-octyl phthalate, carbon disulfide, 4-methylphenol, and propyl benzene were not chosen because of their low frequency of detection. In addition, some of these compounds are common laboratory contaminants and therefore may not actually be present on the site.

3.5.2 Fate and Transport

Chemicals related to former MGP activities are present in the soils and in the shallow and deep groundwater near the former gas plant structures; specifically, the purifier and oxide houses, the relief gas holder, and the filter beds. The concentrations of six (6) compounds (i.e., benzo(a)pyrene, benzene, styrene, total cyanide, iron, and phenolics) and total organics in shallow and deep groundwater exceeded the relative New York State Drinking Water Standards. Benzene and toluene were found in all air quality samples collected, but concentrations did not exceed applicable Occupational Safety and Health Administration (OSHA), American Conference of Governmental Industrial Hygienists (ACGIH), and National Institute for Occupational Safety and Health (NIOSH) standards.

The primary routes identified for off-site chemical migration are via groundwater in the shallow and deep bedrock fractures, and the silty shale fill. Chemical migration is influenced by an east-trending shallow bedrock trough located downgradient of the relief gas holder.

Migratory pathways for chemical migration or transport off-site include air (primarily during excavation of site soils), surface water, groundwater, and sediments.

Potential receptors for chemicals found at the site include more sensitive segments of the population, including the elderly, young children, and the infirm. Additionally, people in the vicinity of the site may be exposed to airborne chemicals predominantly during excavation activities.

3.5.3 Risk Assessment

The significant findings of the Risk Assessment were as follows:

- The contaminants of concern identified in the soil and sediment at the site include carcinogenic PAHs and benzene and several noncarcinogens (toluene, ethylbenzene, styrene, PAHs, trimethylbenzene, xylenes, and cyanide).

- For the public health risk assessment, ABB-ES identified probable exposure pathways by which people could come in contact with site-derived chemicals under current and future conditions, assuming no

remedial action at the site. These included the following: direct contact with and incidental ingestion of surface soil, subsurface soil, and Anthony Kill sediment, and inhalation of volatile compounds and soil particulates.

- Potential carcinogenic and noncarcinogenic risks to human health were estimated under these assumed exposure pathways. Estimated incremental lifetime carcinogenic risks were within the target risk range for both the most probable and realistic worst exposure scenarios, for all of the exposure pathways identified. (USEPA guidelines state that the total incremental carcinogenic risk for an individual resulting from exposure at a hazardous waste site is generally within a range of 10^{-4} and 10^{-6} with a risk of 10^{-4} interpreted as an additional 1 in 10,000 chance of an individual developing cancer during a lifetime, as a result of the exposure.)

- The noncarcinogenic Hazard Indices (HIs) were all well below the cutoff of 1.0, indicating that no significant adverse noncarcinogenic effects would be expected.

- Because Mechanicville site groundwater is not currently used or expected to be used in the foreseeable future as a source of drinking water, public health risks associated with the groundwater are negligible. Groundwater beneath the site, however, does contain several contaminants at levels above both USEPA and New York drinking water standards.

- It is unlikely that the site is significantly utilized by wildlife because of the industrial nature of the area and the lack of suitable habitats. Aquatic organisms in the Anthony Kill, immediately adjacent to the site, were determined to be the environmental receptors most likely to be affected by site-related contamination.

- Contaminated groundwater from the site is discharging to the Anthony Kill; however, due to the dilution, volatilization of VOCs, and sorption of PAHs to soils (PAHs are relatively insoluble in water), no detectable concentrations of site related contaminants are present in surface water samples collected from the Anthony Kill.

3.6 CONCLUSIONS

The conclusions from the Tasks 1 through 4 field investigations and analytical programs are summarized as follows:

- The soils and groundwater in the former active plant area contain chemicals related to the coal gasification process.

- Coal gasification wastes in the subsurface environment are a continuing source of chemicals to soil and groundwater, and groundwater is the primary vehicle of transport.

- Downward seepage gradients within the bedrock trough near North Central Avenue may be carrying chemicals down into shallow and deeper bedrock fractures.

- Compounds are migrating northeasterly in the groundwater at the site, towards the Anthony Kill. The Anthony Kill is a groundwater discharge zone; however, dilution effects, volatilization, and sorption to soils result in the absence of detectable concentrations of VOCs or PAHs in surface water.

- Under current site conditions, the potential for public exposure to the contaminants of concern is low, for two reasons: (1) most of the site is paved or covered with buildings and access to the site is limited, restricting the possibility of contact with contaminated soil or volatilized contaminants; and (2) the groundwater at the site is not used as a drinking water source.

- Therefore, ABB-ES concludes that, under the assumed conditions of exposure, no significant adverse health effects would be anticipated.

- The results of the environmental risk assessment indicate that some potential for impacts does exist for aquatic organisms living in the Anthony Kill immediately adjacent to the site. However, these risks appear relatively minor, for several reasons. Few compounds were present at levels in excess of their environmental criteria, the extent of exceedances was minimal, and potential impacts were associated

only with "worst case" conditions, with no impacts expected under typical conditions. Also, the amount of benthic habitat is limited due to the streambed morphology and exposed bedrock, with little sediment accumulation.

- Finally, there is no evidence that contaminants are being transported downstream at significant levels. Levels of contaminants in the downstream surface water and sediment samples did not exceed protective criteria, even under the most conservative assumptions.

3.6.1 Data Needs and Recommendations for Future Work

Data needs have been identified that must be addressed to meet the requirements of the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) for Remedial Investigations. These data needs are as follows:

- Delineate the nature and extent of site-related contamination east of North Central Avenue. An east-trending bedrock trough was identified in the area of the former relief gas holder and a component of groundwater flow at the site is in an easterly direction.

- Investigate the western portion of the site for groundwater and soil contamination due to the possible disposal of wood chips and oxide wastes in this area. The nature of shallow subsurface anomalies identified during the Task 1 GPR survey will also be assessed.

- Several areas on the eastern and western portions of the site were identified as having been storage areas for PCB-containing transformers and capacitors as well as various electrical equipment. Sampling of these areas for PCB contamination is necessary.

- Investigate the property north of the Anthony Kill across from the site to establish whether a hydraulic connection exists between site groundwater and groundwater north of the Anthony Kill. If a hydraulic connection exists, collection and chemical analyses of groundwater samples may be necessary to evaluate any impacts to groundwater quality caused by the site.

- As has been done in the past, the site Health and Safety Plan (HASP) should be followed during any future exploratory work on the site to prevent or minimize undue exposure.

3.6.2 Recommended Remedial Investigation Objectives

To address the data needs identified in the previous subsection, the Phase IIA Supplemental RI Work Plan was developed. On- and off-site investigation activities are proposed to (1) investigate the potential for PCB contamination on the site, (2) determine the nature and effect of site-derived contamination east of the site, (3) determine if a hydraulic connection exists between the site groundwater and groundwater north of the Anthony Kill, (4) further define the areas and rates of site groundwater discharge to the Anthony Kill, and (5) assess the potential for site-related contamination on the western portion of the site.

4.0 SUMMARY OF PHASE IIA SUPPLEMENTAL RI FIELD PROGRAM

This section presents a summary of the Phase IIA Supplemental RI field work activities. A more detailed description of the Phase IIA Supplemental RI field work activities is provided in the Workplan for Phase IIA Supplemental Remedial Investigation (Section 8.0 of the June 1992 Phase II Supplemental RI Report).

4.1 GEOPHYSICAL INVESTIGATION

A seismic refraction survey was conducted on the Price Chopper property, located directly across North Central Avenue from the site (Figure 4-1). The survey was performed by an experienced ABB-ES geophysicist using a Geometrics ES-2415F Signal Enhancement Seismograph. Individual seismometers (geophones) were separated by 10 feet, and multiple impacts of a 10-pound sledgehammer were used for an energy source. Three (3) impact points were used for each seismic spread. Due to the limited size of the site, the average length of the spreads was 120 feet.

4.2 SOIL INVESTIGATION

The following activities were completed during the soil investigation:

- the investigation of soil conditions east (downgradient) of the site, to assess the potential migration of MGP-related contaminants in this direction;

- the investigation of soil conditions west (upgradient) of the site;

- the investigation of surface soil (0 to 1 foot bgs) conditions in areas formerly used to store transformers, capacitors and other miscellaneous electrical equipment;

- the investigation of surface soil (0 to 1 foot bgs) conditions in the western portion of the site where wood chips and spent oxide wastes may have been periodically disposed.

The locations of all Phase IIA Supplemental RI explorations are shown on Figure 4-2.

4.2.1 Surface Soils (0 to 1 foot bgs)

Surface soil sampling locations are shown on Figure 4-2 and 4-3. Analytical data relating to the surface soil sampling locations are discussed in Subsection 5.2 and summarized in Tables 5-1 and 5-2.

Shallow Subsurface Soil Conditions, in the Western Portion of the Site

Six (6) surface soil samples including one (1) duplicate sample were collected from the western portion of the site for laboratory analyses and analyzed for reactive sulfide and reactive cyanide. All samples were collected from the 0 to 1 foot bgs interval using pre-cleaned stainless steel spoons and bowls. Samples located under asphalt were collected from the 0.25 to 1 foot bgs interval.

Surface Soil Conditions Under Former Transformer Storage Areas

A total of twenty-one (21) surface soil composite samples, including two (2) duplicate samples, were collected and laboratory analyzed for PCBs. The samples were collected from six (6) former transformer storage areas. Four (4) samples were collected from within each of the reported transformer storage areas designated Areas 3, 4, 5, and 6 (see Figure 4-3). Each sample consisted of a composite of four (4) sub-areas. Samples were collected from the 0 to 1 foot bgs interval using pre-cleaned stainless steel spoons and composited in stainless steel bowls. According to photographs, site maps, and interviews with NYSEG employees, transformer storage Area 2 had historically been paved. Based on this information and with the concurrence of the NYSDEC project manager, one (1) sample of accumulated soil was collected from the surface of the asphalt. In transformer storage Area 1, with prior approval of the NYSDEC project manager, two (2) soil samples were collected; one (1) from the accumulated soil from the surface of the asphalt and one (1) shallow subsurface sample (0.15 to 1 feet bgs) collected from beneath the asphalt.

4.2.2 Subsurface Soil (below 2 feet bgs)

Three (3) soil borings (B-16, B-17 and B-18) were drilled during the Phase IIA Supplemental RI field program and completed as groundwater monitoring wells (MW-16, MW-17, and MW-18), respectively. Soil boring/groundwater monitoring well locations are shown on Figure 4-2. Completion of monitoring well borings is discussed in Subsection 4.3.

Two (2) of the borings were completed in the overburden and one (1) (MW-18) was completed in bedrock. Field observations were made on all soil and bedrock samples collected and each soil boring was logged with respect to geologic/soil characterization. Field boring logs and rock core identification logs are presented in Appendix A.

Soil samples (or rock cores) were collected continuously during drilling of all soil borings. Soil samples were collected using a 3-inch outside diameter (OD) split-spoon sampler. All samples were field characterized and instrumentally screened for evidence of VOCs. Rock cores were retrieved using NX core rods and core barrels were then placed in wooden core boxes and stored on site. Three (3) subsurface soil samples, including one (1) duplicate, were submitted for laboratory analyses. Samples were analyzed for VOCs, SVOCs, selected inorganics and total cyanide, reactive cyanide, and reactive sulfide.

4.2.3 Investigation of Former Filter Bed Area

With the concurrence of the NYSDEC project manager, six (6) additional soil borings (borings B-20 through B-25) were completed to investigate subsurface soil conditions in the former filter bed area. The purpose of these borings was to, if possible, locate and sample the residual filter bed material. Field observations were made on all soils samples collected and logged with respect to geologic/soil characterization. Field boring logs are presented in Appendix A.

Soil samples were collected continuously using a 2-inch OD split-spoon sampler. All samples were field characterized and instrumentally screened for evidence of contamination.

4.3 GROUNDWATER INVESTIGATION

4.3.1 Groundwater Monitoring Well Installation

One (1) shallow groundwater monitoring well (MW-16) was installed to characterize groundwater conditions in the overburden soils upgradient of the site. Two (2) collocated groundwater monitoring wells, one (1) screened in the overburden and one (1) screened in the bedrock (MW-17 and MW-18, respectively) were installed downgradient of the site at a location on the Price Chopper property based on the results of the seismic survey.

The overburden groundwater monitoring wells, MW-16 and MW-17, were advanced using 4.25-inch inside diameter (ID) hollow-stem augers. The borings were advanced to competent bedrock which was encountered at depths of 8 and 22.5 feet bgs respectively. The bedrock groundwater monitoring well was advanced to bedrock using the 4-inch ID steel casing and the drive and wash method. The casing was seated approximated 2 feet into the bedrock. The boring was then advanced 15 feet into the bedrock using an NX size core barrel.

All monitoring well screens and risers were constructed of 2-inch ID Schedule 5 stainless steel. The well screens were #10 slot wire-wound and 10 feet in length. Well materials were pre-cleaned by steam-cleaning prior to installation. A sandpack was installed in the annulus between the borehole wall and the screen. The sandpack material, Morie 0 silica sand, was placed at a minimum of 2 feet above the top of the screen. A minimum of 2 feet of bentonite pellets/slurry was placed above the sandpack. Pellets were hydrated with potable water upon installation and allowed adequate time to swell. The remainder of the borehole was backfilled with wet bentonite-cement grout.

Monitoring wells were protected against tampering by installing water-tight, flush-mounted locking curb boxes set in place with a minimum of 2 cubic feet of concrete. After the wells were installed and water levels had equilibrated, water level measurements were recorded.

The elevation of the well risers were surveyed and recorded by David Flanders Associates, Inc. (FLANDERS) (also see Subsection 4.10)

The monitoring well installation diagrams are included in Appendix A. Details of the well installations are listed in Table 4-1.

4.3.2 Piezometers

Seven (7) piezometers (P-3 through P-9) were installed to investigate groundwater flow along the north and south banks of the Anthony Kill. P-10 could not be installed due to the lack of an adequate depth of soil/sediments in the area. Piezometers were constructed of hand slotted 1-inch ID Schedule 40 polyvinyl chloride (PVC), installed in pre-driven holes and cemented in place.

4.3.3 Monitoring Well Development

All three (3) Phase IIA Supplemental RI monitoring wells were developed by pumping using a down hole Whalco submersible pump and periodically stressing the formation with surge and block. A minimum of three (3) well volumes were removed from the well in addition to any volume of water introduced to the formation during drilling activities. At the conclusion of development, purge water clarity varied from clear (MW-17 and MW-18) to slightly turbid (MW-16). Development water was collected in 55-gallon drums, and discharged into the recharge well on-site.

4.3.4 Groundwater Sampling

One (1) round of groundwater sampling, associated with the Phase IIA Supplemental RI field program, was conducted at the site. Monitoring wells were

sampled between 13 and 15 July 1993. Only wells in which no evidence of free-product was observed were sampled.

Prior to sample collection, all wells were checked for both light and dense non-aqueous phase liquids (L and DNAPL [i.e. free product]) utilizing an interface probe. To assure accuracy of the probe, dedicated stainless steel washers were used to sound the bottom of the well instead of the interface probe. If DNAPLs were present, they would be visible on the retrieved washers. LNAPL was observed in one well (MW-3) and DNAPL was observed in five (5) wells (MW-4, MW-5, MW-6, MW-10, and MW-12).

Wells that did not show the presence of free-product were then purged of a minimum of four (4) well volumes. In situ parameters (pH, specific conductivity, and temperature) were recorded periodically during purging. After the field parameters and turbidity stabilized, (typically four [4] to six [6] well volumes) the wells were sampled.

A dedicated Teflon bailer was used to sample each well. After sampling both bailers and pump tubing were containerized with the soil cuttings in U.S. Department of Transportation (DOT) approved 55-gallon drums for off-site disposal.

Samples were submitted to Galson Laboratories (GALSON) of Syracuse, New York. Groundwater samples were collected in appropriate containers supplied by GALSON, preserved in accordance with the Quality Assurance Project Plan (QAPP), and chilled to 4°C prior to priority overnight shipment to GALSON.

Samples were analyzed for VOCs, SVOCs, filtered and unfiltered inorganics, total cyanide (including amenable and iron cyanide), and turbidity.

Water level measurements were taken from all sampled monitoring wells and piezometers. Water levels were measured to the nearest 0.01 foot. Groundwater elevation data are presented in Table 4-2.

4.4 Hydraulic Conductivity and Permeability Testing

In situ hydraulic conductivity tests, commonly referred to as slug tests, were performed on the three (3) Phase IIA Supplemental RI monitoring wells. Data were recorded using a pressure transducer and a Hermitt 2000 data logger. Data were reduced using Aqtesolv software. Permeabilities were calculated using the Bouwer and Rice method. Because the shallow bedrock is highly fractured, it hydraulically resembles a porous media. Data from slug tests performed at MW-18, screened in the shallow bedrock, were treated the same as MW-16 and MW-17, screened in the overburden. Although different methods were used during the Phase IIA Supplemental RI, as compared to previous investigations, calculated values were consistent with previous findings. Hydraulic conductivity data is presented in Appendix B.

4.5 SEDIMENT AND SEEPAGE INVESTIGATION

The primary objective of the seepage and sediment investigation was to evaluate the quality of groundwater discharge (i.e., seepage) to and sediments in the Anthony Kill at locations upstream of, adjacent to, and downstream of the site.

Sediment samples were collected from the bed of the Anthony Kill using a pre-cleaned stainless steel spoon and bowl. Sediments were placed in appropriate jars and labeled in the field with date, time, and location. Sediment samples were screened with a photoionization detector (PID) meter and infrared spectroscopy (IR) and ultraviolet (UV) fluorescence to select specific samples for laboratory analyses. The sediment samples were submitted to GALSON for laboratory analysis for VOCs, SVOCs, metals, total cyanide, and reactive sulfide and cyanide. Locations of the sediment samples are depicted in Figure 4-2.

Four (4) seepage meters were constructed and installed into the bed of the Anthony Kill. The seepage meters consisted of the top (or bottom) third of a 55-gallon steel drum, with 3/8 inch tubing secured with water/air-tight seals. A catheter bag was then attached to the tubing. The locations of the seepage meters are depicted on Figure 4-2.

Seepage samples were collected from seepage meters SP-1, SP-2, and SP-4. Seepage meter SP-3 produced insufficient discharge to collect a sample. Total sample volume and collection time were noted for computation of discharge flow rates. Samples were analyzed for VOCs and for SVOCs, when sufficient volume was available (SP-1 and SP-2).

4.6 LABORATORY ANALYTICAL METHODS

4.6.1 Laboratory Analytical Parameters/Methods

Several analytical methods were employed to analyze the samples collected during the Phase IIA Supplemental RI field program. Six (6) surface samples, including one (1) duplicate, were analyzed for reactive sulfide and reactive cyanide by USEPA Method 9030 and Method 9010 respectively. Twenty-one (21) surface soil samples, including two (2) duplicates, were analyzed for PCBs utilizing NYSDEC Analytical Services Protocol (ASP) 91-3.

Parameter groups selected for laboratory analyses of subsurface soil, groundwater and sediment and seepage samples collected at the site were as follows:

- VOCs using NYSDEC ASP 91-1 and 91-4;
- SVOCs using NYSDEC ASP 91-2;
- Metals (both total and dissolved metals for groundwater samples) using ASP Superfund Contract Laboratory Program (CLP) analytical methods;
- Reactive sulfide using USEPA Test Method 9030 (soil and sediments only);
- Reactive cyanide using USEPA Test Method 9010 (soil and sediments only);
- Turbidity using USEPA Test Method 180.1 (groundwater only); and

- Total and amenable cyanide using USEPA Test Method 9010.

4.6.2 Data Validation

Samples collected during the Phase IIA Supplemental RI field program were subjected to analytical data validation by ABB-ES in accordance with Quality Assurance Data Validation of Analytical Deliverables and the QAPP.

The analytical results for VOCs, SVOCs, inorganics, reactive sulfide and cyanide, and PCBs are generally acceptable and, in most instances, may be used without qualification. A limited number of samples for various analyses were "flagged" with a variety of laboratory analytical qualifiers. Descriptions of data qualifiers along with their flagged symbols are detailed within the validation report in Appendix C-1. Appendix C-2 contains a presentation of the validated data with sample detection limits and data qualifiers flagged for the Phase IIA Supplemental samples.

4.6.3 Data Reduction

The reduced data tables presenting only analytical results reported in concentrations above the laboratory detection limits is presented in Tables 5-1 through 5-8. Results from these tables have undergone sorting and organization for incorporation and presentation in connection with this Phase IIA Supplemental Report.

4.7 Decontamination and Residuals Management

Equipment decontamination during the Phase IIA Supplemental RI field program was conducted in accordance with Subsection 9.0 of the QAPP. All drilling equipment (e.g., drill rig, split-spoon samplers) was decontaminated on-site in a specially constructed decontamination pad. Decontamination fluids were contained either within the decontamination pad or in 55-gallon drums. Soil cuttings and dedicated sampling equipment were containerized in DOT-approved 55-gallon drums. Drums were numbered and labeled specifying content, date, and location. Drums were also tracked in the field log book. Cuttings samples were collected from the drums and analyzed for toxicity characteristic leaching procedure (TCLP) VOCs, SVOCs and inorganics. NYSEG has arranged for the removal and off-site disposal of all drummed residual material.

4.8 Site Topography

A two-phased topographic survey of the site and portions of the adjacent properties was performed by FLANDERS. The first phase was completed on June 26, 1986 and resulted in a topographic base map at a scale of 1 inch equals 50 feet, with 2-foot elevation contours. This map contained exploration locations (Tasks 2, 3 and 4 activities), significant surface features, landmarks of the site, and the portion of the Anthony Kill directly adjacent to the site.

The second phase of the topographic survey was conducted on May 24, 1993. The revised topographic map included the Phase IIA Supplemental exploration locations and significant features and landmarks of the land west of the site, currently occupied by the Price Chopper. The portion of the Anthony Kill adjacent to the Price Chopper was also included in this survey.

During both phases, the topographic map assumed a relative horizontal and vertical datum of 100 feet at the railroad spike in the utility pole located 25 feet south of the intersection of Ferris Lane and North Central Avenue. The location and elevations of monitoring wells, piezometers, soil borings, shallow subsurface soil samples, and seepage meters have been incorporated into the site base map to accurately depict exploration locations (see Figure 4-2 and Figure 4-3). Figure 4-2 depicts exploration locations. Figure 4-3 depicts surficial topography.

5.0 SITE TOPOGRAPHY, GEOLOGY, AND HYDROGEOLOGY

5.1 INTRODUCTION

Data relative to classification of the surface and overburden soils and bedrock at the site were compiled by ABB-ES geologists from an examination of soils and rock cores collected during the Tasks 2, 3, 4, and the Phase IIA Supplemental RI field investigation programs. Examination and classification of the soils were in accordance with the Unified Soil Classification System (USCS). Observations on Phase IIA Supplemental excavations were recorded on soil boring logs and visual rock identification logs and are included in Appendix A.

5.2 SITE TOPOGRAPHY

The original geomorphology of the site has been altered through cultural activities (e.g., construction and high use). During the Phase IIA Supplemental RI, the topographic survey was expanded to include the area east of the site, across North Central Avenue which is principally occupied by a Price Chopper grocery store and parking lot. The surficial topography of the Price Chopper parking lot is relatively flat. Just beyond the northern border of the pavement, the ground surface slopes abruptly downward, approximately 12 to 14 feet to the Anthony Kill. The parking lot drains to the north through a storm culvert that discharges into the Anthony Kill near the North Central Avenue Bridge.

5.3 SITE GEOLOGY

The geologic strata encountered in soil borings indicate that the original ground surface has been reworked and covered with fill. The fill is underlain by a gravelly sand that grades to a silty shale (highly weathered bedrock). The underlying shale bedrock is located 8 to 23 feet bgs.

Three (3) geologic cross-sections have been prepared to visually depict the shallow geology encountered. The location and orientation of the three (3) transects are shown in Figure 5-1. The first cross-section A-A' (Figure 5-2) traverses the eastern border of the site, parallel to North Central Avenue. The second cross-section B-B' (Figure 5-3) traverses the site in a north-south direction, through one of the former gas holders and the filter beds. The third cross-section C-C' (Figure 5-4) traverses the site approximately parallel to the Anthony Kill.

5.3.1 Overburden

The overburden soils consist of fill, gravelly sand and fractured silty shale (weathered bedrock). Small discontinuous lenses of sand and gravel as well as silty clays are also present. The different soil units present at the site are described as follows:

- Fill. The fill consists of brown to black silty sand and gravel with organic matter, ash, brick fragments, glass, and wood chips. Within the fill, heterogeneities include zones of clayey silt and fractured

shales. The fill averages 8 to 28 feet thick, thinning toward the Anthony Kill.

- Gravelly Sand. A brown, dense gravelly sand was encountered at only one (1) soil boring at a depth of 8 feet bgs. The gravelly sand unit is 1.5 to 4 feet thick. This may be interpreted as fill or, if the area has not been disturbed, a glaciofluvial deposit.

- Glacial Till. A thin discontinuous tan to light grey silty clay with fine gravel was encountered at the top of the bedrock surface at soil boring B-4. The till is less than one (1) foot thick and is located along the northern edge of a small bedrock trough.

- Silty Shale. This unit is primarily highly weathered bedrock. It consists of black to gray platy shale fragments in a brown silt matrix that directly overlies the bedrock throughout the site. The native silty shale is approximately 1 to 3 feet thick. At other areas (B-4 and B-8) shale and silt fragments were possibly used as fill material. At these areas, the silty shale has no identifiable structure and is approximately 8 to 9 feet thick.

Two (2) soil borings (B-16, and B-17) were drilled during the Phase IIA Supplemental field investigation program. At boring B-16, soils consisted of fill (silt, gravel sand, glass, and brick) overlying silty shales. The fill/shale contact is at approximately 6 feet bgs. Bedrock was encountered at 8 feet bgs.

Similar soils were encountered at boring B-17. Approximately 12 feet of fill overlies silts and sands which grade to silty shales at approximately 21 feet bgs. Competent bedrock was encountered at 22.5 feet bgs.

5.3.2 Bedrock

The bedrock at the site consists of thinly bedded blue-gray shale with calcite inclusions. The bedrock outcrops at several locations along the southern bank of the Anthony Kill. The exposed bedrock is tightly folded striking east-west, with the fold axes dipping approximately 30 degrees to the south. Because the bedding with the bedrock structure is tight, bedrock groundwater flow will not follow bedding but, rather follows joints and fractures within the formation.

A seismic refraction survey was conducted in the parking lot of the Price Chopper, east of North Central Avenue, to investigate potential presence of an eastward trending bedrock valley in this area. The bedrock surface appears to be relatively flat, with the highest elevation at approximately 21 feet bgs beneath the center of the parking lot. Beneath the eastern border of the parking lot, bedrock dips gently to the east. Based on the seismic refraction data, depth to bedrock was estimated to be 21 to 23 feet bgs. Boring B-17/MW-17 and B-18/MW-18 were drilled to intercept groundwater flow downgradient from the site. In boring B-18, bedrock was encountered at 22.5 feet bgs, confirming seismic refraction data and indicating that the data could be used to map the general contours of the bedrock surface in this area. Results from the seismic refraction slurry are presented in Appendix D.

During the Phase IIA Supplemental field investigation, bedrock was encountered at 8 and 22.5 feet bgs at B-16 and B-17/B-18 respectively. Fifteen (15) feet of rock core was drilled at B-18. The bedrock was composed of blue-grey shales with calcite intrusions along fracture planes (oriented at 60 and 120 degrees from horizontal). The top 5 feet of the bedrock was highly fractured, with competency increasing with depth. These findings are consistent with previous investigations at the site. A bedrock surface contour map interpreted from the seismic surveys and exploration data collected during Tasks 1.2.3, and 4, and the Phase IIA Supplemental RI field investigation program is shown in Figure 5-5.

The topography of the bedrock surface forms a shallow basin centered beneath the eastern portion of the site and sloping to the north towards the Anthony Kill. The basin is asymmetrical in shape with the western and southern perimeters sloping upward more steeply than the eastern perimeter. Beneath the Price Chopper parking lot, the eastern slope of the basin rises to approximately 21 feet bgs and then dips gently to the east (see Figure 5-5).

5.4 SITE HYDROGEOLOGY

The interpretation of hydrogeologic conditions at the site is based on field measurements of groundwater elevations and in situ permeability tests. The water table at the site ranges from 2 to 20 feet bgs, and the saturated thickness in the overburden ranges from 3 to 25 feet. In the portion of the site where gas manufacturing took place, asphalt and buildings cover nearly all of the ground surface, thereby limiting direct infiltration from precipitation. Two storm drains

located in the northern portion of the site collect surface runoff and discharge to the Anthony Kill. As a result, infiltrating precipitation is limited to the western portion of the site that was not acquired by NYSEG until 1952. The limited rainwater infiltration into the site subsurface soils over the years has minimized the potential for contaminant transport within the overburden and bedrock.

Water level measurements were collected from piezometers and all accessible groundwater monitoring wells including the three (3) new groundwater monitoring wells: MW-16 screened in the fill and shallow bedrock; MW-17 screened in the overburden; and MW-18 screened in the shallow bedrock. Table 4-2 presents groundwater elevation data collected during Tasks 2, 3, 4, and the Phase IIA Supplemental field investigation.

Groundwater flow through the overburden is influenced by bedrock and surficial topography and by proximity to the Anthony Kill. Based on information from the piezometers and the new and existing monitoring wells, the estimated direction of overburden groundwater flow is northeasterly, towards the Anthony Kill. With the additional data points at monitoring wells MW-16, MW-17, and MW-18, groundwater flow direction is interpreted to flow in a more northeasterly direction than previously described. Specifically, groundwater at the site flows more toward the Anthony Kill with a smaller component flow to the east. Figures 5-6 and 5-7 depict the potentiometric surface of groundwater in the overburden in March 1988 and July 1993, respectively.

Slug tests conducted in monitoring wells MW-16 and MW-17 indicate that the hydraulic conductivity of the saturated overburden is on the order of 10^{-5} and

10^{-3} cm/sec, respectively. These values are consistent with values calculated during Tasks 1, 2, 3, and 4.

Groundwater elevation measurements collected from groundwater monitoring well pairs screened in the overburden and the bedrock indicate that there is a slight (0.004 ft/ft) downward gradient from the overburden to the fractured bedrock layer at the site. In close proximity of the Anthony Kill, the vertical gradient changes. At MW-5 and MW-15, there is an upward gradient of approximately 0.002 ft/ft.

During the Phase IIA Supplemental field investigation, flow in the Anthony Kill was higher during the May 1993 field investigation than during the July 1993 groundwater and seepage meter sampling event. The tops of the seepage meters, installed into the streambed of the Anthony Kill in May, were nearly exposed at the water surface during the July sampling event. The lower flow conditions observed in July were consistent with seasonal precipitation patterns. Additionally, it was noted by ABB-ES field personnel that the water level in the Anthony Kill fluctuated by as much as 0.5 feet during the July sampling event, and increased in turbidity over a period of several hours. It was also noted that turbidity in the stream increased as the water level was observed to increase. The cause of the rapid fluctuations in stream flow are not known at this time.

Based on the seep measurements, the average flux of groundwater seepage is 0.035 gallons per day per square foot (gal/day/ft^2). Using the seepage meter data from the low flow period and assuming that groundwater discharges from site along the 1,000-foot length of the Anthony Kill and that discharge is limited to

one-half of the stream width (approximately 12 feet), the average flow of groundwater into the Anthony Kill is 0.0057 cubic feet per day per cubic foot ($ft^3/day/ft^2$) or 0.04 gallons per day (gpd) per square foot. This value is lower than the calculated 0.03 $ft^3/day/ft^2$, or 0.224 gpd per square foot. The low seepage rate is likely due to a combination of factors: (1) the low flow conditions of the Anthony Kill; (2) the significant fluctuations in water level during the sampling period; and (3) the statistically few number of data points. Therefore, the seepage rates calculated from these data represent a lower bound of the discharge rate from the site to the Anthony Kill. A summary of seepage sample volumes and rates is presented in Table 5-9.

6.0 PHASE IIA SUPPLEMENTAL FIELD AND LABORATORY DATA

6.1 SUMMARY OF PHASE IIA SUPPLEMENTAL ANALYTICAL DATA - SOIL INVESTIGATION

A total of thirty (30) surface and subsurface soil samples were submitted for laboratory analyses. Analytical results for all detected compounds and analytes are presented in Tables 5-1, 5-2 and 5-3. Summaries of all validated laboratory analytical data including quality control samples are provided as Appendix C to this Report.

6.1.1 Surface Soils

Six (6) surface soil samples, including one (1) duplicate sample were collected from the western portion of the site. The samples were collected from the area where spent oxides were reportedly disposed of and were analyzed for reactive sulfide and reactive cyanide. No reactive sulfide or reactive cyanide was detected in any of these samples. The results of the laboratory analyses are summarized in Table 5-1.

A total of twenty-one (21) surface soil composite samples including two (2) duplicate samples were collected from the six (6) former transformer storage areas and analyzed for PCBs. The results of the laboratory analyses are summarized in Table 5-2. Both Aroclor-1248 and Aroclor-1260 were reported at concentrations all below the method detection limits; as a result the reported

values are estimated. Aroclor-1248 was detected at concentrations ranging from 0.057 to 2.5 ppm in eight (8) composite surface soil samples collected from transformer storage Areas 3, 4, and 4A. Aroclor-1260 was detected at concentrations ranging from 0.047 to 2.6 ppm in eleven (11) surface soil samples collected in Areas 3, 4, 4A, 5, and 6.

6.1.2 Subsurface Soils

Continuous split-spoon soil samples were collected from borings B-16 and B-17. No odors or visual evidence of residual contamination were detected or observed in any soil samples collected from these borings. No PID readings above background levels were detected in any of the soil samples collected from the borings. Soil samples were not collected from boring B-18 because it is collocated with boring B-17.

Three (3) subsurface soil samples, including one (1) duplicate sample, were collected from the Phase IIA Supplemental soil borings and submitted for laboratory analyses. One (1) soil sample was collected from boring B-16 and two (2) soil samples were collected from boring B-17 and submitted for laboratory analyses. The soil samples were collected from overburden soils immediately above the bedrock-overburden contact, at the 6 to 8 feet bgs interval in boring B-16 and the 18 to 20 feet bgs intervals in boring B-17. The results of the laboratory analyses are discussed below.

Volatile Organic Compounds No VOCs were detected in any of the three (3) soil samples submitted for laboratory analyses.

Semivolatile Organic Compounds A limited number of SVOCs were detected in the subsurface soils at concentrations below their respective method detection limits. The reported values have been "flagged" with a "J" qualifier indicating an estimated concentration. The following PAHs were detected in the subsurface soils collected from borings B-16 and B-17: chrysene, fluoranthene, pentachlorophenol, benzo(a)anthracene, benzo(a)pyrene, chrysene, naphthalene, and phenanthrene. In addition, diethylphthalate was detected in the subsurface soil sample collected at B-16. The presence of this compound is not associated with the gas manufacturing process and is likely present as an artifact of sample handling and/or laboratory contamination.

Inorganics The inorganics aluminum, antimony, cadmium, chromium, cobalt, copper, iron, lead, manganese, nickel and zinc were detected in subsurface soil samples. The reported results are within the range of results reported for soil samples collected during previous site investigation activities.

Reactive Sulfide and Cyanide No reactive sulfide or reactive cyanide was detected in any of the subsurface soil samples submitted for laboratory analyses.

Hydrocarbon odors and visual evidence of MGP by-products were observed in soil samples collected from soil borings completed in the former filter bed area (B-20 through B-25). Subsurface soils from approximately 2 feet bgs to bedrock (approximately 6-10 feet bgs) contain visible quantities of coal tar. However, no evidence of waste coke from the former filter beds was observed in any of the collected soil samples; therefore, no samples were submitted for laboratory analyses from these borings.

6.2 SUMMARY OF ANALYTICAL DATA - GROUNDWATER INVESTIGATION

Groundwater quality at the site has been characterized by the evaluation of field and laboratory data collected from fifteen (15) groundwater monitoring wells. Twelve (12) of the groundwater monitoring wells were installed during Tasks 1 through 4, and three (3) additional groundwater monitoring wells were installed during the Phase IIA Supplemental RI.

During the Phase IIA Supplemental RI, groundwater samples were only collected from wells in which no visible evidence of free product was observed. Free product was observed in groundwater monitoring wells MW-3, MW-4, MW-5, MW-6, MW-10, and MW-12. Consequently these wells were not sampled. Eleven (11) groundwater samples, including two (2) duplicates, were collected from the remaining nine (9) groundwater monitoring wells. Analytical results for all detected compounds and analytes are presented in Tables 5-4, 5-5, and 5-6 along with the respective Maximum Contaminant Levels (MCLs) established under the New York State Drinking Water Standards (NYSDWS). The following is a summary of the analytical data from groundwater samples relative to the NYSDWS:

Volatile Organic Compounds: With the exception of two (2) monitoring wells (MW-14 and MW-15), no VOCs were detected at concentrations in excess of the respective NYSDWS MCLs. In groundwater samples collected from monitoring wells MW-14 and MW-15, the following VOCs were detected above the respective MCLs:

benzene
ethylbenzene
methylene chloride
total xylenes
toluene
1,1-dichloroethane
1,1,1-trichloroethane

Benzene, ethylbenzene, total xylenes and toluene were detected well above the NYSDWS MCLs in the groundwater sample collected at MW-14. 1,1-dichloroethane and 1,1,1-trichloroethane were detected only slightly above the respective NYSDWS MCLs in the groundwater sample and duplicate sample both collected at MW-15.

Semivolatile Organic Compounds: SVOCs were detected above MCLs in four (4) samples collected from three (3) groundwater monitoring wells (MW-13, MW-14 and MW-15). The specific compounds exceeding the respective MCLs include:

acenaphthene
2-methylnaphthalene
naphthalene
bis(2-ethylhexyl)phthalate

BEHP slightly exceed the MCLs. When present at low concentrations, BEHP is a common laboratory contaminant and is believed to be an artifact of the analytical process. It is unlikely that BEHP is derived from the site.

Inorganics: Inorganics have been analyzed in both filtered and unfiltered groundwater samples. In general, concentrations in the unfiltered groundwater are higher than those in the filtered samples. This is primarily due to the presence of suspended soil particles in the unfiltered water samples.

Only manganese was detected in the filtered groundwater samples in concentrations exceeding the NYSDWS MCLs. In the unfiltered groundwater samples, chromium, manganese, and iron were detected at concentrations exceeding MCLs in groundwater samples. Chromium was detected in excess of MCLs in monitoring wells MW-1 and MW-17. Iron was detected in excess of MCLs in monitoring wells MW-1, MW-11, MW-16, MW-17, and MW-18.

Turbidity: Turbidity measurements were elevated in groundwater samples collected from monitoring wells MW-16 and MW-17 (1,100 and 4,600 Nephelometric Turbidity Units (NTU), respectively). The detection of elevated concentration of inorganics in the unfiltered groundwater sample reflects the high amounts of suspended particulates. These wells were installed in relatively silty soils and may require additional development prior to any future groundwater sampling activity.

6.3 SUMMARY OF ANALYTICAL DATA - SEDIMENT AND SEEPAGE INVESTIGATION

6.3.1 Sediment Investigation

Seven (7) sediment samples including one (1) duplicate sample were collected for field and laboratory analyses from the Anthony Kill. Using UV/IR field analyses, PAHs were detected in four (4) of the seven (7) sediment samples and a decision was made to submit all seven (7) samples for laboratory analyses. A summary of sediment laboratory data is presented in Table 5-7. The analytical data from these samples have been compared to USEPA/National Oceanic and Atmospheric Administration sediment criteria (USEPA/NOAA criteria). These criteria were developed to assess the potential impacts of sediment contamination on the aquatic life. The following is a summary of this data relative to the USEPA/NOAA criteria.

