I. EXECUTIVE SUMMARY

Gibbs & Hill, Inc. (G&H) has entered into a consulting services agreement with the New York State Department of Environmental Conservation (NYSDEC) Division of Hazardous Waste Remediation to conduct preliminary investigations (Phase I) and field investigations (Phase II) at inactive hazardous waste disposal sites in New York state. This report presents the results of the Phase II investigation of the GAF Dump site (NYSDEC site ID #704011) performed by G&H. A Phase I investigation of this site was completed in April 1986 by Wehran Engineering.

The GAF Dump site is a two-acre inactive disposal area located in the City of Binghamton, Broome County (Figure I-1). The site is adjacent to an Anitec Corporation facility which was formerly a GAF manufacturing plant. GAF retained ownership of the dump area when their plant was sold to Anitec in 1975. An abandoned paved parking lot makes up the eastern half of the site, while the western portion of the site is ungraded and covered with thick weeds. The site is located in a mixed commercial and residential neighborhood. To the west of the site is Veterans Memorial Park, to the north is a residential area, to the east is Spring Forest Cemetery, and to the south is the Anitec Corporation facility (Figure I-2). The area within a three mile radius of the site includes the Chenango River and

several drinking water and industrial wells. The Binghamton water intake is located upstream on the Susquehanna River. A 66-inch storm sewer line known as Trout Brook, approximately 200 feet downslope from the dump site, flows in an easterly direction to the Chenango River.

Nearby wells include those on the eastern side of the Chenango River, the Johnson City well field 1.8 miles west of the site and Anitec production wells 500 feet south of the site.

The dump area was allegedly used during the time GAF owned and operated the plant to dispose of waste liquids from production of photographic material by dumping liquid directly onto the ground. There is no information available regarding when use of the site began. It is known that the plant has been in operation since World War II. It has been reported that GAF stopped disposing of wastes by 1975, [D.1 through D.7].

A Phase II investigation of the site was conducted to gather sufficient information to classify the site and to calculate the final Hazard Ranking System (HRS) scores. Field investigations included a site reconnaissance, a geophysical survey, installation of three groundwater monitoring wells, and collection of nine soil and four groundwater samples.

Groundwater and soil samples were analyzed to define the potential contamination at the GAF Dump site.

On August 4, 1988, a site reconnaissance of the area was undertaken by Gibbs & Hill. No signs of any hazardous waste or leachate were observed. However, results from the chemical analyses of collected samples (Tables IV-1 and IV-2) indicate releases of chloroethane, 2-butanone, and 1,2-dichlorethane from the site to the groundwater and the presence of higher than background concentrations of copper, lead, and zinc in the soil.

The final HRS scores for the GAF Dump site based on the results of this Phase II investigation have been calculated as follows:

$$\begin{aligned} S_M &= 23.00 \\ S_{gw} &= 39.80 \\ S_{sw} &= 0.00 \\ S_a &= 0.00 \\ S_{DC} &= 0.00 \\ S_{FE} &= N/A \end{aligned}$$

The S_M score reflects the potential for harm due to migration of hazardous substances away from the facility. This score is the composite of scores for groundwater (S_{gw}), surface water (S_{sw}), and air (S_a) transport routes. The S_{FE} score reflects the potential for harm from substances that can explode or cause fires, and the S_{DC} score reflects the potential for harm from direct contact with hazardous substances.

II. PURPOSE

The objective of a New York State Superfund Phase II investigation is to determine if contaminants are present at an inactive hazardous waste site which may have an adverse impact on human population and/or the environment.

The goal of the investigation was to collect the information required to classify the site and to develop final HRS scores. This included collecting the field data necessary to identify the occurrence and characteristics of contamination and to determine if a release of contaminants from the site has occurred. This information will be used by NYSDEC to determine if any imminent and/or significant environmental or health hazard exists. Specifically, these objectives were accomplished through the installation of groundwater monitoring wells and the sampling and analysis of groundwater and soil, in accordance with NYSDEC protocols and guidelines.

