1. Introduction

On behalf of Lockheed Martin Corporation (Lockheed Martin), ARCADIS has prepared this report to present the results of the vapor intrusion study for the former French Road Facility Solvent Dock Area (herein the "Site") located in Utica, New York and to evaluate the results based on the criteria set forth in the *Final – Guidance for Evaluating Soil Vapor Intrusion in the State of New York* (NYSDOH 2006). The vapor intrusion study was required by the New York State Departments of Environmental Conservation (NYSDEC) and Health (NYSDOH) to address the vapor intrusion pathway for the Site. The requirement was set forth in an 18 October 2006 letter to Lockheed Martin. The 18 October 2006 letter provided comments on the *Work Plan for the Interim Corrective Measure* (ARCADIS 2006a) including the requirement for delineation of the soil gas plume prior to development and implementation of the interim corrective measure (i.e., vapor depressurization system).

In response to this requirement, ARCADIS prepared a *Supplemental Vapor Intrusion Study* (herein "Study Work Plan") (ARCADIS 2007) dated 14 March 2007 that outlined the program for subslab soil gas and indoor air sampling at the Site, consistent with the discussions during conference calls with the NYSDEC and NYSDOH. The Study Work Plan was approved by the NYSDEC on 22 March 2007 and implemented on 12 April 2007.

This report presents information on the background and site history, the site setting including the results of a previous vapor intrusion study, the sampling approach, and the results and findings of all subslab and indoor air sampling. The summary and conclusions are presented at the end of this report.

2. Background and Site History

The 55-acre property, located in Utica, New York, was initially developed in the early 1950s by General Electric (GE) who constructed an industrial facility that included a 500,000-square foot manufacturing building (Figure 1). Production operations conducted by GE included manufacturing, assembly, and testing of electrical components for the defense and aerospace industries. These production operations were conducted by GE until April 1993, when the facility was acquired by Martin Marietta Corporation (MMC). In March 1995, MMC merged with Lockheed Corporation to form Lockheed Martin Corporation. In March 1996, Lockheed Martin sold the property to Pinnacle Park, Inc., which subsequently sold the property to the Oneida County Industrial Development Agency (OCIDA), the current owner. ConMed

Corporation, a company that manufactures and distributes medical supplies, now occupies the facility and leases it from OCIDA. Although Lockheed Martin no longer owns the property, it has retained responsibility for environmental cleanup activities related to past releases at the Solvent Dock Area which includes the former solvent dock and surrounding area where groundwater is impacted with volatile organic compounds (VOCs).

Historical environmental releases at the Site are associated with a 275-gallon fiberglass overflow retention tank and other underground storage tanks (USTs) that were installed beneath the former solvent dock (part of the loading docks along the eastern section of the building's north wall). The retention tank was designed to contain solvents incidentally spilled and subsequently collected in floor drains at the former solvent dock. Collected waste solvents were periodically sampled, pumped from the retention tank, and disposed by waste haulers. The retention tank remained in service until June 1990, when it was removed. During tank removal, elevated vapor readings were noted, indicating a release. The retention tank was also noted as dented and leaking fluid.

A series of investigations to evaluate the soil and groundwater impacts due to spills and/or leaks associated with the retention tank and other USTs beneath the former solvent dock were subsequently completed, confirming the presence of VOCs in groundwater beneath and downgradient of the former solvent dock.

3. Site Setting

This section presents information on the geology and hydrogeology, the site reconnaissance and building conditions, and a summary of a previous vapor intrusion study completed at the Site.

3.1 Geology and Hydrogeology

Geologic materials (i.e., stratigraphy) encountered during previous investigations in the Solvent Dock Area were generally described as brown silt with fine sand to a maximum depth of approximately 20 feet below land surface (bls), overlying a dense unit composed of silt and fine sand with minor gravel (likely glacial till). This stratigraphy is similar to the regional geology of the Utica area. Groundwater elevation data show that the water table ranges from 5 to 10 feet bls. The general direction of groundwater flow is south-southeast. As such, groundwater moves from the exterior loading dock to beneath the manufacturing building. The Solvent Dock Area is "capped" with asphalt

pavement in the exterior loading area or with the building's concrete foundation and slab.