Volatile Organic Compounds: No VOCs were detected in excess of the USEPA/NOAA criteria. Six (6) VOCs were detected at low concentrations in the sediment samples. Two of the VOCs, acetone and methylene chloride were detected in all samples and are believed to artifacts of the analytical process. The remaining four VOCs (benzene, chloromethane, ethylbenzene and total xylenes) were detected at concentrations ranging from 1.0 to 14.0 ppb. There are no NOAA criteria for the VOCs.

Semivolatile Organic Compounds: SVOCs, specifically PAHs, were detected in excess of the USEPA/NOAA criteria in five (5) of the seven (7) sediment

samples collected from the streambed of the Anthony Kill. The SVOCs detected include:

acenaphthene
anthracene
benzo(a)anthracene
benzo(a)pyrene
fluoranthene
2-methylnaphthalene
naphthalene
phenanthrene

An evaluation of the significance of the exceedances is provided in Subsection 7.5.

Inorganic: No inorganics were detected in excess of the USEPA/NOAA criteria.

6.3.2 Seepage Investigation

During the July 1993 sampling survey, seepage samples could be collected from only three (3) of the four (4) seepage meters installed in the streambed of the Anthony Kill. Due to low groundwater and stream flow conditions, groundwater seep samples were collected from seepage meters SP-1, SP-2, and SP-4. No seepage was collected from seepage meter SP-3.

The small volumes of seepage water that could be collected required a reduction in the list of target compounds that could be analyzed. Groundwater seepage

samples from SP-1 and SP-2 were analyzed for VOCs and SVOCs. The groundwater seepage collected at SP-4 was analyzed for VOCs only. Results for all detected compounds and analytes are presented in Table 5-8. The analytical data from these samples have been compared to New York State Surface Water Quality Standards (NYS SWQS). The following is a summary of the analytical results for the groundwater seepage samples:

Volatile Organic Compounds: No VOCs were detected above NYS SWQS in any of the groundwater seepage samples submitted for laboratory analyses.

Semivolatile Organic Compounds: Two (2) SVOCs (4-methylphenol and BEHP) were detected in the groundwater seepage samples from seepage meters (SP-1 and SP-2) at levels slightly in excess of the NYS SWQS. Neither BEHP or 4-methyl phenol were detected in sediment samples collected from the locations where seepage meters SP-1 and SP-2 were installed (i.e., SD-4 and SD-3, respectively). Therefore, it is likely that these compounds were present in the sample collection catheter bags and associated tubing. It is significant to note that the sediment samples collected adjacent to seepage meters SP-1 (SD-4) and SP-2 (SD-3) contained measurable concentration of PAHs which were not detected in the seepage water collected from these areas.

7.0 SUMMARY OF FINDINGS

This section summarized the findings from the Phase IIA Supplemental activities conducted at the site.

7.1 SITE TOPOGRAPHY

A topographic survey was conducted east of the site, across from North Central Avenue, in an area principally occupied by the Price Chopper store and parking lot and the Anthony Kill, which abuts the northern boundary of the Price Chopper facility. Surficial topography of the Price Chopper parking lot is relatively flat, sloping slightly to the north and west. Just beyond the northern edge of the parking lot, the ground surface slopes steeply downward approximately 12 to 14 feet, to the streambed of Anthony Kill. The parking lot drains to the north through a storm culvert that discharges into the Anthony Kill near the North Central Avenue bridge.

7.2 SITE GEOLOGY

The Mechanicville site occupies a 2.25 acre lot that is mostly paved. The north of the site is bordered by the Anthony Kill, which drains into the Hudson River 1,500 feet to the east. Site geology is characterized by the presence of fill overlying native soils. In many areas of the site, discrimination between native

and fill soils is difficult and definitive delineation cannot be made. The native soils include silt sands, sand and gravel, till, and silty shale. The thickness of overburden soil ranges from 3 to 25 feet thick. The glacial tills and silty shale (weathered bedrock) overlie shale bedrock.

The bedrock surface topography forms a shallow basin centered beneath the former MGP facility. The slopes of the basin are steeper in the south and east and more gentle to the west. The basin drains to the north, toward the Anthony Kill. The bedrock surface topography east of the site appears to be relatively flat with a local bedrock high beneath the center of the parking lot. Bedrock beneath the Price Chopper parking lot is located approximately 20 to 23 feet bgs. The bedrock surface topography is depicted in Figure 5-5. The upper 10 feet of bedrock is highly fractured. The number and size of fractures decrease rapidly with depth; thereby significantly reducing the potential downward movement of groundwater.

7.3 SITE HYDROGEOLOGY

Two water-bearing units are present at the site: the overburden and the bedrock. Monitoring wells and piezometers have been installed in both water-bearing zones. Groundwater flow direction in the overburden is northeasterly. At the southern border of the site, groundwater flows eastward. Closer to the Anthony Kill, the bedrock surficial topography influences the flow direction, and the potentiometric surface contours parallel the banks of the Anthony Kill. Groundwater flow direction in the proximity of the Anthony Kill, is toward the

Anthony Kill. The average calculated groundwater discharge flow into the Anthony Kill is 0.03 $ft^3/day/ft^2$.

Groundwater flow direction in the shallow fractured bedrock is similar to the flow direction in the overburden flow system, indicating that the two water-bearing units are hydraulically connected. Groundwater flow in the deeper bedrock does not appear to be influenced by the Anthony Kill, but flows to the east, toward the Hudson River.

Groundwater elevation measurements collected from groundwater monitoring well pairs screened in the overburden and the bedrock indicate that there is a slight (0.004 ft/ft) downward gradient from the overburden to the fractured bedrock layer at the site. In close proximity of the Anthony Kill, the vertical gradient changes. At MW-5 and MW-15, there is an upward gradient of approximately 0.002 ft/ft.

Groundwater and stream elevations measured during the Phase IIA Supplemental field investigation suggest that during the drier months, flow into the Anthony Kill depends on the water elevation in the Anthony Kill. As discussed in Subsection 5.4, the water level in the Anthony Kill may fluctuate by up 0.5 feet over a period of several hours.

Groundwater elevation measurements collected from piezometers installed on the northern bank of the Anthony Kill are inconclusive. Because the stage of the Anthony Kill varies over a period of several hours, shallow groundwater flow

direction along the northern bank is dependent on the stage elevation of the Anthony Kill.

7.3.1 Hydrogeologic Model

A groundwater flow model for the Mechanicville site was constructed for the purpose of aiding in the interpretation of groundwater flow through the overburden, fractured bedrock and competent bedrock beneath the site. The model was calibrated to observed and interpreted site conditions. Discussion pertaining to the model selection, calibration, aquifer parameters and mass balance consideration are presented in Appendix E. Interpretations of the shallow groundwater flow, based on water level measurements, indicate discharge of shallow groundwater flow to the Anthony Kill.

The model was set up in three layers; Layer 1, groundwater flow in the overburden; Layer 2, groundwater flow through the upper 10 feet of the fractured bedrock; and Layer 3, groundwater flow through the interval of 10 feet to 20 feet into bedrock. These depths correspond to approximate depths of explorations (borings and well) installed at the site, and also to potential depths of interest of the anticipated remedial alternatives to be evaluated.

The important features of this model are the hydraulic conductivities, the recharge over the area, available flux from upgradient, the over-all water balance, and interactions with the Anthony Kill.

Based on the groundwater flow into the model at the upgradient flux boundary, the total flow into the Anthony Kill is approximately 3 gallons per minute (gpm). The approximated flow rates in each of the layers are: 31.3 cu ft/d (12.3%) in Layer 1; 158.3 cu ft/d (62%) in Layer 2; and 65.2 cu ft/d (26%) in Layer 3. Additional recharge occurs to Layer 1 over the model, however, in the model formulation all flow to the Anthony Kill occurs through Layer 2, the upper 10 feet of fractured bedrock. (See Figure 7-1.)

7.4 CONTAMINANT DISTRIBUTION

7.4.1 Soils

Surface soil samples were collected to evaluate the potential presence of reactive materials in surface soils in the unpaved western portion of the site and to evaluate the potential presence of PCBs in former transformer storage areas.

No reactive sulfide or cyanide was detected in the surface soils west of the site.

Twenty-one (21) surface soil samples were collected and analyzed for PCBs. Aroclor-1248 was detected in eight (8) samples collected from Transformer Storage Areas 3, 4, and 4A, at concentrations ranging from 0.057 to 2.5 ppm. Aroclor-1260 was detected in eleven (11) surface soil samples at concentrations ranging from 0.047 to 2.6 ppm. Aroclor-1260 was detected in samples collected from Transformer Storage Areas 3, 4A, 5, and 6.

Subsurface soils samples were collected for laboratory analyses from two (2) soil borings completed during the Phase IIA Supplemental RI to assess the potential presence of MGP-related constituents in subsurface soils. The laboratory analyses found that:

- No evidence of MGP residuals was observed in subsurface soil samples collected from the two (2) soil borings (B-16 and B-17) completed during the Phase IIA Supplemental field investigation;

- No VOCs were detected in subsurface soil samples;

- Ten (10) SVOCs were detected in subsurface soils collected from boring B-16 and B-17. All compounds were detected at concentrations below the method detection limit and, therefore, the reported values are estimated;

- Eleven (11) inorganic analytes were detected in subsurface soil samples collected from boring B-16 and B-17. Concentrations of these analytes were well within the range of results of previous subsurface soil analyses;

- No reactive cyanide or reactive sulfide was detected in subsurface soil samples; and

- No evidence of filter bed materials were observed in subsurface soils collected at boring B-20 through B-25.

7.4.2 Groundwater

Groundwater samples were collected from nine (9) of the fifteen (15) groundwater monitoring wells which have been installed at the site. The remaining six (6) monitoring wells were not sampled because the presence of DNAPL and/or LNAPL was detected in each well. The monitoring wells in which L or DNAPLs were detected are all located within the perimeter of that portion of the site on which the former gas manufacturing facility was located. The findings of the Phase IIA Supplemental groundwater sampling survey are summarized below: Six (6) VOCs were detected at concentrations in excess of their NYSDWS MCLs in samples collected from monitoring wells MW-14 and MW-15. No VOCs were detected above the NYSDWS MCLs in the seven remaining monitoring wells from which groundwater samples were collected (i.e., MW-1, MW-2, MW-11, MW-16 and MW-17 and MW-18).

Four (4) SVOCs were detected at concentrations in excess of the respective NYSDWS MCLs. Exceedances were detected in groundwater samples collected from groundwater monitoring wells MW-13, MW-14, and MW-15. No SVOC exceedances were detected in groundwater samples collected from MW-16, MW-17, or MW-18.

Inorganics were analyzed in both filtered and unfiltered samples. In general, concentrations in unfiltered groundwater samples are higher than those in the filtered samples. This is due to sorption to soil particulates present only in the unfiltered samples.

Only manganese was detected in the filtered groundwater samples in concentrations exceeding NYSDWS. In the unfiltered groundwater samples, chromium was detected at monitoring wells MW-1 and MW-17. Iron was detected in excess of MCLs at monitoring wells MW-1, MW-11, MW-16, MW-17, and MW-18.

Turbidity was measured at each of the nine (9) sampled groundwater monitoring wells. Samples from both monitoring well MW-16 and MW-17 contained very high (1,100 and 4,600 NTUs) suspended particulates. The detection of elevated inorganics in the unfiltered groundwater samples is likely the result of the presence of suspended particulates in the samples.

7.4.3 Sediments and Groundwater Seepage

Seven (7) sediment samples including one (1) duplicate were collected from areas upstream, adjacent to and downstream of the site. Laboratory analyses of the samples detected both VOCs and SVOCs in all samples. No VOCs were detected above the respective USEPA/NOAA criteria. SVOCs were detected at concentration in excess of USEPA/NOAA criteria in four (4) sediment samples (SD-2, SD-3, SD-4, and SD-5) collected from the streambed of the Anthony Kill. No SVOCs were detected at concentrations in excess of the USEPA/NOAA criteria from the sediment samples SD-1, collected adjacent to the site and sample SD-6 collected downstream from the site. No inorganics were detected at concentrations in excess of the USEPA/NOAA criteria.

The concentrations of SVOCs detected in sediment samples collected during the Phase IIA Supplemental field investigation are comparable to SVOC concentrations detected in sediment samples collected during previous RI activities at the site.

Three (3) groundwater seepage samples were collected from seepage meters SP-1, SP-2, and SP-4. Seepage meter SP-3 did not produce sufficient volume to collect a sample. The results of the analyses are compared to the NYS SWQ Standards. No VOCs were detected at concentrations in excess of their respective MCLs. Two (2) SVOCs were detected at levels exceeding NYS SWQ Standards. BEHP was detected at both SP-1 and SP-2 at 9J and 4J μg/l, respectively. 4-Methylphenol was detected at SP-2 at 2J μg/L. Both BEHP and 4-methylphenol were also detected in the sediment samples SD-4 and SD-2, collected in the proximity of the seepage meters SP-1 and SP-2, respectively. Phenol was also detected in elevated levels (430 and 160 μg/L) in seepage samples SP-1 and SP-2. Phenol was not detected in sediment samples collected immediately adjacent to the seepage meter installation locations and is, therefore, believed to be artifacts of the sample collection process.

7.5 RISK ASSESSMENT

A Task 4 Risk Assessment was conducted in August of 1990 to investigate potential risks to human health and the environment associated with exposures to chemicals present in air, soil, sediment, and groundwater at the site. Results of the risk assessment indicated that risks from both carcinogenic and

noncarcinogenic chemicals in soil, sediment, and air to the identified receptors (children and site workers) and environmental receptors (aquatic organisms) were within USEPA acceptable ranges.

Subsequent to the Task 4 Risk Assessment, additional analytical data for sediments, surface soil, subsurface soil, and groundwater were collected in May and July of 1993. This subsection provides a review of these additional surface soil, subsurface soil and groundwater sediment and seepage data and an evaluation of the importance with regard to the Task 4 public health risk assessment.

7.5.1 Data Summary

Data summaries that include the arithmetic mean (which was calculated assuming one-half the sample quantitation limit (SQL) for non-detects), maximum and minimum detected concentrations, and frequency of detections for chemicals identified in surface soil, subsurface soil, and groundwater are presented in Tables 7-1, 7-2, and 7-3, respectively. In some cases, calculated mean concentrations exceed maximum detected concentrations. This is the result of the range in detection limits seen in some samples. The maximum detected concentration is the appropriate estimator of concentrations in these cases.

Surface soil was analyzed for PCBs, reactive cyanide, and reactive sulfide. Samples for PCB analysis were collected from sampling locations SS-25, SS-29 through SS-41, and SS-45 through SS-48. The PCBs Aroclor-1248 and Aroclor-1260 were detected in the May 1993 and July 1993 samples, respectively,

at maximum concentrations of 2.5 and 2.4 ppm, respectively (Table 7-1). Samples for reactive cyanide and sulfide were collected from SS-20, SS-22, SS-23, and SS-24. These analytes were not detected in any surface soil samples. Subsurface soil was collected from boring locations B-16 and B-17. Nine (9) SVOCs and ten (10) inorganics were identified in the subsurface soil (Table 7-2). Groundwater was collected from monitoring wells MW-1, MW-2, MW-11, and MW-13 through MW-18. Seven (7) VOCs, fourteen (14) SVOCs, and eleven (11) inorganics were detected in these samples. Table 7-3 presents total concentrations of analytes. Results of inorganic analyses for MW-16 and MW-17 were excluded from this summary because turbidity levels in these wells would render them unusable as a potable source.

7.5.2 Evaluation of Surface Soil Exposure

PCBs were not detected in the surface soil data collected in the 1990 sampling round. Therefore, risk estimates were calculated to assess additional potential risks associated with exposures to the Aroclors detected in the 1993 sampling effort.

7.5.3 Evaluation of Groundwater Exposure

Groundwater analytical data were compared to NYSDWS MCLs (November 1993) and USEPA MCLs (May, 1993) (Table 7-4). Mean and maximum detected concentrations of detected VOCs except 1,1-Dichloroethane exceeded NYSDWS MCLs, and the maximum detected concentrations of three (3) VOCs exceeded USEPA MCLs. The mean and maximum detected concentrations of 2-

methylnaphthalene and naphthalene, and the maximum detected concentrations of acenaphthene, phenol, and BEHP exceeded NYSDWS MCLs. The mean and maximum detected concentrations of aluminum, antimony, iron, lead, and manganese, and the maximum detected concentrations of chromium and nickel exceeded either NYSDWS or USEPA MCLs. Standards for aluminum, iron, and manganese, however are secondary. Secondary MCLs are not health based and are for contaminants which may affect the aesthetic qualities of drinking water (i.e., color, odor and taste).

7.5.4 Sediments and Seepage

The Task 4 Risk Assessment also investigated potential risks to environmental receptors associated with current exposures to surface water and sediment. Results of the environmental risk assessment indicated that some potential risks to aquatic organisms may exist in Anthony Kill directly adjacent to the site. Of the site related contaminants detected in surface water, only 2-methylnaphthalene exceeded Ambient Water Quality Criteria (AWQC). Task 4 also reported that the average carbon-normalized phenanthrene concentration detected at sampling locations adjacent to the site exceeded the lower confidence interval of the Sediment Quality Criteria (SQC).

Subsequent to the 1990 Task 4 Risk Assessment, additional analytical data for sediment were collected in the Anthony Kill in the vicinity of the Mechanicville site in May 1993. These data are presented in Table 5-7. In general, the additional analytical data are consistent with the results of previous sampling events and substantiate the findings reported in the environmental assessment

components of the Task 4 Risk Assessment. Six (6) compounds that had not been previously detected in Anthony Kill sediments were detected in the sediment samples collected in May 1993. These compounds are chloromethane, xylenes (total), carbazole, diethylphthalate, dibenzofuran, pentachlorophenol. In addition, aluminum, chromium, cobalt, copper, lead, manganese, and nickel, were detected in the May 1993 samples, these inorganic compounds had not been previously analyzed for. Toluene and di-n-octylphthalate were not detected in these new sediment results although they had been reported in earlier data.

With respect to the sediment constituents that were quantitatively evaluated in the Task 4 Risk Assessment (i.e., acenaphthene, benzo(a)anthracene, benzo(b)pyrene, fluoranthene, phenanthrene, and pyrene), the supplemental sediment analytical data substantiate previous risk conclusions. Excepting acenaphthene, the maximum detected concentrations of these sediment constituents are less than the average concentrations previously used to evaluate environmental impacts. Acenaphthene was detected at sediment sampling location SD-3 at a concentration of 1.6 ppm (0.840 ppm in the duplicate sample), which is higher than the average of 0.590 ppm used to evaluate environmental risk in the Task 4 Risk Assessment. Nonetheless, the carbon-normalized acenaphthene concentration detected in the two samples from SD-3 does not exceed even the lower confidence interval of the SQC for this compound (57 and 64 ppm C, respectively). Carbon-normalized phenanthrene concentrations reported in the May 1993 analytical data exceed the lower confidence interval of the SQC at both the "upstream" and "downstream" sampling locations, but <u>not</u> adjacent to the site.

The Task 4 Risk Assessment also evaluated the potential exposures associated with the discharge of groundwater form the site, using a simplistic and conservative groundwater flow model. Results of this analysis indicated that the estimated low flow concentrations of all groundwater constituents would discharge into the Anthony Kill at concentrations below AWQC. Subsequent to the 1990 Task 4 Risk Assessment, groundwater seepage samples were collected from three locations in the Anthony Kill and analyzed for VOCs and SVOC at SP-1 and SP-2 and VOCs at SP-4. As presented in Table 5-9, no detectable concentrations of PAHs or VOCs were detected in these seep samples. Phenol was detected at both seep sampling locations SP-1 and SP-2 (reported concentrations were 0.430 and 0.16 ppm, respectively. However, the presence of this compound in these seep samples may be a sampling artifact. However, the detected concentrations are below freshwater chronic AWQC (i.e., 2.56 ppm). The low groundwater flow conditions that existed at the time that these samples were collected suggests that the groundwater flows data may underestimate worst case discharge rates. The analytical data do substantiate the earlier groundwater modeling results that suggested that groundwater discharge into the Anthony Kill would not result in exposures to aquatic environmental receptors (e.g., fish, amphibians, and freshwater invertebrates) likely to result in adverse impacts.

7.5.5 Summary

In summary, analytical data from the 1993 sampling effort does not suggest any significant changes in risks from potential exposure to surface soil or subsurface soil at the site compared to risks identified in the Task 4 report. Risks associated with exposure to surface soils samples collected in 1993 containing PCBs are not

appreciably elevated compared to those quantified in 1990. The total risks using both old and new data are within the USEPA target risk range.

A comparison of subsurface soil data collected in 1993 to that summarized in the 1990 Task 4 report indicates that similar or lower concentrations of analytes are found in 1993 data. Thus, similar or lower levels of risks would be associated with exposure to these soils. A variety of organic and inorganic analytes in groundwater were found to exceed New York State and USEPA MCLs.

Compared to the Task 4 report, analytical data from the 1993 sampling effort do not suggest any significant changes in risks from potential exposure to sediments. The data are consistent with the result of previous sampling events. Analytical results from the groundwater seepage samples indicate that the seepage does not pose an unacceptable risk to aquatic life in the Anthony Kill.

8.0 CONCLUSIONS AND RECOMMENDATIONS OF THE PHASE IIA SUPPLEMENTAL REMEDIAL INVESTIGATION

The following subsections present the conclusions and recommendations of the remedial investigation program at the Mechanicville site based on a review of the findings of the all previous remedial investigation activities and the findings of the Phase IIA Supplemental RI reported herein.

8.1 CONCLUSIONS

8.1.1 Site Topography, Geology and Hydrogeology

1. The site is located in a topographic low area adjacent to the south band of the Anthony Kill. The site and adjoining areas have been substantially altered by cultural activities including significant excavation and subsequent filling of lands bordering North Central Avenue and the site. The gas manufacturing facilities have been demolished and majority of the area on which the facilities were located has been paved or is covered by the slab and/or foundation(s) of the of the former structures. As a result, precipitation does not infiltrate into the subsurface soils, thereby reducing the potential flushing of MGP related residuals into the groundwater system that underlies the Site.

2. The site geology consists of 8 to 23 feet of overburden material overlying bedrock. Overburden soils consist of fill, silty sands (tills) and silty shales. The depositional history of the site cannot be clearly discerned; however, the presence of the silty shale layer provides a relatively permeable layer in the overburden through which it is likely that the majority of groundwater flow in the overburden is occurring. Bedrock is composed of a blue-gray shale which is highly weathered in the upper 5 to 10 feet. The size and frequency of fracturing decrease rapidly with depth thereby reducing the effective permeability of bedrock formation with depth.

3. The topography of the bedrock surface forms a shallow basin centered beneath the eastern portion of the site and sloping downward to the north in the direction of the Anthony Kill. The basin is asymmetrical in shape with the western and southern perimeters sloping upward more steeply than the eastern perimeter. The Phase IIA Supplemental RI confirmed the general shape of the basin and demonstrated that the bedrock surface rises to the east of the site, thereby eliminating concerns relative to potential off-site migration of free-product in this direction.

4. Groundwater flow in the overburden and in the shallow fractured bedrock zones is generally to the north toward the Anthony Kill. Hydraulic modeling of the groundwater system indicates that groundwater flow across the entire site is on the order of 4,000 to 5000 gallons per day (i.e., 3 to 5 gpm). Based on the modeling output, it is estimated that approximately 50 percent of groundwater flow crossing the site discharges directly to the Anthony Kill adjacent to the site. The remainder of the groundwater flow

is believed to flow in an easterly direction ultimately discharging to the Hudson River.

5. The Anthony Kill has been designated as a Class C stream by NYSDEC. The streambed in the vicinity of the site is primarily exposed bedrock with a relatively thin veneer of accumulated sediment along the stream banks and in low velocity zones. Hydrologic maps of the area indicate the low flow (7Q10) for the Anthony Kill is approximately 17 cubic feet per second. As a consequence of the low groundwater discharge rates to the Anthony Kill estimates of dilution factors of groundwater discharge to the Anthony Kill under low flow conditions are in the range of 5,000 to 1 further reducing the potential for aquatic impacts associated with contaminant discharges from the site.

8.1.2 Soils

1. Surface soils (0 to 2 feet bgs) contain low levels of certain constituents including PCBs, PAHs, and inorganics associated with former gas manufacturing and service center activities which have occurred at the site. Based on the results of the risk assessment, the presence of these constituents does not pose an unacceptable risk to human health provided that site use is limited to commercial activities which do not result in disturbance of the unpaved areas of the site and maintain the integrity of the pavement in the remainder of the site.

2. Subsurface soils within limited areas of the former gas manufacturing facility contain free phase coal tar both above and below the water table. Coal tar has also been observed in the underlying bedrock, and was found near the streambed of the Anthony Kill by the North Central Avenue bridge. Given that the majority of the former gas manufacturing facility area is currently covered by asphalt or building foundations and slabs, the principal driving force for inducing further migration of the coal tar (i.e., precipitation) has been eliminated. Transport in the groundwater flow system is also expected to be very slow given the extremely low groundwater velocities and the reduced groundwater recharge rates associated with the extensive amount of paved and otherwise impermeable areas both on-site and upgradient of the site. However, in spite of the above mentioned mitigating factors, the presence of coal tar in the subsurface soils represents a continuing source of contamination to both soils and groundwater beneath the site.

3. Based on the results of the risk assessment, the presence of residual material associated with former gas manufacturing and service center operations do not pose a risk to public health so long as the facility continues to be used for commercial purposes and any excavation work is conducted under an appropriate HASP.

4. The presence of waste coke associated with the former filter beds located near the bank to the Anthony Kill could not be confirmed during the Phase IIA Supplemental field investigation. A sample collected by NYSEG in 1981 was submitted for laboratory analysis and failed for reactive sulfide,

reporting concentrations in excess of the reactivity threshold concentration. No evidence of waste coke was identified during the Phase IIA Supplemental field program. It is concluded that the areal extent of this material is limited and the potential volume which must be assessed for potential remediation is also likely to be small (i.e., less than 30 cubic yards)

8.1.3 Groundwater

1. Groundwater flow is primarily confined to the overburden and shallow bedrock units. The hydraulic permeability of the underlying bedrock formation rapidly decreases with depth and flow in the deep bedrock is primarily along fracture and joint planes. The presence of free phase coal tar has been observed in six (6) of the monitoring wells installed in the overburden and shallow bedrock systems. These wells are all located within the perimeter of the former gas manufacturing facility. The free phase coal tar has not been observed as seepage into the Anthony Kill and has not been observed in perimeter monitoring wells MW-14, MW-17 and MW-18. It is concluded that the migration of coal tar from the site is extremely slow under current site conditions.

2. The low permeability of both the overburden soils and the underlying bedrock formation indicate that groundwater will not sustain a viable water supply. This conclusion is supported by the fact that the nearest water supply well is located approximately 5,000 feet southwest of the site. Alternate water supplies represent better alternatives to installation of a

well in this heavily developed area. Further, other potential sources of groundwater contamination, including gas stations, petroleum fuel storage facilities, rail yard and manufacturing facilities, are also present in close proximity to the site and could represent additional threats to any planned water supply installation near the site.

3. Based on results of the risk assessment, the presence of site related contaminants in groundwater does not pose an unacceptable threat to public health. This is primarily due to the fact that there is no current use of groundwater as a water supply. Given the low yield potential of the overburden and bedrock formations and the probable existence of other sources of contamination to groundwater, it is improbable that any new water supplies will be developed near the site.

8.1.4 Surface Water and Sediments

1. The chemical analyses of sediment samples collected at six (6) locations adjacent to and downgradient from the site detected the same constituents at similar concentrations as were reported in earlier phases of the RI. Based on this additional data, it is concluded the presence of these constituents in the sediments of the Anthony Kill does not pose an unacceptable risk to aquatic life in the Anthony Kill.

2. The seepage meter investigation measured groundwater discharge rates were at the low end of the range estimated in the groundwater modeling effort. In addition, the concentrations of contaminants detected in seepage

water samples were significantly below the assumed concentrations. The assumed concentrations were used to assess the potential aquatic impacts associated with the discharge of contaminated groundwater from the site to the Anthony Kill. Because the actual concentrations were lower, the risk assessment approach applied to the assessment of potential surface water impacts is very conservative. Given that this conservative assessment did not identify any adverse impacts to surface water, it is concluded that no further investigation of potential surface water impacts is warranted at this time.

8.2 RECOMMENDATIONS

Recommendations will be developed by ABB-ES and NYSEG and included in this subsection.

1. In that environmental conditions have been adequately characterized at the Mechanicville site, NYSEG recommends that no further investigation activities be conducted. However, NYSEG recognizes that specific additional investigation and/or monitoring activities may be warranted to support the development of remedial actions or to monitor the effectiveness of any remedial actions which are selected for implementation based on the results of the FS.

2. In that the evaluation of public health impacts associated with the former gas manufacturing operation have been based on commercial (i.e., non-

residential) use of the property, NYSEG recommends that site use remain limited to commercial activities. This limitation will continue until such time as a reassessment of site conditions concludes that the public health risks associated with less restrictive uses are within the generally accepted range of risk values (currently 10^{-4} to 10^{-6}) in place at the time that the reassessment is performed.

3. In that the RI program has not identified any current and ongoing threats to public health or the environment, NYSEG recommends that the feasibility study focus on: 1) control of site related residuals to maintain current conditions; and 2) the identification of practicable remedial measures which could mitigate potential future impacts associated with the residuals identified at the site.

9.0 FEASIBILITY STUDY INTRODUCTION

ABB-ES prepared this FS for the Mechanicville former MGP site located in the City of Mechanicville, Saratoga County, New York. The primary objective of this FS is to develop and evaluate appropriate remedial alternatives such that an appropriate remedial response can be selected. This FS was conducted in accordance with guidelines in the NYSDEC Technical and Administrative Guidance Memorandum (TAGM) 90-4030: "Selection of Remedial Actions at Inactive Hazardous Waste Sites" (NYSDEC, 1990); the National Oil and Hazardous Substances Pollution Contingency Plan (NCP) (USEPA, 1993c and USEPA, 1990); and the "Guidance for Conducting Remedial Investigations and Feasibility Studies under CERCLA" (USEPA, 1988, Interim Final).

This FS is based on results of the four-phase RI conducted for the Mechanicville site during 1986 through 1990, and the Phase IIA Supplemental Remedial Investigation conducted in May 1993. The RI consisted of a Preliminary Site Evaluation (Task 1), an Initial Field Investigation Program (Task 2), an Expanded Problem Definition Program (Task 3), a Risk Assessment (Task 4), and the Phase IIA Supplemental RI (Task 5). The results and conclusions of Tasks 1 through 4 were presented in the Phase II Remedial Investigation Report and Work Plan for the Phase IIA Supplemental Remedial Investigation and Feasibility Study (ABB-ES, 1992), which are summarized in Section 3.0 of this report. The results and conclusions from work conducted under the Phase IIA Supplemental RI are presented in Sections 4.0 through 8.0 of this report.

9.1 PURPOSE

The primary objective of this FS is to develop and evaluate appropriate remedial alternatives such that an appropriate remedial response can be selected. The FS process used for the Mechanicville site is consistent with the NYSDEC TAGM 90-4030 for the Selection of Remedial Actions at Inactive Hazardous Waste Sites (NYSDEC, 1990) and involves identifying and evaluating suitable technologies for monitoring, containing, treating, and/or removing site wastes (Figure 9-1). Those technologies considered feasible were assembled into remedial alternatives that were evaluated in detail using the evaluation criteria specified in the NYSDEC TAGM 90-4030. The goal of the remedial response selection process is to select remedies that are protective of human health and the environment and maintain protection over time.

9.2 SCOPE OF FEASIBILITY STUDY

The RI identified and investigated various media potentially impacted by coal gasification activities at the Mechanicville site. These media included:

- surface soil
- subsurface soil
- subsurface coal tar
- overburden groundwater
- bedrock groundwater
- surface water of the Anthony Kill

- sediment of the Anthony Kill
- air

The risk assessment (see Subsections 3.4, 3.5, and 7.5) for the site was conducted to identify and assess the potential risks associated with exposure to chemicals detected on-site in these various media. For the public health risk assessment, the potential carcinogenic and noncarcinogenic risks from site-related exposures under baseline conditions (i.e., current conditions and future conditions, assuming no construction or remedial action) were estimated for sediments, soils, and exposure to VOCs and particulate dust from excavation activities during utility repair work. Because surface water data collected from the Anthony Kill do not indicate that site-related contaminants are present at detectable levels, exposure to public health by this pathway was not assessed. The environmental assessment evaluated present and future impacts to environmental receptors for potentially affected media including surface water, sediment, soil, and groundwater.

The FS provides the basis for selecting and implementing remedial actions at the Mechanicville site. This begins with the development of site-specific response objectives, qualitative goals established on the basis of the nature and extent of contamination, the resources currently or potentially threatened, and the potential for human and/or environmental exposures. Existing site-specific data collected during the RI and the risk assessment form the basis for selecting the media for which response objectives should be developed. The rationale for selection of media to be addressed in this FS follows.

Soil. The human health risk evaluation concluded that direct contact with on-site soil (surface and subsurface) by area residents (specifically, older children that may trespass), or utility workers, would not be expected to pose a significant health risk under the assumed exposure conditions (i.e., current conditions and future conditions, assuming no construction or remedial action). Both carcinogenic and noncarcinogenic risks were within target risk levels. Based on the results of the baseline risk assessment, and because no change in site use is planned in the foreseeable future, development of remedial response objectives for surface and subsurface soil is not warranted.

However, because the risk assessment for surface soils was based on current site use, administrative actions (i.e., deed restrictions, easements, zoning) will be a component of each alternative developed in this FS to restrict future noncommercial use of the site. In addition, laboratory analysis of one soil sample, collected by NYSEG in November 1981 from the filter beds, detected the presence of reactive sulfides at a concentration of 1,300 ppm. This concentration exceeds the threshold concentration for the hazardous waste reactivity test. In an attempt to further delineate soils associated with the former filter beds, additional soil borings were completed in this area during the 1993 Phase IIA Supplemental RI (see Subsection 6.1.2). Although no evidence of waste coke was observed in samples collected during the investigation, excavation and treatment and/or disposal of potentially reactive soils will also be a component of each remedial alternative.

Because coal tar constituents that could potentially impact groundwater quality have been detected in subsurface soils at the Mechanicville site, New York State's TAGM 92-4046, "Determination of Soil Cleanup Objectives and Cleanup Levels"

(NYSDEC, 1992), was evaluated. This TAGM provides guidance for establishing target cleanup objectives for contaminants in soil that will be protective of groundwater quality. Recommended soil cleanup objectives cited in the TAGM for VOCs, SVOCs, and PCBs were compared to concentrations detected in subsurface and surface soils at the Mechanicville site. Site-specific cleanup levels were not calculated for organic compounds using actual soil organic carbon content because sufficient background information was not available. In accordance with the TAGM, background levels for the inorganic contaminants of concern, iron (27,000 ppm) and zinc (260 ppm), were used as soil cleanup objectives.

Based on cleanup levels established in this TAGM, VOCs (e.g., benzene, toluene, ethylbenzene) and SVOCs (e.g., PAHs) detected in soil may have a potential impact on site groundwater. However, most samples where organic contaminants were detected at levels in excess of the cleanup levels established by the TAGM are associated with areas where (1) non-aqueous phase liquids (NAPLs) are present in monitoring wells or (2) boring or test pit logs indicate the presence of coal tar. Remedial options for coal tar and soils associated with coal tar are discussed as a separate media in this subsection.

PCB concentrations in surface soils were reported at concentrations below the method detection limit; as a result, the reported values are estimated. The estimated PCB concentrations were either below or slightly above the goal of 1 ppm for surface soils. Because of the low concentrations detected and because all concentrations are estimated, minimal risk is anticipated based on PCBs detected in soil at the site. Therefore, no further action relative to PCBs is proposed for surface soils.

Iron and zinc concentrations in the majority of soil samples were close to background levels with one exception: zinc was detected in the sample from B-5, located near the former filter beds, at a concentration of 1,600 ppm. Several other constituents associated with coal tar (e.g., PAHs) were also detected in this sample. In addition, coal tar has been encountered in the groundwater monitoring well (i.e., MW-5) installed in the boring from which the sample was collected. Soil in this area will therefore be addressed in conjunction with coal tar.

Coal Tar. Based on observations during the investigation program, coal tar is present in both the vadose and saturated zones beneath the Mechanicville site. The presence of free-phase coal tar has been observed in six (6) of the monitoring wells installed in the overburden and shallow bedrock systems, all located within the perimeter of the former gas manufacturing facility. The free-phase coal tar has not been observed as seepage into the Anthony Kill and has not been observed in perimeter monitoring wells (i.e., MW-14, MW-17, and MW-18).

DNAPLs such as coal tar are difficult to treat even in highly permeable soils. Because coal tar has migrated into the saturated zone and into fractured bedrock, efficient coal tar recovery is even more difficult, if not impossible. Although many DNAPL recovery technologies are being tested, there have been no field demonstrations to date (USEPA, 1992b and 1993a). Traditional pump-and-treat methods typically recover only a small fraction of trapped DNAPLs and in situ methods (e.g., bioremediation, soil flushing, vacuum extraction, bioventing), capable of potentially treating contaminants associated with coal tar (e.g., VOCs, PAHs, cyanide, iron) are not demonstrated and would be ineffective for treatment of free-phase coal tar.

Attempts to excavate and treat/dispose of vadose zone soils contaminated with coal tar would also likely prove ineffective because coal tar is dispersed throughout the site at various depths, including the fractured bedrock below the site. Because most of the site is covered with asphalt and buildings, excavation would require demolition, removal, and disposal of a large quantity of construction/demolition debris. In addition, much of the coal tar beneath the site is located below the water table, which ranges from 2 to 20 feet bgs. As a result, excavation would likely require either lowering the water table or dewatering excavated saturated soils. Emissions of toxic and volatile contaminants during large-scale excavation of the entire site may also be a health and safety concern to construction workers and downgradient receptors. All these factors would result in a very costly, potentially ineffective remedial action. In addition, because coal tar has migrated into bedrock, excavation of overburden soil would only be effective at removing a portion of the coal tar associated with the site.

Finally, investigations indicate that migration of coal tar from the site is extremely slow under current site conditions and that existing conditions effectively limit migration of coal tar to the Anthony Kill. Free phase coal tar has not been observed as seepage into the Anthony Kill and has not been observed in perimeter monitoring wells MW-14, MW-17, and MW-18. The majority of the area on which the former gas manufacturing facilities were located is ether paved or is covered by the slab and/or foundation(s) of the former structures. As a result, infiltration by precipitation to subsurface soils is minimized, thereby reducing potential flushing of site-related residuals into the groundwater system beneath the site. In addition, the risk assessment concluded that because groundwater discharge rates to the Anthony

Kill are very low, the potential for aquatic impacts associated with contaminant discharges from the site is minimal.

Based on this evaluation, control of coal tar migration rather than remedial activities that involve removal and/or treatment of coal tar is proposed at this time. Migration of coal tar to the Anthony Kill could potentially be controlled via management of the migration of overburden groundwater, which will be evaluated as part of this FS. Although migration of coal tar from the site appears to be extremely slow under current site conditions, control of coal tar migration contributes to the long-term management of contaminant migration by minimizing further contamination of surface water and limiting the spread of the potentially mobile coal tar source. Effective control of coal tar may also facilitate use of new and emerging technologies that may be available in the future.