III. SCOPE OF WORK

A. INTRODUCTION

Gibbs & Hill, Inc. entered into a consulting services agreement on October 16, 1986 with the NYSDEC Division of Hazardous Waste Remediation to conduct preliminary investigations (Phase I) and field investigations (Phase II) at inactive hazardous waste disposal sites in New York State. G&H and its subcontractors completed Phase I investigations of 30 sites under the provisions of this agreement.

The original agreement was amended January 21, 1988 (Amendment 1) to include an additional 25 sites to receive Phase II investigations. This report presents the results of the Phase II investigation of the GAF Dump site (NYSDEC site ID #704011) performed by G&H. A Phase I investigation of this site was completed in April 1986 by Wehran Engineering.

The Phase II field investigations at the GAF Dump site began in August 1988 and were completed in February 1989. An updated work plan, approved by NYSDEC, was prepared by G&H to define the scope of drilling and sampling activities at the site (Appendix A). The Phase II investigation consisted of a review of

relevant literature, field investigations and the preparation of final HRS scores. Field activities included an initial site reconnaissance, a geophysical investigation, installation of groundwater monitoring wells, and groundwater and soil sampling and analysis. The scope of work of the investigation is summarized in Table III-1.

B. GEOPHYSICAL SURVEY

Geophysical surveys were conducted at the GAF Dump site on August 10, 1988, by Roux Associates to characterize subsurface conditions. A magnetometer was used at proposed monitoring well locations to detect ferromagnetic objects which might be encountered during drilling. A resistivity survey was performed to determine the depth to the water table and to locate anomalies which could indicate groundwater quality changes resulting from the landfill. A terrain conductivity survey was performed to characterize shallow subsurface conditions. The summarized results of this survey are presented in Section IV, and the Survey Report is enclosed in Appendix A.

C. MONITORING WELL INSTALLATION

Three overburden monitoring wells were installed to establish the groundwater quality of the aquifer beneath the dump site.

The locations of these wells are shown on Figure I-2. The monitoring wells were installed by drilling with 6.25-in. I.D. hollow stem augers to depths ranging from 18 feet to 40 feet.

MONITORING WELL LOCATION AND SPECIFICATION

| Well No. | Location | Boring Depth (ft) | Well Type |
|----------|--------------|-------------------|------------|
| GW-1 | Upgradient | 40 | Overburden |
| GW-2 | Downgradient | 18 | Overburden |
| GW-3 | Downgradient | 20 | Overburden |

Each well was logged during the drilling activities and split spoon samples were taken at five-foot intervals during the drilling. Soil from the last split spoon sample of each well was collected and analyzed for grain size distribution. Aquifer characteristics were evaluated by slug tests. All monitoring well locations and elevations were surveyed, and the relative depths to groundwater were determined.

All field procedures, boring logs, well schematics, and grain size analyses are included in Appendix B.

D. GROUNDWATER SAMPLING AND ANALYSIS

Three groundwater samples, and one duplicate sample, were collected November 1, 1988. These samples were analyzed for Target Compound List (TCL) metals, volatiles, semi-volatiles and pesticides/PCBs. H2M Labs (Melville, New York) performed the analyses in accordance with November 1987 NYSDEC Contract Laboratory Protocols (CLP). OBG Laboratories (Syracuse, New York) performed an independent data validation. The chemical analytical results are discussed in Section IV and included in their entirety in Appendix C.2. The relevant field procedures are outlined in Appendix C.1.

E. SOIL SAMPLING AND ANALYSIS

Subsurface soil samples were collected from nine different locations. Seven of the samples were collected from a depth of 3 to 5 feet, one of these was a background sample collected from off-site (SS-1). The two remaining samples (SS-8 and SS-9) were collected from a depth of 8 to 10 feet. These two sampling points were located at the southernmost boundary of the site. Sample locations are shown on Figure I-2.