Several solvent storage tanks were removed from service during the late 1970s and the early 1980s, with the last tank (the overflow retention tank) removed from the Solvent Dock Area in 1990. Due to the detection of organic vapors during the removal of the overflow tank, a series of investigations to evaluate potential soil and groundwater impacts due to spills and/or leaks from the former solvent tanks was completed. These historical investigations determined that groundwater in and around the northeast corner of the main manufacturing building (i.e., the Solvent Dock Area) had been impacted by VOCs. Groundwater samples collected during the past 10 to 15 years from piezometers installed through the building slab have yielded detectable levels of VOCs including 1,1-dichloroethane (1,1-DCA), trichloroethene (TCE), tetrachloroethene (PCE), cis-1,2-dichloroethene (cis-1,2-DCE), trans-1,2-dichloroethene (trans-1,2-DCE), and vinyl chloride. Concentrations of total VOCs in these samples have recently been in the range of 500 to 1,000 micrograms per liter (µg/L). Water quality data for wells in the Solvent Dock Area are shown on Figure 2.

3.2 Site Reconnaissance and Building Conditions

Site reconnaissance was conducted by EarthTech, on behalf of Lockheed Martin in March 2005 and February 2006. The focus of the reconnaissance was to select sampling locations, evaluate the building condition, identify chemical usage in the building, and to identify and minimize conditions that may interfere with the planned sampling activities. The building floor was noted to be in good condition and free of cracks and holes (which represent target sampling locations). Therefore, sample locations were identified in areas with potential worker exposure. During the reconnaissance, several rooms in the building were identified as being under positive pressure. These areas are shown on Figure 3.

A copy of the product inventory completed during the reconnaissance is provided in Appendix A. Workers initially indicated that solvent use was limited to citrus degreasers. However, during sampling events and additional inquiries at the ConMed facility, TCE and other chemicals, including petroleum products and methylene chloride, were identified in the eastern portion of the building near molding machines.

3.3 Previous Vapor Intrusion Study

In February 2006, EarthTech collected ten subslab soil gas and indoor air samples and one ambient air sample at the ConMed facility. Sample locations, except ambient air, are shown on Figure 3. The ambient air sample was located outside of the northwest corner of the building approximately 750 feet west of the Solvent Dock Area. Sample results were submitted to the NYSDEC in a letter report dated April 17, 2006 (EarthTech 2006). The sample results showed that both TCE and PCE were detected in subslab soil gas and indoor air at concentrations greater than NYSDOH air guidelines at some locations (Tables 1 and 2). Concentrations of TCE in indoor air ranged from non-detect to 73 micrograms per cubic meter (µg/m^3). PCE was detected in indoor air at concentrations that ranged from 2.8 µg/m^3 to 97 ug/m^3. In subslab soil gas, TCE levels ranged from 2.5 µg/m^3 to 680 µg/m^3 and PCE levels ranged from 5.0 µg/m^3 to 21,000 µg/m^3.

Based on the results of the initial sampling event and in response to the presence (and perhaps use) of TCE in the building, EarthTech conducted a second sampling event at two locations (I1 and I4) (EarthTech 2006). The results of the re-sampling event detected the same concentration of TCE at I1 (41 µg/m^3) and a lower concentration of TCE at I4 (6.7 µg/m^3).

4. Sampling Approach

The 12 April 2007 sampling event conducted by ARCADIS was implemented in accordance with the Study Work Plan (ARCADIS 2007) and the *Vapor Intrusion Work Plan - Revised* (Lockheed Martin 2005). The sampling locations are shown on Figure 3. Sampling logs are provided in Appendix B. The study area consisted of the eastern section of the manufacturing building where groundwater is impacted with VOCs.