Exposure to subsurface contamination would likely occur only during excavation activities in the future (i.e., servicing of underground sewer, water, or other utility lines). Other human health exposure scenarios are unlikely because access to the site is restricted and most of the ground surface above areas where coal tar has been observed is covered by asphalt or buildings/foundations. Because of the industrialized nature of the area, and the lack of suitable habitats, it is unlikely that the site is significantly used by wildlife. As a result, risk to human health and the environment would be minimal. Remedial alternatives developed to address overburden groundwater will, however, consist of placing deed restrictions on the property to restrict noncommercial use of the site in the future. Further, in accordance with the NYSDEC TAGM 90-4030 for the Selection of Remedial Actions at Inactive Hazardous Waste Sites (NYSDEC, 1990), because wastes would remain

on-site, five-year site reviews will be a component of each remedial alternative developed for the site. Remedial options for coal tar will be reevaluated at this time.

Groundwater. As described in Section 5.0, groundwater flow beneath the Mechanicville site is primarily confined to the overburden and shallow bedrock units. Groundwater flow in these units is generally north toward the Anthony Kill. The hydraulic permeability of the underlying bedrock formation rapidly decreases with depth and flow in the deep bedrock, primarily along fracture and joint planes.

Hydraulic modeling of the groundwater system indicates that groundwater flow across the entire site is on the order of 4,000 to 5,000 gallons per day (i.e., 3 to 5 gpm). Based on the modeling output, it is estimated that approximately 50 percent of groundwater flow crossing the site discharges directly to the Anthony Kill adjacent to the site. The remainder of the groundwater flow is believed to flow in an easterly direction ultimately discharging to the Hudson River.

The low permeability of both the overburden soils and the underlying bedrock formation indicate that groundwater will not sustain a viable water supply. This conclusion is supported by the fact that there are no known current users of the groundwater near or downgradient of the Mechanicville site. The nearest water supply well is located approximately 5,000 feet southwest of the site, and no active industrial wells were identified in the Mechanicville area. In addition, the City of Mechanicville obtains its drinking water from a surface water reservoir approximately three miles northeast of the site, at an elevation approximately 160 feet higher than the site. Alternate water supplies represent better alternatives to installation of a well in this heavily developed area. Further, other potential sources of groundwater

contamination, including gas stations, petroleum fuel storage facilities, rail yards, and manufacturing facilities, are also present near the site and could represent additional threats to any planned water supply installation near the site.

As a result, because there appear to be no potential exposures, groundwater is not considered a potential current or future exposure pathway and was therefore not evaluated as part of the human health risk assessment.

Although no environmental receptors are exposed directly to groundwater at the site, approximately 50 percent of groundwater flow crossing the site discharges to the Anthony Kill, and stream quality could be affected. Therefore, an assessment of the potential impact of groundwater constituents discharging to the Anthony Kill was conducted. Based on this evaluation, estimated low stream flow concentrations of site-derived contaminants are below surface water quality criteria for all chemicals of concern, resulting in minimal risk to environmental receptors.

Groundwater is currently not a source of drinking water, nor does it represent a future potential source. In addition, the ecological risk assessment concluded that the potential impact of groundwater constituents discharging to the Anthony Kill is minimal. However, free-phase coal tar and concentrations of site-related constituents at concentrations in excess of their respective MCLs and NYSDEC criteria (i.e., MCLs and Class GA groundwater criteria) were encountered in both overburden and bedrock groundwater associated with the Mechanicville site. As a result, groundwater containing contaminants in excess of these criteria which discharge to the Anthony Kill could potentially impact ecological receptors. Therefore, this FS includes development of remedial response objectives for protection of ecological

receptors by addressing the release of site-related contaminants in overburden groundwater to the Anthony Kill.

The FS will not address bedrock groundwater for several reasons. First, as described above, groundwater is currently not a source of drinking water. The formation beneath the site does not represent a potential source in the future primarily because it will not yield water in usable quantities. In addition, there are ample surface water supplies available for use by the City of Mechanicville.

Second, based on observations during the RI, the upper portion of bedrock beneath the Mechanicville site contains fractures spaced between 2 inches to 1 foot apart. Although deeper bedrock contained fewer fractures, some fractures contained coal tar or had a distinct coal tar odor. In addition, coal tar has been observed as DNAPL in a number of monitoring wells screened in the bedrock. To remove the coal tar from the bedrock aquifer, it would be necessary to establish the number, density, size, and direction of the fractures, which represent the principal hydraulic route in this formation. This would be difficult to accomplish because of the extreme heterogeneity of a typical fractured system and lack of efficient and economical aquifer characterization techniques (USEPA, 1992a).

In general, DNAPLs are difficult to extract even in highly permeable soils and the technology for their removal is still evolving and not demonstrated (USEPA, 1992b, 1993a, and 1993b). Extraction is difficult primarily because of the tendency for DNAPLs to flow through the interconnected fractures and settle in dead-end segments of the fracture system. When traditional pump and treat systems are installed to clean up aquifers in fractured bedrock formations, improvements in water

quality are very slow because little or no water flushes through dead-end fractures or through the porous rock matrix, both of which are likely to contain the majority of the DNAPL mass (Mackay and Cherry, 1989). Because of the potential impact that DNAPL contamination in bedrock may have on achievement of remediation goals is so significant, USEPA is currently developing specific recommendations for management of sites where DNAPL is present (USEPA, 1993b).

Guidance has been developed by USEPA to clarify how the agency will assess whether restoration of groundwater at a particular site is technically impracticable and what, if any, alternative actions must be taken to ensure protection of human health and the environment (USEPA, 1993b) in the event that restoration is not practicable. This guidance specifies a number of factors that can inhibit groundwater restoration including site use, chemical properties of the contaminants of concern, contaminant distribution, geology, and hydrogeologic factors. Using the approach developed by USEPA, the relative difficulty of groundwater restoration at the Mechanicville site was assessed. The results, presented in Figure 9-2, show that Mechanicville site characteristics severely restrict the restoration potential of the bedrock aquifer beneath the site.

Therefore, because of the difficulty, ineffectiveness, and lack of demonstrated technologies available for extracting DNAPL, particularly from bedrock, remediation of bedrock groundwater beneath the Mechanicville site will not be evaluated as part of this FS. However, in accordance with the NYSDEC TAGM 90-4030 for the Selection of Remedial Actions at Inactive Hazardous Waste Sites (NYSDEC, 1990), five-year site reviews will be a component of each remedial alternative developed for

the site because wastes will remain on-site. Remedial options for bedrock groundwater will be reevaluated as part of this review process.

Anthony Kill Surface Water and Sediment. The risk assessment concluded that direct contact with Anthony Kill sediments by area residents (specifically, older children which are most likely to trespass) or construction workers would not be expected to pose a significant health risk under the assumed exposure conditions. Both carcinogenic and noncarcinogenic risks were within target risk levels. Because surface water data collected from the Anthony Kill do not indicate that site-related contaminants are present at detectable levels, exposure to public health by this pathway was not assessed.

An evaluation of the environmental risks posed by contaminants detected in surface water and sediment suggests that a minimal potential for negative impacts does exist for organisms in the Anthony Kill. These risks appear to be relatively minor for several reasons. Few compounds were determined to exceed their media-specific protective criteria, and the extent of these exceedances were minimal. Moreover, negative impacts were associated only with "worst case" conditions (e.g., stream low-flow conditions and use of maximum analyte levels for criteria comparisons), with no adverse impacts expected under more typical assumptions. Finally, there is no indication that contaminants are impacting downstream receptors. Levels of contaminants detected in the downstream surface water and sediment samples never exceeded relevant protective criteria, even under the most conservative assumptions.

Because the baseline risk assessment indicated that no unacceptable risk currently exists from exposure to Anthony Kill surface water and sediment, development of remedial response objectives for these media is not warranted.

Air. Both carcinogenic and noncarcinogenic risk estimates were calculated for exposure of nearby residents to fugitive emissions of VOCs and particulate-borne SVOCs with dust originating from a hypothetical soil pile excavated and stockpiled on-site during utility repair work. It was concluded that inhalation of contaminants, volatilized or aerosolized by potential future site activities involving soil excavation, does not pose a significant health risk to the general population. As a result, development of remedial response objectives for this media is also not warranted in this FS. However, in the event that activities involving intrusive/exploratory work are required on the site, an appropriate HASP should be developed and followed to prevent or minimize undue exposure.

Summary. The scope of this FS includes the development of remedial response objectives to control migration of coal tar and groundwater contaminants in overburden to the Anthony Kill. Remedial technologies and alternatives capable of achieving these response objectives will be evaluated.

In addition, because the risk assessment for surface soils was based on commercial site use, administrative actions (i.e., deed restrictions, easements, zoning) will be a component of each alternative developed in this FS to restrict future noncommercial use of the site. In accordance with the NYSDEC TAGM 90-4030 for the Selection of Remedial Alternatives at Inactive Hazardous Waste Sites, five-year site reviews will also be conducted to evaluate the effectiveness of remedial actions implemented

at the site and to evaluate the need for additional remedial actions. Finally, excavation and treatment and/or disposal of soils from the filter beds area that failed the reactivity test in 1981 will be a component of each of the remedial action alternatives.

9.3 FEASIBILITY STUDY ORGANIZATION

This FS evaluates management of migration and source control technologies designed to minimize migration of groundwater and coal tar from the site. This RI/FS report consists of eight sections that comprise the FS portion of the report. In addition to this introductory Section 9.0, Section 10.0 identifies the standards, criteria, and guidelines (SCGs) governing the extent of site remediation and establishes the remedial action objectives that will be used to develop detailed remedial alternatives to mitigate existing or future threats to human health and the environment. Site-specific considerations and assumptions made in defining these objectives are discussed.

Section 11.0 identifies and screens remedial technologies for controlling migration of overburden groundwater and coal tar at the Mechanicville site. In Section 12.0, remedial alternatives are assembled with different combinations of technologies based on observed contamination and site features. Section 13.0 screens the assembled alternatives using the criteria of implementation, effectiveness, and cost. Section 14.0 analyzes in detail the three alternatives that emerged from the alternatives screening. The seven evaluation criteria discussed in the NYSDEC TAGM 90-4030 for the Selection of Remedial Actions at Inactive Hazardous Waste

Sites (NYSDEC, 1990) serve as a basis for conducting the detailed analysis of the three remedial alternatives.

Section 15.0 is a comparative analysis of the remedial alternatives discussed in Section 14.0. The purpose of Section 15.0 is to compare the advantages and disadvantages of each of the three remedial alternatives, relative to one another, with regard to the evaluation criteria. This comparison serves as the basis for selecting an appropriate remedial action in Section 16.0. In accordance with the NYSDEC TAGM 90-4030 (NYSDEC, 1990), a scoring of each alternative was conducted to aid in the comparative analysis of alternatives. The detailed breakdown of how each of the alternatives was scored is presented in Appendix F.

Previous Feasibility Study Work. As part of the Phase II Remedial Investigation Report and Work Plan for the Phase IIA Supplemental Remedial Investigation and Feasibility Study (ABB-ES, 1992), a Phase IIA Supplemental Focused Feasibility Study Work Plan was developed. The Work Plan identified response objectives and the proposed technical approach for a focused FS, which included identification of potential remedial technologies and alternatives to reduce the release of site-related contaminants to the Anthony Kill.

Six alternatives that have the potential to mitigate contaminant migration to the Anthony Kill, plus a no action alternative, were identified. The seven alternatives included:

1. No Action
2. Downgradient Subsurface Drains

3. Downgradient Barrier Wall
4. Downgradient Extraction Wells
5. Downgradient Barrier Wall with Extraction Wells
6. Upgradient Subsurface Drains
7. Upgradient Subsurface Drains with Downgradient Barrier Wall

The applicability of each of these alternatives to site conditions was reevaluated for this FS based on additional data collected during the Phase IIA Supplemental RI and groundwater modeling conducted to evaluate potential alternatives (see Appendix E). Based on this analysis, the technical approach described in the Work Plan was not changed, with two exceptions.

First, the No Action Alternative was changed to a Minimal Action Alternative that includes environmental monitoring, administrative controls (e.g., deed restrictions), five-year site reviews, and asphalt cover maintenance. This alternative represents the minimal effort that would be made to provide protection and will provide a baseline with which to compare other remedial alternatives in this FS. Second, Alternative 5 was not developed into a stand-alone, separate alternative. Based on modeling conducted to evaluate the alternatives, perimeter containment wells at the barrier wall will likely not be required to prevent mounding of groundwater at the wall because of low groundwater flow in the overburden unit beneath the site (Appendix E). As a result, rather than conducting a detailed analysis for this alternative, the addition of perimeter containment wells is evaluated as a potential action to be evaluated in the future in the event that Alternative 3: Downgradient Barrier Wall is selected as the preferred remedial alternative. In addition, because this FS has been developed in accordance with the NYSDEC TAGM 90-4030 for

Selection of Remedial Actions at Inactive Hazardous Waste Sites (NYSDEC, 1990), the FS is no longer considered a "focused" FS and will not be referred to as such.

10.0 IDENTIFICATION OF STANDARDS, CRITERIA, AND GUIDELINES

10.1 IDENTIFICATION OF STANDARDS, CRITERIA, AND GUIDELINES (SCGS)

The SCGs identified in this section are used to (1) evaluate the appropriate extent of site cleanup, (2) define and formulate remedial action alternatives, and (3) govern implementation and operation of the selected action. SCGs include both state and federal laws, regulations, guidance, and criteria that directly apply to site-specific conditions, features, or remedial actions.

Because of their site-specific nature, identification of SCGs requires evaluation of the body of federal, state, and local environmental and health regulations with respect to chemicals of concern, site characteristics, and proposed remedial alternatives. Requirements that pertain to a remedial response can be categorized into three distinct areas:

- **Chemical-specific** requirements generally involve health- or risk-based numerical values or methodologies that establish site-specific acceptable concentrations and/or amounts. The values are used to develop action levels, cleanup concentrations, and/or discharge limits.

- **Location-specific** requirements involve restrictions established for specific substances or activities because of the location or characteristics of a site.

- **Action-specific** requirements are generally technology- or activity-based limitations that direct how remedial actions are conducted.

10.1.1 Chemical-specific SCGs

Chemical-specific SCGs are numerical values or procedures that, when applied to a specific site, establish numerical limits for individual chemicals or group of chemicals. These SCGs are generally health- or risk-based standards limiting the concentration of a chemical found in or discharged to the environment. They govern the extent of site remediation by providing either actual cleanup levels, or the basis for calculating such levels. Table 10-1 summarizes chemical-specific SCGs, listed by the media to which they apply.

10.1.2 Location-specific SCGs

Location-specific SCGs represent restrictions placed on the concentration of hazardous substances or the conduct of activities because of the location or characteristics of a site. These SCGs set restrictions relative to special locations such as wetlands, floodplains, sensitive ecosystems, as well as historic or archeological sites, and provide a basis for assessing existing site conditions. No location-specific SCGs have been identified for this site.

10.1.3 Action-specific SCGs

Action-specific SCGs provide a basis for screening remedial technologies, developing remedial alternatives, and assessing the feasibility and effectiveness of each remedial

alternative retained for detailed evaluation. Action-specific SCGs, unlike location- and chemical-specific SCGs, are usually technology- or activity-based limitations that direct how remedial actions are conducted. The applicability of this set of requirements is directly related to the components of the remedial alternatives developed for the site. Potential action-specific SCGs are presented in Table 10-2.

10.2 DEVELOPMENT OF REMEDIAL OBJECTIVES

This subsection describes the basis for developing and comparing remedial technologies or alternatives. In Subsection 10.2.1, remedial response objectives developed based on an evaluation of information gathered during the field investigations and assessment activities are identified. The preliminary remediation goals for the Mechanicville site are established in Subsection 10.2.2. An understanding of site environmental contamination and remedial actions that will be considered to meet the response objectives is presented in Subsection 10.2.3. Subsection 10.2.4 describes the general response actions that will be used to identify technologies. The information presented in this section forms the basis for developing and comparing remedial alternatives.

10.2.1 Identification of Remedial Response Objectives

Response objectives are site-specific, qualitative, initial cleanup objectives established on the basis of the nature and extent of contamination, the resources currently or potentially threatened, and the potential for human and environmental exposure.

These response objectives are used to develop remedial action objectives and appropriate remedial alternatives.

Using the results of the RI and risk assessment, media potentially impacted by site-related contaminants were evaluated in Section 9.0 to assess the media for which remedial response objectives should be developed. Based on this assessment, as well as SCGs identified in Subsection 10.1, the goal of the FS is to evaluate what, if any, additional remedial actions should be implemented to mitigate potential impacts to ecological receptors in the Anthony Kill. Therefore, the response objectives for the Mechanicville site include managing of the release of site-related contaminants to the Anthony Kill in terms of the following migration pathways:

- the movement of coal tar into the Anthony Kill; coal tar was observed in subsurface explorations above a confining silt layer 1 to 4 feet above the bedrock surface; and

- the discharge of site-contaminated groundwater to the Anthony Kill.

10.2.2 Identification of Preliminary Remediation Goals

The purpose of evaluating cleanup goals is to establish the extent of cleanup required for a site. Cleanup levels will generally be set at health-based levels that reflect current and potential use and exposure. However, the Mechanicville site is not located over a water supply and the nearest known water supply wells are approximately 1 mile southwest (upgradient) of the site in the Town of Halfmoon. Therefore, because Mechanicville groundwater is not currently used as a public

potable water supply, drinking water standards (i.e., federal and New York State MCLs) are not currently applicable.

In addition to state MCLs, NYSDEC has promulgated standards for the protection of groundwater quality (6 NYCRR Parts 700 - 705). All fresh groundwaters in the State of New York are classified as Class GA groundwaters. The best usage of Class GA groundwater is as a potable water source; the standards and guidance values are therefore set at concentrations to protect human health and drinking water sources and are referred to as health (water source) values. However, as previously discussed (see Subsection 9.2), because groundwaters in the vicinity of the Mechanicville site are not a current source of drinking water, nor a likely potential future source, application of these standards is not appropriate. Further, other potential sources of groundwater contamination, including gas stations, petroleum fuel storage facilities, rail yards, and manufacturing facilities are also nearby the site and represent additional threats to any planned water supply installation near the site. Finally, it is highly unlikely that Class GA groundwater standards could be achieved within a reasonable time frame or cost given potential off-site sources contributing to groundwater contamination and the presence of DNAPLs in the fractured bedrock unit beneath the site (see Subsection 9.2).

Cleanup levels for groundwater that may be extracted from beneath the site will depend on the selected discharge location (e.g., publicly owned treatment works [POTW] or Anthony Kill). Once a discharge location has been selected, discharge criteria will be negotiated with the appropriate agency (e.g., POTW or NYSDEC).

10.2.3 Remedial Action Objectives

Remedial action objectives are site-specific, quantitative goals defining the extent of cleanup required to achieve response objectives. They include preliminary target cleanup levels, the area of attainment, and the restoration time frame, as appropriate. Remedial action objectives are developed during the FS process and are used as the framework for developing detailed remedial alternatives. The objectives are formulated to achieve the overall goal of protecting human health and the environment and are established with consideration given to the site location and present and future use.

Because existing site conditions effectively control migration of coal tar to the Anthony Kill (see Subsection 9.2), the remedial action objectives for the Mechanicville site are:

- Control migration of coal tar to the Anthony Kill to maintain levels that do not pose a risk to ecological receptors.

- Control migration of contaminants in groundwater to the Anthony Kill to maintain levels that do not pose a risk to ecological receptors.

10.2.4 General Response Actions

General response actions describe general categories of remedial technologies that may be employed to address remedial action objectives, and lay the groundwork for identifying specific technologies in Section 11.0. For controlling migration of coal tar

and overburden groundwater, these general response actions may include one or a combination of the following:

- no action
- institutional controls
- groundwater monitoring
- containment
- extraction
- treatment
- disposal

For the Mechanicville site, the primary general response action will be to control migration of coal tar and contaminants in groundwater to the Anthony Kill. The no action alternative is considered a baseline against which other alternatives can be compared. For the purposes of this FS, the no action alternative involves minimal, limited sampling and administrative controls. Therefore, the baseline alternative will be referred to as "minimal action" for the remainder of this FS.

11.0 IDENTIFICATION AND SCREENING OF APPLICABLE TECHNOLOGIES

This section identifies and screens technologies for controlling migration of overburden groundwater and coal tar at the Mechanicville site. This process was completed in accordance with the NYSDEC TAGM 90-4030 for the Selection of Remedial Actions at Inactive Hazardous Waste Sites (NYSDEC, 1990), the NCP (USEPA, 1993c and USEPA, 1990), and USEPA RI/FS guidance (USEPA, 1988). The result is a list of potential remedial technologies that will be developed into remedial alternatives. Technologies were identified to attain the remedial action objectives established in Subsection 10.2.3, and to fit into the categories of general response actions described in Subsection 10.2.4. The demonstrated performance of each technology was considered, and the applicability of a technology was established by considering site and waste characteristics.

Site characteristics that were considered include:

- site geology, hydrogeology, and terrain
- availability of space and resources necessary to implement the technology
- presence of special features at the site (e.g., floodplains)

Waste characteristics that were considered include:

- contaminated media
- types and concentrations of waste constituents
- physical and chemical properties of the waste (e.g., volatility, solubility, density, viscosity, and mobility)
- location of contaminants (e.g., fractured bedrock)

The technology screening process reduces the number of potentially applicable technologies by evaluating each technology as to its **effectiveness** in providing protection to human health and the environment and to the reduction in toxicity, mobility, or volume of the waste; **implementability**, as a measure of both the technical and administrative feasibility of constructing, operating, and maintaining a remedial technology; and **cost**, as compared to other technologies providing similar performance.

Table 11-1 identifies general response actions and potential remedial technologies for controlling migration of overburden groundwater and coal tar at the Mechanicville site. Technology screening is presented in Table 11-2. Technologies judged not effective nor implementable were eliminated from further consideration. A summary of the technologies retained for remedial alternatives development for overburden groundwater are presented in Figure 11-1.

12.0 DEVELOPMENT OF REMEDIAL ALTERNATIVES

Based on remedial action objectives, location- and chemical-specific SCGs, and screening of applicable technologies, six remedial alternatives were developed for control of overburden groundwater and coal tar at the Mechanicville site. A range of control alternatives was developed to include minimal action, containment, and containment combined with extraction/treatment alternatives. The alternatives developed for control of overburden groundwater and coal tar at the Mechanicville site and the major technical components of each are presented in Table 12-1.

13.0 INITIAL SCREENING OF THE MECHANICVILLE SITE ALTERNATIVES

In this section, the six alternatives developed for the Mechanicville site are screened for effectiveness, implementability, and cost. Criteria considered for each factor during the initial screening of alternatives are presented in Table 13-1. Tables 13-2 through 13-7 present the initial screening of each alternative. Table 13-8 summarizes the status of each alternative based on the initial screening.

14.0 DETAILED ANALYSIS OF REMEDIAL ACTION ALTERNATIVES

This section presents the detailed analysis of remedial action alternatives for the Mechanicville site. Subsection 14.1 discusses the general approach to the detailed analysis; and Subsections 14.2 through 14.4 present the detailed analyses for Alternatives 1, 2, and 3, respectively, which were retained for further evaluation as discussed in Section 13.0.

14.1 GENERAL APPROACH TO THE DETAILED ANALYSIS

The detailed analysis is intended to provide decision-makers with sufficient information to select the appropriate remedial alternative for management of overburden groundwater and coal tar residuals at the Mechanicville site that best meets the following NYSDEC requirements:

- is protective of public health and the environment
- attains SCGs (or provides grounds for invoking a waiver)
- provides preference for treatment that reduces toxicity, mobility, or volume as a principal element (or provides an explanation in the decision document as to why it does not)
- is cost-effective

The detailed analysis has been conducted in accordance with the NYSDEC TAGM 90-4030 for the Selection of Remedial Actions at Inactive Hazardous Waste Sites (NYSDEC, 1990), the NCP (USEPA, 1993a and USEPA, 1990), and USEPA RI/FS guidance (USEPA, 1988), and includes the following:

- detailed description of each remedial alternative emphasizing the application of various technologies as components of the alternative; and

- detailed analysis of each alternative against the evaluation criteria described in TAGM 90-4030 (NYSDEC, 1990).

The detailed description of the technologies or processes used for each alternative includes, where appropriate, preliminary site layouts and a discussion of the limitations, assumptions, and uncertainties for each component. These descriptions are intended to provide a conceptual design of each alternative and are used for cost purposes only. Costs presented in this analysis are based on existing data and knowledge of the site and will be reevaluated at the time of remedial action implementation. The three remedial alternatives are subsequently evaluated according to the seven criteria listed in Table 14-1.

The following three remedial alternatives are being considered for implementation at the Mechanicville site:

- Alternative 1: Minimal Action
- Alternative 2: Downgradient Barrier Wall

- Alternative 3: Upgradient Subsurface Drain with Downgradient Barrier Wall

14.2 DETAILED ANALYSIS OF ALTERNATIVE 1: MINIMAL ACTION

14.2.1 Description

The Minimal Action Alternative was developed as a baseline with which to compare other remedial alternatives and represents the minimal effort that would be taken to provide protection. Components of the alternative include the following:

1. Environmental Monitoring
2. Institutional Controls
3. Five-year Site Reviews
4. Asphalt Cover Maintenance
5. Bedrock Mapping

Environmental Monitoring. The objective of the environmental monitoring program would be to monitor site conditions at the Mechanicville site and evaluate whether the risk to human health and the environment changes over time. Based on current site conditions, no significant human health or ecological risk currently exists at the Mechanicville site.

Monitoring would involve routine periodic sampling and analysis of surface water, sediment, and groundwater. The long-term monitoring plan developed and described

below is conceptual. The final, detailed monitoring plan would be developed and submitted for regulatory agency review and comment before implementation.

It is assumed that environmental samples would be collected annually over a period of 30 years, with the frequency reduced over time if no adverse changes in site conditions were observed. Therefore, the estimated costs are believed to be conservative. Based on field investigations conducted to date, all samples would be analyzed for Target Compound List VOCs and SVOCs.

It is assumed that up to four (4) surface water and four (4) sediment samples would be collected along the southern bank of the Anthony Kill annually. Analytical results would be used to detect and evaluate potential migration of coal tar into the stream and its potential impact on ecological receptors.

Groundwater samples would be collected from two (2) existing groundwater monitoring wells (MW-16 and MW-17), one (1) new downgradient monitoring well in overburden, and one (1) new seepage meter installed in the Anthony Kill (Figure 14-1). The upgradient monitoring well, MW-16, would be monitored to provide information on the background concentrations of contaminants in overburden groundwater. The new downgradient well screened at the overburden/bedrock interface and the new seepage meter installed in the Anthony Kill would be monitored to detect and evaluate potential contaminant migration into the Anthony Kill. Monitoring well (i.e., MW-17) would be monitored to evaluate overburden groundwater conditions in the downgradient area east of the site. Water level data would be collected from all existing wells on the site in which free phase coal tar is not encountered to evaluate hydraulic conditions and flow.

Institutional Controls. Institutional controls in the form of deed and land-use restrictions would be implemented to restrict future noncommercial use of the site, thereby limiting the potential for exposure to site contaminants. The controls would also prohibit groundwater use within the site. These controls would be drafted, implemented, and enforced in cooperation with the state and local governments.

Five-year Site Reviews. In accordance with the NYSDEC TAGM 90-4030 for the Selection of Remedial Actions at Inactive Hazardous Waste Sites (NYSDEC, 1990), a remedial action that results in contaminants remaining on site should be reviewed at least once every five years. Data collected during the environmental monitoring program would provide useful information for this review. The review would assess potential impacts of contaminants to the Anthony Kill and downgradient overburden groundwater, and evaluate risks to human health and the environment. In addition, the review would assess technologies that have emerged and been demonstrated over the previous five years for the extraction and treatment of coal tar present in the overburden and bedrock beneath the site. It was assumed that no site investigation activities would be required as part of this review.

Asphalt Cover Maintenance. The majority of the area on which the former gas manufacturing facilities were located is either paved or is covered by the slab and/or foundation(s) of the former structures. As a result, infiltration by precipitation to subsurface soils is minimized, thereby reducing potential flushing of site-related residuals into the groundwater system beneath the site. In addition, the asphalt cover reduces potential direct contact with site soils. To maintain these benefits, periodic maintenance and/or repair of the asphalt cover is included as part of this alternative. It was assumed that the existing asphalt cover at the site would be inspected annually

to assess its integrity and ability to continue to reduce infiltration to the site. The cap would be visually inspected and repaired (e.g., resurfaced, patched, etc.), as necessary.

Bedrock Mapping. Because bedrock fractures are the primary contaminant pathway for discharge to the Anthony Kill, bedrock mapping would be conducted to identify significant fracture trends in the site vicinity and the general orientation of bedrock fractures in the Anthony Kill. This information would be used to evaluate potential groundwater discharge points and migration pathways in bedrock, and to assess the need to implement additional remedial actions at the site. It was assumed that mapping would include a photolineament survey of the area, a field survey of the streambed of the Anthony Kill, and that no intrusive activities would be required.

14.2.2 Compliance with SCGs

Because Alternative 1 would not involve any remedial actions, contaminated overburden groundwater and coal tar could migrate toward the Anthony Kill and potentially have an adverse impact on ecological receptors. However, investigations indicate that migration of coal tar from the site is extremely slow under current site conditions. Free phase coal tar has not been observed as seepage into the Anthony Kill and has not been observed in perimeter monitoring wells MW-14, MW-17, and MW-18. The risk assessment concluded that because groundwater discharge rates to the Anthony Kill are very low, the potential for aquatic impacts associated with contaminant discharges from the site is minimal. Therefore, because existing site conditions are effective in limiting the migration of coal tar, the Minimal Action

Alternative would maintain the current level of protection and would meet response objectives.

No location-specific SCGs were identified for this site.

The only intrusive actions associated with Alternative 1 would be monitoring well and seepage meter installation and sampling of surface water, sediments, and groundwater. These activities would be conducted according to regulations outlined by OSHA.

14.2.3 Overall Protection of Human Health and the Environment

Groundwater beneath the site is currently not a source of drinking water, nor does it represent a potential future source, and is therefore not a risk to human health because no exposure pathway exists. The risk assessment also concluded that groundwater presents minimal risk to environmental receptors. However, contaminant concentrations in excess of MCLs and NYSDEC criteria have been detected in groundwater, and coal tar present in the subsurface acts as a continuing source to groundwater contamination. Because groundwater and coal tar associated with the site would not be contained or controlled, contaminants in excess of groundwater criteria could migrate to the Anthony Kill, resulting in potential risk to the environment. Monitoring would be necessary to evaluate if this is occurring and, if so, whether it results in unacceptable risk to the environment after reaching the Anthony Kill.

14.2.4 Short-term Impacts and Effectiveness

Individuals accessing the site for sampling activities would be required to be trained in health and safety procedures for work at hazardous waste sites. The existing site-specific HASP would be updated, approved, and followed, and applicable OSHA regulations would be followed.

Because no remedial activities would be implemented under this alternative, no adverse effects on the local community and the environment are anticipated.

14.2.5 Long-term Effectiveness and Permanence

Because no treatment or containment technologies would be implemented, the Minimal Action Alternative would not be a permanent remedy. Containment and control of coal tar and contaminated groundwater would be limited to reductions achieved by the existing asphalt paving and existing site conditions, which, based on existing data, are effective in controlling migration of coal tar. Although no actions would be taken to control potential future ecological risks due to migration of coal tar and contaminants in site groundwater to the Anthony Kill, the risk assessment concluded groundwater discharge currently presents minimal risk to aquatic receptors. Therefore, although the remedial action goal of permanence would not be met, existing conditions are providing protection to human health and the environment.

14.2.6 Reduction of Toxicity, Mobility, and Volume

The existing asphalt cover minimizes precipitation infiltration to subsurface soils, thereby reducing potential flushing and mobility of site-related residuals into the groundwater system beneath the site. Additional treatment (e.g., destruction, separation/treatment, or solidification/chemical fixation technologies) or containment processes would not be employed to address site contamination. Therefore, no reduction over existing site conditions in toxicity, mobility, or volume of contaminants would be achieved.

14.2.7 Implementability

Environmental monitoring, institutional controls, five-year site reviews, asphalt cover maintenance, and bedrock mapping would be the only activities associated with this alternative. Equipment, materials, and services for all activities are readily available. Some coordination among NYSEG, state, and local officials would be required to conduct these activities and to implement institutional controls. Detailed plans for environmental monitoring and bedrock mapping would require development and implementation. These plans would be subject to regulatory review and approval. Institutional controls and five-year reviews would likely be easy to implement. The Minimal Action Alternative would not interfere with possible future remedial actions at the site and will facilitate use of more technically and cost effective technologies for coal tar remediation.

14.2.8 Cost

A cost estimate was prepared for Alternative 1 to help select a remedial alternative. The estimate contains the following principal elements:

- capital cost
- operation and maintenance cost

Capital cost consists of direct and indirect costs. Typically, these costs include those expenditures initially incurred to develop, construct, and implement the remedial alternative. For Alternative 1, direct costs include expenditures for the equipment, labor, and materials necessary to establish institutional controls and conduct bedrock mapping. A 25 percent contingency was included in direct cost items to account for unforeseen project complexities.

Indirect costs include expenditures for contractors' overhead and profit. Additional administrative, engineering, and legal services include engineering expenses, legal fees, health and safety costs, and contingency allowances.

Engineering design and services (i.e., documentation and resident engineering) was estimated at 5 percent of the direct costs. Costs for health and safety activities conducted at Level D were estimated at 2 percent of direct costs. Legal, administrative, and permitting costs were estimated at 2 percent of direct costs.

Operation and maintenance costs refer to expenditures associated with long-term environmental monitoring and maintenance of the environmental systems (i.e., groundwater monitoring wells) and asphalt cover and five-year site reviews.

The estimated total present worth (i.e., 5 percent for 30 years) of Alternative 1 is $685,000. Total estimated engineering, and administrative costs for institutional controls and bedrock mapping are $55,000. The present worth of operation and maintenance costs are estimated at $630,000. Table 14-2 summarizes the costs estimated for Alternative 1.

To generate these costs, the following assumptions were made with respect to Alternative 1:

- the Mechanicville site would be reviewed every five years for a period of 30 years; and

- environmental monitoring (i.e., groundwater, surface water, and sediment) and asphalt cover maintenance would be conducted annually for 30 years.

14.3 DETAILED ANALYSIS OF ALTERNATIVE 2: DOWNGRADIENT BARRIER WALL

14.3.1 Description

Alternative 2 consists of the following major components:

1. Environmental Monitoring
2. Institutional Controls
3. Five-year Site Reviews
4. Asphalt Cover Maintenance
5. Bedrock Mapping
6. Site Preparation
7. Removal and Treatment/Disposal of Filter Bed Soil
8. Installation of Downgradient Barrier Wall

Components 2, 3, 4, and 5 would be performed as described for Alternative 1 (see Subsection 14.2.1). The remaining four major components are described in the following paragraphs.

Environmental Monitoring. The environmental monitoring program would be similar to that described for Alternative 1 (see Subsection 14.2.1). The principal difference would be the objectives of the program which, for Alternative 2, would be to evaluate the effectiveness of the downgradient barrier wall installed at the site and to continue to assess groundwater beneath the site.

Site Preparation. Site preparation would include activities required to prepare the site for mobilization and construction of the barrier wall. Because the gas manufacturing facilities have been demolished and the majority of the area on which the facilities were located has been paved or is covered by the slab of the former structures, minimal clearing of vegetation would be required. It will, however, be necessary to clear some vegetation on the southern bank of the Anthony Kill to allow construction equipment access for installation of the barrier wall. It is assumed that construction of access roads and/or upgrading existing roads to handle heavy equipment would not be required. In addition, because geophysical investigations have been conducted as part of the site investigation (see Sections 3.0 and 4.0), it was assumed that additional surveys to locate underground structures and to delineate bedrock surface would not be required for installation of the downgradient barrier wall. Additional site preparation activities that would be required before work could commence include locating and removing above-ground and subsurface utilities and/or obstructions, establishing a stockpile/storage area for equipment and materials, mobilizing a field office, and establishing a decontamination and trash disposal area.

Removal and Treatment/Disposal of Filter Bed Soil. In November 1981, NYSEG collected soil samples from the filter beds area and the relief gas holder foundation. Laboratory analysis of one (1) sample from the filter beds detected the presence of reactive sulfides at a concentration of 1,300 ppm. This concentration exceeds the threshold concentration for the hazardous reactivity test. In an attempt to further delineate soils associated with the former filter beds, additional soil borings were completed in this area (see Subsection 6.1.2).

Although no evidence of waste coke from the former filter beds was observed in any of the split-spoon soil samples collected in 1993, it was assumed that a test pit survey would be conducted in this area to attempt to locate residual waste coke from the former filter beds. Based on visual observations, soils that contain waste coke would be collected and disposed of appropriately. It was assumed that waste coke might be observed in an estimated 30 cubic yards of soil. This volume estimate was developed assuming an average depth of 8 feet and half the area encompassed by the six (6) borings completed in the former filter bed area (see Subsection 6.1.2). These soils would be excavated, sampled, and disposed of at an appropriate disposal facility. It was assumed that the soils would fail the hazardous test for reactivity, and would therefore require treatment/disposal in an approved, licensed hazardous waste landfill.

Installation of Downgradient Barrier Wall. A low permeable barrier wall is a vertical barrier placed in the subsurface to minimize fluid flow. Barrier walls have been used for many years in civil engineering projects, where they are used for reducing groundwater inflow into excavations or beneath dams. Use of barriers for environmental control purposes is more recent. Goals typically are to prevent contaminated groundwater from crossing site boundaries or discharging into surface waters. At the Mechanicville site, the purpose of the downgradient barrier wall would be to control migration of overburden coal tar to the Anthony Kill.

As described in Section 13.0, a number of techniques are used for constructing barrier walls including slurry walls, grout curtains, and sheet pile walls. Based on current site conditions, a sheet pile wall was selected for analysis in this FS. Sheet pile systems offer a number advantages over other barriers, including:

- The sheet pile system can be installed with minimal excavation, minimizing potential health and safety concerns and disposal of contaminated soils.

- The sheet pile system can achieve low permeabilities if the joints are sealed to prevent potential leakage.

- Minimal construction equipment and ancillary facilities are required, making it more suitable for use at sites where access is limited compared to alternative barrier technologies.

If alternative barrier wall technologies are evaluated during the design and found to be more effective, a different technology may be used at this site.

Sheet piling structures consist of individual sheet piles that are fitted together and driven into the ground. Adjacent sheets are connected by interlocking joints that are designed for mechanical strength rather than to prevent water passage. Because the goal of the downgradient barrier wall at the Mechanicville site is to prevent migration of coal tar to the Anthony Kill, sealing of these joints would likely be necessary to prevent leakage. Various methods are available for sealing joints between sheet piles including placing a sealant into each joint before the sheets are coupled and driven into the ground, grouting the soil adjacent to each joint after the sheets have been driven, or installing sheets designed to allow injection of sealant into joints after being driven into the ground (Starr, et al., 1992). For cost estimating purposes in this FS, the last method was selected.

A patented steel sheet piling whose interlocking joints between individual sheets are constructed with a cavity that can be filled with sealant after driving the sheet piles into the subsurface has been developed. The cavity can be cleaned before and after driving to ensure it is clean and free of soil and/or other foreign material (e.g., rust, grease, etc.). The type of material used to seal the joints is dependent on contaminants present and site conditions. Materials that have been field tested and demonstrated include bentonite grouts, an organic polymer that absorbs water and swells, and epoxy resins. Based on current site conditions at the Mechanicville site, it was assumed that a cement/bentonite grout would be an effective sealant. However, compatibility testing may be needed during design to evaluate effectiveness of the selected grouting material.

For the Mechanicville site, construction of the sheet pile system would begin with excavation and removal of portions of the two existing storm water outfalls that the barrier wall will cross (Figure 14-2). It was assumed that excavated soils generated during removal of the outfalls would be collected and disposed of off-site. The excavated area would subsequently be backfilled with clean fill to provide access for the driving operation.