All nine soil samples were analyzed for TCL metals by H2M Labs in accordance with November 1987 NYSDEC CLP and the results

validated by OBG Laboratories. The chemical results are discussed in Section IV. The field procedure is outlined in Appendix C.1

F. AIR SURVEY

In accordance with appropriate health and safety procedures, a photoionization detector (PID) was used to monitor the air in the working zone for organic vapors during site activities. In addition, split spoon samples were scanned with a PID immediately upon their removal from the split spoon.

G. SOURCE OF INFORMATION

The following individuals and agencies with knowledge of the site were contacted:

Charles Bien
Environmental Engineer
GAF Corp. Building No. 10

TABLE III-1

SCOPE OF WORK

| Task | Description |
|------------------------------------|--|
| Record search and data compilation | Review Phase I information and any additional new information that is available. |
| Site reconnaissance | Note site changes since NYSDEC initial reconnaissance, assess access to monitoring well and sampling locations, and become familiar with the site. |
| Geophysical studies | Conduct geophysical survey. Based on the survey results, revise the location of monitoring wells. |
| Updated work plan | Revise preliminary NYSDEC work plan based on results of record search, site reconnaissance and geophysical studies. Prepare health and safety plan and define drilling and sampling protocols and procedures. |
| Monitoring wells | Install three overburden wells to depths ranging between 18 and 40 feet. Collect split spoon samples at five-foot intervals. Perform grain size analysis on deepest split spoon samples for each well. Develop wells to at least a turbidity of 50 NTU, or lowest possible, and perform permeability tests. Survey all monitoring well locations and elevations. Determine the relative depths to groundwater. |

TABLE III-1 (Continued)

Sampling and analysis

Groundwater

Collect groundwater samples from each well and one additional duplicate groundwater sample from a downgradient well. Analyze these samples for TCL metals, volatiles, semi-volatiles and pesticides/PCBs.

Soil

Collect nine subsurface soil samples, seven from a depth of 3 to 5 feet, including one background off-site sample, and two from 8 to 10 feet. Analyze soil samples for TCL metals.

Investigation Report

Prepare a report containing significant Phase I information, additional field data, final HRS scores, HRS documentation records, and site assessments.

IV. SITE ASSESSMENT

A. SITE DESCRIPTION AND HISTORY

The GAF dump site is a two-acre inactive disposal area located in the City of Binghamton, Broome County (Figure I-1). The site is adjacent to an Anitec Corporation facility which was formerly a GAF manufacturing plant. GAF retained ownership of the dump area when their plant was sold to Anitec Corporation in 1975. An abandoned paved parking lot makes up the eastern half of the site, while the western portion of the site is ungraded and covered with thick weeds. The site is located in a mixed commercial and residential neighborhood. To the west of the site is Veteran's Memorial Park, to the north is a residential area, to the east is Spring Forest Cemetery, and to the south is the Anitec Corporation facility (Figure I-2).

The site was allegedly used as a dump area during the time GAF owned and operated the plant. Liquids from production of photographic material were allegedly dumped directly onto the ground. GAF has no record or knowledge of anyone who can provide information concerning the type or quantity of wastes disposed at the site. There has not been, to GAF's knowledge, any health or environmental problem resulting from disposal of

waste at the site. It is known that the plant facility has been in operation since World War II. It is estimated that GAF stopped disposing wastes by 1975. Twelve to sixteen years ago the site was filled with approximately ten feet of demolition debris and cinders and presumably covered with soil [D.3]. Gibbs & Hill's soil samples did not reveal any of these materials. However, soil samples from downgradient wells (MW-2 and MW-3) were dark grayish brown, with significant amounts of silt and some clay, indicative of a swampy environment [B.2]. The site is currently unused.

A 66-inch storm sewer line known as Trout Brook, approximately 200 feet downslope from the dump site, flows in an easterly direction to the Chenango River. In 1971 this storm sewer was sampled by the Broome County Health Department. The principal toxic waste found was silver. It was believed that the silver detected was the result of amounts of silver nitrate being discharged from the plant. Zinc was also found in some samples. These data are difficult to assess due to the lack of background data and sampling protocols [D.8 and D.9].