Eight co-located subslab soil gas and indoor air sampling locations were initially identified as part of this supplemental study. As requested by NYSDEC and NYSDOH, samples were biased towards the north, south, and west and focused on the portions of the building located outside of the positive pressure rooms and where the groundwater plume is not well defined (beneath the building toward the west). All samples were collected as proposed in the Study Work Plan, with the exception of a subslab soil gas sample at location 6SD. At location 6SD, the thickness of the slab (greater than 16 inches) prevented the collection of any subslab soil gas sample. As a result, only an indoor air sample was collected from this location.

As provided for in the Study Work Plan, the subslab soil gas samples were initially analyzed. The indoor air samples were placed on hold pending receipt and review of the subslab soil gas sample results. A discussion of the subslab sampling results was held with the NYSDEC and NYSDOH on 24 April 2007. During the conference call, it was decided that analysis of five indoor air samples (i.e., AA-2SD, AA-3SD. AA-4SD, AA-6SD, and AA-8SD) would be appropriate for the study.

5. Results and Findings

In this section, the results of the subslab soil gas and indoor air sampling conducted by ARCADIS in April 2007 and EarthTech in February/March 2006 are presented and evaluated according to the criteria set forth in the *Final – Guidance for Evaluating Soil Vapor Intrusion in the State of New York* (herein "Final Guidance"). The results of the April 2007 subslab soil gas and indoor air sampling are presented in Table 3 and Table 4, respectively. The results of the February/March 2006 subslab soil gas and indoor air sampling are presented in Table 1 and Table 2, respectively. Table 5 presents a summary of the data including the frequency of detection and minimum and maximum detected concentration for each constituent. Complete analytical results from the April 2007 sampling event are provided in Appendix C.

5.1 Evaluation of Subslab Soil Gas and Indoor Air Results

Consistent with the Final Guidance, subslab soil gas and indoor air data from all sampling events (i.e., February/March 2006 and April 2007) were evaluated using the following steps.

- First, concentrations detected in indoor air were compared to applicable NYSDOH air guideline values provided in the Final Guidance.

- Second, concentrations detected in indoor air were compared to generic background concentrations referenced by the NYSDOH in the Final Guidance.

- Third, the subslab soil gas data were evaluated using the matrices provided in the Final Guidance.

Each of the evaluation steps is described below.

5.1.1 Comparison to Air Guideline Values

The constituents detected in indoor air were evaluated through a comparison to air guideline values. As developed by NYSDOH, concentrations in indoor air greater than the air guidelines values may need to be addressed if the source of these exceedances is from the subsurface (i.e., groundwater or soil gas). The air guideline values were not designed to address current work place exposures associated with active manufacturing processes for which the Occupational Safety and Health Administration (OSHA) has established permissible exposure limits.

The Final Guidance presents guideline values for three VOCs: methylene chloride, TCE, and PCE. Table 6 presents the comparison of constituents in indoor air to the air guideline values. Methylene chloride was detected in indoor air at concentrations greater than its air guideline value (60 µg/m^3) during the April 2007 sampling event. In all cases, methylene chloride was detected at a higher or similar concentration in indoor air compared to subslab soil gas indicating an indoor source unrelated to groundwater. As noted in the product inventory (Appendix A), methylene chloride is stored in the facility.

TCE was detected in indoor air at concentrations greater than its air guideline value (5 µg/m^3) during the February 2006 sampling event. TCE was generally detected at higher concentrations in subslab soil gas indicating contribution from a source beneath the building, presumably related to groundwater. However, at three locations (EarthTech sampling locations 4, 5, and 8), TCE was detected at higher concentrations in indoor air indicating contribution of an indoor source unrelated to groundwater. Although sample locations were not replicated between the two sampling events, TCE concentrations measured in indoor air were lower during the April 2007 sampling round and were less than NYSDOH air guideline values. As noted in the product inventory (Appendix A), TCE is stored in the facility.