The contractor would subsequently begin driving the sheet piles using standard techniques for sheet pile wall construction. A 200-foot wall with 30-foot wings on either side would be installed between the south bank of the Anthony Kill and an existing concrete pad (see Figure 14-2). It was assumed that the sheet pile sections would be driven through the overburden soils beneath the site and keyed one to two feet into weathered bedrock. The depth of the sheets would vary between approximately 10 and 28 feet bgs, depending on the depth to bedrock. After driving,

all foreign matter would be removed from the joints by high pressure water blasting. A grouting tube would subsequently be lowered to the bottom of the joint, sealant injected, and the tube withdrawn as the cavity is filled with sealant.

Once the sheet piles are in place, the contractor would excavate down to the storm drain locations, cut holes into the sheet pile wall, and reinstall the two storm drains. The pipe penetrations within the wall would be sealed with bentonite and the area backfilled with clean fill material.

All wash water generated while cleaning the joints and any groundwater encountered during installation of the sheet pile wall would be collected, sampled, and analyzed to determine disposal requirements. It was assumed that this water would be transported to an off-site treatment/disposal facility.

The primary function of this alternative would be to control coal tar migration in the overburden to the Anthony Kill, thus providing protection to aquatic receptors. However, based on groundwater modeling conducted to evaluate remedial alternatives (see Appendix E), the downgradient barrier would not be effective for controlling overburden groundwater flow. The downgradient barrier would only direct groundwater flow in the overburden more easterly in the vicinity of the barrier, and eventually into the Anthony Kill. Flow could also potentially be diverted under the downgradient barrier wall. Groundwater discharging into the Anthony Kill along the length of the barrier is estimated to decrease only about three percent, while no change in overall flow is estimated (see Appendix E).

Groundwater modeling was also conducted to evaluate the potential benefits of perimeter containment wells at the ends of the barrier to relieve mounding and control lateral flow around the barrier (see Appendix E). The model first evaluated the impact on groundwater flow if two (2) perimeter wells were installed in the overburden. Results indicated that the simulated wells could not be pumped at more than a total of 0.05 gpm before creating excessive drawdown. As a result, containment wells were simulated to extend through the overburden and approximately 5 feet into bedrock. The model predicted greater total flow (up to 0.13 gpm before the overburden became dry), but still did not provide significantly greater control of groundwater (only a decrease of 5 percent of total flow and a reduction of approximately 10 percent in flow to the stream along the location of the barrier). In addition, because pumping these wells would lower the water table, migration of overburden coal tar into the bedrock could increase.

Based on the modeling of the remedial system, it was assumed that perimeter containment wells would not be required because the model predicts that groundwater mounding against the downgradient barrier would be minimal (i.e., approximately 0.5 feet, see Appendix E). However, environmental monitoring and visual inspections would be conducted to evaluate the need for future controls such as hydraulic controls.

If conditions indicate the need for perimeter containment wells, it is anticipated that two (2) wells installed on the eastern and western ends of the sheet pile system would be required (Figure 14-3). These wells would be installed five feet into bedrock with 10-foot screens across overburden and shallow bedrock to maintain flow without drying out the overburden. Although modeling estimated that the two

(2) wells would be capable of pumping a total of approximately 0.1 to 0.2 gpm, it was assumed that up to 1 gpm total flow could effectively be removed. Extracted groundwater would be pumped to an on-site treatment unit where it would undergo treatment to remove NAPLs that may be present and potentially treatment to remove inorganic and/or organic contaminants. Treated water would subsequently be discharged to one of the following locations:

- Anthony Kill; or
- local POTW.

The discharge location and degree of treatment required would be negotiated with the POTW and/or NYSDEC prior to installation of the perimeter containment wells. Estimated costs to install, operate, and maintain such a system are discussed in Subsection 14.3.8.

14.3.2 Compliance with SCGs

Location-specific SCGs have not been identified for the Mechanicville site. The components of Alternative 2 would be designed and executed to comply with applicable chemical-specific and action-specific SCGs identified in Tables 10-1 and 10-2, respectively. OSHA requirements for training, safety equipment, and recordkeeping would be met during construction activities at the site.

Alternative 2 would only partially achieve response objectives because contaminated overburden groundwater would continue to migrate to the Anthony Kill. However, the risk assessment concluded that because groundwater discharge rates to the

Anthony Kill are very low, the potential for aquatic impacts associated with contaminant discharges from the site is minimal. Migration of overburden coal tar to the Anthony Kill would be controlled.

14.3.3 Overall Protection of Human Health and the Environment

Alternative 2 would provide some additional protection to ecological receptors by controlling migration of coal tar in the overburden to the Anthony Kill. Because groundwater would only be diverted around and potentially under the downgradient barrier, this alternative would not effectively control migration of overburden groundwater in the long-term. However, groundwater in the area is currently not a source of drinking water, nor does it represent a future potential source, and is therefore not a risk to human health.

Because of the industrialized nature of this area, and the lack of suitable habitats, no significant impacts to area wildlife would be anticipated from implementation of this alternative.

The most significant human health risks would be associated with the use of heavy machinery. To minimize these risks, a HASP would be developed and implemented and OSHA regulations would be followed. Because limited excavation would be required, exposure to contaminated soil during installation of the barrier would be minimal.

14.3.4 Short-term Impacts and Effectiveness

None of the components of Alternative 2 would have significant short-term impacts on the local community and environment. Although land use in the immediate vicinity of the site is both residential and commercial, all activities would be conducted on the site. Local truck traffic along North Central Avenue and noise levels in the vicinity of the site may increase slightly during implementation of this alternative.

The only excavation required as part of this alternative would be excavation associated with temporary removal and replacement of two outfalls and removal of soils from the filter bed area. Because minimal excavation activities would be required, generation of fugitive dust or air emissions is anticipated to be minimal. The site would, however, be monitored and dust suppression measures, such as water sprays, would be used, as necessary. In addition, air zones would be monitored for specific contaminants, and appropriate measures such as use of personal protective equipment would be implemented if health and safety action criteria are exceeded. Workers may also be exposed to contaminants through direct skin contact. Appropriate dermal personal protective equipment would be worn. Workers would be exposed to hazards associated with heavy equipment and the excavation. OSHA guidelines would be followed to minimize the potential for construction-related accidents and a HASP would be developed and followed to address worker health and safety during the remedial action.

Mobilization and site preparation activities would take approximately one week. Installation of the downgradient barrier wall would require four to six weeks. Site

restoration and demobilization would take approximately one week. The total time required to implement this alternative would be approximately eight weeks.

14.3.5 Long-term Effectiveness and Permanence

Alternative 2 is a control technology that would not be considered a permanent remedy because no treatment technologies would be implemented. However, as described in Subsection 9.2, DNAPLs such as coal tar are difficult to extract even from highly permeable soils. Because coal tar has migrated into the saturated zone and into fractured bedrock, efficient recovery is even more difficult, if not impossible. Control of coal tar via a downgradient barrier wall would contribute to the long-term management of the contaminant migration by minimizing further contamination of surface water and limiting the spread of the potentially mobile coal tar source. Because Alternative 2 is not a permanent remedy and because wastes would remain on site, potential future remedial options for the site would be assessed as part of the five-year site review.

The performance life of sheet pile barrier walls can vary from 30 to more than 100 years. The design life of the wall depends on the soil and groundwater conditions at the site and the materials used to construct the barrier. Prior to implementation, site conditions would be thoroughly evaluated to determine the most appropriate construction materials. Because the sheet piles would be driven through overburden soils and keyed one to two feet into weathered bedrock, increased fracturing in bedrock may result. Flow of coal tar could potentially increase due to the increased fracturing and result in further spread of contaminants. To mitigate this effect, grout could be injected into the fractures at the bottom of the sheet pile

wall to prevent leakage through the fractures. However, grouting fractures may not stop all leakage. Environmental monitoring and visual inspections would aid in evaluating the need for such controls.

The existing asphalt cover on the site mitigates exposure to surface and subsurface soil through direct contact, incidental ingestion, and fugitive dust inhalation. Annual maintenance of the cover would therefore be conducted to maintain the integrity of the cover.

If soils associated with the former filter bed are encountered that contain waste coke, these soils would be removed from the site and disposed of off-site. Treatment/disposal of waste in a hazardous waste landfill is a commonly used method of remediation. Material containing waste coke would be sampled and analyzed before transporting off-site to determine if treatment before land disposal is required.

14.3.6 Reduction of Toxicity, Mobility, and Volume

Alternative 2 would decrease the mobility of contaminants by controlling the migration of overburden coal tar into the Anthony Kill. However, mobility of contaminants in groundwater would not be controlled because the barrier would only divert groundwater to a discharge location downstream. Installation of perimeter containment wells may aid in controlling the migration of groundwater to the Anthony Kill. However, groundwater modeling predicted minimal additional control of groundwater (i.e., a decrease of 5 percent of total flow and a reduction of approximately 10 percent in flow to the stream along the location of the barrier).

No reduction in toxicity or volume would be achieved because removal or treatment processes would not be employed with the exception of the soils from the former filter bed containing waste coke. It is assumed that approximately 30 cubic yards of soil containing waste coke would be excavated and disposed of off-site. Hazardous waste landfills are designed to reduce the mobility of contaminants through use of synthetic and clay liners and caps. Landfilling of these soils would not reduce the volume or toxicity of the waste.

14.3.7 Implementability

Activities associated with this alternative include: environmental monitoring, institutional controls, five-year site reviews, bedrock mapping, asphalt cover maintenance, site preparation, disposal of excavated soils from the filter beds, and installation of the downgradient barrier wall. Equipment, materials, and services for all activities are readily available. Some coordination among NYSEG, state, county, and local officials, and adjoining property owners would be required to conduct these activities. Detailed plans for environmental monitoring would require development and implementation. These plans would be subject to regulatory review and approval. Institutional controls and five-year reviews would likely be easy to implement. Installation of the downgradient barrier wall would not impact implementation of possible future remedial activities at the site.

Construction of sheet pile barrier walls utilizes standard construction techniques and equipment and materials that would be readily available. Actual construction may, however, be difficult because of the potential presence of underground structures and

debris and proximity of the downgradient barrier wall to the Anthony Kill. Once constructed, no operation and minimal maintenance would be required.

14.3.8 Cost

A cost estimate was prepared for Alternative 2 to help select a remedial alternative. The estimate contains the following principal elements:

- capital cost
- operating and maintenance cost

Capital cost consists of direct and indirect costs. Typically, these costs include those expenditures initially incurred to develop, construct, and implement the remedial alternative. Direct costs include expenditures for the equipment, labor, and materials necessary to establish institutional controls and access restrictions, prepare the site, excavate and dispose of filter bed soils, and construct the barrier wall. Direct capital costs include construction, labor, and equipment; land and site development; and materials. A 25 percent contingency was included in direct cost items to account for unforeseen project complexities (e.g., adverse weather conditions, inadequate site characterization, and increased construction standby times).

Indirect costs include expenditures for contractors' overhead and profit. Additional administrative, engineering, and legal services that are not actually part of the alternative, but are required to complete implementation of the alternative, include engineering expenses, legal fees, health and safety costs, and contingency allowances.

Engineering design and services during construction (i.e., QA testing, construction oversight, documentation, and resident engineering) for Alternative 2 were estimated at 10 percent each of the direct cost. Costs for health and safety activities conducted at Level D protection were estimated at 5 percent of the direct cost. Legal, administrative, and permitting costs were estimated at 5 percent of the direct cost.

Operating and maintenance costs refer to expenditures associated with the five-year site review, environmental monitoring, and asphalt cover maintenance.

The estimated direct, indirect, operation and maintenance, and total present worth costs for Alternative 2 are presented in Table 14-3. The total present worth cost for Alternative 2 is estimated at $1,184,000. Total estimated construction, engineering, and administrative costs are $554,000. The present worth of operation and maintenance costs is $630,000.

To generate these costs, the following assumptions were made with respect to Alternative 2:

- the Mechanicville site would be reviewed every five years for a period of 30 years;

- environmental monitoring and asphalt cover maintenance would be conducted annually;

- a 200-foot sealable joint sheet pile wall with 30-foot wing walls on the eastern and western sides of the wall would be installed;

- all joints would be sealed with a cement/bentonite grout;
- installation of perimeter containment wells to reduce groundwater mounding upgradient of the wall would not be required; and
- 30 cubic yards of soils from the filter beds area would be excavated and disposed of as hazardous waste.

If installation of two perimeter wells is required, the cost to implement Alternative 2 would increase substantially, primarily because of increased operation and maintenance costs that would be associated with treatment and disposal of contaminated groundwater (Table 14-4). Capital costs, which would include installation of two (2) perimeter containment wells, collection piping, treatment building construction, and the actual treatment system is estimated to range between approximately $321,000 and $440,000. Present worth operation and maintenance costs, which include power requirements, treatment residuals disposal, and system monitoring, are estimated to range from $335,000 to $781,000. Capital and operation and maintenance costs would vary depending on the final discharge location and degree of treatment required. Based on this analysis, the present worth cost associated with groundwater interception and treatment could range from $656,000 to $1,221,000 (see Table 14-4). Therefore, the total present worth cost for Alternative 2 with containment wells and treatment could range from $1,917,000 to $2,482,000.

The low range of this estimate assumes minimum treatment, which would include pretreatment with an oil/water separator and, because of the potential treatment

capabilities of a POTW, discharge to the local POTW. If additional treatment for inorganic and/or organic contaminants is required, costs increase. The high range of the estimate includes pretreatment in an oil/water separator, treatment to remove inorganic constituents using chemical precipitation, and treatment to remove organic compounds using carbon adsorption. Because of costs associated with discharge to the local POTW (i.e., the POTW would charge a per gallon fee for use of the facility), this estimate also assumes the treated water would subsequently be discharged to the POTW. Discharge to the Anthony Kill would be a slightly less. The discharge location would dictate the amount of treatment required.

14.4 DETAILED ANALYSIS OF ALTERNATIVE 3: DOWNGRADIENT BARRIER WALL WITH UPGRADIENT SUBSURFACE DRAIN

14.4.1 Description

Alternative 3 consists of the following major components:

1. Environmental Monitoring
2. Institutional Controls
3. Five-year Site Reviews
4. Asphalt Cover Maintenance
5 Bedrock Mapping
6. Site Preparation
7. Removal and Treatment/Disposal of Filter Bed Soil
8. Installation of Downgradient Barrier Wall

9. Installation of Upgradient Subsurface Drain

Components 2, 3, and 4 would be performed as described for Alternative 1 (see Subsection 14.2.1). Components 5, 7, and 8 would be completed as described for Alternative 2 (see Subsection 14.3.1). The remaining major components are described in the following paragraphs.

Environmental Monitoring. The environmental monitoring program would be similar to that described for Alternative 1 (see Subsection 14.2.1). The principal difference would be the objectives of the program, which would be to evaluate the effectiveness of the downgradient barrier wall and the upgradient subsurface drain installed at the site.

Site Preparation. Site preparation would include activities required to prepare the site for mobilization and construction of the barrier wall and subsurface drain. Minimal clearing of vegetation would be required for installation of the barrier wall, but none would be required for the subsurface drain. It is assumed that construction of access roads and/or upgrading existing roads would not be required. Additional site preparation activities that would be required before work could commence include locating and removing above-ground and subsurface utilities (i.e., gas mains which are connected to the gas regulator house) and/or obstructions, establishing a stockpile/storage area for equipment, excavated soil, and materials; mobilizing a field office; and establishing a decontamination and trash disposal area.

Installation of Upgradient Subsurface Drain. The upgradient subsurface drain would consist of a buried conduit which collects and conveys groundwater discharge by

gravity flow. Subsurface drains are a traditional civil engineering technique for lowering the water table and diverting groundwater flow. More recently, drains have been used as environmental controls to contain or remove a groundwater plume, or to prevent contact of groundwater with waste material. For the purposes of this FS, the 170-foot long upgradient drain would be installed in the overburden (invert slightly above top of rock) to divert flow and subsequently reduce groundwater flow across the site. The subsurface drain, in conjunction with the downgradient barrier wall, would therefore reduce total flow to the Anthony Kill. The major components of a typical drain system include the following:

- drain pipe to collect and convey flow to a wet well
- filter to prevent fine particles from migrating into and clogging the system
- backfill to restore the surface to grade
- impermeable downgradient barrier (e.g., geomembrane) to reduce flow from the north side of the subsurface drain
- manhole to allow access to the drain for flushing and maintaining the system
- wetwell for collecting groundwater for discharge
- submersible pump to discharge groundwater

Traditional construction techniques would be used to install the drain. A backhoe and/or other excavation equipment would be used to open cut the trench estimated to be 170 feet long, 4 feet wide, and 15 to 18 feet deep (see Figure 14-4). The invert of the drain would be installed on the shallow bedrock layer which is 15 to 18 feet bgs in the proposed location (Figure 14-5). During construction, the excavation would require sheeting or shoring to prevent the side walls from collapsing and provide worker safety. Site conditions would determine whether shoring would be achieved hydraulically, mechanically, or by using a trench box or sheet piling. For cost estimating purposes, use of a trench box was assumed.

The bedrock surface would be contoured by removing bedrock so that the slope would allow gravity flow from the ends of the drain to a low point in the middle. Once the proper slope is attained, the pipe bedding would be laid atop the shallow bedrock. The bedding would be made of granular material coarse enough to allow flow to the pipe but fine enough to prevent infiltration of soils from the side walls. A 4-inch perforated HDPE pipe would be laid atop the bedding, and the trench would be backfilled to the high groundwater mark, approximately 8 feet bgs, with filter sand. The remainder of the trench would be backfilled with clean excavated material. To determine if material is suitable for backfill, all excavated soil would be screened visually and with portable detection equipment before using as backfill.

It was assumed that a wetwell and a pump would be installed to collect and discharge the diverted groundwater to the Anthony Kill (see Figure 14-4). Diverted groundwater could also potentially be discharged to the local POTW if discharge to the Anthony Kill is not feasible. Construction of the discharge system would consist of excavating a trench 3 to 4 feet deep by 1.5 feet wide between the drain and the

Anthony Kill. Gravel bedding would be laid above the high groundwater level so as not to create a preferential path to the Anthony Kill for groundwater. The non-perforated discharge pipe would be laid atop the bedding, and the trench would be backfilled. If the pipe is laid above the frost line to accommodate the high groundwater level, a layer of insulation would be installed at 1 to 2 feet bgs to protect the discharge pipe from freezing. It is assumed that the proposed location of the discharge pipe would be in an area not impacted by coal tar. Therefore, on-site soils would be used to backfill the trench. However, the excavated soil would be screened visually and with portable detection equipment. If soils impacted by coal tar are observed, the soil would be temporarily stockpiled and sampled, and samples would be analyzed by an off-site laboratory. The soil would be disposed of at an appropriate off-site facility based on analytical results. The trench would be backfilled with clean fill. After backfilling the pipe trenches, the disturbed areas would be restored to original conditions.

Groundwater flow with Alternative 3 in place was modeled, and results are presented in Appendix E. At best, the upgradient drain is predicted to be able to intercept approximately 700 gallons of groundwater per day. The drain may also increase the flux rate from upgradient locations slightly by reducing head and creating a preferential pathway for groundwater flowing toward the drain. The net result would only be a decrease of about 16 percent in the total groundwater discharge across the site to the Anthony Kill.

Discharge to the stream along the downgradient barrier wall frontage would be reduced by about 21 percent. This is, however, a fairly minimal reduction in total groundwater flow because the majority of flow across the site is not associated with

overburden but with shallow bedrock (see Subsection 7.3.1). Groundwater flow in the vicinity of the barrier wall would be diverted easterly around the wall while some would be forced under the wall into the Anthony Kill, similar to predicted conditions for Alternative 2.

14.4.2 Compliance with SCGs

Location-specific SCGs have not been identified for the Mechanicville site. Alternative 3 would be designed and executed to meet relevant federal and state action-specific and chemical-specific SCGs summarized in Tables 10-1 and 10-2, respectively. OSHA requirements for training, safety equipment, and record keeping would be met during construction activities at the site. Because this alternative proposes diverting upgradient groundwater to the Anthony Kill, a State Pollution Discharge Elimination System (SPDES) permit would be obtained. The discharge system would be monitored to verify compliance with the permit. Soils excavated during trenching activities would be analyzed and taken to an appropriate off-site disposal/treatment facility.

Alternative 3 would only partially achieve response objectives because contaminated overburden groundwater would continue to migrate to the Anthony Kill. However, the risk assessment concluded that because groundwater discharge rates to the Anthony Kill are very low, the potential for aquatic impacts associated with contaminant discharges from the site is minimal. Migration of coal tar in the overburden to the Anthony Kill would be controlled.

Because this alternative involves discharging upgradient groundwater to the Anthony Kill, groundwater quality in the vicinity of the proposed drain location, as represented by groundwater at monitoring well MW-1, was compared to AWQC. Groundwater quality data summarized in Tables 5-6 and 5-7 indicate that no organic compounds were detected in the well. However, manganese was detected in the filtered inorganic analysis at a concentration of 123 ppb which is greater than its AWQC (50 ppb). Chromium, iron, manganese, and nickel were detected in the unfiltered inorganic analysis at concentrations greater than AWQC. However, because the inorganic analytes in groundwater are naturally occurring and thus discharging to the Anthony Kill, this alternative assumes that no treatment would be required. Groundwater would initially be monitored on a monthly basis to evaluate its quality. Subsequent sampling and analysis frequency will be determined as conditions merit.

14.4.3 Overall Protection of Human Health and the Environment

This alternative would provide some additional protection to ecological receptors by controlling migration of overburden coal tar to the Anthony Kill. However, based on modeling results, this alternative would not significantly reduce the discharge of site-impacted groundwater to the Anthony Kill. Therefore, risk to the environment, which is minimal under current conditions, would not change appreciably. Currently there is minimal risk to human health at the Mechanicville Site.

As described in Subsection 14.3.3, because of the industrialized nature of this area, and the lack of suitable habitats, no significant impacts to area wildlife would be anticipated from implementation of this alternative.

The most significant human health risks would be associated with the use of heavy machinery. To minimize these risks, a HASP would be developed and implemented and OSHA regulations would be followed. Because limited excavation would be required, exposure to contaminated soil during installation of the barrier would be minimal.

14.4.4 Short-term Impacts and Effectiveness

None of the components of this alternative would have significant short-term impacts to the local community and environment. Although land use in the immediate vicinity of the site is residential and commercial, all activities would be conducted at the site. Local truck traffic along North Central Avenue and noise levels in the vicinity of the site may increase slightly during implementation of this alternative.

The short-term impacts and effectiveness of excavation activities associated with construction of the downgradient barrier wall and removal of soils from the filter beds are presented in Subsection 14.3.4 for Alternative 2 and would be similar for Alternative 3.

It is assumed that trenching activities associated with the upgradient subsurface drain would take place in soils not impacted by coal tar. However, if coal tar is encountered during implementation of this alternative, appropriate personnel protective equipment would be worn to minimize exposure through incidental ingestion, inhalation, and direct skin contact. OSHA guidelines would be followed to minimize construction-related accidents. A HASP would be developed and followed to address worker health and safety during remedial action.

Mobilization and site preparation activities would take approximately one week. Installation of the downgradient barrier wall and upgradient subsurface drain would require four to six weeks. Site restoration and demobilization would take approximately one week. The total time required to implement this alternative would be approximately eight weeks.

14.4.5 Long-term Effectiveness and Permanence

Alternative 3 is a control technology that would not be considered a permanent remedy because no treatment technologies would be implemented. However, as described in Subsection 9.2, DNAPLs such as coal tar are difficult to extract even from highly permeable soils. Because coal tar has migrated into the saturated zone and into fractured bedrock, efficient recovery is even more difficult, if not impossible. Control of coal tar via a downgradient barrier wall and an upgradient subsurface drain would contribute to the long-term management of the contaminant migration by minimizing further contamination of surface water and limiting the spread of the potentially mobile coal tar source. Because Alternative 3 is not a permanent remedy and because wastes would remain on site, potential remedial options for the site would be assessed as part of the five-year site review.

According to the risk assessment, the only potential impact to the environment is migration of coal tar and groundwater to the Anthony Kill. The effect of the asphalt cover and upgradient subsurface drain would be a slight reduction of groundwater flow through the site. The system would experience a slight lowering of the water table which, according to modeling results, would have only minimal effect on

groundwater migration because most of the groundwater flow through the site is in the shallow bedrock layer (see Subsection 7.3.1).

The long-term effectiveness and permanence associated with the asphalt cover and removal of soils associated with the former filter bed are presented in Subsection 14.3.5 for Alternative 2 and would be similar for Alternative 3.

14.4.6 Reduction of Toxicity, Mobility, and Volume

Alternative 3 would reduce the mobility of contamination by further reducing the migration of coal tar to the Anthony Kill from overburden soils. According to the modeling results, the upgradient subsurface drain with the downgradient barrier wall would provide some control of overburden groundwater flow. By controlling overburden groundwater migration to the Anthony Kill, coal tar migration would be further controlled.

This alternative would not reduce the toxicity and volume of media impacted by coal tar because neither removal or treatment processes would be employed with the exception of soils from the former filter bed containing waste coke. As in Alternative 2 (see Subsection 14.3.6), soil containing coke would be excavated and disposed of off-site, which would provide some reduction in volume of waste at the site.

14.4.7 Implementability

As described in Subsection 14.3.7, site preparation would be readily implemented at the site. Common construction equipment and methods would be required for this alternative. Services are relatively reliable and several contractors would be available to participate in a competitive bidding process.

Excavation for the subsurface drain would primarily require a backhoe, concrete cutting equipment to dig through the former distribution holder foundation, and a trench box. A jack-hammer attachment to the backhoe would be used to remove enough bedrock to provide a sufficient slope for groundwater to drain to the wetwell. When construction is completed, minimal operations and maintenance would be required for the asphalt cover and discharge system.

14.4.8 Cost

A cost estimate was prepared for Alternative 3 to help select a remedial alternative. The estimate is based on the same principal elements discussed in Alternative 2.

The estimated direct, indirect, operation and maintenance, and total present worth costs for Alternative 3 are presented in Table 14-5. The total present worth cost for Alternative 3 is estimated at $1,690,000. Total estimated construction, engineering, and administrative costs are $818,000. The present worth of operation and maintenance costs is $894,000.

To generate these costs, the following assumptions were made with respect to Alternative 3:

- the Mechanicville site would be reviewed every five years for a period of 30 years;
- environmental monitoring and asphalt cover maintenance would be conducted annually;
- a 200-foot sealable joint sheet pile wall with a 30-foot wing wall on the eastern and western sides of the wall would be installed;
- all joints would be sealed with a cement/bentonite grout;
- a 170-foot upgradient subsurface drain would be installed 10 to 12 feet bgs;
- approximately 50 percent of excavated soil would require off-site disposal;
- diverted groundwater discharged to the Anthony Kill would be monitored in accordance with SPDES requirements;
- diverted groundwater would not require pretreatment for discharge to Anthony Kill; and

- approximately 30 cubic yards of soil from the former filter beds area would be excavated and disposed of as hazardous waste.

15.0 COMPARATIVE ANALYSIS OF ALTERNATIVES

The comparative analysis presented in this section compares the three remedial action alternatives relative to the evaluation criteria used during the detailed analysis of alternatives. The purpose of the comparative analysis is to identify the advantages and disadvantages of the alternatives relative to one another and to aid in the eventual selection of a remedial alternative for overburden groundwater at the Mechanicville site. Subsection 15.1 presents the approach of the comparative analysis and Subsection 15.2 presents the comparison of the alternatives.

15.1 APPROACH TO THE COMPARATIVE ANALYSIS

Specific factors are considered when comparing alternatives for selection of a preferred site remedy. To the extent practicable, the selected alternative should:

- be protective of human health and the environment
- comply with SCGs (or provide grounds for invoking a waiver)
- use permanent solutions and alternative treatment technologies to the maximum extent practicable

- satisfy the preference for treatment that reduces toxicity, mobility, or volume as a principal element; if this preference is not satisfied, the decision document must explain why

- be cost-effective

In accordance with the NYSDEC TAGM 90-4030 for the Selection of Remedial Actions at Inactive Hazardous Waste Sites (NYSDEC, 1990), the comparative analysis is conducted to evaluate the relative performance of each alternative in relation to each of the seven evaluation criteria. NYSDEC has categorized the evaluation criteria into two groups: threshold and balancing. A discussion of each criteria group is provided below.

15.1.1 Threshold Criteria

Because the selected remedy must be protective of human health and the environment and comply with SCGs, NYSDEC has designated (1) overall protection of human health and the environment, and (2) compliance with SCGs, as the two threshold criteria. An alternative must meet both criteria to be eligible for selection as the site remedy.

15.1.2 Primary Balancing Criteria

The five primary balancing criteria are long-term effectiveness and permanence; reduction of toxicity, mobility, or volume through treatment; short-term effectiveness; implementability; and cost. This balancing provides a preliminary assessment of the

maximum extent to which permanent solutions and treatment can be used practicably in a cost-effective manner.

The alternative that is protective of human health and the environment, is SCG-compliant, and affords the best combination of attributes is identified as the preferred alternative. The balancing emphasizes long-term effectiveness and reduction of toxicity, mobility, or volume through treatment.

15.2 COMPARATIVE ANALYSIS OF ALTERNATIVES

Table 15-1 presents the comparative analysis for the three Mechanicville site remedial alternatives. The comparative analysis highlights the results of the detailed analysis. In accordance with the NYSDEC TAGM 90-4030 (NYDEC, 1990), a scoring of each alternative was conducted to aid in the comparative analysis of alternatives. The TAGM assigns each of the seven criteria a relative weight which results in a maximum score of 100 points (e.g., compliance with SCGs is assigned a relative weight of 10, etc.). Based on the performance of an alternative, as well as how well it meets the objectives of the evaluation criterion, points are assigned. A low total score is an indication that an alternative may not sufficiently achieve the goals and objectives of remedial actions at the Mechanicville site. The total score for each alternative is presented in Table 15-1. A detailed breakdown of how each alternative was scored is presented in Appendix F.

15.2.1 Comparison of Threshold Criteria

The alternatives were first compared relative to the two threshold criteria, overall protection of human health and the environment and compliance with SCGs.

Alternative 1, Minimal Action, was developed as a baseline with which to compare other alternatives. Because Alternative 1 would not involve any remedial actions, contaminated groundwater and coal tar would continue to migrate toward the Anthony Kill at the current rate, a condition which does not currently result in significant adverse impacts on ecological receptors. Investigations indicate that migration of coal tar from the site is extremely slow under current site conditions. The risk assessment concluded that because groundwater discharge rates to the Anthony Kill are very low, the potential for aquatic impacts associated with contaminant discharges from the site is minimal.

Alternative 1 would be designed to comply with all applicable action-specific and chemical-specific SCGs (no location-specific SCGs were identified for the site).

Alternatives 2 and 3 would only partially achieve response objectives. Migration of overburden coal tar to the Anthony Kill would be controlled via the downgradient barrier wall installed as part of both alternatives. However, this is of limited benefit because site investigations indicate that coal tar migration occurs at a very slow rate. Alternative 2 would provide minimal control of contaminated overburden groundwater. Alternative 3 would provide slightly greater control (i.e., total groundwater discharge to the Anthony Kill would be reduced by approximately 16

percent). The effect on the surface water and sediment quality of the Anthony Kill from implementing either of these two alternatives is expected to be minimal.

Both Alternative 2 and 3 would be designed to comply with all applicable action-specific SCGs.

15.2.2 Comparison of Balancing Criteria

As discussed, the primary balancing criteria emphasize long-term effectiveness and permanence, and reduction in toxicity, mobility, or volume through treatment. Although minimal risk is present under existing site conditions, Alternative 1 would not reduce future potential risks to ecological receptors because migration of overburden groundwater and coal tar would not be further controlled and would continue to migrate to the Anthony Kill at current migration rates. Potential options that would provide a permanent solution to the remediation of the site would be evaluated as part of the five-year review process.

Although neither Alternative 2 nor 3 would comply with NYSDEC's preference for treatment, both would increase the control of coal tar migration. Control of coal tar via a downgradient barrier wall would contribute to the long-term management of contaminant migration by reducing further contamination of surface water and limiting the spread of the potentially mobile coal tar source. Alternative 3 would provide slightly greater control of overburden groundwater compared to Alternative 2. Potential options that would provide a permanent solution to the remediation of the site would be evaluated as part of the five-year review process.

None of the components of Alternatives 1, 2, and 3 would result in significant short-term environmental impacts because of the urban/commercialized nature of the area, and lack of suitable habitat for potential ecological receptors. Impacts to worker health and safety would be slightly greater for Alternative 3 compared to Alternative 2 because of the excavation and trenching required to install the upgradient subsurface drain. OSHA guidelines and an approved HASP would be followed to address worker health and safety.

The implementation of Alternatives 2 and 3 would be similar; however, Alternative 3 would require interception and discharge of upgradient groundwater to the Anthony Kill in accordance with a SPDES permit. Water quality would be monitored to determine that it meets applicable criteria. Additionally, Alternative 3 would be the most costly of the alternatives. The increased cost is primarily associated with installation of the subsurface drain and operation and maintenance requirements associated with discharge of upgradient groundwater to the Anthony Kill.

16.0 RECOMMENDATION OF REMEDIAL ACTION

The evaluations and discussions presented in Sections 9.0 through 15.0 provide a basis for selecting a remedial action for the Mechanicville site. The recommended remedial action at the Mechanicville site is the Minimal Action Alternative described in Subsection 14.2. This alternative consists of long-term environmental monitoring, institutional controls, five-year site reviews, asphalt cover maintenance, and bedrock mapping.

Based on the comparative analysis of alternatives, the expected performance of all three alternatives would be essentially the same. Because coal tar has migrated into the saturated zone and into fractured bedrock, efficient recovery would be difficult, if not impossible. Although installation of a downgradient barrier wall may reduce migration of coal tar to the Anthony Kill, investigations indicate that migration of coal tar from the site is extremely slow under current site conditions. Free phase coal tar has not been observed as seepage into the Anthony Kill and has not been observed in perimeter monitoring wells MW-14, MW-17, and MW-18. Based on groundwater modeling conducted to evaluate remedial alternatives, neither Alternative 2 nor Alternative 3 would have a significant impact on total flow of overburden groundwater into the Anthony Kill. Alternative 3 would be slightly more effective, with reductions in total flow to the stream estimated at approximately 16 percent (compared to no reduction for Alternatives 1 and 2). The resulting benefits are, however, expected to be minimal. Finally, the risk assessment concluded that because groundwater discharge rates to the Anthony Kill are very low, the potential for aquatic impacts associated with contaminant discharges from the site

is minimal. Therefore, the Minimal Action Alternative is maintaining protection by using existing site conditions to effectively limit migration of coal tar to the Anthony Kill.

Site-related contaminants have been detected in groundwater beneath the site at concentrations in excess of federal and state drinking criteria (e.g., MCLs) and New York State Class GA criteria. However, as previously presented (see Subsections 9.2 and 10.2.2), because groundwaters in the vicinity of the Mechanicville site are not a current source of drinking water, nor are they a likely potential future source, application of these standards is not appropriate. Further, other potential sources of groundwater contamination, including gas stations, petroleum fuel storage facilities, and manufacturing facilities, are also in close proximity to the site and could represent additional threats to any planned water supply installation near the site. Finally, it is highly unlikely that Class GA groundwater standards could be achieved within a reasonable time frame or cost given potential off-site sources contributing to groundwater contamination and the presence of DNAPLs in the fractured bedrock unit beneath the site (see Subsection 9.2).

Therefore, because the effectiveness of control alternatives is questionable and investigations conducted to date indicate that impacts to human health and the environment from site-related contamination are minimal, the Minimal Action Alternative is recommended. As part of this alternative, the following components would be implemented:

- environmental monitoring to monitor site conditions and periodically evaluate risks to human health and the environment;

- institutional controls to restrict future noncommercial use of the site and to restrict groundwater use within and around the site;

- five-year site reviews to assess (1) potential impacts of site-related contaminants to human health and the environment and (2) technologies that have emerged and been demonstrated for the extraction and treatment of coal tar present in the overburden and fractured bedrock beneath the site;

- asphalt cover maintenance to assess the cover integrity and ability to continue to reduce infiltration to the site; and

- bedrock mapping to facilitate potential future remedial actions by evaluating potential migration routes in bedrock to the Anthony Kill.

Each of these components is described in detail in Subsection 14.2. A brief description of implementation of the Minimal Action Alternative follows.

Before commencing environmental monitoring activities, a site-specific monitoring and maintenance plan would be developed. This plan would detail long-term maintenance of the site and include details with regard to environmental monitoring, asphalt cover maintenance, and five-year site reviews. General components of long-term monitoring and maintenance that would be addressed include:

- objectives of the plan;
- sampling frequency and locations;

- sampling equipment and procedures;
- analytical methods;
- quality assurance and quality control requirements;
- asphalt cover inspection and maintenance requirements; and
- five-year site review requirements.

A work plan for conducting bedrock mapping would also be developed to provide the approach and methodology proposed to complete the task. All plans would be subject to regulatory review and approval before implementation. Finally institutional controls in the form of deed and land-use restrictions would be implemented. These restrictions would require coordination between NYSEG, state, county, and local officials and would require enforcement to be effective.

ABB Environmental Services, Inc.

4945-09

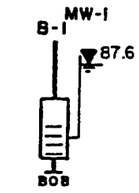
GEOLOGIC DESCRIPTIONS

FILL: PRIMARILY SILTY SAND AND GRAVEL WITH ORGANIC MATTER, ASH, BRICK FRAGMENTS, GLASS, AND WOOD CHIPS WITH ZONES OF HIGHER CLAYEY SILT AND FRACTURED SHALE CONTENT.



GRAVELLY SAND: DISCONTINUOUS BROWN TO DARK GRAY SAND AND GRAVEL.

SILTY SHALE: BLACK TO GRAY PLATY SHALE FRAGMENTS WITH INTERSTITIAL SILT. LOOSE AND SATURATED. POSSIBLY FILL.

TILL: DISCONTINUOUS TAN TO LIGHT GRAY SILTY CLAY TILL WITH FINE GRAVEL.

SHALE BEDROCK: LAMINATED, BROKEN, DARK GRAY SHALE WITH CALCITE VEINS AND INCLUSIONS. BEDDING DIPS 30-40° FROM HORIZONTAL; FRACTURES ARE 0-90° FROM BEDDING PLANES. UPPER 1 TO 2 FEET SEVERELY WEATHERED.

Examples of Factors Affecting Groundwater Restoration[1]

Certain size characteristics may limit the effectiveness of subsurface remediation. The examples listed below are highly generalized. The particular factor or combination of factors that may critically limit restoration potential will be site specific.

NOTES:

▼ Indicates Interpreted Mechanicville Site Characteristics

[1] **Source:** Adapted from Figure 1; USEPA, "Guidance for Evaluating the Technical Impracticability of Ground-water Restoration"; EPA/540-R-93-080; SEPTEMBER 1993.