Although PCE was detected in 9 out of 15 indoor air samples, all concentrations were less than the air guideline value (100 µg/m^3).

5.1.2 Comparison to Background Concentrations

The constituents detected in indoor air were compared to the generic background indoor air concentrations reported by the USEPA (2001) as part of the building

assessment and survey evaluation (BASE) database. The BASE database includes indoor air results from approximately 100 commercial and public office buildings. As a result, these values are expected to significantly underestimate background concentrations at active manufacturing facilities where chemicals may be used as part of normal operations. However, because background data from such facilities is not currently available, the 90th percentile value from the BASE database (as recommended by NYSDOH) was used for comparative purposes (Table 6).

A total of 13 constituents including TCE, PCE, and methylene chloride were detected at least once in indoor air samples at concentrations greater than background concentrations. However, as described in Section 5.1.1, air guideline values are available for TCE, PCE, and methylene chloride and these values are used as the more appropriate criteria for comparison. The 10 constituents above background concentrations without air guidelines are as follows:

- 1,2,4-trimethylbenzene
- 1,3,5-trimethylbenzene
- 1,4-dichlorobenzene
- acetone
- 4-ethyltoluene
- ethylbenzene
- methyl ethyl ketone (MEK)
- m&p-xylene
- o-xylene
- toluene

Although these constituents, including TCE, PCE, and methylene chloride were measured at concentrations greater that conservative background levels, they are not expected to cause unacceptable human health impacts at the levels currently measured inside the building. Indeed, the background concentrations used for the above comparisons only indicate the levels typically measured inside commercial buildings and are orders of magnitude lower than health-based concentrations used for occupational settings.

5.1.3 Evaluation of Data Using NYSDOH Matrices

The final step in the data evaluation was to compare the subslab soil gas results to the matrices presented in the Final Guidance. The indoor air data were not considered in conjunction with the subslab soil gas data because, as described in Section 3.2, TCE and other chemicals, including petroleum products and methylene chloride, were identified in the eastern portion of the building near the molding machines. The results indicate that several constituents, including TCE and methylene chloride were present in indoor air due to background sources located within the building (i.e., observed storage of chemicals and their potential use). Therefore, indoor air data are not reliable indicators of the need to monitor or mitigate subslab soil gas.

Matrix 1 is applicable to TCE and carbon tetrachloride. Matrix 2 is applicable to PCE and 1,1,1-trichloroethane (1,1,1-TCA). Table 7 presents a comparison of subslab soil gas results and the matrix recommended action for TCE, PCE, and 1,1,1-TCA. Carbon tetrachloride was not detected in subslab soil gas and therefore, was not considered as part of the data evaluation. The matrices allow for four different options or actions:

- No further action
- Take reasonable and practical actions to identify source(s) and reduce exposures (i.e., concentration is likely associated with background)
- Monitor
- Mitigate

As presented on Table 7, there were 17 subslab soil gas sample results. Figure 4 shows the results of the matrix comparisons for TCE, PCE, and 1,1,1-TCA. As shown on Figure 4 and presented in Table 7, the NYSDOH matrices recommend mitigation at two locations (S1 and S2) based on TCE and/or PCE concentrations. In addition, the NYSDOH matrices recommend monitoring at five locations (S4, S5, S6, S10, and VP-2SD). At all other locations, a no further action decision would be appropriate.

In addition to background sources (i.e., sources unrelated to the subsurface impacts from former operations at the Site), groundwater was evaluated as a potential source of the TCE and PCE detected in subslab soil gas. Both TCE and PCE have high Henry's Law constants (i.e., greater than 10^{-5} atm m^3/mol), therefore, the dissolved phase concentrations measured in groundwater at the Solvent Dock Area could generate the concentrations of TCE and PCE detected in subslab soil gas.

NYSDOH has recently (July 2007) added three VOCs (1,1-dichloroethene, cis-1,2-dichloroethene, and vinyl chloride) to the Final Guidance matrices (although the Final Guidance has not been updated). Therefore, these VOCs are included in the matrix evaluation presented in Table 7. The addition of these VOCs did not change the matrix recommendations based on the original VOCs presented in the Final Guidance.

5.2 Vapor Intrusion Pathway Evaluation

The potential exists for the vapor intrusion pathway (groundwater to soil gas) to be complete for several constituents including TCE and PCE. Dissolved phase concentrations in groundwater are sufficient to produce the concentrations measured in subslab soil gas for these constituents.

Several constituents detected in indoor air may not be related to subsurface conditions, but could be present due to background sources. Background constituents, including TCE, PCE and methylene chloride would not be mitigated by the subsurface depressurization system proposed in the *Work Plan for the Interim Corrective Measure* (ARCADIS 2006a). If deemed necessary or appropriate by the owner, tenant, or regulatory agency, mitigation of background constituents in indoor air should be addressed separately from Lockheed Martin's obligations at the Solvent Dock Site.

6. Summary and Conclusions

NYSDEC and NYSDOH required Lockheed Martin to conduct a vapor intrusion study to address the vapor intrusion pathway at the Solvent Dock Area of the former French Road facility in Utica, New York. Seven subslab soil gas and four indoor air samples were collected and analyzed in April 2007. Previously, ten subslab soil gas and eleven indoor air samples were collected in February/March 2006. The 17 subslab soil gas samples and 15 indoor air samples were evaluated based on the criteria set forth in the *Final – Guidance for Evaluating Soil Vapor Intrusion in the State of New York* (NYSDOH 2006). As part of the study, the groundwater quality data and subslab soil gas results were used to evaluate the vapor intrusion pathway at the Solvent Dock Area. The conclusions of the study are presented below.

- In the northeast portion of the manufacturing building, measured concentrations of TCE and PCE in subslab soil gas warrant mitigation per the *Final – Guidance for Evaluating Soil Vapor Intrusion in the State of New York* (NYSDOH 2006). The vapor intrusion study has delineated subslab soil gas that warrants mitigation.

- Dissolved phase concentrations of several constituents including TCE and PCE present in groundwater are sufficient to produce the concentrations measured in subslab soil gas for these constituents.

- Measured concentrations of TCE and methylene chloride in indoor air exceed the NYSDOH air guideline values. However, the concentrations detected in indoor air are less than available OSHA work place standards.

- Several constituents detected in indoor air do not appear to be related to subsurface conditions, but may be present due to background sources (this conclusion is supported by the observation of chemical storage and/or use in the facility). These conditions would not be mitigated by the subsurface depressurization system proposed in the *Work Plan for the Interim Corrective Measure* (ARCADIS 2006a). If deemed necessary or appropriate by the owner, tenant, or regulatory agency, mitigation of background constituents in indoor air should be addressed separately from Lockheed Martin's obligations at the Solvent Dock Site.

Lockheed Martin will resample subslab soil gas at locations S1 and S2. Pending confirmation of the subslab conditions, Lockheed Martin will seek the concurrence of the regulatory agencies to install the vapor depressurization system contemplated in the *Work Plan for the Interim Corrective Measure* (ARCADIS 2006a) to mitigate the subslab soil gas impacts beneath the northeastern portion of the manufacturing building. Prior to installation, Lockheed Martin will revise the *Work Plan for the Interim Corrective Measure* (ARCADIS 2006a) and submit the revised plan to NYSDEC and NYSDOH for review. The revisions will account for the new information reported herein and the comments offered by NYSDEC/NYSDOH in letter dated 18 October 2006. Upon agency approval, Lockheed Martin will install the vapor depressurization system.