[2] Volume estimate assumes all overburden soils and the first 10 feet of bedrock in the area of the former gas manufacturing facility are contaminated.

cy = cubic yard

bgs = below ground surface

[d] Value is USEPA treatment technique action level.
[e] Average concentration exceeds maximum concentration, therefore mean concentration was not compared to MCL.
ppb - parts per billion

TABLE 10-1

CHEMICAL-SPECIFIC STANDARDS, CRITERIA, AND GUIDANCE
NYSEG FORMER COAL GASIFICATION SITE
MECHANICVILLE, NEW YORK

MEDIA	REQUIREMENT	REQUIREMENT SYNOPSIS	CONSIDERATION IN THE REMEDIAL RESPONSE PROCESS
GROUNDWATER AND SURFACE WATER			
Federal Standards	Safe Drinking Water Act (SDWA) - Maximum Contaminant Levels (MCLs) (40 CFR 141.11 - 141.16)	MCLs have been promulgated for common organic and inorganic contaminants. These levels regulate the concentration of contaminants in public drinking water supplies, but may also be considered relevant and appropriate for groundwater aquifers used for drinking water.	Groundwater is not used as a drinking water source in the vicinity of the site; therefore, MCLs are not applicable to the remediation of the Mechanicville Site.
	SDWA - Maximum Contaminant Level Goals (MCLGs) (40 CFR 141.50 - 141.51)	MCLGs are health-based criteria at which no known or anticipated adverse health effects are expected. MCLGs are available for a number of organic and inorganic contaminants.	Groundwater is not used as a drinking water source in the vicinity of the site; therefore MCLGs are not applicable to the remediation of the site.
	Federal Clean Water Act (CWA) Ambient Water Quality Criteria (AWQC)	Federal AWQC are health-based criteria developed for carcinogenic and noncarcinogenic compounds and parameters in surface water bodies. AWQC for the protection of human health provide criteria for exposure from drinking water and consuming aquatic organisms, and from consuming fish alone.	These criteria are the most commonly used numeric standards for determining discharge limits for treated groundwater to a surface water source. These criteria would be applicable to those alternatives proposing direct discharge to the Anthony Kill.
Federal Guidance and Criteria To Be Considered	USEPA Risk Reference Doses (RfDs) and Risk Reference Concentrations (RfCs)	RfDs/RfCs are estimates of a daily exposure level for the human population without an appreciable risk of deleterious effects during a lifetime.	USEPA RfDs/RfCs are used to characterize risks due to noncarcinogens in various media.
	USEPA Carcinogen Assessment Group Cancer Slope Factors (CSFs)	Carcinogenic effects present the most up-to-date information on cancer risk potency available from USEPA's Integrated Risk Information System (IRIS).	USEPA CSFs are used to compute the individual incremental cancer risk resulting from exposure to certain compounds.
	USEPA Health Advisories (HAs)	HAs are issued as non-regulatory guidance. HA values represent the concentration of contaminants in drinking water at which adverse health effects would not be expected to occur. HAs are established for one-day and ten-day exposure durations.	USEPA HAs are used to evaluate noncarcinogenic effects for oral exposures of shorter duration.
State Standards	New York Department of Health Drinking Water Supplies (10 NYCRR Subpart 5-1)	Under this Subpart, MCLs have been promulgated for organic and inorganic contaminants. These standards have been promulgated for the protection of present or future drinking water supplies.	Groundwater is not used as a drinking water source in the vicinity of the site; therefore, MCLs are not directly applicable to the remediation of the Mechanicville Site.

TABLE 10-1

CHEMICAL-SPECIFIC STANDARDS, CRITERIA, AND GUIDANCE
NYSEG FORMER COAL GASIFICATION SITE
MECHANICVILLE, NEW YORK

MEDIA	REQUIREMENT	REQUIREMENT SYNOPSIS	CONSIDERATION IN THE REMEDIAL RESPONSE PROCESS
	New York Water Quality Regulations for Surface Waters and Groundwaters (6 NYCRR Parts 700 - 705)	New York State has classified groundwater based on best usage. All fresh groundwaters in the State of New York are classified as Class GA where the best usage is as a source of potable water supply. This rule also establishes numeric limits for individual chemical compounds detected in surface water sources, also based on the best usage of the surface water body.	Groundwater is not used as a drinking water source in the vicinity of the site; therefore, class GA standards are not applicable to the remediation of the site. Standards for the protection of surface water would be applicable to establishing any limits for direct discharge of treated groundwater to the Anthony Kill.
SOIL			
State Criteria and Guidance to be Considered	Division of Technical and Administrative Guidance Memorandum (TAGM): Determination of Soil Cleanup Objectives and Cleanup Levels (HWR-92-4046)	This TAGM provides the basis and procedures for establishing soil cleanup levels at inactive hazardous waste sites, when restoration to pre-disposal conditions is not feasible. The TAGM provides four alternative bases for establishing soil cleanup objectives that are protective of human health, protective of groundwater/drinking water quality based on standards, background values for contaminants, and detection limits. Recommendation of the appropriate cleanup objective is based on the criterion that produces the most stringent cleanup level.	This TAGM will be evaluated with respect to remediation of surface and subsurface contamination.

NOTES:

AWQC = Ambient Water Quality Criteria
CFR = Code of Federal Regulations
CSF = cancer slope factor
CWA = Clean Water Act
HAs = health advisories
IRIS = Integrated Risk Information System
MCL = Maximum Contaminant Level
MCLG = Maximum Contaminant Level Goal
NYCRR = New York Codes, Rules, and Regulations
RfC = reference concentration
RfD = reference dose
SDWA = Safe Drinking Water Act
TAGM = Technical and Administrative Guidance Memorandum
USEPA = U.S. Environmental Protection Agency

TABLE 10-2

POTENTIAL ACTION-SPECIFIC STANDARDS, CRITERIA, AND GUIDANCE
NYSEG FORMER COAL GASIFICATION SITE
MECHANICVILLE, NEW YORK

REQUIREMENT	REQUIREMENT SYNOPSIS	CONSIDERATION IN THE REMEDIAL RESPONSE PROCESS
Federal Standards		
Occupational Safety and Health Administration (OSHA) - General Industry Standards (29 CFR Part 1910)	These regulations specify the 8-hour time-weighted average concentration for various organic compounds. Training requirements for workers at hazardous waste operations are specified in 29 CFR 1910.120.	Proper respiratory equipment would be worn if it is impossible to maintain the work atmosphere below the threshold concentration. Workers performing activities would be required to have completed specific training requirements.
OSHA - Safety and Health Standards (29 CFR Part 1926)	This regulation specifies the type of safety equipment and procedures to be followed during site remediation.	All appropriate safety equipment would be on-site. In addition, safety procedures would be followed during on-site activities.
OSHA - Recordkeeping, Reporting, and Related Regulations (29 CFR 1904)	This regulation outlines the recordkeeping and reporting requirements for an employer under OSHA.	These requirements apply to all site contractors and subcontractors, and must be followed during all site work.
Clean Water Act (CWA) - National Pollution Discharge Elimination System (NPDES) (40 CFR Parts 122, 125)	This requirement implements the NPDES program that specifies the applicable effluent standards, monitoring requirements, and standards and special conditions for direct discharge to surface water bodies.	CWA NPDES requirements, including discharge limitations, monitoring requirements, and best management practices would apply to alternatives proposing direct discharge of treated groundwater to the Anthony Kill. Discharges would require NPDES compliance and a NPDES permit.
CWA - Pretreatment Standards for Publicly Owned Treatment Works (POTW) Discharge (40 CFR Part 403)	This regulation specifies pretreatment standards for discharges to a POTW. If treated groundwater is discharged to a POTW, the POTW must have mechanics available to meet the requirements of the National Pretreatment Program. Introduction of pollutants which cause pass through or interference are prohibited. Discharges must also comply with any local POTW regulations.	If treated groundwater is discharged to a POTW, the treated water must meet all discharge limitations imposed by the POTW.
U.S. Department of Transportation Rules for Transportation of Hazardous Materials (49 CFR Parts 107, 171.1 - 172.558)	This regulation outlines the procedures for packaging, labeling, manifesting, and transporting of hazardous materials.	If excavated soils or residuals from groundwater treatment fail characteristic hazardous waste analyses, they will be excavated and transported off-site. Those soils will packaged, manifested, and transported to a licensed off-site disposal facility in compliance with these regulations.
State Standards		
New York State Regulations on State Pollutant Discharge Elimination System (SPDES) (6 NYCRR Parts 750 - 758)	Compliance with the New York SPDES is required for discharge of treatment process water. Under these regulations the New York Department of Environmental Conservation may impose treatment standards for discharge, monitoring, reporting, and recordkeeping requirements.	Compliance with these regulations may be attained through compliance with the NPDES program under the CWA for alternatives proposing to discharge treated groundwater to the Anthony Kill. Consideration of additional actions to meet New York SPDES requirements may be necessary.
New York State Identification and Listing of Hazardous Waste Regulations (6 NYCRR Part 371)[1]	These regulations identify the procedures for identifying those solid wastes that are subject to regulation as hazardous under 6 NYCRR Parts 370 - 373.	These regulations will be used in evaluating whether certain on-site soils exhibit the characteristic of a reactive hazardous material. If excavated soils fail characteristic testing they will be handled in accordance with New York State Hazardous Waste Regulations.

TABLE 10-2

POTENTIAL ACTION-SPECIFIC STANDARDS, CRITERIA, AND GUIDANCE
NYSEG FORMER COAL GASIFICATION SITE
MECHANICVILLE, NEW YORK

REQUIREMENT	REQUIREMENT SYNOPSIS	CONSIDERATION IN THE REMEDIAL RESPONSE PROCESS
New York State Water Pollution Control Regulations (6 NYCRR Part 608)	Part 608 sets forth requirements for the protection of streams, ponds, and lakes. Work conducted within 50 feet of the mean high water line of a protected water body requires obtaining prior approval and a permit from NYSDEC.	A permit will be required for those alternatives proposing major invasive or excavation work within 50 feet of the Anthony Kill.

NOTES:

CFR = Code of Federal Regulations
CWA = Clean Water Act
NPDES = National Pollution Discharge Elimination System
NYCRR = New York Codes Rules and Regulations
NYSDEC = New York State Department of Environmental Conservation
OSHA = Occupational Safety and Health Administration
POTW = publicly owned treatment works
SPDES = State Pollution Discharge Elimination System

[1]In the event that hazardous wastes are encountered at the site, additional federal and state action-specific standards, criteria, and guidelines (SCGs) for handling the wastes will be applicable. Removal and treatment/disposal of all hazardous wastes will be in accordance with all applicable requirements and regulations.

TABLE 11-1

GENERAL RESPONSE ACTIONS AND POTENTIAL REMEDIAL TECHNOLOGIES
NYSEG FORMER COAL GASIFICATION SITE
MECHANICVILLE, NEW YORK

General Response Action	Process/ Technology	Description
Minimal Action	Deed Restrictions Zoning Town Ordinance Environmental Monitoring	Restrict withdrawal and use of groundwater containing site chemicals, restrict noncommercial use of the site, and conduct environmental monitoring to assess groundwater and surface water quality.
Containment	Grout Curtain	Inject a fluid material into the overburden soil to reduce water and coal tar movement. Once in place within the formation voids, the fluids solidify or gel, thus greatly reducing the permeability.
	Slurry Wall	Excavate a trench through or under a slurry of bentonite clay and water. The trench is backfilled with an engineered mixture of materials having the desired permeability properties to form a barrier to coal tar movement.
	Sheet Pile	Interlocking steel sheet piles are driven into the ground with a drop or vibratory hammer. With time, fine soil particles are washed into the seams and water cutoff is effected. For applications in very coarse soils, it is possible to grout the pile seams. No excavation is required.
Groundwater Extraction and Treatment	Vertical Extraction Wells	Intercept and extract groundwater and coal tar for treatment and/or discharge using a series of drilled pumping wells.
	Downgradient Subsurface Drains	Intercept and collect contaminated groundwater and coal tar using a one-sided subsurface drain.
	Upgradient Subsurface Drains	Intercept upgradient groundwater and divert it into the Anthony Kill to minimize flow across the site.
In Situ Treatment	Bioremediation	Inject nutrients and/or an oxygen source into the aquifer to encourage development of a microbial population that degrades compounds of concern.
Disposal	Off-site Discharge	Discharge groundwater (meeting negotiated discharge limits) into the Anthony Kill or to the local POTW.
Ancillary	Treatment	Treat extracted groundwater using mobile process units. Treatment could involve oil/water separation, metals precipitation, and/or carbon adsorption for treatment of organics (e.g., VOCs, PAHs, etc.)

TABLE 11-2

TECHNOLOGY SCREENING
NYSEG FORMER COAL GASIFICATION SITE
MECHANICVILLE, NEW YORK

TECHNOLOGY/ PROCESS	ADVANTAGES	DISADVANTAGES	SCREENING STATUS	COMMENTS
Minimal Action: Administrative Actions to prevent exposure (e.g., deed restrictions, easements, zoning, town ordinance) and monitoring.	Groundwater currently is not used as a drinking water source. Site contaminants currently pose minimal risks to human health and the environment. Restricts withdrawal and use of contaminated groundwater and noncommercial use of the site. Reduces the potential for ingestion and exposure to site chemicals. Provides current information on distribution of chemicals in groundwater, surface water, and/or treatment effectiveness. Minimal capital and operating costs.	Does not reduce mobility, toxicity, or volume of site chemicals. Coal tar will continue to be a source of groundwater and surface water contamination. May not provide a permanent solution. Requires long-term enforcement (maintenance). Requires periodic operational and administrative activity.	Retained	USEPA RI/FS guidance suggests retaining for feasibility study analysis and baseline comparison.

TABLE 11-2

TECHNOLOGY SCREENING
NYSEG FORMER COAL GASIFICATION SITE
MECHANICVILLE, NEW YORK

TECHNOLOGY/ PROCESS	ADVANTAGES	DISADVANTAGES	SCREENING STATUS	COMMENTS
Grout Curtain	Reduces mobility of contaminants in groundwater and coal tar. No operation and minimal maintenance required.	Technology is seldom used for containing groundwater flow in unconsolidated materials. Achieving low permeabilities in unconsolidated material is often difficult. Contaminants present in groundwater may interfere with grout setting reactions and/or reduce grout durability. Extensive treatability testing would be required to evaluate waste grout interaction and compatibility. Gaps in grout curtain due to non-penetration of grout may allow contaminants to migrate off-site. Unproven long-term effectiveness. More costly to install than alternative barrier technologies (e.g., slurry wall).	Eliminated	Significant potential for not meeting response objectives. More economical and effective barriers available.

TABLE 11-2

TECHNOLOGY SCREENING
NYSEG FORMER COAL GASIFICATION SITE
MECHANICVILLE, NEW YORK

TECHNOLOGY/ PROCESS	ADVANTAGES	DISADVANTAGES	SCREENING STATUS	COMMENTS
Slurry Wall	Reduces mobility of contaminants in groundwater and coal tar. Experienced vendors are available to install the slurry wall. No operations and minimal maintenance required.	Requires a large work area to install. Treatability testing would be required to evaluate contaminant/backfill compatibility. Slurry wall may not effectively contain chemicals in groundwater. Compounds present may have adverse effects on the slurry wall and reduce its effectiveness. Unproven long-term effectiveness. Contaminated soils requiring treatment/disposal would be generated during excavation of trench.	Eliminated	Would be difficult to install due to limited space available along the stream bank. Potential for not meeting response objectives.

TABLE 11-2

TECHNOLOGY SCREENING
NYSEG FORMER COAL GASIFICATION SITE
MECHANICVILLE, NEW YORK

TECHNOLOGY/ PROCESS	ADVANTAGES	DISADVANTAGES	SCREENING STATUS	COMMENTS
Sheet Pile Wall	Reduces mobility of contaminants in groundwater and coal tar. No operation and minimal maintenance required. Performance life of sheet pile can vary from 30 to more than 100 years, depending on soil and groundwater conditions and materials used to construct the barrier. Experienced vendors are available to install the sheet piles. Least costly barrier to install. Does not require large work area to install. No excavation required.	May be necessary to grout the piling seams to prevent leakage through interlocking joints. Cannot penetrate competent bedrock. Driving of sheet piles may cause increased fracturing in bedrock and accelerate flow into rock, thereby decreasing barrier effectiveness in overburden.	Retained	Would meet response objectives. Easiest of barriers to implement and lowest cost.

TABLE 11-2

TECHNOLOGY SCREENING
NYSEG FORMER COAL GASIFICATION SITE
MECHANICVILLE, NEW YORK

TECHNOLOGY/ PROCESS	ADVANTAGES	DISADVANTAGES	SCREENING STATUS	COMMENTS
Downgradient Extraction Wells	Would reduce and eventually eliminate off-site groundwater contamination and contaminant migration into the Anthony Kill. Easy to implement - No trenching required. Proven technology. May be less costly to install compared to subsurface drains.	Does not isolate wastes from groundwater, therefore would not prevent leaching of wastes by groundwater. Extracted water would require treatment and/or discharge. Requires long-term pumping, energy supply, and long-term monitoring, operation, and maintenance costs, if chemicals continue to be released from source. May not effectively capture coal tar in saturated zone. Operation and maintenance costs are high.	Retained	System would intercept contaminated groundwater migrating from the site.

TABLE 11-2

TECHNOLOGY SCREENING
NYSEG FORMER COAL GASIFICATION SITE
MECHANICVILLE, NEW YORK

TECHNOLOGY/ PROCESS	ADVANTAGES	DISADVANTAGES	SCREENING STATUS	COMMENTS
Downgradient Subsurface Drains	Would reduce and eventually eliminate contaminant migration into the Anthony Kill. Would require fewer pumps relative to extraction via downgradient wells. Proven technology. Lower operation and maintenance costs compared to extraction wells.	Does not isolate wastes from groundwater, therefore would not prevent leaching of wastes by groundwater. Extracted water would require treatment and/or discharge. Requires long-term pumping energy supply, and long-term monitoring, operation, and maintenance costs, if chemicals continue to be released from source. Trench excavation required for installation. Shoring may be required during installation for worker health and safety. Contaminated soils requiring treatment/disposal would be generated during excavation of trench. May be more costly to install compared to extraction wells.	Retained	System would intercept contamination migrating into the Anthony Kill.

TABLE 11-2

TECHNOLOGY SCREENING
NYSEG FORMER COAL GASIFICATION SITE
MECHANICVILLE, NEW YORK

TECHNOLOGY/ PROCESS	ADVANTAGES	DISADVANTAGES	SCREENING STATUS	COMMENTS
In Situ Bioremediation	Reduces toxicity, mobility, and volume of contaminants in soil and/or groundwater. Does not expose public or environmental receptors to site chemicals in groundwater.	Site-specific information must be collected to determine site-limiting characteristics for biodegradation. May be difficult to support microbial population in free-phase coal tar present in the saturated zone. Need to inject foreign materials (e.g., nutrients) into the groundwater to enhance biodegradation. Treatability studies would be required to determine system requirements (e.g., flow rates, nutrients) and effectiveness. Uncertain cost, effectiveness, and implementability regarding ability to enhance microbial growth by introducing nutrients.	Eliminated	Coal tar present in the saturated zone would make it difficult to maintain the environment necessary to support a microbial population. Technology may be considered in the future to augment other technologies as site conditions become more favorable.

TABLE 11-2

TECHNOLOGY SCREENING
NYSEG FORMER COAL GASIFICATION SITE
MECHANICVILLE, NEW YORK

TECHNOLOGY/ PROCESS	ADVANTAGES	DISADVANTAGES	SCREENING STATUS	COMMENTS
Upgradient Subsurface Drains	Would reduce, after time, mobility, toxicity, and volume of contaminants in groundwater on-site and off-site by minimizing groundwater movement through the contaminated zone. Quality of intercepted groundwater may not require treatment prior to discharge or use, or may require only short-term treatment. Because the site is paved, downgradient recharge would be minimal, as would groundwater discharge from the site. Proven technology. Passive system not requiring long-term energy or operation costs. No contaminated water would be extracted from the ground.	Coal tar would remain as a source of contamination to groundwater. Although infiltration is minimized, potential existing for coal tar to flow toward Anthony Kill by gravity. Extracted groundwater may require long-term monitoring and treatment. Requires long-term monitoring, operation, and maintenance costs. Further site exploration and testing would be required to determine if the technology is technically feasible and to design the system. Trench excavation required for installation. Shoring may be required during installation for worker health and safety.	Retained	Mobility of contaminants would be reduced by minimizing groundwater movement through the contaminated zone.

TABLE 11-2

TECHNOLOGY SCREENING
NYSEG FORMER COAL GASIFICATION SITE
MECHANICVILLE, NEW YORK

TECHNOLOGY/ PROCESS	ADVANTAGES	DISADVANTAGES	SCREENING STATUS	COMMENTS
Off-Site Discharge	Two options exist: discharge to the Anthony Kill or discharge to the local POTW. Anthony Kill is nearby and easily accessible. Discharge to POTW may have less stringent treatment requirements than discharge to the Anthony Kill because of treatment capabilities of the POTW.	Requires a discharge pipeline from vicinity of site to the river and/or POTW. Long-term availability of POTW is determined by others (no control). May pose additional administrative and liability issues for POTW and site administrators. Long-term feasibility may be questionable if POTW effluent quality restrictions are modified. Dependent on compliance status of POTW. Dependent on negotiations with POTW and state agency representatives to determine if POTW is willing and able to accept wastestream.	Retained	Would be used in combination with other technologies.

TABLE 11-2

TECHNOLOGY SCREENING
NYSEG FORMER COAL GASIFICATION SITE
MECHANICVILLE, NEW YORK

TECHNOLOGY/ PROCESS	ADVANTAGES	DISADVANTAGES	SCREENING STATUS	COMMENTS
Ancillary Groundwater Treatment with On-site Mobile Treatment Unit(s).	Would reduce toxicity and mobility of contaminants in groundwater. Several types of mobile treatment units are available for use.	Appropriate disposal of treatment residuals (e.g., free-phase product, sludges, carbon) would be required.	Retained	Would be used in combination with other technologies.

TABLE 12-1

COMPONENTS OF THE REMEDIAL ALTERNATIVES
NYSEG FORMER COAL GASIFICATION SITE
MECHANICVILLE, NEW YORK

ALTERNATIVE	KEY COMPONENTS
Minimal Action	• Environmental monitoring • Institutional controls (deed restrictions, zoning) • Five-year site reviews • Maintenance of asphalt cap • Mapping of bedrock along southern bank of Anthony Kill
Downgradient Subsurface Drain	• Environmental monitoring • Institutional controls (deed restrictions, zoning) • Five-year site reviews • Maintenance of asphalt cap • Mapping of bedrock along southern bank of Anthony Kill • Site preparation • Removal and disposal of filter bed soil • Trench excavation • Installation of subsurface drain and extraction system • Pretreatment of groundwater prior to discharge • Discharge to POTW or Anthony Kill • Disposal of excavated soil containing coal tar, if necessary

TABLE 12-1

COMPONENTS OF THE REMEDIAL ALTERNATIVES
NYSEG FORMER COAL GASIFICATION SITE
MECHANICVILLE, NEW YORK

ALTERNATIVE	KEY COMPONENTS
Downgradient Barrier Wall	• Environmental monitoring • Institutional controls (deed restrictions, zoning) • Five-year site reviews • Maintenance of asphalt cap • Mapping of bedrock along southern bank of Anthony Kill • Site preparation • Removal and disposal of filter bed soil • Installation of sheet pile barrier wall • Disposal of excavated soil containing coal tar, if necessary
Downgradient Extraction Wells	• Environmental monitoring • Institutional controls (deed restrictions, zoning) • Five-year site reviews • Maintenance of asphalt cap • Mapping of bedrock along southern bank of Anthony Kill • Site preparation • Removal and disposal of filter bed soil • Installation of extraction wells • Pretreatment of groundwater prior to discharge • Discharge to POTW or Anthony Kill

TABLE 12-1

COMPONENTS OF THE REMEDIAL ALTERNATIVES
NYSEG FORMER COAL GASIFICATION SITE
MECHANICVILLE, NEW YORK

ALTERNATIVE	KEY COMPONENTS
Upgradient Subsurface Drain	• Environmental monitoring • Institutional controls (deed restrictions, zoning) • Five-year site reviews • Maintenance of asphalt cap • Mapping of bedrock along southern bank of Anthony Kill • Site preparation • Removal and disposal of filter bed soil • Trench excavation • Installation of drain • Disposal of excavated soil containing coal tar, if necessary
Upgradient Drain with Downgradient Barrier	• Environmental monitoring • Institutional controls (deed restrictions, zoning) • Five-year site reviews • Maintenance of asphalt cap • Mapping of bedrock along southern bank of Anthony Kill • Site preparation • Removal and disposal of filter bed soil • Trench excavation • Installation of upgradient drain • Installation of downgradient sheet pile barrier wall • Disposal of excavated soil containing coal tar, if necessary

TABLE 13-1

CRITERIA FOR INITIAL SCREENING OF ALTERNATIVES
NYSEG FORMER COAL GASIFICATION SITE
MECHANICVILLE, NEW YORK

EFFECTIVENESS	IMPLEMENTABILITY	COST
• Compliance with SCGs	• Technical Feasibility	• Equipment/Construction
• Reduction in Toxicity, Mobility, or Volume of Contaminants	• Demonstrated Performance	• Operation and Maintenance
• Protection of Human Health and the Environment	• Availability of Equipment, Space, and Services	
• Adverse Short- and Long-term Effects Caused by Implementation	• Administrative Feasibility	

NOTE:

SCGs = standards, criteria, and guidelines

TABLE 13-2

SCREENING OF REMEDIAL ALTERNATIVES
NYSEG FORMER COAL GASIFICATION SITE
MECHANICVILLE, NEW YORK

MINIMAL ACTION

Synopsis: This alternative would include implementation of deed restrictions to restrict non-commercial use of and access to the site. Groundwater and surface water quality would be monitored and the asphalt cap would be maintained.

EFFECTIVENESS	IMPLEMENTABILITY	COST
Advantages	**Advantages**	**Advantages**
• Site contaminants currently pose minimal risks to human health and the environment.	• Most easily implemented because no remedial actions are required.	• Minimal capital and O&M costs are required.
• Low potential for contaminant exposure during implementation.	• Services and materials are readily available.	
• Site would be monitored for contaminant migration.		
• Institutional controls would restrict future use of the site.		
Disadvantages	**Disadvantages**	**Disadvantages**
• Coal tar would continue to be a source of groundwater contamination.	• May require future remedial actions.	• Because this alternative does not involve remedial actions, and because the potential for future remedial action exists, this alternative may ultimately be more costly.
• Would not achieve remedial response objectives.	• Long-term monitoring and maintenance would be required.	
• Would not reduce toxicity, mobility, or volume of contaminants.		

Conclusion: The Minimal Action Alternative is retained for comparison with the remaining alternatives.

TABLE 13-3

SCREENING OF REMEDIAL ALTERNATIVES
NYSEG FORMER COAL GASIFICATION SITE
MECHANICVILLE, NEW YORK

DOWNGRADIENT SUBSURFACE DRAIN

Synopsis: This alternative would include installation of a one-sided subsurface drain to intercept and collect contaminated groundwater and coal tar, preventing migration to the Anthony Kill. Collected groundwater would be pretreated and discharged to the local POTW or Anthony Kill. Coal tar would be disposed of off-site at an appropriate disposal facility. Deed restrictions would be imposed to restrict noncommercial use and access to the site. Groundwater and surface water quality would be monitored and the asphalt cap would be maintained.

EFFECTIVENESS	IMPLEMENTABILITY	COST
Advantages	**Advantages**	**Advantages**
• Would reduce migration of coal tar and contaminated groundwater to the Anthony Kill.	• Would require standard construction techniques.	• Capital costs are readily defined.
• Would reduce mobility and volume of contaminants.	• Would require fewer pumps and less energy than downgradient extraction wells.	• O&M less costly than wells.
Disadvantages	**Disadvantages**	**Disadvantages**
• Coal tar may clog the drain.	• Long-term monitoring and maintenance would be required.	• Long-term O&M may be more costly than other alternatives.
• Drain may cause a change in direction of groundwater flow and/or draw surface water from the Anthony Kill into the drain because of a head differential.	• Construction may be difficult because of underground structures and proximity to the bank of the Anthony Kill.	• Excavated contaminated soil would require treatment and/or disposal.
• Drain may not effectively intercept coal tar.	• Off-gas controls may be required during excavation of contaminated soil.	
	• Excavated contaminated soil would require treatment and/or disposal.	
	• Contaminated groundwater would require pretreatment before discharge.	

Conclusion: Because this alternative may be difficult to implement and maintain, and may not effectively control migration of coal tar, the Downgradient Subsurface Drain Alternative is not retained for detailed analysis.

TABLE 13-4

SCREENING OF REMEDIAL ALTERNATIVES
NYSEG FORMER COAL GASIFICATION SITE
MECHANICVILLE, NEW YORK

DOWNGRADIENT BARRIER WALL

Synopsis: This alternative would include installation of sheet piles to prevent groundwater and coal tar from migrating off-site to the Anthony Kill. Deed restrictions would be imposed to prevent noncommercial use of and restrict access to the site. Groundwater and surface water quality would be monitored and the asphalt cap would be maintained.

EFFECTIVENESS	IMPLEMENTABILITY	COST
Advantages	**Advantages**	**Advantages**
• Would reduce migration of coal tar to the Anthony Kill.	• Would require standard construction techniques.	• Engineering and capital costs may be less expensive than with a subsurface drain.
	• No groundwater treatment, therefore, minimal O&M required.	
	• No excavation required.	• Minimal O&M costs.
	• Does not require large work area to install.	• Minimal costs for disposing of excavated contaminated soil.
Disadvantages	**Disadvantages**	**Disadvantages**
• May cause mounding of contaminated groundwater upgradient of the barrier.	• Long-term monitoring would be required.	• Higher capital and O&M costs would be incurred if installation of perimeter containment wells is required.
• Mounding may increase migration of coal tar downward into the bedrock and alter groundwater flow patterns.	• Driving sheet piles may further fracture bedrock, increasing potential for coal tar migration.	
• Would not reduce toxicity or volume of contaminants.	• Construction may be difficult due to underground structures and proximity to the Anthony Kill.	
• Would not reduce migration of contaminated groundwater to Anthony Kill.	• May be necessary to grout piling seams to prevent leakage through interlocking joints.	
	• May be necessary to install perimeter containment wells near barrier to prevent mounding of contaminated groundwater upgradient of the barrier.	

Conclusion: Because this alternative would effectively control the migration of coal tar to the Anthony Kill, it is retained for detailed analysis.

TABLE 13-5

SCREENING OF REMEDIAL ALTERNATIVES
NYSEG FORMER COAL GASIFICATION SITE
MECHANICVILLE, NEW YORK

DOWNGRADIENT EXTRACTION WELLS

Synopsis: This alternative would include installation of extraction wells to intercept and collect contaminated groundwater and coal tar discharging to the Anthony Kill. Extracted groundwater would be discharged to the local POTW or the Anthony Kill after pretreatment. Deed restrictions would be imposed to restrict noncommercial use of and access to the site. Groundwater and surface water quality would be monitored and the asphalt cap would be maintained.

EFFECTIVENESS	IMPLEMENTABILITY	COST
Advantages	**Advantages**	**Advantages**
• Would reduce migration of contaminated groundwater and coal tar to the Anthony Kill.	• Easier to install wells than to construct subsurface drain or barrier. Would require standard drilling techniques.	• Engineering and capital costs may be less expensive than downgradient drain.
• Would reduce mobility and volume of contaminants.	• No excavation of contaminated soil, hence, less health and safety and waste disposal concerns.	• Minimal costs for disposing of contaminated soil cuttings.
Disadvantages	**Disadvantages**	**Disadvantages**
• May not be capable of intercepting coal tar potentially migrating to the Anthony Kill.	• Long-term monitoring and maintenance would be required.	• Higher O&M costs than other alternatives.
• An excessive number of wells would be required to capture contaminant plume.	• Underground structures may prevent adequate well spacing and placement.	• Largest volume of groundwater to treat and dispose compared to other alternatives.
• Well point control may not be as effective as downgradient subsurface drains.		
• Coal tar may clog well screens.		

Conclusion: Because this alternative may not effectively capture coal tar potentially discharging to the Anthony Kill, it is not retained for detailed analysis.

TABLE 13-6

SCREENING OF REMEDIAL ALTERNATIVES
NYSEG FORMER COAL GASIFICATION SITE
MECHANICVILLE, NEW YORK

UPGRADIENT SUBSURFACE DRAIN

Synopsis: This alternative would include installation of a subsurface drain upgradient of the site to divert uncontaminated groundwater around the site followed by discharge to the Anthony Kill. The drain would minimize migration of contaminated groundwater and coal tar to the Anthony Kill by minimizing groundwater flow across the site. Deed restrictions would be imposed to restrict noncommercial use of and access to the site. Groundwater and surface water quality would be monitored and the asphalt cap would be maintained.

EFFECTIVENESS	IMPLEMENTABILITY	COST
Advantages	**Advantages**	**Advantages**
• Would reduce migration of contaminated groundwater and coal tar to the Anthony Kill by minimizing groundwater flow across the site.	• Would require standard construction techniques.	• Lower capital cost required than other alternatives.
	• Less health and safety concerns during excavation because drain would not be installed in contaminated soils.	• No contaminated soil treatment/disposal costs.
Disadvantages	**Disadvantages**	**Disadvantages**
• Would not fully achieve response objectives because coal tar would remain as source to groundwater contamination.	• Long-term monitoring and maintenance would be required.	• Higher capital costs may be incurred if groundwater requires pretreatment.
• Would not reduce toxicity and volume of contamination.	• Pretreatment would be required before discharge to the Anthony Kill if upgradient groundwater does not meet ambient water quality standards.	
• May cause change in groundwater gradient on-site which would result in contaminated groundwater and coal tar flowing toward the drain.		
• Would lower water table on-site which may increase migration of coal tar downward into bedrock aquifer.		
• Although lateral flow is reduced, would be potential for gravity flow of coal tar to Anthony Kill.		

Conclusion: This alternative is not retained for detailed analysis because it would not meet response objectives. This alternative may also require groundwater treatment prior to discharge to the Anthony Kill, and it may increase coal tar migration to the bedrock.

TABLE 13-7

SCREENING OF REMEDIAL ALTERNATIVES
NYSEG FORMER COAL GASIFICATION SITE
MECHANICVILLE, NEW YORK

UPGRADIENT SUBSURFACE DRAIN WITH DOWNGRADIENT BARRIER

Synopsis: This alternative would combine installation of a subsurface drain upgradient of the site with construction of a downgradient subsurface barrier. The drain would divert groundwater away from the site, and the sheet piles would mitigate migration of contaminated groundwater and coal tar to the Anthony Kill. Deed restrictions would be imposed to restrict noncommercial use of and access to the site. Groundwater and surface water quality would be monitored and the asphalt cap would be maintained.

EFFECTIVENESS	IMPLEMENTABILITY	COST
Advantages	**Advantages**	**Advantages**
• Would reduce migration of coal tar and contaminated groundwater to the Anthony Kill.	• Would require standard construction techniques.	• Construction costs readily estimated.
• Would reduce mobility of contaminants.	• Less health and safety concerns during excavation because drain would not be installed in contaminated soils.	• No contaminated soil treatment/disposal costs.
• Would minimize groundwater flow across the site.		
Disadvantages	**Disadvantages**	**Disadvantages**
• May cause change in groundwater gradient on-site which would result in contaminated groundwater and coal tar flowing toward the drain.	• Long-term monitoring and maintenance would be required.	• Higher capital costs incurred if groundwater requires pre-treatment.
• Would lower water table on-site which may increase migration of coal tar downward into bedrock aquifer.	• Driving sheet piles may further fracture bedrock, increasing potential for coal tar migration.	
• Would not reduce volume of contaminants	• Pretreatment may be required before discharge to the Anthony Kill if upgradient groundwater does not meet ambient water quality standards.	
	• Sheet pile construction may be difficult because of underground structures and proximity to Anthony Kill.	
	• May be necessary to grout piling seams to prevent leakage through interlocking joints.	

Conclusion: This alternative is retained for detailed analysis because it would effectively control migration of coal tar to the Anthony Kill.

Downgradient Extraction Wells	Eliminated
Upgradient Subsurface Drain	Eliminated
Upgradient Subsurface Drain with Downgradient Barrier	Retained

TABLE 14-1

CRITERIA FOR DETAILED ANALYSIS OF ALTERNATIVES
NYSEG FORMER COAL GASIFICATION SITE
MECHANICVILLE, NEW YORK

CRITERIA	DESCRIPTION
Overall protection of human health and the environment	Describes how each alternative, as a whole, protects and maintains human health and the environment.
Compliance with SCGs*	Describes how the alternative complies with SCGs or if a waiver is required and how it is justified.
Long-term effectiveness and permanence	Evaluates the effectiveness of alternatives in protecting human health and the environment after response objectives have been met.
Reduction of mobility, toxicity, or volume through treatment	Evaluates the anticipated performance of the specific treatment technologies.
Short-term effectiveness	Examines the effectiveness of alternatives in protecting human health and the environment during the construction and implementation period until the response objectives are met.
Implementability	Assesses the technical and administrative feasibility of alternatives and the availability of required resources.
Cost	Evaluates the capital and operation and maintenance costs of each alternative.

Notes:

*SCGs = standards, criteria, and guidelines.

TABLE 14-2

COST SUMMARY TABLE FOR ALTERNATIVE 1: MINIMAL ACTION
NYSEG FORMER COAL GASIFICATION SITE
MECHANICVILLE, NEW YORK

DIRECT COST	$49,000
Direct costs include institutional controls, bedrock mapping, and monitoring well/seepage meter installation.	
INDIRECT COST	$6,000
Indirect costs include health and safety, legal, administration, permitting, engineering, and services during construction.	
TOTAL CAPITAL (DIRECT AND INDIRECT) COSTS	$55,000
PRESENT WORTH OF O&M COSTS (@ 5% FOR 30 YEARS)	$630,000
Operating and maintenance costs include environmental monitoring, five-year site reviews, and asphalt cover maintenance.	
TOTAL PRESENT WORTH FOR ALTERNATIVE 1	$685,000

Notes:

Cost estimates are based on available information and professional judgment. Changing market conditions and regulatory requirements may cause actual costs to vary from the estimated costs.

A contingency of 25 percent has been included in each direct, indirect, and O&M cost item.

TABLE 14-3

COST SUMMARY TABLE FOR ALTERNATIVE 2: DOWNGRADIENT BARRIER WALL
NYSEG FORMER COAL GASIFICATION SITE
MECHANICVILLE, NEW YORK

DIRECT COST	$426,000
Direct costs include institutional controls, mobilization/demobilization, site preparation, bedrock mapping, excavation and disposal of filter bed soils, and downgradient barrier wall installation.	
INDIRECT COST	$128,000
Indirect costs include health and safety, legal, administration, permitting, engineering, and services during construction.	
TOTAL CAPITAL (DIRECT AND INDIRECT) COSTS	$554,000
PRESENT WORTH OF O&M COSTS (@ 5% FOR 30 YEARS)	$630,000
Operating and maintenance costs include environmental monitoring, five-year site reviews, and asphalt cover maintenance.	
TOTAL PRESENT WORTH FOR ALTERNATIVE 2	$1,184,000

Notes:

Cost estimates are based on available information and professional judgment. Changing market conditions and regulatory requirements may cause actual costs to vary from the estimated costs.

A contingency of 25 percent has been included in each direct, indirect, and O&M cost item.

TABLE 14-4

COST SUMMARY TABLE FOR PERIMETER GROUNDWATER CONTAINMENT WELLS
NYSEG FORMER COAL GASIFICATION SITE
MECHANICVILLE, NEW YORK

DIRECT COST	$247,000 - $338,000
Direct costs include installation of perimeter containment wells, collection piping, treatment building construction, and the treatment system.	
INDIRECT COST	$74,000 - $120,000
Indirect costs include health and safety, legal, administration, permitting, engineering, and services during construction.	
TOTAL CAPITAL (DIRECT AND INDIRECT) COSTS	$321,000 - $440,000
PRESENT WORTH OF O&M COSTS (@ 5% FOR 30 YEARS)	$335,000 - $781,000
Operating and maintenance costs include power requirements, treatment residuals disposal, and treatment system monitoring.	
TOTAL PRESENT WORTH	$656,000 - $1,221,000

Notes:

Cost estimates are based on available information and professional judgment. Changing market conditions and regulatory requirements may cause actual costs to vary from the estimated costs.

A contingency of 25 percent has been included in each direct, indirect, and O&M cost item.

Cost estimate is for installation and O&M of groundwater containment wells only.

TABLE 14-5

COST SUMMARY TABLE FOR ALTERNATIVE 3: UPGRADIENT SUBSURFACE DRAIN WITH DOWNGRADIENT BARRIER
NYSEG FORMER COAL GASIFICATION SITE
MECHANICVILLE, NEW YORK

DIRECT COST	$670,000
Direct costs include institutional controls, mobilization/demobilization, bedrock mapping, excavation and disposal of filter bed soils, upgradient subsurface drain installation, and downgradient barrier wall installation.	
INDIRECT COST	$202,000
Indirect costs include health and safety, legal, administration, permitting, engineering, and services during construction.	
TOTAL CAPITAL (DIRECT AND INDIRECT) COSTS	$872,000
PRESENT WORTH OF O&M COSTS (@ 5% FOR 30 YEARS)	$818,000
Operating and maintenance costs include environmental monitoring, five-year site reviews, and asphalt cover maintenance.	
TOTAL PRESENT WORTH FOR ALTERNATIVE 3	$1,690,000

Notes:

Cost estimates are based on available information and professional judgment. Changing market conditions and regulatory requirements may cause actual costs to vary from the estimated costs.

A contingency of 25 percent has been included in each direct, indirect, and O&M cost item.

TABLE 15-1

COMPARATIVE ANALYSIS OF ALTERNATIVES
NYSEG FORMER COAL GASIFICATION SITE
MECHANICVILLE, NEW YORK

ALTERNATIVE	THRESHOLD CRITERIA		BALANCING CRITERIA					
	OVERALL PROTECTION OF HUMAN HEALTH AND THE ENVIRONMENT	COMPLIANCE WITH SCGs	LONG-TERM EFFECTIVENESS AND PERMANENCE	REDUCTION OF TOXICITY, MOBILITY, & VOLUME	SHORT-TERM EFFECTIVENESS	IMPLEMENTABILITY	COST	SCORE[1]
Alternative 1 Minimal Action	Existing site conditions are effective in controlling migration of coal tar. Currently no unacceptable risk to human health and the environment.	No location-specific SCGs apply to this site. Would comply with action-specific and chemical-specific SCGs.	Would maintain risk at current, insignificant level. Would not reduce potential future risk to ecological receptors.	Maintains reduced mobility due to asphalt cover integrity.	Impacts to community and site worker health and safety during implementation would be unlikely. Minimal short-term environmental impacts.	All components of Alternative 1 would be readily implementable.	Least costly of the alternatives. NPW = $0.7 M	69
Alternative 2 Downgradient Barrier Wall	Would reduce migration of overburden coal tar to Anthony Kill; would provide only minimal control of overburden groundwater.	No location-specific SCGs apply to this site. Would comply with action-specific and chemical-specific SCGs.	Alternative 2 may be slightly more effective than Alternative 1 in the long-term for controlling migration of overburden coal tar to the Anthony Kill. Minimal reduction of total overburden groundwater flow would be achieved.	Migration of overburden coal tar would be controlled.	Implementation impacts, air impacts, and nuisance dust would be minimal. Implementation time estimated to be 2 months to construct.	Well-developed, reliable technology. Requires standard construction techniques to implement. Construction may be difficult because of underground structures and proximity to Anthony Kill.	Least costly of the two remedial action alternatives. NPW = $1.2 M	64
Alternative 3 Upgradient Subsurface Drain with Downgradient Barrier Wall	Would reduce migration of overburden coal tar to Anthony Kill; would reduce total flow of overburden groundwater to stream by approximately 16 percent.	No location-specific SCGs apply to this site. Would comply with action-specific and chemical-specific SCGs.	Alternative 3 would provide similar long-term effectiveness to Alternative 2. It would, however, provide slightly greater control of total overburden groundwater flow to the Anthony Kill (i.e., 16 percent reduction).	Migration of overburden coal tar would be controlled. Total flow of overburden groundwater to Anthony Kill would be reduced slightly.	Impacts to worker health and safety would be slightly greater for Alternative 3 compared to Alternative 2 because of excavation and trenching required to install the subsurface drain. Implementation time estimated to be 2 months.	Well-developed, reliable technology. Requires standard construction techniques. Implementation requires obtaining a SPDES permit to discharge diverted, upgradient groundwater.	Most costly of the alternatives. NPW = $1.7 M	61

Notes:
SCGs = standards, criteria, and guidelines
MCL = Maximum Contaminant Level
NPW = net present worth
[1]Alternative score based on criteria in the NYSDEC TAGM 90-4030 for Selection of Remedial Alternatives at Inactive Hazardous Waste Sites (NYSDEC, 1990) (see Appendix F).

Mechanicville, New York

Introduction

During the Phase IIA Supplemental RI, the hydraulic conductivity (K) of the overburden and bedrock water bearing zones beneath the Mechanicville site have been estimated through the performance of in situ rising head tests. During in situ tests, the water bearing zones were stressed by lowering the water level in monitoring wells and recording the rate of water level recovery to prestress conditions. The water level recovery data was then input to mathematical formulas to estimate the K of the water bearing zones in which the monitoring wells were screened.

In Situ Tests

In accordance with the Phase IIA Supplemental RI Work Plan, in situ rising head tests were performed at MW-16, MW-17 and MW-18. A weighted PVC slug was use to displace the water.

Prior to in situ testing at each monitoring well, the cap was removed to allow the water level in the well to stabilize (reach its static condition). After the water level stabilized, a pressure transducer was lowered into the well and placed approximately 6 inches above the bottom of the well. The pressure transducer, which reads and transmits the overlying water pressure data, was connected to a Hermit 2000 Data Logger. The Data Logger, which converts the pressure readings to water levels, records and stores the data for future analysis. For in situ tests the data logger initially records water levels approximately every 1/2 second. This rate decreases after two minutes into the test when water levels are recorded every 30 seconds.

After installation of the pressure transducer and data logger, slug tests, utilizing a weighted PVC slug, were performed the Phase IIA Supplemental RI monitoring wells, MW-16, MW-17 and MW-18. The slug was carefully lowered into the well, so not to disturb the transducer. After the water level had returned to static conditions, the slug was rapidly removed from the water, causing a sudden decrease in the water level. Simultaneously, the data logger was activated and the water level recovery was recorded. When the water level in the well recovered to its static condition, the test was complete. Two (2) to three (3) tests were performed on each monitoring well.

In Situ Test Analysis

All slug tests were analyzed by the Bouwer-Rice method (1976) for slug tests in unconfined aquifers. This analysis is incorporated in the Aqtesolv$_{tm}$ computer program, which was used to calculate K estimates. This appendix contains: Table B-1 which presents the test results; the time-displacement graphs; and the equation used in the program's application of the Bouwer-Rice method.

Conclusion

The Bouwer-Rice method yields realistic estimates of K that are consistent with previous work conducted at the Mechanicville site. Hydraulic conductivity test performed during Tasks 2, 3, and 4 report average K values of 3.3 X 10^{-4}, 6.2 X 10^{-4}, and 2.7 X 10^{-4} measured at monitoring wells screened in the overburden, overburden/shallow bedrock, and bedrock respectively. Hydraulic conductivity test performed at MW-17, MW-16 and MW-18, screened in the overburden,

overburden/shallow bedrock, and bedrock estimated K at values of 1 X 10^{-3}, 4 X 10^{-5}, and 1 X 10^{-5} respectively.

MW-16	Overburden/Shallow Bedrock	16.0	89.3 - 79.3	12	Rising Head	3.9 E-5
MW-17	Overburden	22.5	85.7 - 75.7	12	Rising Head	1.2 E-3
MW-18	Bedrock	38.0	70.1 - 60.1	12	Rising Head	1.1 E-5

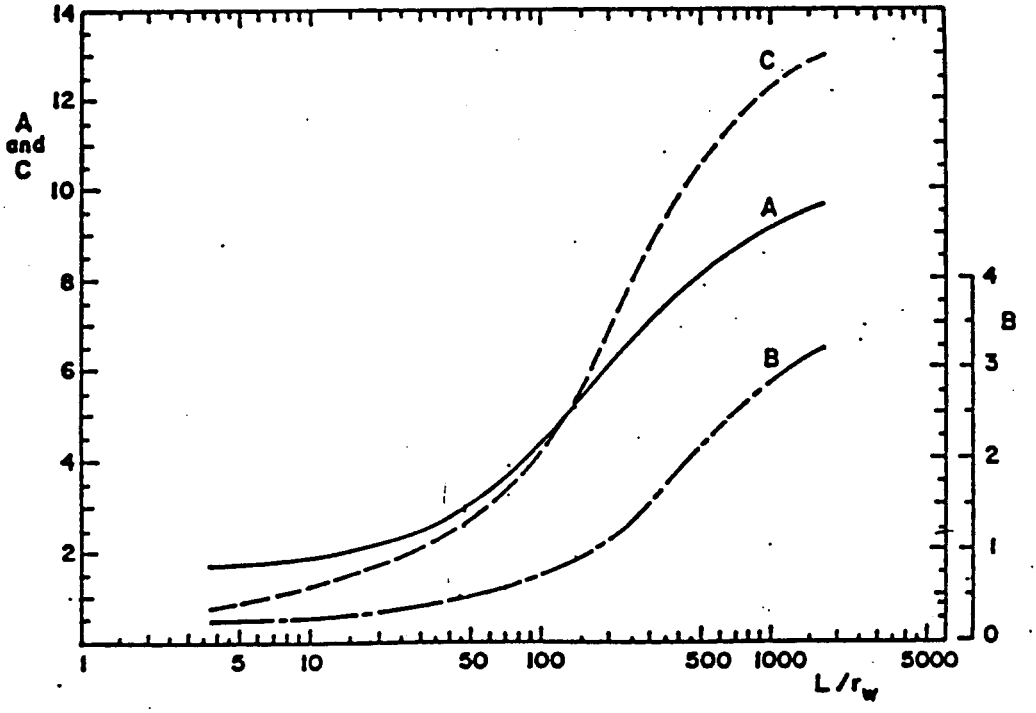
Notes:

1) BGS - below ground surface
2) Elevation relative to 100-foot datum
3) cm/sec - centimeters per second

Bouwer-Rice Equation for Hydraulic Conductivity

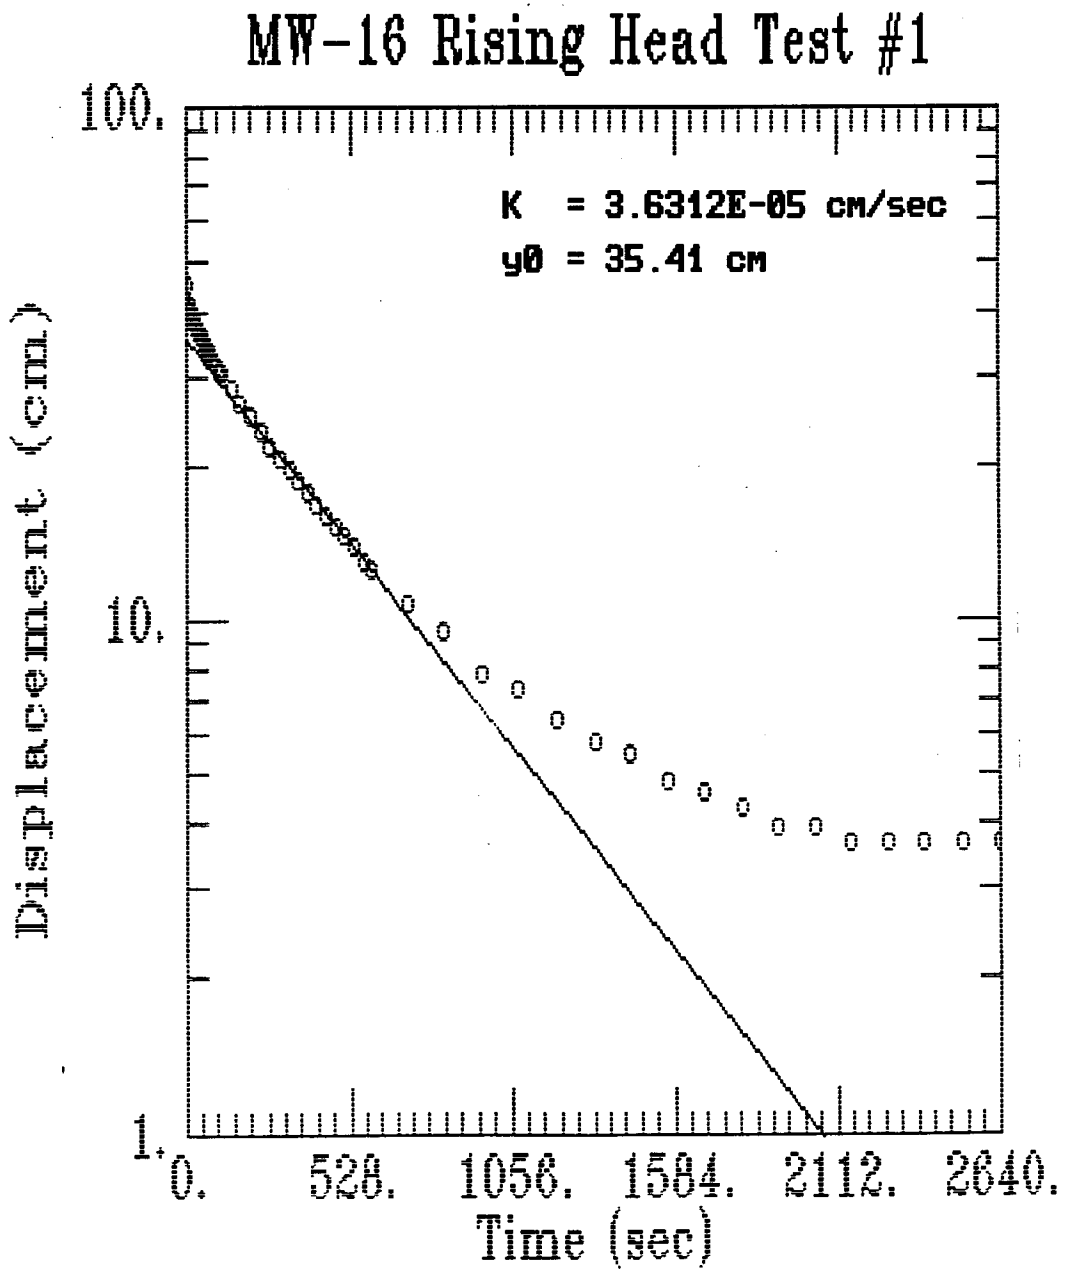
Basic Equations:

Equation 1

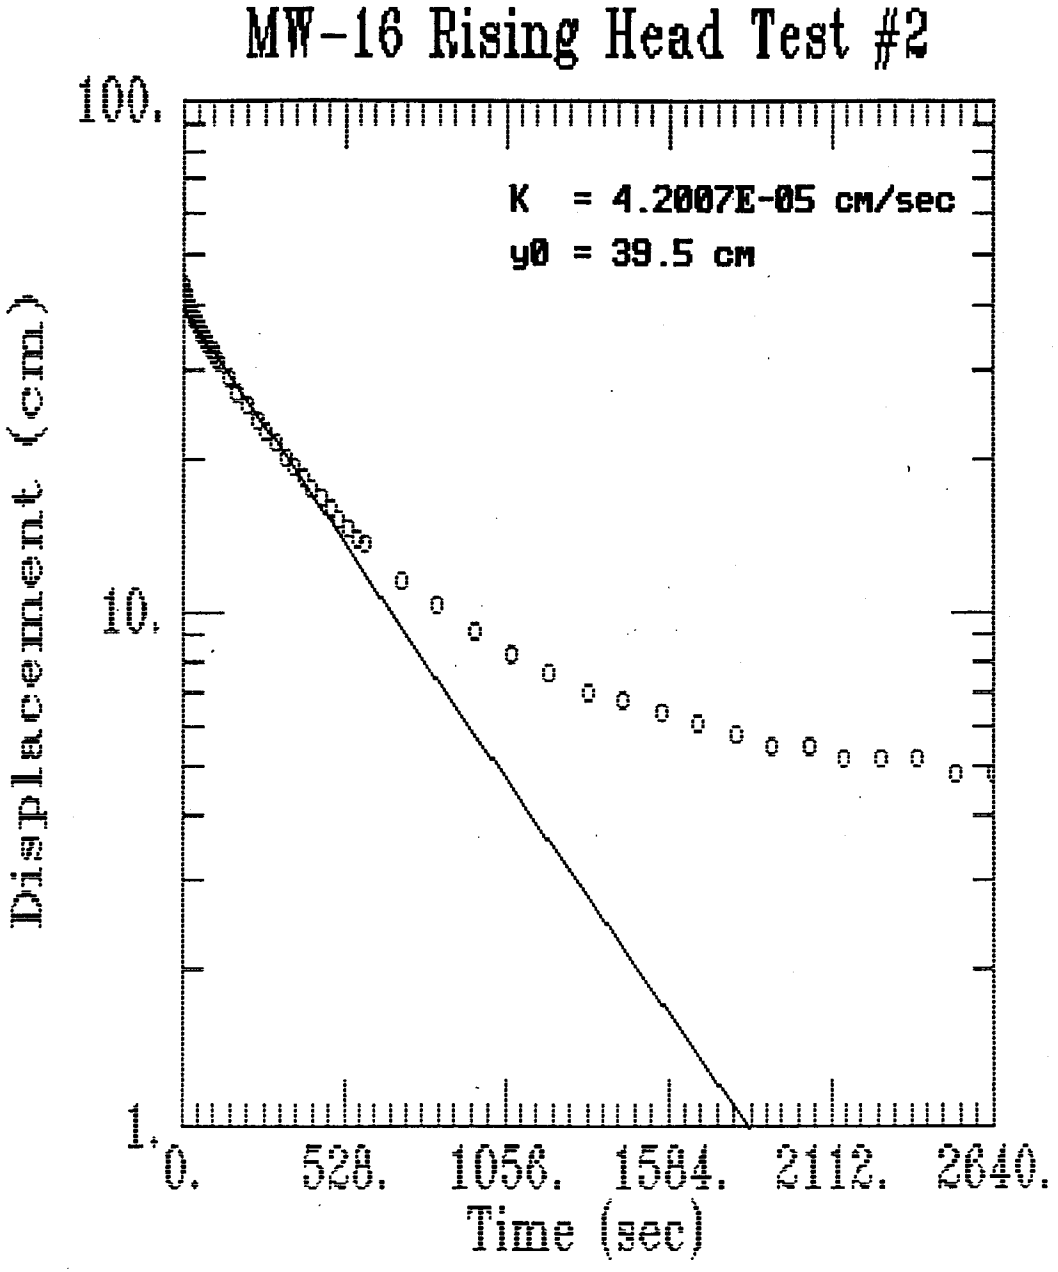


$$\ln \frac{R_e}{R_w} = \left[\frac{1.1}{\ln \frac{H}{r_w}} + \frac{C}{\frac{L}{r_w}}\right]^{-1}$$

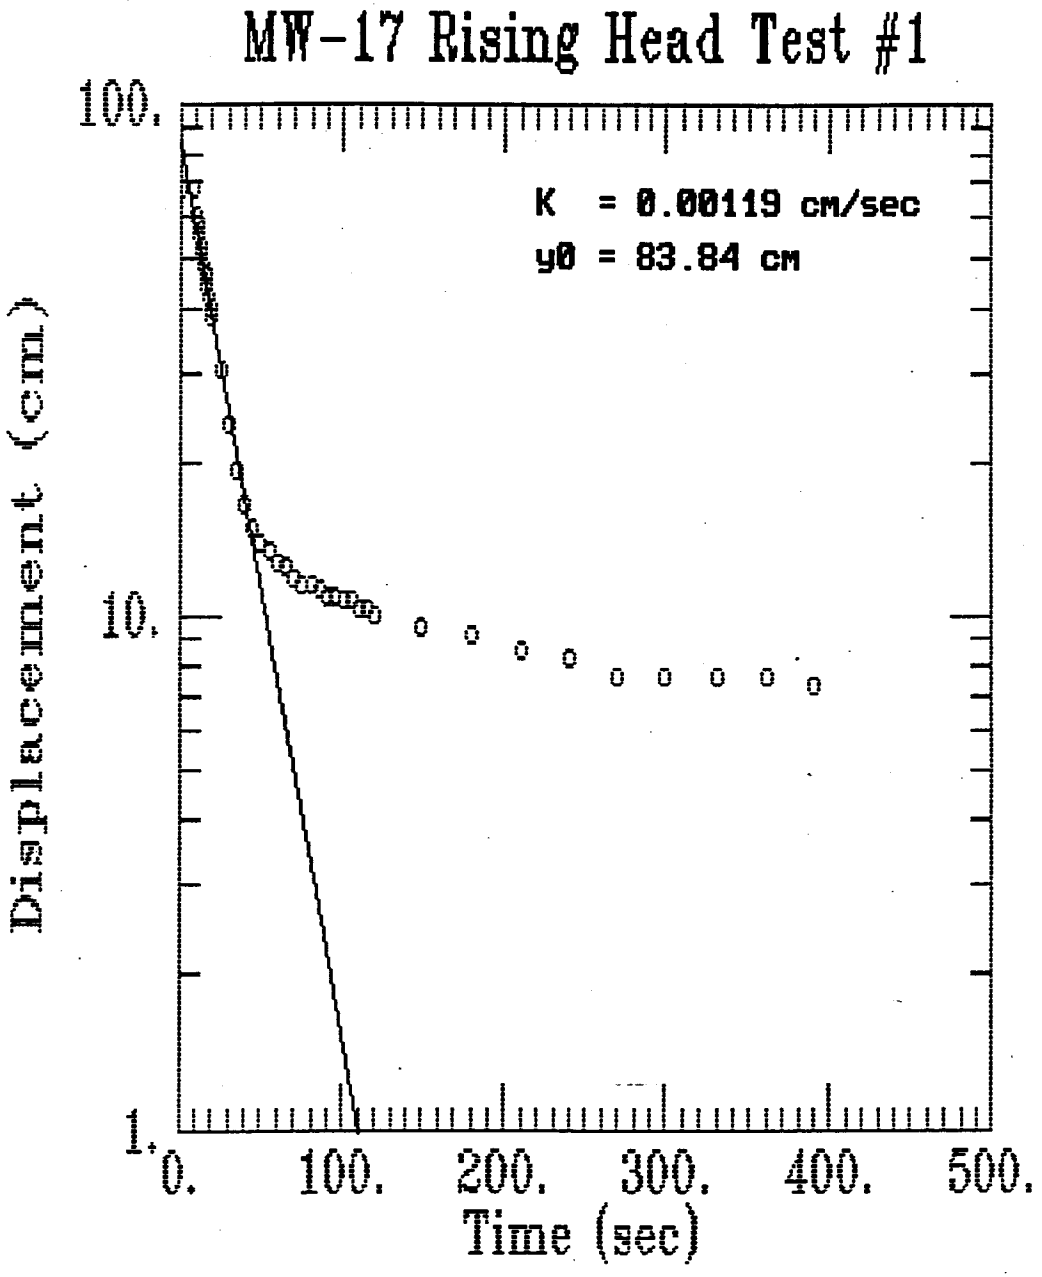
Equation 2



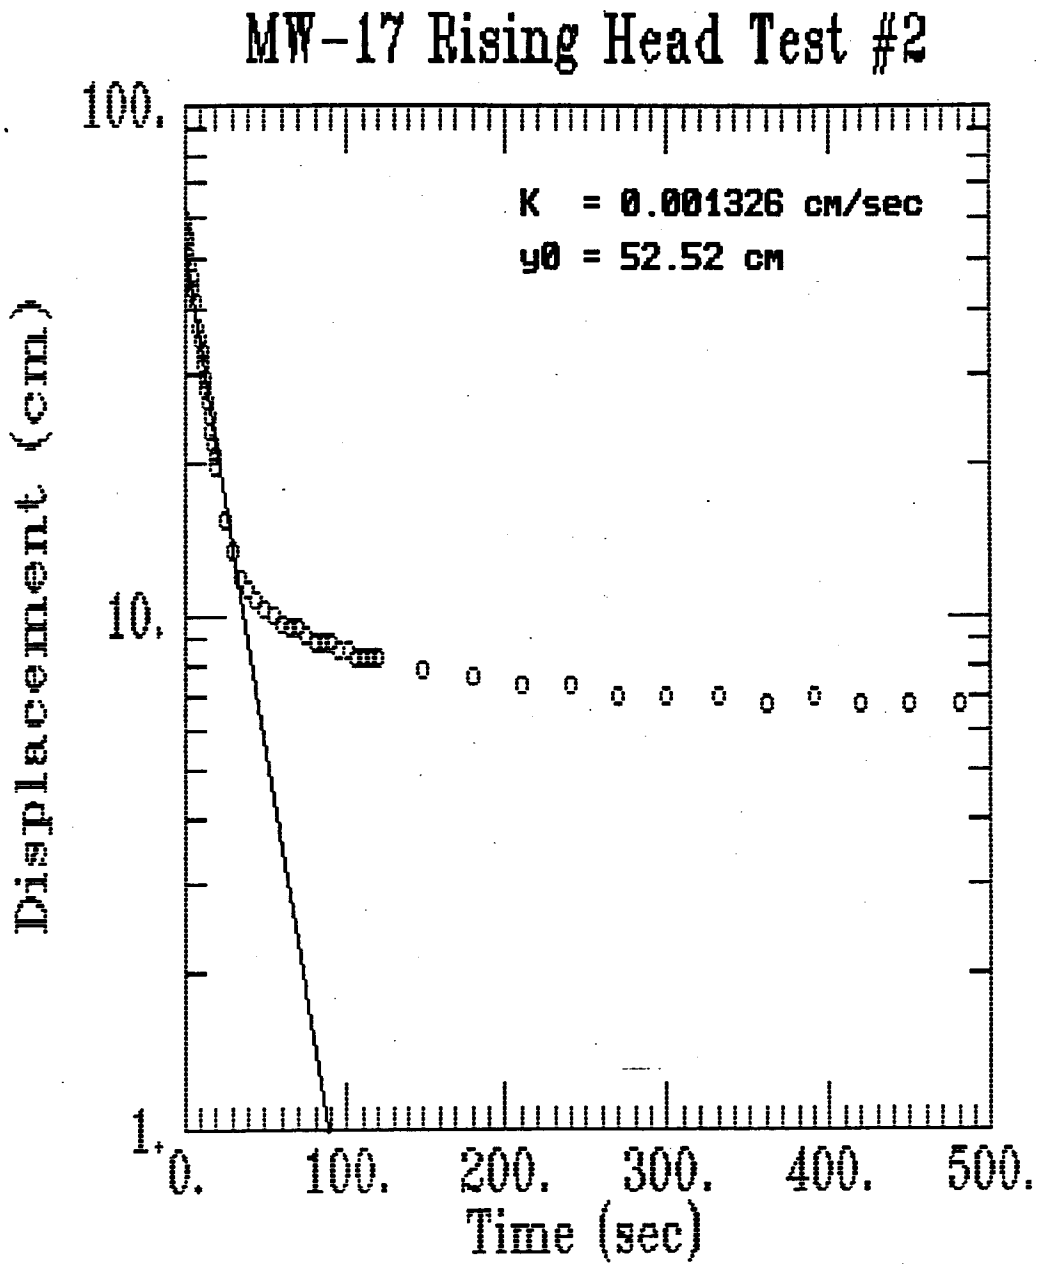
$$K = \left[\frac{r_c^2 \ln \frac{R_e}{R_w}}{2L}\right] \frac{1}{t} \ln \frac{y_o}{y_t}$$

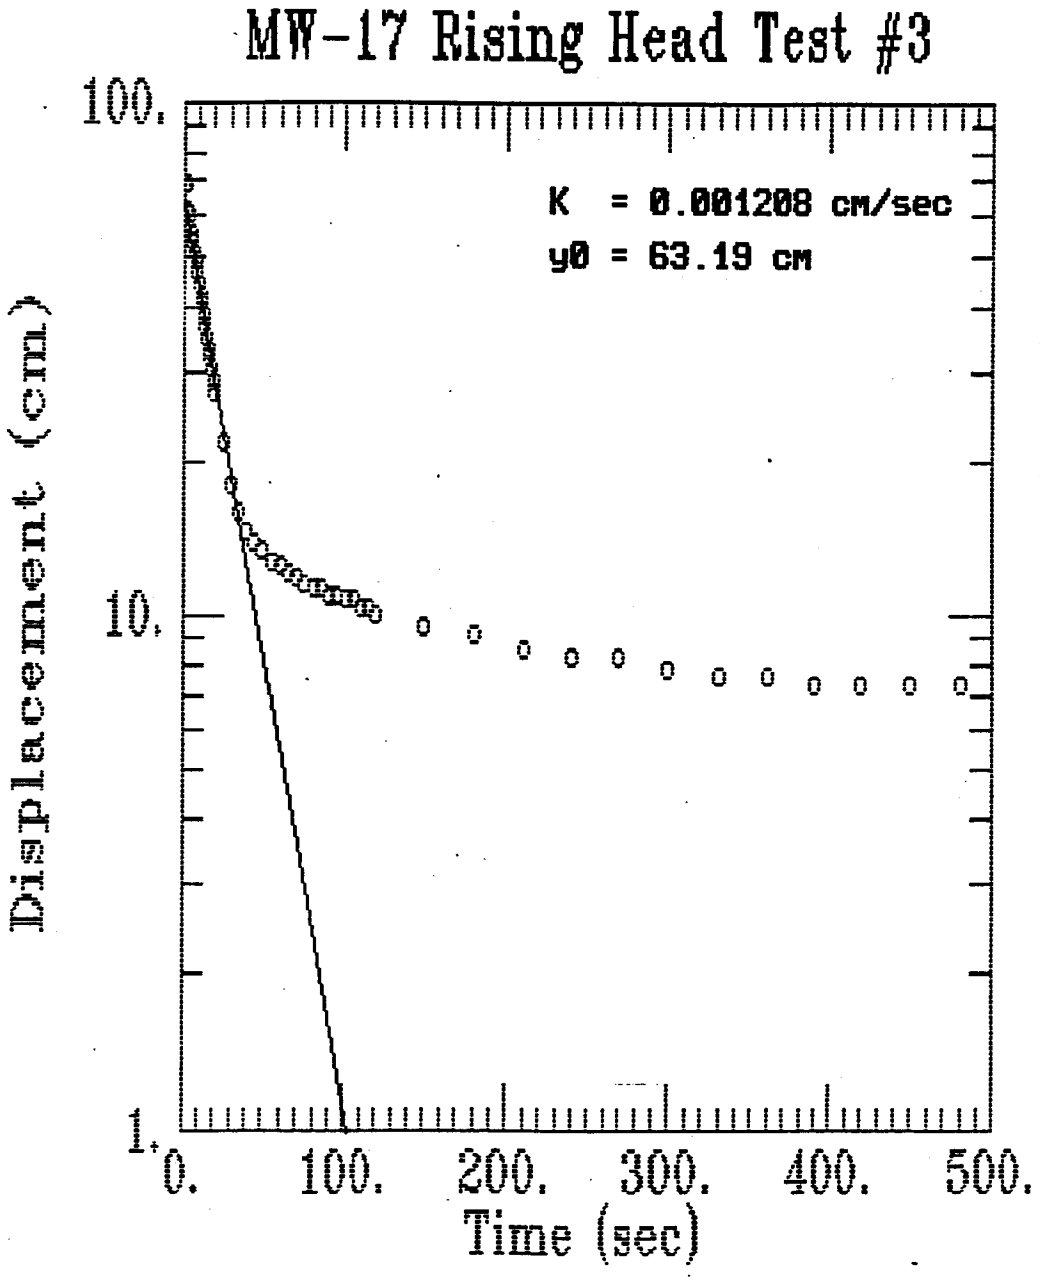


where



- R_c - radius of the well casing
- R_w - radius of the bore hole
- H - static height of water in the well
- L - effective screen length
- t_o - start time
- t - time in seconds
- Y_o - displacement at time = t_o
- K - hydraulic conductivity
- C - a dimensionless variable derived from the Bouwer-Rice A, B, C, vs. L/r_w graph





Curves relating coefficients A, B, and C to L/R_w. (From Bouwer and Rice, 1976).

APPENDIX C

Validation Report/ Laboratory Results

Former Coal Gasification Site
Mechanicville, New York

APPENDIX C-1

Validation Report

Former Coal Gasification Site
Mechanicville, New York

Sampling Dates: May 17-22, 1993

Review is complete for the data package generated by Galson Laboratories pertaining to soil samples collected at the Mechanicville site. Review was performed following NYSDEC criteria and USEPA Region II guidelines. All samples analyzed for PCBs were validated at Level III. One sample (METDEEXX05/11) was validated at Level IV for the volatile, semivolatile, and inorganic analyses. The remaining samples were blank evaluated. Samples were analyzed for volatiles, semivolatiles, PCBs, and inorganics using NYSDEC ASP 91-1, 91-2, 91-3, and Superfund-CLP, respectively. Samples were also analyzed for reactive cyanide and reactive sulfide using SW846.

The data table referenced in this memo includes Table 2, Validation/Summary Table, included in Appendix C-2.

The following subsections summarize the qualifications/edits that have been determined by validation.

All Organic Analyses

Compound results below the contract required quantitation limit (CRQL) were flagged with a J by the laboratory and were considered estimated and flagged J.

Compound results greater than the calibration range were diluted and reanalyzed. The diluted results for all compounds beyond calibration range were inserted into the original results and the

remainder of the diluted analysis deleted.

PCB results which exhibited a percent difference greater than 25% between quantitation results on the two columns used for analysis were considered estimated and flagged J.

Inorganic Analyses

Analyte results below the contract required detection limit (CRDL) were considered estimated and flagged with a J.

Volatile Analyses - Qualifications/Edits

1. Acetone was detected in two of the laboratory method blanks at 6 μg/L and 7 μg/L. Equipment blank MEEXB-XXSB/11, which was associated with several of the soil boring samples, also contained 10 μg/L of acetone. As a result acetone should be considered nondetect in all associated soil samples.

2. Initial calibration criteria for linearity were not met for acetone. Positive results were estimated in sample METDEEXX05/11. 2-Butanone did not meet linearity criteria, and the nondetected result in this sample was estimated (UJ).

Volatile Analyses - Comments

Please see items 1 and 2 under **Qualifications/Edits**. All hold times, instrument tunes, internal standards, and surrogate recoveries were within QC limits for the sample validated at Level IV.

All matrix spike and matrix spike duplicate recoveries and RPDs met QC criteria.

Semivolatile Analyses - Qualifications/Edits

3. Naphthalene was detected at 17 μg/kg in the GPC blank associated with the sediment samples. Naphthalene detected at less than 170 μg/kg should be considered nondetect.

4. Source water MEEXB-SR/11 contained di-n-butylphthalate at 3 J μg/L and bis(2-ethylhexyl)phthalate at 18 μg/L. Bis(2-ethylhexyl)phthalate concentrations less than 5994 μg/kg were considered nondetect in the associated samples. Di-n-butylphthalate was not detected in any of the associated samples.

5. Several compounds did not meet percent difference criteria during the continuing calibration for sample METDEEXX05/11. N-nitroso-di-n-propylamine, benzoic acid, 2,4-dinitrophenol, di-n-octylphthalate, and pentachlorophenol were qualified as estimated.

Semivolatile Analyses - Comments

Please see items 3 - 5 under **Qualifications/Edits**. All hold time, instrument tune, internal standard, and surrogate recovery criteria were met for the sample validated at Level IV. Matrix spike and matrix spike duplicate recoveries and RPDs were within recommended limits.

PCB Analyses - Qualifications/Edits

6. Due to shipping delays, the majority of the sample results required qualification since the samples arrived at the laboratory with no ice left in the cooler. The only samples not

affected were MEEISHXX29/11, MEEISHXX30/11, MEEISHXX31/11, and MEEISHXX32/11.

7. Surrogate recoveries were above QC limits for the following samples:

MEEISHXX33/11	MEEISHXX34/11
MEEISHXX35/11	MEEISHXXDU/13
MEEISHXX48/11	

No action was required.

PCB Analyses - Comments

Please see items 6 and 7 under **Qualifications/Edits**. All method blanks and field blanks were compliant. All matrix spike and matrix spike duplicate recoveries and RPDs were within the required limits.

The majority of the samples were contained in a data package that contained only surrogate recovery forms, matrix spike and matrix spike duplicate recovery forms, and method blank summary forms. These data were already estimated due to the shipping problem mentioned in item 6 above. Initial and continuing calibration, calibration sequence, and retention time window criteria were also reviewed for the remaining samples listed in item 6.

Inorganic Analyses - Qualifications/Edits

8. Matrix spike recovery criteria were not met for zinc. Zinc results were estimated in sample METDEEXX05/11.

9. Analytical spike recovery for antimony was less than 85% during the analysis of sample METDEEXX05/11, and antimony results were estimated.

10. Several analytes were detected in source water blank MEEXB-XXSR/11. Results in the associated samples were considered nondetect if they were less than the value given below for the following compounds:

Aluminum	990 mg/kg
Iron	2068 mg/kg
Manganese	116 mg/kg
Zinc	18.5 mg/kg

Inorganic Analyses - Comments

Please see items 8 - 10 under **Qualifications/Edits.** All appropriate QC criteria were reviewed and found acceptable for the sample validated at Level IV unless noted under

Qualifications/Edits.

Reactive Cyanide and Reactive Sulfide Analyses - Qualification/Edits

There were no qualifications or edits to these data.

Reactive Cyanide and Reactive Sulfide Analyses - Comments

All associated blanks were compliant. Reactive cyanide and reactive sulfide were not detected in any of the samples.

Sampling Dates: July 13-15, 1993

Review is complete for the data package generated by Galson Laboratories pertaining to groundwater samples collected at the Mechanicville site. Samples were analyzed for volatiles, low level volatiles, semivolatiles, PCBs, and inorganics using NYSDEC ASP 91-1, 91-4, 91-2, 91-3, and Superfund-CLP, respectively. Samples were also analyzed for reactive cyanide and reactive sulfide using SW846. Two leachate samples, COMP-3 and COMP-4, were analyzed for TCLP volatiles, semivolatiles, and inorganics. Review was performed following NYSDEC criteria and USEPA Region II guidelines. All samples analyzed for PCBs were validated at Level III. One sample (MEGDMW8715/11) was validated at Level IV for the volatile, semivolatile, and inorganic analyses. Sample MEGDMW9317/11 was validated at Level IV for the low level volatile analysis. The remaining samples were blank evaluated.

The data tables referenced in this memo includes Table 2, Validation/Summary Table, included in Appendix C-2.

The following subsections summarize the qualifications/edits that have been determined by validation.

All Organic Analyses

Compound results below the CRQL were flagged with a J by the laboratory and were considered estimated and flagged J.

Compound results greater than the calibration range were diluted and reanalyzed, and the diluted

results flagged with a D by the laboratory. The diluted results for all compounds beyond calibration range were inserted into the original results and the remainder of the diluted analysis deleted.

Inorganic Analyses

Analyte results below the CRDL were considered estimated and flagged with a J.

Volatile Analyses - Qualifications/Edits

1. Trip blanks MEXXXXXXTB/11 and MEXXXXXXTB/12 contained methylene chloride at 0.6 and 5 μg/L, respectively. All associated sample results less than ten times the associated blank concentration were considered non-detect.

2. Initial calibration criteria for linearity were not met for methylene chloride and 1,2-dichloroethene (total). Positive results were estimated in sample MEGDMW8715/11.

3. Methylene chloride did not meet percent difference criteria during continuing calibration. Results for this compound was estimated in sample MEGDMW8715/11.