APPENDIX A
PRODUCT INVENTORY

ConMed Facility
525 French Road
Utica, NY

Location	Product Description	Chemical Ingredients	Size	Condition
Mold Storage	waste hydraulic oil	petroleum	6 - 55 gal	good
Storage Room (near	lim603080 - pail kit	silicon	12-80 lb	New
solvent dock)	Synpro	polymer	2-25lb	New
Material Storage/Mix	Cyro-Acrylic Molding-Cyrolite - large boxes	proprietary	4 boxes	New
	Slide Mold Cleaner with Rust Preventer	*TCE (50-65%)*	*2-10 oz*	*Fair*
	Stoner Non-Flammable Cleaner Degreaser	*TCE (90-100%)*	*2-10 oz*	*Fair*
"Currently Vacant Room"	Lexan - 45lb bags GE Plastics	Polycarbonate resin	8 bags	New
Aisle *	ColorRite-Polymer-Unichem Vinyl Compound	proprietary		
(east of "currently vacant"	94-532Blue-497 - in Boxes	proprietary	5-1500lb	New
room)	Liquid Silicon rubber (Rhodia) - in pails	Silicon	17-43lb	New
Mechanical Room	FTS-321- Chiller Liquid	Unknown	1-55gal	In Use
	FTS-933- Chiller Liquid	Unknown	2-55gal	In Use
	Boiler Treatment Chemicals	*Unknown*	*5-55 gal*	*Fair*
	Paint	*Petroleum distillates*	*1-gal*	*Fair*
	Waste Refrigerant	*Ethylene Glycol*	*1-55 gal*	*Fair*
Chemical Storage**	waste hydraulic oil	petroleum	8-55gal	good
	New hydraulic oil	petroleum	8-55gal	New
	Cyclohexanone	Cyclohexanone	1-55 gal	good
	Cyclohexanone	Cyclohexanone	1-55 gal	New
	Isopropyl alcohol	Isopropyl alcohol (99%)	9-55gal	New
	Methylene Chloride	Methylene Chloride	1-1gal	New
	Methylene Chloride	Methylene Chloride	12-1gal	good
	Propane gas cylinders	Propane	2-16oz	New
	Zep Degreaser	*Proprietary*	*2-30 gal*	*Empty*
Mold Maintenance	Latex paint	Latex paint	1-1gal	Used
	white lithium grease	petroleum	1-3oz	In Use
	Citrus Power - bulk mold cleaner		5-5 gal	New
	Used Oil	*Petroleum*	*1-55 gal*	*Fair*
	Dynaclean	*Proprietary*	*2-55 gal*	*New*
	Xylene	*Xylene*	*1-1 gal*	*Fair*
	Xenit Citrus Degreaser	*Petroleum Distillates*	*8-10 oz*	*Fair*
	Simple Green	*Proprietary*	*1-1 gal*	*Good*
Molding Facility	*Slide Mold Cleaner with Rust Preventer*	*TCE (50-65%)*	*2-10 oz*	*Fair*
	Stoner Non-Flammable Cleaner Degreaser	*TCE (90-100%)*	*3-10 oz*	*Fair*
	Xenit Citrus Degreaser	*Petroleum Distillates*	*4-10 oz*	*Fair*

Notes

1. Observations made on March 25, 2005, except those noted in italics, which were made during February and March 2006.
2. Aisle *- This area is full of large boxes and bins of proprietary resin and resin ingredients. All are odorless, and in a solid state. Examples of two types of materials stored in the aisle are tabulated above.
3. Chemical Storage**- In addition to the above list, a chemical storage cabinet blocked by 55-gallon drums could not be inventoried.

Sample Depth: 8" bgs

Sample Method: Tubing clamped to canister after helium test conducted.

Sample Device: TO-15 canister

Remarks: No helium leak detected sampled directly from tubing. Sample DUP-1SD at sample time as VP-7SD.

Constituents Sampled: TO-15 Sampling Personnel: KW

gpm Gallons per minu N/A Not Applicable

mg/L Miligrams per lite COC Chain of Custody