Volatile Analyses - Comments

Please see items 1 - 3 under **Qualifications/Edits**. All hold time, instrument tune, internal standard, method blank, and surrogate recovery criteria were met for the sample validated at Level IV. All matrix spike and matrix spike duplicate recoveries and RPDs also met QC

criteria.

Low Detection Limit Volatile Analyses - Qualifications/Edits

4. Linearity criteria were not met for vinyl chloride and methylene chloride during the initial calibration. Since these compounds were not detected in any samples, no action was required.

Low Detection Limit Volatile Analyses - Comments

Please see item 4 under **Qualifications/Edits**. All hold time, instrument tune, internal standard, surrogate recovery, and method blank criteria were met.

Semivolatile Analyses - Qualifications/Edits

5. Equipment blank MEXXMWXXFB/11 contained phenol at 6 J μg/L, diethylphthalate at 1 J μg/L, di-n-butylphthalate at 3 J μg/L and bis(2-ethylhexyl)phthalate at 2 μg/L. All associated sample results less than ten times the associated blank concentration were considered non-detect.

6. Internal standard area responses were below QC limits for two internal standards during the analysis of sample MEGDMW8715/11. All compounds quantitated using these internal standards were qualified as estimated for both positive and non-detected results.

7. Bis(2-ethylhexyl)phthalate did not meet field duplicate precision criteria for samples

MEGDMW8715/11 and MEGDMW87DU/11. Results for this compound were qualified as estimated in both samples.

Semivolatile Analyses - Comments

Please see items 5 - 7 under **Qualifications/Edits.** All hold time, instrument tune, method blank, and surrogate recovery criteria were met for the sample validated at Level IV. Matrix spike and matrix spike duplicate recoveries and RPDs were within recommended limits.

PCB Analyses - Qualifications/Edits

No qualification of these data was required.

PCB Analyses - Comments

All method blanks and field blanks were compliant. All matrix spike and matrix spike duplicate recoveries and RPDs were within the required limits. All other appropriate QC were reviewed and found acceptable.

Total and Dissolved Inorganic Analyses - Qualifications/Edits

8. Aluminum percent recovery was greater than QC limits during laboratory control sample analysis. The positive result in the sample reviewed was qualified as estimated.

Total and Dissolved Inorganic Analyses - Comments

Please see item 8 under **Qualifications/Edits.** All appropriate QC criteria were reviewed and found acceptable for the sample validated at Level IV unless noted under **Qualifications/Edits.**

Reactive Cyanide and Reactive Sulfide Analyses - Qualification/Edits

There were no qualifications or edits to these data.

Reactive Cyanide and Reactive Sulfide Analyses - Comments

All associated blanks were compliant. Reactive cyanide and reactive sulfide were not detected in any of the samples.

TCLP Volatiles, Semivolatiles, and Inorganics Analyses - Qualifications/Edits

There were no qualifications or edits to these data.

TCLP Volatiles, Semivolatiles, and Inorganics Analyses - Comments

No contaminants were detected in the associated blanks.

APPENDIX C-2

Laboratory Results with Detection Limits and Data Qualifiers

Former Coal Gasification Site
Mechanicville, New York

DATA QUALIFIERS

Analytical data qualifiers appear on each table as appropriate and are applied by the laboratory or data reviewer. The descriptions of these data qualifiers are as follows:

Data Qualifiers:

J (organic) Laboratory flag which indicates an estimated concentration because results are either below the contract required quantitation level (CRQL) or quality control criteria were not met.

J (inorganic) Laboratory flag which indicates an estimated concentration because results are either below the contract required detection level (CRDL) or quality control criteria were not met.

U Indicates that compound was analyzed but not detected.

UJ Indicates that quantitation level was estimated because QC criteria were not met.

D Indicates that sample concentration was obtained by dilution to bring result within calibration range.

Other Notations:

NR Analysis not requested.

ND Not detected.

APPENDIX D

Seismic Refraction Survey Report

Former Coal Gasification Site
Mechanicville, New York

Introduction

A seismic survey was conducted in the Price Chopper parking lot adjacent to the NYSEG Former Coal Gasification Site in Mechanicville, New York. The survey was conducted to investigate for the presence of a bedrock low hypothesized to exist and to guide the location of a monitoring well pair (MW-17 and MW-18). Seismic methods are often employed to map bedrock surfaces and structural features. Seismic surveying was conducted on 17 May 1993. Find attached to this memorandum seismic data reports for each seismic line.

Instrumentation and General Survey Information

Three 120 foot long seismic lines were shot in the Price Chopper parking lot (located between the Price Chopper and North Central Avenue. Figure 4-1 in the RI illustrates the location of each seismic spread. A Geometrics ES-2515F seismograph was used for seismic data collection. A 12-channel geophone array was used where geophone spacing was 10 feet. A 10 pound sledgehammer was used as an energy source, an offset of 5 feet was used. Analog strip chart recordings were obtained and interpreted in the field. First-break pick analysis and preliminary depth calculations were also made in the field. Seismic data was later processed using various applications software. In order to minimize the adverse effects of cultural noise (primarily vehicular traffic), the survey was conducted between 2:00 a.m. and 4:30 a.m.

Seismic Survey Results

Tables D-1, D-2, and D-3 in the seismic data reports present calculated depths to bedrock beneath each seismic profile line. Figures D-1 through D-3 show these data plotted as depth

to bedrock. Seismic velocities calculated for bedrock ranged between 9,000 and 15,000 feet per second (ft/sec). These values are indicative of weathered and competent shale bedrock. Seismic Line 1 suggests that bedrock lies between 23 and 25 feet below ground surface (bgs). Seismic Line 2 shows that a slight bedrock high may exist paralleling the general structural trend of nearby outcrop. Seismic data indicates that bedrock is found between 20 and 21 feet bgs along Seismic Line 2. Data collected from Seismic Lines 1 and 2 correlate well with the depth of bedrock determined during the subsequent construction of MW-17 and MW-18 (22.5 feet bgs). The bedrock surface appears deeper beneath Seismic Line 3 ranging from 25 to 28 feet bgs.

Groundwater Modeling

Former Coal Gasification Site
Mechanicville, New York

INTRODUCTION

A groundwater flow model for the Mechanicville site was constructed for the purpose of aiding in the evaluation of remedial alternatives. The model, calibrated to observed and interpreted site conditions, was then used to simulate effects of various alternatives on groundwater flow directions and overall water balances in the model domain.

CONCEPTUAL MODEL

The site is situated along the south bank of the Anthony Kill, and about 1,200 feet west of the Champlain Canal of the Hudson River. Interpretations of the shallow groundwater flow at the site, based on water level measurements, indicate discharge of shallow groundwater flow to the Anthony Kill. Review of the topographic map of the area suggests a groundwater divide for shallow groundwater south of the site and extending eastward toward the Hudson. The conceptual model considers that the shallow flow (i.e., extending 20 feet into the shaley bedrock) constitutes the shallow flow system to be considered in evaluations of remedial alternatives. This depth is somewhat arbitrary, but is reasonable when considering the principal use of the model to compare and evaluate remedial measures for control of the tar in the overburden and shallow groundwater flow. Deeper flow in bedrock would be expected to flow toward the much larger sink, the Hudson River, with flow patterns determined by fracture distributions and orientations in the rock. The 20-foot depth is also about the vertical limit of information currently available for the site. Bedrock is inferred to become more competent with depth, and flux rates are expected to be much lower in the deeper rock. The inferred groundwater flow

direction perpendicular into the Anthony Kill east and west of the site, and the Anthony Kill as the conservatively assumed ultimate receptor for all shallow groundwater flow, results in an inference of recharge and upgradient groundwater flux as the sources of groundwater in the model, and of the Kill as the sole receptor. While the bedrock is not a porous medium, it has been modeled so here due to the relatively high reported hydraulic conductivities for the rock, reports of highly weathered and fractured shallow rock, the similar inferred groundwater flow directions for the overburden and shallow rock, and the lack of suitable fractured rock models. The model deals only with groundwater flow, and cannot predict any potentials for further migration of coal tars at the site.

MODEL SELECTION

The U.S. Geological Survey (USGS) groundwater model code MODFLOW (Harbaugh, 1988) was selected as appropriate for modeling the groundwater flow regime at the site, having the flexibility and capabilities to simulate the various boundary conditions and alternatives desired in the model. ABB-ES uses Geraghty and Miller's packaging of MODFLOW on a 486 DOS-based PC running at 50 Mhz. The output is handled through a postprocessor and printed out as a SURFER plot of contoured head values. A simple site map identifying a few of the key buildings provides a visual frame of reference.

MODEL SETUP AND BOUNDARIES

The model was set up with respect to expected simulation needs and available site data. The model covers an area of 300 feet (north-south) by 740 feet (east-west), and is discretized uniformly as 10-foot square elements, leading to 74 rows and 30 columns in the model. The model grid is shown on Figure E-1.

Vertically, the bottom of the water table aquifer was taken as the top of competent rock. A top-of-rock surface was kriged based on 94 selected points over the model area (from geophysical data and including a few assumed points along the model south boundary where no data were available, see Figure E-2). The kriged surface was transformed in SURFER to provide a matrix of values as input to the model as the bottom of layer one (the overburden). This matrix was further transformed by successively subtracting 10 feet to create bottom of layer two (the weathered rock with higher conductivity), and the bottom of layer three (the rock with lower conductivity). These depths corresponded to approximate depths of explorations (borings and wells) installed at the site, and also to potential depths of interest for the anticipated remedial alternatives to be evaluated.

The east and west boundaries of the model were assumed to be no-flow boundaries since they paralleled interpreted groundwater flow lines. The south boundary was split as a flux boundary (using MODFLOW's general head boundary package) opposite the site, and a no-flow boundary (along an apparent divide) further east of the site. The northern boundary of the model was assumed to be the river, which was represented by MODFLOW's river package. Since there is exposed bedrock along much of the Anthony Kill in the model domain, the overburden was assumed

to be absent over the river area, and in the model these areas were made inactive in layer one and the river was designated as active only with layer two, the upper rock. The Anthony Kill, then, becomes the sole sink for groundwater in the model under natural conditions. Diffuse recharge was applied over the model area with consideration to the extensive paving over much of the site area. No seeps could be simulated along the river bank due to limitations of the model to represent seepage faces.

The model was conducted in the steady-state mode as long-term effects were to be considered, and available data for water levels were considered representative of average conditions for the site (moderately low seasonal variations reported for water levels).

GROUNDWATER AQUIFER PARAMETERS AND MASS BALANCE CONSIDERATIONS

The objective of the construction and calibration of the model was to provide a mathematical framework for remedial alternative evaluation. This required encompassing the main features of the groundwater flow system, i.e., flow direction, over-all water balance and fluxes, and interactions between model layers and the Anthony Kill. The model input data and computed fluxes, then, should be consistent with observations or estimates based on measurements.

The important features of this model are the hydraulic conductivities, the recharge over the area, available flux from upgradient, the over-all water balance, and interactions with the Anthony Kill. Hydraulic conductivity (K) data for the site

indicated the following ranges of values for each layer: layer one from 0.06 to 0.57 feet per day (ft/d) with geometric mean 0.23 ft/d; layer two from 0.03 to 3.1 ft/d with geometric mean 0.74 ft/d; and layer three from 0.28 to 0.72 ft/d with geometric mean 0.47 ft/d. Net recharge over the model area was considered by zones with assumptions of 2 inches per year or less for new well-paved areas, 2 to 4 inches per year over site old paved areas, and 10 to 12 inches per year for unpaved or open areas. Available recharge over the model area was calculated from about 250 to 400 cubic feet per day (cu ft/d).

Several methods were applied for estimating the total flow available in the modelled system. Available flux from upgradient was estimated by using average K values, an overall gradient of 0.06, thickness of model layers, and a site width of about 400 feet. This resulted in an estimate of about 200 to 300 cu ft/d. Summing the recharge (i.e., 250 to 400 cu ft/d) and upgradient influx, the overall water available to the model was estimated to be about 450 to 700 cu ft/d. Other estimates were obtained by calculating an apparent linear discharge rate to the Anthony Kill based on reports of a 2 cubic foot per second (cfs) gain between an upstream gaging station and the confluence with the Hudson. This produced an estimate of about 2,300 cu ft/d in the model, which is probably high because this section of the stream is lies primarily directly on bedrock, whereas other reaches intersect the overburden (whose K value is probably higher at other locations than at the site). Another estimate of total flux was based on the seepage meter results, which showed a range of 0.00025 to 0.0114 cu ft/sq ft/d. The higher end of this range results in an estimate of discharge to the Anthony Kill of 114 cu ft/d. Based on evaluation of these various methods, a reasonable estimate for a range of flux to the Anthony Kill is from 100 to 1,000 cu ft/d.

In the model, flux rates and head distributions at the river are controlled primarily by the selected or estimated value of the conductance term, which incorporates the resistance of the river bottom sediments to surface and groundwater exchange. This value is seldom known accurately, and is usually a calibration parameter. This is discussed in the calibration section.

CALIBRATION

Concern for some of the extreme boundary conditions in the model led to an approach of roughly calibrating a preliminary model and applying anticipated remedial measure simulations to identify any numerical stability problems in the model and to provide an initial look at the balances and the probable effects of the alternative measures. When the model proved stable under these conditions, and discussions were held with the feasibility study team to revise the simulation scenarios, the model was recalibrated and the revised simulations run.

In the calibration process, the principal parameters varied were in the general head boundary package (the input data file specifying parameter values controlling the upgradient flux into the model), the river conductance (controlling heads near the river bank), the recharge, and the hydraulic conductivities. During the calibration procedure, the K values in layers one and two were split into two zones based on the observed lower head in MW-10 and to more accurately capture the more easterly flow in this portion of the model. The K values in the final calibration run were 0.1 and 0.2 ft/d in layer one, 0.5 and 0.6 ft/d in layer two, and a constant 0.4 ft/d in layer three. The length of the flux boundary along the southern model perimeter was

also adjusted. In the final calibration, after the flux boundaries and hydraulic conductivities were reasonably set, the final parameter to be adjusted, and the one that seemed most sensitive in obtaining the best point fit with observed heads at wells, was the river conductance. Geraghty and Miller's MODFLOW statistical utility was used to generate the best overall fit with the lowest sum of squares of residuals while varying the conductance value. For the final calibration run (Run 13), the mean residual (observed minus computed) was 0.08 ft, with a standard deviation of 1.3 ft and a ratio of standard deviation to range of heads within the model of about 9 percent (see Calstats output of the fit analysis at the end of this Appendix). Most of the statistical error was in layers one and three, for which the least data were available.

Plotted and contoured model output heads for Run 13 matched interpreted groundwater flow directions and gradients quite well. The overall water balance for the calibrated model included an upgradient flux of 255 cu ft/d, a net recharge of 250 cu ft/d, and a total flow to the Anthony Kill of 505 cu ft/d (2.62 gpm). Thus, total average flows in the modelled system are quite small. Graphical results for each of the three layers for Run 13 are found at the end of this appendix. The black areas in the western portion of the site correspond to the bedrock high in this area, with the model showing layer one to be dry here.

SIMULATIONS

Once the model was calibrated, simulations were run for:

1. an upgradient diversion drain with downgradient barrier, both in the overburden (Run 14);
2. a downgradient overburden barrier only (Run 15);
3. a downgradient overburden barrier with added extraction wells near the ends (Run 16); and
4. the downgradient barrier only, but with site paving extended and improved to allow only 2 inches/yr of net recharge (Run 17).

The results of these simulations are discussed in the following paragraphs. Locations of the remedial measures referenced in the discussion are shown on Figure E-3. The graphical output of the runs are found at the end of this appendix. Note that the modeling provides only one aspect for the consideration of the appropriateness of any remedial measure. Implementability is a particularly important consideration. See Section 14.0 of this FS for a complete discussion of the evaluation and selection of alternatives.

Run 14: Upgradient diversion drain with downgradient barrier. This alternative evaluated the effect of a 170-foot long upgradient drain in the overburden (invert slightly above top of rock) to divert flow, to reduce groundwater flow across the site, and reduce discharge to the river in conjunction with a downgradient barrier wall. At best, the drain was able to intercept about 700 gallons per day, but also increased the flux rate from upgradient slightly. Only part of this increase in upgradient flux may be a long-term contribution, as the upgradient total flow is limited by recharge available to the upgradient recharge area (the model may slightly overestimate available flow from upgradient under an upgradient drain stress). The net result was only a decrease of about 16 percent in the total groundwater discharge to the

Anthony Kill. Discharge to the stream along the barrier wall frontage was reduced by about 21 percent. Flow in the vicinity of the wall is diverted easterly around the wall while some is forced under the wall into the Anthony Kill.

Run 15: Downgradient barrier only. This alternative looked at a 200-foot long barrier in the overburden (seated on top of, or slightly into, the upper shalely bedrock between the site and the Anthony Kill. The primary function of the barrier is to control migration of the coal tar and possible groundwater seeps in that area into the stream. Only slight groundwater mounding occurred in the model run (about 0.5 ft on average along the barrier). Groundwater in the overburden would be directed more easterly in the vicinity of the barrier, but still reach the stream. The groundwater discharge to the stream along the length of the barrier wall decreased only about 3 percent, while overall flow to the stream remained about the same as the simulated present conditions.

Run 16: Downgradient barrier with perimeter containment wells. This simulation evaluated the potential benefits of perimeter containment wells upgradient of the barrier to relieve mounding and control flow. Two wells were located in the overburden, but the simulated wells could not be pumped at more than a total of 0.05 gpm before creating excessive drawdown. Wells were simulated extending through layers one and two, which allowed greater total flow (up to 0.13 gpm before the overburden became dry), but still did not provide significantly greater control of groundwater (only a decrease of 5 percent of total flow and a reduction of about 10 percent in flow to the stream along the location of the barrier). In addition, pumping in the rock could further increase the migration potential of the coal tar into the rock.

Run 17: Downgradient barrier with improved expanded site paving. This remedial action would reduce recharge to the site and lower migration potentials of site contaminants. The model results showed a decrease in total recharge from 245 cu ft/d to 181 cu ft/d. Part of this gain was offset by a slight increase in upgradient flux to 263 cu ft/d. As discussed under Run 14, the model may slightly overestimate flow from upgradient when heads on-site are lowered (by drains or reduced recharge). Total discharge to the Kill was lowered only by about 12 percent. Along the length of the barrier wall, discharge to the Anthony Kill was reduced by about 13 percent. The most noticeable effect was a larger area of layer one going dry near the bedrock high in the western portion of the site.

SUMMARY

This groundwater modeling was conducted to provide a reasonable representation of the site groundwater flow system, and provide a mathematical framework for aiding in the evaluation of the remedial alternatives under consideration. While the modeling has limitations, particularly since fractured rock forms part of the aquifer system, the model behaves much as interpreted from site data, parameter values are consistent with observed and measured values, and mass balances are reasonable. The application of the model provides a rational basis for the comparative analysis of the remedial alternatives and insight into the behavior of the site groundwater system. Even if final calibrated model estimates of total flows are on the low side, estimates of the upper end of probable overall site flows are less than 5 times the best fit analysis. Hence upper end flow estimates would still be only about 13 gpm for the entire modelled system, and only a fraction of that actually flows through the

site. Further, as long as the ratios of the hydraulic conductivities for the layers remains the same, then the remedial alternative simulations would closely retain their relative effectiveness (i.e., with regard to the percentage reductions in flow in the model and to the Anthony Kill along the proposed location of the downgradient barrier wall).

APPENDIX B

NOTES

Blank : Indicates parameter was not analyzed for.

ND: Indicates parameter was not detected.

<: Indicates parameter was not detected at the quantitation limit shown.

J: Indicates an estimated concentration.

B (Organics): Indicates the parameter was detected in the laboratory blank.

B: (Inorganics): Indicates the parameter result is between the IDL and the contract required detection limit (CRDL)

VOCs: Volatile Organic Compounds

SVOCs: SemiVolatile Organic Compounds

PCBs: Polychlorinated Biphenyls

APPENDIX D
FIELD METHODS

1.0 SAMPLING PROCEDURES

The scope of work for the field investigation of the *SRI* at the site consisted of the following:

X Advanced soil borings;

X Installed additional (overburden and bedrock) monitoring wells;

X Collected surface soil samples;

X Measured groundwater elevations;

X Checked wells for liquid phase hydrocarbons;

X Collected groundwater samples from monitoring wells; and

X Collected sediment samples.

Project Files

Throughout the field investigation, URS field personnel maintained field notebooks to document project activities. Each individual making an entry into a field notebook dated and signed their entry. The field notebook entries contain accurate and inclusive information of the project activities. Only facts and observations were written in the field notebooks.

In addition, URS field personnel did note all measurements, calculations, as well as all data relating to location, date, time, weather conditions, and sample types directly on the appropriate field record.

The field notebooks, field records, and photos are maintained in the project files. The original (final) copies of the field sheets are maintained by the field personnel and project manager in URS' office in Clifton Park, New York. The project manager will keep copies of all files while the project is active.

Other data files maintained in the project files, include, equipment calibration sheets, air monitoring records, analytical requests to subcontract laboratories, survey data, photographs and chains of custody documentation.

Originals of the contract laboratory reports are stored in the project files and maintained at the contracted laboratory. The laboratory analytical data was entered into the laboratory's computer database. The data was manipulated in order to achieve the quality assurance/quality control (QA/QC) and reporting requirements described in the *Quality Assurance Project Plan* (QAPP).

1.1 SAMPLE LOCATION DESIGNATION

The names of each soil boring, monitoring well, sediment sampling location, and surface water sampling location follow the guidelines below.

Soil borings were designated by a "SB". Each surficial soil sampling location was designated by an "SS". A number followed the "SB" or "SS" name to associate the boring with a specific location.

The monitoring wells installed in the relief holder have been designated by "RH", followed by the number "1". The well names for the remaining wells have been designated by a "MW", followed by a one or two digit number to associate the well with a specific location. Because many proposed wells were installed in pairs or clusters to target overburden and bedrock geologic units in the same area, a suffix was added to each well name to indicate the screened geologic unit. Monitoring wells installed to screen the overburden unit were denoted with a suffix "S" (e.g., monitoring well MW-15S). Monitoring wells installed to screen the shallow bedrock are denoted with a suffix "I" (e.g., MW-15I). Monitoring wells installed to screen the deep bedrock were denoted with a suffix "D" (e.g., MW-15D). The overburden well installed in the relief holder is identified as RH-1S and the proposed deep bedrock monitoring well was identified as RH-1D.

The sediment sampling locations in the Anthony Kill were denoted with "SED00", followed by a number. The sediment sampling locations in the Hudson River are denoted with "SED-H", followed by a number.

Sample names were designated using NYSEG's sample identification system, which is described in Section 3.0.

1.2 SUBSURFACE SOIL SAMPLING PROCEDURES

Soil borings were advanced and continuous overburden soil samples were obtained to verify the geologic profile and assure proper placement of the well screens at boring locations completed as wells. The collection of subsurface soil sampling was conducted using spilt-spoon samplers during drilling with a conventional drill rig or using MacroCore® open samplers with a Geoprobe® unit mounted to a truck or van.

1.2.1 Field Equipment

Some or all of the following equipment was used during soil sampling:

X Field boring log sheet and field notebook;
X Photo-ionization detector (PID);
X Stainless-steel knife, trowels, spoons, scoops, and bowls;
X Personal protective equipment (PPE);
X Disposable gloves;
X Distilled/deionized water;
X Cleaning detergents and decontamination chemicals;
X Five-gallon pails for decontamination;
X Brushes;
X Sample bottles;
X Coolers;
X Sufficient ice or freezer packs to maintain the samples at four degrees Celsius; and
X Chain of Custody (COC) forms.

1.2.2 Soil Sampling Using Split-Spoons

The soil samples were collected using two-inch diameter by two-foot long split-spoons in accordance with ASTM D-1586-84: *Standard for Penetration Test and Split-Barrel Sampling of Soils*. The split-spoons are driven into the overburden materials using a 140-pound hammer-drop system until the desired depth of the boring is reached. The blow counts for each six-inch increment of penetration was recorded on the boring log. At each boring location, drilling was conducted through a mud box or at a minimum a sheet of plywood with a hole cut through the center to contain the drill cuttings. The hollow stem augers (HSAs) were advanced two feet after each split spoon was collected to avoid borehole cave-in. Furthermore, a plug inside of the HSAs was advanced during drilling. At locations where borings were completed as monitoring wells in a well cluster, the deepest well was drilled and continuously sampled first. Subsequent borings in the cluster were not sampled.

The length of sample recovery, percent recovery, and soil description, including odors is recorded on the boring log. Immediately upon retrieval of the split spoon, an aliquot of soil was transferred into the VOC sample containers. The VOC sample containers were completely filled in order to minimize head-space in the containers.

A second aliquot of soil from the split spoon was immediately retained for head-space analysis using a PID. Calibration of the PID and more detailed head-space analysis procedures are described in Section 1.2.4.1. The rationale behind this sequence of procedures (i.e., collecting a sample first, and then screening) is to minimize the loss of VOCs from samples that will be sent to a laboratory for analysis.

The remaining soil was placed in a clean re-sealable plastic bag. After removal of any stones, large twigs, or other vegetation, the sample was thoroughly homogenized by mixing the sample in the bag. After mixing, the sample was placed into containers for non-volatile constituent analysis. This type of homogenized sample will not be analyzed for VOCs.

Field personnel wore disposable gloves for the collection and handling of samples. The gloves were changed between samples. Any reuseable equipment was decontaminated between samples in accordance with Section 1.11.

Delineation of contaminated zones within a boring were based on the following field screening parameters:

X discoloration or staining;
X unusual odors or VOC head-space measurements (PID);
X unusual textures; and
X presence of liquid phase hydrocarbons or other anthropogenic features.

During sample collection, the field geologist recorded a soil description on the basis of visual observations in accordance with the Unified Soil Classification System (equivalent to ASTM D 2487-69) on a soil boring log or in a field notebook. The soil boring log and field notebook entries included the following information:

X Soil sampling location;
X Weather conditions;
X Notes on the physical appearance of the soil, including unique or unexpected colors or odors;
X Date and time of sample collection;
X Name of sample collector; and
X Notes on unexpected or unique conditions or events related to sample collection.

The samples were packed into sample coolers containing sufficient bags of ice or freezer packs to maintain the samples at 4º Celsius.

Upon completion of sampling at each location, all sampling equipment was decontaminated in accordance with the procedures described in Section 1.11. Quality assurance samples, including duplicate samples and trip blanks were collected as necessary in accordance with the procedures described in Section 1.10. The sample custody procedures for the soil samples are described in Section 3.0.

1.2.3 Soil Sampling Using Geoprobe® Equipped With MacroCore® Samplers

Soil borings which were not completed as monitoring wells were advanced using a Geoprobe unit mounted to a truck or van. Macro Core open samplers were used to collect the samples. These samplers had an open tube design and measure approximately two-inches in diameter (outer) by 44-inches long. The samplers were fitted with a removable cutting shoe and disposable acetate liners. Each of the samplers were fitted with a new acetate liner prior to collection of a sample. The acetate liner was split open to collect the soil.

The length of sample recovery, percent recovery, and soil description, including odors was recorded on the boring log. The soil samples obtained from the Macro Core open samplers were collected and handled in a similar manner as the soil samples obtained from split spoon samplers, described in Section 1.2.2.

All acetate liners were discarded after use. Upon completion of sampling at each location, all sampling equipment was decontaminated in accordance with the procedures described in Section 1.11. Quality assurance samples, including duplicate samples and trip blanks were collected as necessary in accordance with the procedures described in Section 1.10. The sample custody procedures are described in Section 2.0.

1.2.4 Field Screening Methodologies

Field screening methodologies included screening the headspace of each sample with a PID. This field screening method is described below.

1.2.4.1 Head-Space Analysis Procedures

Field screening of collected soil samples was completed using head-space analysis using a PID to detect the presence of VOCs. The operation, maintenance, and calibration of the PID (Thermo Environmental Instruments, Inc., Model 580B) was performed in accordance with the manufacturer's specifications and the Quality Assurance Project Plan for this project.

This section describes the maintenance, calibration, and operation of the PID and its accessories in the field.

The activities covered by this procedure did:

X Ensure quality control in field use of a PID;

X Provide uniformity and continuity in operation, calibration, and maintenance of both the equipment and measuring techniques by different qualified field analysts or technicians;

X Provide semi-quantitative data of the presence of volatile organic compounds in the head-space air of field samples. (It should be noted that the PID's utility as a quantitative measuring tool cannot be established and is questionable); and

X Indirectly serve as a means to evaluate the air quality near the sampling or field work locations.

EQUIPMENT:

X PID and its accompanying probe;

X Flow regulator or a rotameter T-connector;

X Calibration gas; and

X Battery charger.

A Thermo Environmental Organic Vapor Meter (OVM) 580B PID with a 11.8 eV lamp was used by URS field personnel. At the start of each day, the PID was examined for cleanliness and checked for defects and any possible need of repair. The battery check included measurements to determine if it is functional to full scale. The PID was recharged, overnight, as required, with the probe connected to the detector inlet. The probe check consisted of making sure that the probe was properly functioning by checking UV light flow when connected to the meter. Scheduled maintenance included daily checks by URS personnel according to procedures provided by the equipment's manufacturer. The PID was calibrated with 10 ppm isobutylene in accordance with the manufacturer's specifications and the Quality Assurance Project Plan for this project. Once the instrument was calibrated and recorded on instrument calibration log, the PID was used to collect head-space measurements. If the calibrated PID was not to used immediately, it was turned off.

Immediately upon retrieval of a soil sample, two aliquots of soil were collected. One aliquot was used to completely fill the VOC sample containers and the second aliquot was used for head-space analysis using a PID. The rationale behind this sequence of procedures (i.e., collecting a sample first, and then screening) was to minimize the loss of VOCs from samples that were sent to the laboratory for analysis. The soil was placed in new sealable polyethylene bags for head-space analysis. Each bag was labeled with the location, depth interval, and date of the soil sample.

The soil was allowed to warm to room temperature (approximately 68° Fahrenheit) to allow the vapors in the soil to equilibrate with the air in the bag. A measurement was collected by inserting the probe of the PID through an opened corner of the bag. Care had to be taken to avoid uptake of water droplets and soil particles. The highest meter response was recorded as the head-space concentration. Each PID measurement was recorded on the appropriate soil boring log or in a field notebook.

1.3 MONITORING WELL INSTALLATION PROCEDURES

This section describes the procedures that were used to install monitoring wells using a drill rig. The procedures described in this section did:

X Provide reliable information about penetrated soils;
X Provide representative samples of groundwater for analysis;
X Permit collection of representative water level data; and
X Effectively isolate the separate hydrogeologic strata penetrated during drilling.

EQUIPMENT:

X Drilling rig, drilling tools, and support truck with water tanks;
X Sheet of plywood, or mud box;
X Core boxes;
X Steam cleaner;
X Tremie pipe;

X Two-inch or four-inch flush threaded polyvinyl chloride (PVC) well risers and screens with a minimum wall thickness of Schedule 40. Screen slot sizes of 0.010-inch, 0.020-inch, and 0.040-inch;

X Seven-inch outside diameter by 4-inch inside diameter by 18-inch long polyethylene mechanical packer;

X Six-inch carbon steel casing;

X Four-inch carbon steel casing;

X Schedule 40 PVC or steel well caps and bottom plugs;

X Washed Morie No. 0 or equivalent quartz sand for filter pack with 0.010-inch slot screen;

X Washed Morie No. 1 or equivalent quartz sand for filter pack with 0.020-inch slot screen;

X Washed Morie No. 3 or equivalent quartz sand for filter pack with 0.040-inch slot screen;

X Portland cement, Type I or II;

X Bentonite pellets;

X Powdered bentonite;

X Protective casings and/or roadboxes, and padlocks;

X Concrete mix for surface completions;

X Polyethylene sheeting; and

X Field notebook, soil boring logs, and well construction logs.

1.3.1 Drilling, Borehole Logging, Well Installation, and Construction

All necessary drilling/well permits (if applicable) and utility clearances from NYSEG and non-NYSEG utilities were obtained prior to the start of drilling operations. All drill rigs used necessary tools, supplies, and equipment, which were supplied by the drilling subcontractor. The drill crew consisted of a licensed and experienced driller and one or more driller's assistants. Appropriate URS personnel was onsite to supervise the drill crew and for logging the soils and sampling. Drilling subcontractor personnel transported water to the rigs, cleaned tools, assisted in the installation of security and marker pipes, constructed the concrete aprons, and developed the wells.

All soil boring and well construction details were properly logged by the supervising field geologist. All notes were entered on a standard boring log sheet marked with indelible ink. The following information was recorded on the boring log sheet: project name and number, boring or well number and location, drilling contractor, drilling method and equipment, sampling method and equipment, start and finish, time and date, and name of the supervising field geologist.

Supplies and equipment were transported to the lay-down area designated onsite. Before moving onto the first well location, all reusable drilling equipment and tools were steam-cleaned at a designated onsite decontamination station using a portable steam cleaner supplied by the drilling subcontractor. Decontamination procedures are in Section 1.11.

Standard penetration tests were performed in accordance with ASTM D-1586-84: *Standard for Penetration Test and Split-Barrel Sampling of Soils*. Soil sampling procedures, including field screening of the soil samples using head- space analysis are described in Section 1.4. At the proposed well cluster locations, the soils were continuously sampled and logged at only one of the well locations.

At each boring location, drilling was conducted through a mud box or at a minimum a sheet of plywood with a hole cut through the center to contain the drill cuttings. Hollow stem augers (HSA), drive and wash casing or air rotary tools were used to drill through the overburden materials. A plug was lowered to the bottom of the HSA drill string (inside of the HSAs) and advanced with the HSAs during drilling.

Shallow Monitoring Well Construction

Shallow monitoring wells were installed in the unconsolidated material by using continuous-flight, 4.25-inch diameter (or larger as necessary) inner diameter (ID) hollow-stem augers (HSAs) for two-inch wells.

URS onsite personnel prepared a soil boring log and a time log of significant events during each working day. The soil boring logs were used to record field classification of soils, sampling types and number of samples, sampling depths, first encountered and static groundwater levels, progress of drilling, final completion depth, and the nature and resolution of any problems encountered. The Unified Soil Classification (USC) System was used for soil descriptions. The information recorded on well construction logs was used to create computer-generated soil boring and well construction logs for each boring location.

After the boring is drilled to the required depth, a string of flush-threaded, new PVC well riser and screen was installed through the HSAs. A threaded bottom plug was placed in the bottom of the screen and the top of the wells were protected with a vented cap. The wells were set at the desired horizon of the overburden materials. The lengths of the monitoring well screens were ten to 15 feet. The well risers were of sufficient length to extend from the top of the screen to approximately six inches below grade for wells to be completed as flush-mount wells. If the well was to be completed above grade, the well riser was of sufficient length to extend from the top of the screen to approximately two to three feet above the ground surface.

Two- inch diameter schedule 40 PVC screens and risers were used for overburden monitoring wells unless significant amounts of NAPL were observed in the soil during drilling. Where significant amount of NAPLs was observed in the soils, four-inch diameter well construction was used to allow for more efficient NAPL recovery. Furthermore, a two-foot long riser with a bottom cap (installed into rock) was installed below the well screen to serve as a sump for NAPL recovery at all locations that were suspected to contain NAPLs, based on soil borings. The sumps were sealed to the borehole by bentonite, to prevent any NAPL accumulation outside of the sump.

The screen slot sizes were determined by the URS personnel supervising the well installation based on the visual inspection of particle size of the material to be screened. The screen slot size (0.010, 0.020 or

0.040-inch) and appropriate sand pack materials were chosen to adjust for grain size variations in the formation.

Where fine-grained sand and silt were present in the screened interval, a 0.010-inch slot size screen were used, otherwise a 0.020-inch slot size screen were used for the coarser formation material. A 0.040-inch slot size screen was selected for monitoring well RH-1S to promote NAPL accumulation in the well sump for recovery. Washed Morie No. 0 or equivalent sand was used for 0.010-inch slot screens. Washed Morie No. 1 or equivalent sand was used for 0.020-inch slot screens. Washed Morie No. 3 or equivalent sand was used for 0.040-inch slot screen.

Where groundwater conditions permitted, the top portion of the shallow well screens were set approximately two feet above the water table to detect light nonaqueous phase liquids (LNAPLs) such as petroleum products (if any) and to allow for observations of seasonal water level fluctuations.

URS marked a survey reference point on the top of the well riser. Water level recordings will be made with respect to this reference mark. All risers and screens were wrapped in plastic during transport to the site and prior to installation in the borehole.

A sand pack was installed around well screens to a depth extending two to three feet above the top of the screen. During installation of the sand pack, the augers were withdrawn in small increments so as to avoid disturbing the sand pack. URS field personnel recorded the amount of sand used. A weighted fiberglass tape was used to measure the top of the sand pack and detect bridging of the sand pack material. If bridging was detected it was corrected prior to the addition of more filter pack material. If a two-foot long PVC sump was installed into the weathered bedrock at an overburden monitoring well due to the presence of NAPL in the soil, then the sump was sealed to the borehole with bentonite. The bentonite seal will prevent any NAPL from the weathered bedrock to preferentially migrate and collect around sump in the weathered bedrock. A 24-inch thick (minimum) seal of bentonite pellets was placed over the sand pack and hydrated. For shallow monitoring wells, where the top of the screen is above the water table, hydration of the bentonite clay pellets was accomplished using distilled or potable water.

A bentonite-cement grout consisting of approximately seven pounds of powdered bentonite per 94-pound sack of Portland cement, and not more than six gallons of clean water per 94-pound sack of cement, was introduced into the borehole annular space by injection under pressure using a tremie pipe. The grout was allowed to set and cure for at least 48 hours before commencing well development or other activities, which might disturb the seal.

Shallow Bedrock Monitoring Well Construction

At the shallow bedrock monitoring well locations, single-cased wells were installed using four or six-inch diameter (overburden) casing. The screened interval for the shallow bedrock monitoring wells are either open hole or two-inch diameter screens (double-cased well). Drilling through the overburden was conducted using 8-1/4-inch ID HSAs with continuous split spoon sampling. Continuous split-spoon samples will be collected in the overburden, described by a field geologist, and field screened for the presence of NAPLs and VOCs. At each well cluster, the overburden was continuously sampled and logged at only the deepest well location. At the well locations where soil samples were not collected, the overburden was drilled using HSAs equipped with a bottom plug or air rotary drilling tools (roller bit or air hammer).

A 7 7/8-inch air or wash-rotary bit was be used to install a rock socket, a minimum of two feet into the bedrock. Then, the four-inch diameter schedule 40 PVC or six-inch diameter steel casing was installed into the shallow bedrock to seal off the overburden and upper bedrock. The casings were equipped with a bottom plug to prevent cross contamination from the overburden or upper bedrock. Prior to lowering casing into the borehole, the lower portion of the borehole was filled with cement bentonite grout. The casings were either threaded or welded together in ten to 20 foot long sections. As the casing was lowered into the borehole, potable water was added to the inside of the casing in order to displace the air inside so the casing would sink. The annular space between the outside of the casing and the borehole walls was sealed with cement-bentonite grout.

After the grout had been allowed to cure for at least 48 hours, bedrock was drilled using HQ (3.75-inch nominal diameter) core sample tools or a 3 7/8 or 5 7/8 inch diameter wash roller bit to the desired total depth.

In addition to fracture size and orientation from each bedrock core run, URS also calculated and recorded a Rock Quality Determination (RQD). The RQD is typically most useful for geotechnical purposes (i.e., foundation stability), however, it is routinely used for evaluating the rock quality for environmental purposes. The RQD is calculated by measuring the total length of all sound pieces of core four or more inches long, dividing this total length by the length of the core run, and multiplying by 100 to convert to a percent. When considering breaks in the recovered rock core, mechanical breaks are treated as sound rock. Higher RQDs correspond to higher rock quality and more competent rock.

Based on the observations from the bedrock core, the well remained open hole, or the boring was reamed out to allow for construction of a two-inch diameter monitoring well. If a monitoring well screen was installed, then the well construction included a two-foot sump (constructed of a riser with a bottom cap). The two-foot long sump was sealed to the borehole using bentonite. Furthermore, if well casing and screen were installed, the annulus between the well screen and the borehole was filled with a sand pack. A minimum of a two-foot thick bentonite seal was placed above the sand pack. The remaining portion of the annulus, above the bentonite seal, was filled with cement-bentonite grout.

Deep Bedrock Monitoring Well Construction

Deep bedrock wells were single, double, triple or quadruple-cased monitoring wells and installed in the competent bedrock. The goal for the deep bedrock monitoring wells was to set the screened or open hole portion on the monitoring well beneath any NAPL bearing zones, resulting in "clean" (NAPL free) wells.

These monitoring wells were drilled by first sealing off the overburden material with either a permanent steel or PVC casing grouted in place, or a temporary steel casing hammered into the bedrock to create a temporary seal. Both the permanent and temporary casings were advanced a minimum of two feet below the

bedrock surface. Temporary casings were only used in locations were NAPLs were not encountered in the overburden.

After the grout had cured for at least 48 hours, the bedrock was cored to the target depth. Bedrock core samples were collected using HQ, NQ, or AX core sampling tools to evaluate the bedrock and the presence of NAPL in the bedrock.

At selected boreholes, packer testing was typically performed at twenty-foot intervals in order to evaluate groundwater yield and the presence or absence of NAPLs. Groundwater samples for laboratory analysis were collected from some of these intervals.

After a twenty-foot long section of bedrock was cored, the HQ core pipe was removed from the core-hole and the packer testing apparatus was lowered in to the hole. The packer testing apparatus consisted of a four-foot long by 3.5 inch outside diameter inflatable stainless steel and rubber packer attached to two-inch PVC and an air-line for inflating the packer. Ten-foot sections of PVC riser were threaded onto the packer as it was lowered into the corehole by the drill rig's wire line winch. The packer was lowered to the top of the 20-foot interval to be tested and the rubber exterior of the packer was inflated with compressed air. This secured and sealed the packer to the inside of the corehole, so the zone beneath the packer was isolated.

A Grundfos® Redi-flo II submersible pump equipped with new 0.5 inch inside diameter polyethylene tubing was lowered inside the two-inch PVC riser through the packer and to the bottom of the corehole. The pump was turned on to a steady flow rate. The water level draw down was monitored with a water level indicator. If the interval was not pumped dry or if NAPL did not enter the packer testing interval, a groundwater sample was collected directly from the tubing after three times the amount of standing water in the tested interval was removed. If the interval was pumped dry, recovery was monitored with a water level indicator. Once a sufficient amount of water entered the interval, the pump was turned back on to collect a groundwater sample. In some cases the pump was removed from the core hole after the interval was pumped dry. In these cases a water sample was collected with a disposable polyethylene bailer. If, after pumping the interval dry and waiting for approximately 20 to 30 minutes, there was no groundwater

recharge, the interval was considered 'dry' and no samples were collected. If NAPL entered the packer testing interval, no samples were collected.

Once the packer test was completed, the PVC, packer, pump and tubing were removed. The PVC piping was set aside and steam cleaned. The packer and pump were decontaminated with a non-phosphate detergent wash and water rinse. The tubing was disposed in a roll-off container.

The final depth of each well was established based on the observations from the packer tests and bedrock cores, including RQD determinations in the field.

When NAPL was encountered during coring, the borehole was cored a minimum of 20 feet past the NAPL bearing zone. The borehole was then reamed using an appropriately sized (a minimum diameter of 2 inches larger than the casing diameter that was to be set) wash rotary bit. After reaming, the borehole was sealed off by pressure grouting a carbon steel or PVC casing in place with a bentonite-cement grout mixture. After the grout cured for at least 48 hours, bedrock coring resumed to the target depth or at least 20 feet past any signs of NAPL. Where NAPL was encountered, the same reaming casing and coring procedures as described above were performed until the vertical extent of the NAPL was delineated. This process of coring, reaming and setting casings resulted in double triple and one (RH-1D) quadruple cased monitoring wells

Where DNAPL was not visible in the bedrock cores, the boring was advanced to the desired depth. After completing coring, the borehole was reamed using a 5 7/8 inch diameter wash rotary bit to the total cored depth of the borehole. A four-inch casing with a mechanical doughnut style packer at the base was then installed to the desired depth above the bottom of the borehole and grouted in place. The purpose for the mechanical packer is to hold the casing at the desired depth and to create a shelf seal for the grout.

All wells were completed with protective stickup risers or flush-mounted roadboxes. For stickup wells, a steel outer protective riser with a hinged, lockable cover was installed in the grout to a depth of 2.5 feet and equipped with a padlock. For flush-mount wells, a steel protective cover with water-tight seal was installed

in the grout. The integrity of the wells were protected with a new, lockable, sealing, vented well cap with an expandable O-ring which forms an air-tight seal. All locks are keyed alike.

For stickup wells, the drilling subcontractor constructed a (2' x 2' x 0.5') concrete apron around each well. Concrete aprons are sloped to promote runoff away from the well. For the flush-mount wells, the space around the flush-mount road box was filled with concrete and sloped to promote runoff away from the well.

Quality Control Requirements for drilling are described below. Drilling procedures did:

X Prevent cross-contamination;
X Minimize the disruption of existing conditions;
X Minimize long-term impacts to adjacent water-bearing zones; and
X Ensure worker safety.

Cuttings were containerized in Department of Transportation (DOT) approved 55-gallon drums or in an approved lined roll-off container and disposed of in accordance with all relevant regulations. Drilling fluids were containerized in polyethylene holding tanks for off-site disposal. The drums, roll-off and tanks were labeled, staged on-site, and subsequently removed for proper off-site disposal by NYSEG.

Drilling tools were steam cleaned between each drilling location to prevent cross-contamination. Decontamination was performed on the temporary decontamination pad that was constructed in an area specified by the client. In some cases split-spoon samplers were cleaned near the drilling rig, in a designated area equipped with large buckets or other containers capable of containing the decontamination water. All decontamination water was subsequently containerized for proper off-site disposal.

1.3.2 Well Development

This section describes the groundwater well development procedures and quality control requirements.
EQUIPMENT:

X Centrifugal, Waterra inertial, or submersible pump;

X Air lift purging apparatus

X High density polyethylene (HDPE) tubing;

X Foot valves;

X Surge blocks;

X Generator and extension cords;

X ASTM Type II or analyte-free distilled water;

X Water level indicator;

X Five-gallon bucket;

X Fifty-five gallon drums;

X Polyethylene sheeting; and

X Well development record and field notebook.

Well development began no sooner than 48 hours after grout placement and was accomplished through a combination of surging and high volume pumping using a centrifugal, Waterra, or submersible pump.

Development of overburden wells began by lowering submersible pump equipped with polyethylene tubing to the bottom of the well. Approximate flow rate, water color, appearance, odors, sheens or presence of NAPLs, and water level were recorded on a well development log. The position of the pump intake was raised and lowered across the screened interval to remove sediment and drilling fluids from the sand pack.

Development of bedrock wells began by lowering high density polyethylene tubing attached to a Grundfos Redi-Flo II submersible pump, Waterra inertial or air lift system to the bottom of the well. The pump was started and approximate flow rate, water color, appearance, odors, sheens, or presence of NAPLs, and water levels were recorded on a well development log. The position of the pump intake or tubing was raised and lowered across the open interval to remove any sediment and drilling fluids from the formation.

Development was continued until three to five well volumes were removed, the well was pumped dry or until the discharged water contained no visible particles or turbidity. Well development procedures were documented in the field notebook or on a well development record.

The development water from each well was containerized and stored on-site in DOT-approved 55-gallon drums or a holding tank for later off-site disposal in accordance with all relevant regulations.

1.3.3 Well Surveying

The locations and elevations of all new wells were surveyed by a New York licensed surveyor, using a United States Geodetic Survey benchmark as a datum. NYSEG provided surveying services for this project. The survey data was essential for construction of potentiometric maps from which groundwater gradients were determined. The geographic location or horizontal survey measurement was surveyed to an accuracy of one foot.

A reference point was marked on the top of the well riser at the time of construction. The elevation of the well riser was surveyed to the reference point, and all water level recordings have been made with respect to the reference point. The elevation of the reference mark at the top of the well riser on all monitoring wells was surveyed to the nearest 0.01 foot. The ground elevation at the base of each well was surveyed to an accuracy of 0.01 foot.

The surveyor provided tabular summaries of the vertical elevations and horizontal coordinates of the boring locations, benchmarks, and other reference points as specified in the work plan. The survey data was used to update the existing computer-aided design (CAD) base map that depicts boring locations, samples, and other reference points.

1.4 MANUAL COLLECTION OF SURFACE SOIL SAMPLES

Surface soil samples (0 to 2-inches below ground surface) were collected using hand augers and stainless-steel trowels. In some cases, the surface soil samples were collected from two-inches beneath the vegetative cover. The following section describes the equipment and procedures for soil sample collection with a hand auger or stainless-steel trowel.

EQUIPMENT:

X Hand auger with stainless-steel scoop or stainless-steel hand trowel;
X Clean, airtight soil sampling jars to store samples;
X Photo-ionization detector (PID); and
X Field soil boring log or field notebook.

The trowel or hand auger were decontaminated, examined for cleanliness, and checked for defects or any need of repair. Decontamination procedures are described in Section 1.11. A description of the sampling area from which the sample was taken, and other pertinent sample information was recorded on a field soil boring log or in a field notebook.

PROCEDURES:

Surface soil samples were either scooped up with a trowel and put into the sample jars or when the hand auger was used, the sample was scooped from auger into the sample jars using a trowel. If the soil was analyzed for VOCs, an aliquot of soil was immediately transferred into the VOC sample containers. The VOC sample containers were completely filled in order to minimize head-space in the containers. A second aliquot of soil was immediately retained for head-space analysis using a PID. The remaining sample containers were then filled (grab samples).

Calibration of the PID and more detailed head-space analysis procedures are described in Section 2.2.4.1. The rationale behind this sequence of procedures (i.e., collecting a sample first, and then screening) was to minimize the loss of VOCs from samples that will be sent to a laboratory for analysis.

If a homogenized sample was needed for non-volatile constituent analysis, additional soil was placed in a clean stainless-steel bowl. After removal of any stones, large twigs, or other vegetation, the sample was thoroughly homogenized by mixing the sample in the bowl with a stainless-steel spoon. The sample was then quartered in the bowl and each quarter mixed separately, before finally mixing the entire sample again. The sample was then placed in sample containers using a trowel for non-volatile constituent analysis. This type of sample, defined as a homogenized sample, was not analyzed for VOCs.

The field observations and sample details were recorded in a field notebook. Sample labels were filled out away from the sample bottles whenever possible. All soil sample locations were marked on the ground. Identification materials and markings, lasted until the locations were surveyed.

To prevent cross-contamination of samples, the field personnel wore disposable gloves when collecting and handling samples. The gloves were changed between samples. The hand augers and stainless-steel hand trowels were decontaminated between samples.

1.5 GROUNDWATER LEVEL MEASUREMENTS

After the new wells were developed, the new wells and the existing and accessible wells at the site were gauged using an electronic water level meter or interface probe to obtain water level elevations. The water level data was used to further refine the groundwater flow regime beneath the site.

The depth to groundwater in the new and existing wells was measured using an electronic interface probe (i.e., Model P-1 Solinst or equivalent). The electronic interface probe was used to detect LNAPL in the wells (Section 1.6). Groundwater levels were measured in all monitoring wells using the following procedures:

1. Verify the identification of the monitoring well.
2. Observe the wellhead for signs of deterioration. Record observations.
3. Identify the surveyed elevation point on the well. If one does not exist, create a mark using a permanent ink marker. This mark was the measuring point for subsequent rounds of water level measurements.
4. Slowly lower the electronic water level indicator probe into the well.
5. When the water level indicator contacts groundwater, note the point on the water level indicator as referenced by the measuring point on the well.
6. Record the water level to within 0.01 foot in the field notebook and/or gauging form.
7. Retrieve the water level indicator and re-lock the well.
8. Decontaminate the water level indicator after each use with an Alconox/distilled water wash followed by a distilled water rinse.

The order of gauging was based on the known level of contamination in the well. The clean wells were checked first. The gauging data was recorded on a gauging form.

1.6 CHECK WELLS FOR NAPL

All new and existing monitoring wells were checked for the presence of NAPL. After the newly installed wells were allowed to equilibrate for one to two weeks following development, the depth to water in each existing and newly installed well was measured using the procedure described in Section 1.5. Wells in which NAPL was observed during drilling were monitored for the presence of NAPLs using a dedicated chain and cotton or nylon string. The chain was lowered to the water surface and retrieved to check for the presence of LNAPLs. If LNAPLs were observed the chain was decontaminated using a biodegradable degreaser. In each well that contained NAPL the thickness was monitored using an electronic interface probe. In wells where NAPL was observed, checks were continued either weekly or biweekly.

The procedure for detecting LNAPL using a oil/water interface probe is described below.

1. Verify the identification of the monitoring well.
2. Observe the wellhead for signs of deterioration. Record observations.
3. Identify the surveyed elevation point on the well. If one does not exist, create a mark using a steel file. This mark will be the measuring point for subsequent rounds of water level measurements.
4. Slowly lower the oil/water interface probe into the well.
5. When the oil/water interface probe contacts the light phase and air interface, note the point on the oil/water interface probe as referenced by the measuring point on the well.
6. Record the level to within 0.01 foot in the field notebook or gauging form.
7. Continue to lower the probe through the light phase layer. Record the depth to the water level in the field notebook.
8. Retrieve the oil/water interface probe and re-lock the well.
9. Decontaminate the oil/water interface probe after each use with a Alconox/distilled water wash followed by a distilled water rinse.

1.7 GROUNDWATER SAMPLING PROCEDURES

Upon completion of the gauging event, all new wells and existing wells were sampled. The upgradient and background wells were purged and sampled before downgradient wells. Prior to purging a well, the presence or absence of NAPLs was evaluated by using the procedures described in Section 1.6. Wells that contained NAPLs were not sampled.

Groundwater sampling procedures that were followed at the site to obtain representative groundwater samples from the existing wells, and proposed monitoring wells are described below.

1.7.1 WELL PURGING AND STABILIZATION

Purging procedures have a great influence on the reliability of groundwater samples, and inconsistent purging can be a source of variability among groundwater analyses. Therefore, purging procedures were standardized as much as possible as described below. Once a specific purging procedure has been used and documented on a well, the same procedure will be used in subsequent purging events, when possible. Waterra hydrolift or Grundfor Rediflo II pumping equipment was used for well purging. The purge water from each well was containerized and stored on-site in holding tanks for later off-site disposal in accordance with all relevant regulations.

Upgradient wells, background wells, and other wells that are considered to be relatively uncontaminated, based on available data, were purged and sampled first, whenever feasible. This practice is intended to guard against cross-contamination from more contaminated wells.

All wells were purged before sampling. A minimum of three and a maximum of six well volumes were purged from those wells that were not purged dry. A well volume is defined as the volume of water within the screen and riser. The volume of water in the well was calculated using the following equation:

V (in cubic feet) = pr^2h or
V (in gallons) = h x (d^2 x 0.0408).

where:

V = volume of water in well;

h = height of the water column in the well in feet. and

d = well diameter in inches

r = well radius in inches

The depth to water was measured to the nearest 0.01-foot. The total depth of the well was determined from well installation logs or by sounding the depth of the well by lowering the water level indicator to the bottom of the well.

The pump or tubing intake was lowered to approximately two feet from the bottom of the well. The purge rate was at a rate equal to or less than 2 gallons per minute (gpm). Once the pumping is started, the flow rate will be checked using a stopwatch and five-gallon bucket. Pumping will continue until three to five well volumes have been removed or until the well is purged dry.

During purging, the pH, conductivity, dissolved oxygen, oxidation-reduction potential and temperature measurements of the water will be monitored continuously using a flow-through cell or equivalent meter. The end of the discharge tubing was connected to the flow-through cell where groundwater is constantly being analyzed by the various monitoring probes prior to coming into contact with air. The field parameter values are displayed on a hand held monitor. Measurements were recorded at consistent intervals on a groundwater sampling data sheet. The stabilization of temperature, pH, and specific conductance during purging increases confidence that samples are representative of the groundwater (Keely and Boateng, 1987).

Criteria for stabilization are as follows:

X Temperature does not vary by more than 2°C between three successive five minute readings.

X pH does not vary by more than 0.1 standard units between three five minute readings.

X Specific conductance does not vary by more than 10% between three five minute readings.

If all three parameters had stabilized after purging three well volumes, purging was considered complete. If any parameter had not stabilized, purging continued until all parameters stabilized or until six well volumes had been purged. Stabilization of dissolved oxygen and oxidation-reduction potential will not be required prior to sampling a well

Turbidity measurements of the purge water were also continuously monitored using a turbidity meter. An attempt was made to stabilize the turbidity of the purge water from each well at a value of 50 nephelometric units (NTUs) or less, prior to sample collection. The turbidity was controlled by decreasing the flow rate. If turbidity stabilized above 50 NTUs at any given groundwater sampling location, this condition was documented on the groundwater sampling data sheet.

URS will followed the calibration procedures for all sampling and monitoring equipment in accordance to the manufacturers instructions.

1.7.2 GROUNDWATER SAMPLING METHODS

This procedure describes steps involved in collecting groundwater samples using dedicated tubing and a hydrolift or submersible pump.

The objectives of the activities covered by this procedure were to:

X Obtain groundwater samples for laboratory and field analysis;

X Ensure that the groundwater samples will be representative of actual groundwater quality;

X Ensure quality control and consistency during sampling; and

X Serve as a means to allow traceability of error(s) in sampling and data recording.

When using a hydrolift pump at wells that were not purged dry, groundwater sampling commenced immediately after purging without turning the pump off, The discharge hose was disconnected or cut off from the flow-through cell prior to sampling to minimize cross-contamination. The groundwater samples were collected using VOC sampling kits compatible with the hydrolift pump. Disposable weighted polyethylene bailers were used to collect the VOC groundwater samples when using a submersible pump.

Containers used for VOC analysis were filled first using bottom-filling, small diameter tubing designed for VOC sampling with the pump, which reduces air bubbles and minimizes agitation so as to prevent aeration. The pumping rate was lowered while VOC vials are being filled.

Groundwater samples for metals analysis included both unfiltered and field filtered samples. At well locations where turbidity was greater than 50 NTUs then the groundwater samples for metals analysis was field-filtered. Filtered samples for analysis were field filtered using a 0.45-micron (µm) in-line disposable filter. The field filtered aliquot for metals analysis was preserved by adding a sufficient amount of concentrated nitric acid to maintain the sample at a pH of less than 2 SU.

The sample containers were wiped dry and each sample container was labeled. The sample number, date, time, location, depth, type of analysis, preservative, and sample collector's name was recorded on the sample label. This information was also recorded on the groundwater sampling data sheet along with a description of the physical appearance of the sample including color, clarity, suspended solids, and odor.

The samples were placed in coolers with sufficient bagged ice or ice packs to maintain a temperature of 4ºC during shipment. Sample vials for VOC analyses were placed in resealable plastic bags prior to placement in the coolers.

1.8 SEDIMENT SAMPLING PROCEDURES

Sediment samples were collected from the Anthony Kill and the Hudson River. Access to the Anthony Kill and the Hudson River was from NYSEG's property or from public access points. Therefore, access agreements from off-site properties were not necessary.

Sediment samples were collected with a stainless steel trowel from the Anthony Kill. Personnel collecting the sediment samples approached the sampling location from the downstream direction. Disposable gloves were worn during collection and handling of the samples. The gloves were changed between samples.

Sediment samples collected from the Hudson River were collected using a vibratory coring subcontractor. The crew accessed the river via an outboard motor boat equipped with front and rear anchors and vibratory sampling equipment. The sediment was sampled using a ten-foot long by three-inch diameter aluminum pipe equipped with Lexan liners. The sampling apparatus was driven into the sediment with a pneumatic vibrator that was attached to the aluminum pipe. After the sampler was driven to the desired depth, the sampler was removed and the liner was cut open. URS personnel described the sediment and placed a portion of the sample into sample jars for laboratory analyses. Disposable gloves were worn during collection and handling of the samples. The gloves were changed between samples. The remaining sediment and other waste was returned to the site and contained for off-site disposal.

All data relating to weather conditions, time of collection, sampling method, field observation, sample location, and analysis was recorded on a field sampling record or field notebook.

1.9 SURFACE WATER GUAGING

Three staff gauges were installed in the portion of the Anthony Kill along the site's northern boundary. The gauges were surveyed by a New York State certified surveyor provided by NYSEG. Surface water levels were gauged during the groundwater level measuring rounds to help evaluate the relationship between surface

water and groundwater at the site. Access to the Anthony Kill was from NYSEG's property. Therefore, access agreements from off-site properties were not necessary.

1.10 QUALITY ASSURANCE SAMPLES

As part of the quality assurance (QA) program, QA samples were prepared and collected to provide control over the collection of environmental measurements and subsequent validation and interpretation of the analytical data. Three types of QA samples were prepared or collected: 1) trip blanks; 2) field (equipment rinseate) blanks; and 3) duplicate samples. Field blanks and duplicate samples were prepared for all sampling parameters. Trip blanks were only analyzed for VOCs when aqueous sampling for VOCs was conducted. The three types of QA samples are discussed in the following sections.

1.10.1 Trip Blanks

The primary purpose of a trip blank is to detect sources of VOCs that might potentially influence VOC concentration values reported in actual samples. Thus, trip blanks serve as a mechanism of control on sample bottle preparation and blank water quality, as well as, sample handling. The trip blank is prepared by the laboratory and travels to the site with the empty sample bottles and back from the site with the collected samples in an effort to simulate sample handling conditions.

Contaminated trip blanks may indicate inadequate bottle cleaning or blank water of questionable quality. The following have been identified as potential sources of contamination:

X Laboratory reagent water;

X Sample containers;

X Cross contamination in shipment;

X Ambient air or contact with analytical instrumentation during preparation and analysis at the laboratory; and

X Laboratory reagents used in analytical procedures.

A trip blank consists of a set of sample bottles filled at the laboratory with analyte-free water. The trip blank and laboratory method blank water must originate from one common source and physical location within the laboratory. Trip blanks were handled, transported, and analyzed in the same manner as the other analytical samples, except that the sample containers for the trip blanks were not be opened in the field. Trip blanks must return to the lab with the same set of bottles they accompanied to the field.

The trip blanks were shipped and analyzed at a frequency of one trip blank per shipment of aqueous samples for VOC analysis. Trip blank sample identification consists of a "TB" followed by the six digit date (i.e.,: TBYYMMDD). Note that trip blanks are not required for solid samples.

1.10.2 Field And Equipment Rinseate Blanks

A field blank is used to test for potential contamination from ambient air. An equipment rinseate blank is used to test for potential contamination from sampling instruments used to collect and transfer samples from point of collection into sample containers. Field blanks were collected at the discretion of the project manager. If re-usable equipment is used, equipment rinseate blanks were collected at a rate of one per 20 samples per matrix. Field and equipment rinseate blanks were collected in the most contaminated area of the site in order to simulate a worst case scenario regarding ambient air contributions to sample contamination.

A field blank is prepared by filling a sample container with analyte-free water from the laboratory. This container is then opened and exposed to the ambient atmosphere in the most contaminated area of the site. After this exposure, the field blank container is sealed and the field blank is then handled, transported, and analyzed in the same manner as the other analytical samples. Field blanks were denoted as "FB" followed by the six digit date (i.e., FBYYMMDD).

Equipment rinseate blanks were prepared by passing laboratory-supplied analyte-free water (or the distilled/deionized water that is used for decontamination) through decontaminated sampling equipment and collecting it in an empty sample container for analysis. Rinseate blanks were denoted with a "RB" followed by the six digit date (i.e.,: RBYYMMDD).

1.10.3 Duplicate Samples

The analysis of blind duplicate samples provides a means of evaluating the relative precision of the sample collection and analytical procedures. An important factor in evaluating the analytical data from sample pairs is the homogeneity of the analyte within the sample matrix. Therefore, whenever possible, one will homogenize an aliquot from a discrete location or interval before the sample and duplicate are collected. However, VOC samples must never be homogenized in order to prevent the loss of VOCs. In general, the handling of VOC samples was minimized to preserve the physical integrity of the VOC fraction. Duplicate samples were prepared for each sample matrix at a rate of one duplicate per twenty samples. Duplicates were designated with "DUP" followed by a six-digit date (ie. DUPYYMMDD).

Duplicates of liquid samples were obtained by alternately filling the sample and duplicate containers with aliquots of liquid collected with the same sampling device. VOC samples and duplicates were collected first in order to minimize the potential for loss of VOCs. After the VOC samples were collected, any liquid remaining in the sampling device was equally apportioned among all the sample containers. Upon retrieval of the next aliquot of liquid, the order in which the sample bottles were filled changed by one increment.

Duplicates of solid samples for VOC analysis were obtained by alternately filling the sample containers for the sample and duplicate for VOC analysis with aliquots collected form the same discrete location or interval. Once samples for VOC analysis have been collected, the sample was thoroughly homogenized. Following homogenization, the sample containers for the remaining parameters were filled.

1.11 SAMPLING EQUIPMENT DECONTAMINATION PROCEDURES

Sampling equipment was decontaminated in the laboratory or the field prior to site use and between sampling locations. The sampling device and equipment decontamination method involved a non-phosphate detergent wash, tap water rinse, distilled/deionized water rinse, air drying, and a second distilled/deionized water rinse.

Drilling tools were steam cleaned between each drilling location to prevent cross-contamination. If steam cleaning did not remove coal tar from the drilling tools or other equipment, then a biodegradeable degreaser (CitruSolv) was sprayed onto the drill tools and a scrub brush was used to help breakdown the coal tar. A tap water rinse followed by another round of steam-cleaning completed decontamination. Decontamination was conducted on the temporary decontamination pad constructed north of the storage and tool house. The decontamination fluids were containerized for proper off-site disposal.

Following well development and prior to sampling, the depth to groundwater in the new and existing wells were measured using an electronic water level meter or interface probe. To avoid cross-contamination between wells, the water level meter or interface probe was decontaminated after each use with an Alconox/distilled water wash followed by a distilled water rinse. The use of dedicated weighted cords to check wells for NAPL precluded the need to decontaminate between wells.

2.0 SAMPLE HANDLING AND CUSTODY

All samples were collected and handled in a manner such that sample agitation, cross-contamination, and contact with the atmosphere is reduced or kept to minimum. Field personnel wore disposable gloves when collecting and handling samples.

Sample chain of custody was initiated by the laboratory with the selection and preparation of the sample containers. To reduce the chance for error, the number of personnel assuming custody of the sample and sample containers was held to a minimum. Personnel involved in the chain of custody and transfer of samples were briefed on the procedures and their purposes prior to the initiation of sampling.

2.1 Field Sample Custody

A Chain of Custody (COC) form accompanied the sample from initial sample container selection and preparation commencing at the laboratory, to the field for sample containment and preservation, through its return to the laboratory.

The Project Manager notified the laboratory of upcoming field sampling activities and the subsequent transfer of samples to the laboratory. This notification included information concerning the number and type of samples to be shipped as well as the anticipated date of arrival. Sample shipping containers (coolers or "shuttles") were provided by the laboratory. The shipping containers were insulated. All sample bottles within each shipping container were individually labeled with an identification label.

All sample bottle labels included the following information:

a. site name;
b. sample number;
c. name of collector;
d. date and time of collection;

e. place of collection;

f. type of sample;

g. sample volume;

h. analyses required; and

i. preservative (if used).

If a sample shipping container was assigned a unique identification number by the laboratory, then this number was recorded on the COC.

Personnel receiving the sample containers checked each cooler for the integrity of the seals. Coolers or shuttles with broken seals were returned to the laboratory, and the sample containers were not used. The receiving personnel broke the seal, inspect the contents for breakage, and record and sign on the chain-of-custody form that the sample containers have been received. A temporary seal was affixed to each cooler until the sample containers were filled.

Sample Designation

Each sample collected was designated using NYSEG's sample identification system. NYSEG's sample identification system allows a unique code (a combination of up to 12 letters and numbers) to be established for every sample collected. By following NYSEG's sample identification system, persons familiar with the system can deduce the project location, the sample media, the depth interval of the sample, the year the well was installed or sample was collected, and the sampling location number from the sample name. NYSEG's sample identification system is described below.

Each surface soil sample was identified by using the following code MESSXY01ZZ where:

ME = Mechanicville Central Avenue site;

SS = surface soil sample;

X = starting depth (inches) of sample interval;

Y = ending depth (inches) of sample interval;

01 = sample collected in 2001; and

ZZ = sample number.

For example, a sample collected from the top two inches (zero to two inches) at surface soil location SS-15 would be coded MESS020115.

For each subsurface soil sample collected from a soil boring location was identified using the following code MESBXXYY01ZZ where:

ME = Mechanicville Central Avenue site;

SB = soil boring;

XX = the starting depth (feet) of the interval from which the sample was collected;

YY = the end depth (feet) of the interval from which the sample was collected;

01 = boring installed in 2001; and

ZZ = the boring number.

For example, a subsurface soil sample collected from 8-10 from soil boring SB-24 would be coded MESB08100124.

Groundwater samples were identified by using the following code MEG@##01ZZ where,

ME = the Mechanicville Central Avenue site;

G = groundwater sample;

@ = location relative to the "source on the site" which is very subjective, but in general U is for an upgradient well, D is for a downgradient well, and C is for a cross-gradient well;

= the depth of the well, SH is for shallow wells, IM is for intermediate wells, and D- is for deep wells;

01 means the well was installed in 2001; and

ZZ is the well number.

For example, groundwater samples to be collected from the two proposed wells MW-10I and MW-10D will be coded MEGCIM0110 for the intermediate well and MEGCD-0110 for the deep well. Groundwater samples collected from proposed overburden monitoring well RH-1S and deep bedrock monitoring well RH-1D were coded MEGCSH01RH1 and MEGCD01RH1.

Each surface water sample was identified using the following code MESW--01ZZ where:

ME = Mechanical Central Avenue site;
SW = surface water sample;
-- = will always be the same in surface water samples because there is no true depth for which the sample is collected;
01 = sample collected in 2001; and
ZZ = the sample number.
For example, a surface water sample collected from surface water sampling location SW-2 would be coded MESW--0102.

This system allows a unique code to be established for every sample collected, even if samples were collected from different depths at the same location. QC samples can be coded using this same system and simply adding a MS or MSD (for matrix spike, or matrix spike duplicate) to the end of the code. Note that during this investigation MS and MSD samples were not collected.

Once the sample containers are filled, the samples were immediately preserved, as required and stored at 4ºC until delivered to the laboratory. Preservation requirements are provided in Table 1. The samples were kept cool at 4ºC using insulated containers containing sufficient ice or ice packs. If ice was used, the ice was double-bagged at a minimum. VOC sample jars were placed in resealable plastic bags prior to placement in coolers. The field sampler indicated sample designation/location number in the spaces provided on the appropriate COC for each sample of water or soil. The COC was signed and placed in the cooler. The cooler was sealed. The samples were delivered to the laboratory no later than 24 hours after sample collection.

If samples were split and sent to different laboratories, a copy of the COC accompanied the replicate sample. The original COC accompanied the sample for the primary laboratory. The "remarks" column of the COC was used to record specific considerations associated with sample acquisition such as: sample type, container type, sample preservation methods, and analyses to be performed. The laboratory maintained on file the completed original forms. Copies are submitted as a part of the final analytical report.

The specific analyses for each sample were outlined in the workplan. Samples were collected according to the procedures in this *FSP*. Samples were hand-delivered or shipped in coolers with sufficient packing material and ice to insure that samples arrived at the laboratory intact, below 4ºC, and within 18 hours of shipping.

2.2 Laboratory Sample Custody

Receipt, storage, and tracking of samples submitted to the laboratory were conducted according to NYSDEC protocol to prevent sample contamination or loss, as well as, the production of invalid laboratory data as a result of sample deterioration or tampering.

TABLE 1

SAMPLE PRESERVATION AND HOLDING TIME REQUIREMENTS

NYSEG CENTRAL AVENUE FORMER MGP SITE
MECHANICVILLE, NEW YORK

TYPE OF ANALYSIS	SAMPLE VOLUME/CONTAINER	PRESERVATION REQUIREMENTS	MAXIMUM HOLDING TIMES
NON-AQUEOUS SAMPLES			
TCL (EPA Method 8260)	4 oz. Glass jar, Teflon cap	Cool 4 ^{o}C	Analyze within 14 days.
SVOCs (EPA Method 8270, Base/Neutral Extractables)	1-6oz. Glass jar, Teflon cap	Cool 4 ^{o}C	Extract within 14 days; analyze within 40 days.
PCBs (EPA Method 8082)	1-6oz. Glass jar, Teflon cap	Cool 4 ^{o}C	Extract within 14 days; analyze within 40 days
PPL Metals (EPA Method 6010)	1-6oz. Glass jar, Teflon cap	Cool 4 ^{o}C	Analyze within 6 months.
Acid Volatile Sulfide/ Simultaneously Exractable Metals (EPA Method 6010)	1-6oz. Glass jar, Teflon cap	Cool 4 ^{o}C	Analyze for most metals within six months Except for Sulfide analyze within 7 days.
Cyanide Total, Amenable (EPA 9012/335.3)	1-6oz. Glass jar, Teflon cap	Cool 4 ^{o}C	
Weak and Dissociable Cyanide	1-6oz. Glass jar, Teflon cap	Cool 4 ^{o}C	
Total Phenols (EPA Method 9065/420.1)	1-6oz. Glass jar, Teflon cap	Cool 4 ^{o}C	
TOC, Dissolved (EPA 415.2)	1-6oz. Glass jar, Teflon cap	Cool 4 ^{o}C	
BTU (ASTM D240)	1-6oz. Glass jar, Teflon cap	Cool 4 ^{o}C	
AQUEOUS SAMPLES			
TCL (EPA Method 8260)	Two (2) 40 ml septa vials, Glass	HCL to pH < 2	Analyze within 14 days.
SVOCs (EPA Method 8270, Base/Neutral Extractables)	1 Liter Glass	Cool 4 ^{o}C	Extract within seven days; analyze within 40 days
PCBs (EPA Method 8082)	1 Liter Glass	Cool 4 ^{o}C	Extract within 14 days; analyze within 40 days
PPL Metals (EPA Method 6010)	32 oz., Plastic	HNO_3	Analyze within 6 months.
Total Phenols (EPA Method 9065/420.1)	500 ml, Glass	H_2SO_4 to pH < 2	
Cyanide Total, Amenable (EPA 9012/335.3)	8 oz., Plastic	NaOH to pH > 12 0.6g ascorbic acid	
Weak and Dissociable Cyanide	8 oz., Plastic	NaOH to pH > 12 0.6g ascorbic acid	
Alkalinity (EPA 310.1)	4 oz., Glass	Cool 4 ^{o}C	
Chloride (EPA 9252/325.3)	32 oz., Plastic	Cool 4 ^{o}C	
TOC, Dissolved (EPA 415.2)	8 oz., Plastic	Cool 4 ^{o}C	

TABLE 1

SAMPLE PRESERVATION AND HOLDING TIME REQUIREMENTS

NYSEG CENTRAL AVENUE FORMER MGP SITE
MECHANICVILLE, NEW YORK

TYPE OF ANALYSIS	SAMPLE VOLUME/CONTAINER	PRESERVATION REQUIREMENTS	MAXIMUM HOLDING TIMES
Nitrate (EPA 9200/353.1)	8 oz., Plastic	H_2SO_4	
Nitrite (EPA 1983/354.1)	32 oz., Plastic	Cool 4 ^{o}C	
Sulfate (EPA 9038/375.4)	32 oz., Plastic	Cool 4 ^{o}C	
sulfide (EPA 9030/376.2	8 oz., Plastic	NaOH / Zinc Acetate	
Dissolved Iron (EPA 200.7)	8 oz., Plastic	Cool 4 ^{o}C	
Ethane, Ethene, Methane (GC)	40 ml (2 per sample), Glass	Cool 4 ^{o}C	
Ignitability (EPA 1010)	All of these parameters can be done on the same sample in one 32oz. Plastic container	Cool 4 ^{o}C	
Corrosivity (SM16 203)			
Reactivity (SM 7.3.2.1.)			

Notes:
VOCs indicates Volatile Organic Compounds
SVOCs indicates Semivolatile organic compounds
PCBs indicates polychlorinated biphenyls
PPL indicates Priority Pollutant Metals (Al, Sb, As, Ba, Cd, Cr, Cu, Fe, Pb, Ni, Mn, Hg, Se, Ag, V, Zn)
Selected samples may be initially processed using the Toxicity Characteristic Leachate Procedure (TCLP) (Method 1311).

NEW YORK STATE ELECTRIC & GAS
MECHANICVILLE FORMER MGP SITE

BEDROCK CORE LOG NOTES

Well No.	Identifies a bedrock well at the Mechanicville Fomer MGP Site.
Elevation	Surface elevation in feet relative to mean sea level.
TD	Total depth of well boring in feet below grade.
Run #	Identifies the portion of rock core that was retrieved from a given core barrel.
Depth	Depth or depth interval of a stratigraphic marker or fracture in feet below grade.
Elevation	Depth or depth interval of a stratigraphic marker or fracture in feet relative to mean sea level.
	[ ] Elevation below sea level.
Fractures	Identifies fractures, if present:
	HF High angle filled fracture (>30^{o} inclination); the fracture is annealed, typically with calcite.
	HO High angle open fracture (>30^{o} inclination); the fracture may be mineral-coated or -stained.
	LF Low angle filled fracture (<30^{o} inclination); the fracture is annealed, typically with calcite.
	LO Low angle open fracture (<30^{o} inclination); the fracture may be mineral-coated or -stained.
Angle	Approximate or average inclination of fracture or bedding from horizontal.
Marker Type	Identifies the lithology or mineralogy of a stratigraphic marker:
	cc Calcite band or vein.
	py Pyrite band or pyrite layer, consisting of finely to densely disseminated pyrite.
Marker Form	Identifies the thickness of a given stratigraphic marker (in inches).
Faults	Identifies features of brittle deformation, if present:
	SS Polished slickenside surfaces, frequently with slickenfibers or striations.
	BC Breccia, ranging in thickness from less than 0.1 inches to several feet; typically annealed with calcite or an anastomosing set of thin calcite veins.
HIF	Depth of High Intensity Fractures in feet relative to mean sea level (> 1 fracture/inch).
	LI Fracture intensity is less intense (1 fracture/1-6 inches).
	SI Fracture intensity is semi-intense (1 fracture/6-8 inches).
	V Vertical fractures.
IPC	Depth of Intense Pencil Cleavage in feet relative to mean sea level.
	M Minor pencil cleavage .
	VM Very minor pencil cleavage.
Comments	Describes the characteristics of a stratigraphic marker or a fracture:
	REC Percent recovery of core.
	RQD Rock quality designation.
	cc Calcite annealed fracture.
	gra Graphite annealed or coated fracture.
	tight Fracture is not annealed, and does not appear as open fracture.
	v. thin Very thin hairline fracture, typically less than 0.02 inch thick.
	GB General bedding.

LABORATORY REPORT

for

URS/Dames & Moore
646 Plank Road
Suite 202
Clifton Park, NY 12065

Attention: Eriko Fujtia

Purchase Order #: 30309T194 (#5)

Report date: 04/25/01
Number of samples analyzed: 7
AES Project ID: 010406 K
Invoice #: 226362

ELAP ID#: 10709

AIHA ID#: 100307