An Anitec Well No. 3 sample was analyzed in December 1982 for purgeable priority pollutants and none were detected. In March 1983, samples were taken from Anitec Well No. 5 and were analyzed for volatiles, semi-volatiles, and inorganics.

Concentration of methylene chloride, a chemical necessary in making plastic base for most films, was found at a level five times above the detection limit [D.10 and D.11].

On August 4, 1988 a site reconnaissance of the study area was undertaken by Gibbs & Hill. The eastern portion of the site is presently covered by an abandoned asphalt parking lot. The remaining western portion is ungraded and covered with thick weeds. No signs of any hazardous waste or leachate were observed. No containment practices were visible [Appendix A].

On August 10, 1988, Roux Associates conducted a geophysical survey. Results of the geophysical survey indicated that there were no buried ferromagnetic objects in the vicinity of the monitoring wells. The terrain conductivity survey located an area of higher readings for the upper 20 feet at the southwest portion of the site. The absence of large changes in resistivity at the 30 to 40 feet interval implies that a conductant leachate plume has not been detected at this depth [Appendix A, D.6].

B. TOPOGRAPHY

The site and surrounding area slope 4 percent toward the southern property boundary with Anitec Corporation. A

residential neighborhood, located to the north on Prospect Street, is uphill of the site. An abandoned parking lot is immediately to the east of the investigated area. Veteran's Memorial Park is on the west and downhill of the site.

Trout Brook, approximately 200 feet downslope from the alleged dump site, flows in an easterly direction to the Chenango River. It has been converted to a closed storm sewer line.

The Johnson City well field is located 1.8 miles northwest of the site [Figure I-1]. Based on the regional hydrology, it appears that the well field is upgradient of the alleged dump area. The City of Binghamton water intake is located upstream on the Susquehanna River. The City also operates wells on the eastern side of the Chenango River.

Anitec Corporation installed five wells for cooling water supply approximately 500 feet south of the site (see Figures IV-2 and IV-3).

C. HYDROLOGY

1. Regional Hydrology

The triple cities of Binghamton, Johnson City, and Endicott

are underlain by sedimentary rocks of Upper Devonian Age. The bedrock is mostly composed of fractured and slightly folded shales and siltstones. In the western part of the City of Binghamton and in Johnson City, adjacent to where the Susquehanna River flows, low hills of till or bedrock form an impermeable barrier three miles long that separates the river from the sand and gravel aquifer known as the Clinton Street-Ballpark aquifer. [D.14]

The Clinton Street-Ballpark aquifer, a federally designated sole source aquifer, is the most productive in the region and is the aquifer of concern in the study area. The aquifer was formed about 17,000 years ago as the last glacier retreated from south-central New York. Deep valleys, originally covered by streams, had been widened and deepened by advancing ice. While the glacier was melting, lakes formed between the remaining ice and older sediment down valley. Turbulent rivers of meltwater deposited outwash material beyond the margins of the ice sheets. Where the rivers entered lakes, silt, clay, and very fine sand settled to the lake bottom. The Clinton Street-Ballpark aquifer borders two major streams, the Chenango and the Susquehanna. Much of the sediment that was deposited west of the Chenango River in Binghamton and in Johnson City is permeable sand and gravel. In this

region, groundwater easily move back and forth between the aquifer and the rivers. [D.14]

The Clinton Street-Ballpark aquifer underlies an urban area that is occupied primarily by houses and also includes some large commercial and industrial buildings. Possibly 20 to 30 percent of the land surface above the aquifer is covered by streets, paved parking lots and buildings. Even so, most precipitation infiltrates into the aquifer. After percolating downward to the water table, the water generally flows to the east until it reaches and seeps into the Chenango or Susquehanna River. Since at least the late 1940s, however, the water table has been lowered below river level in enough places that ground water no longer empties into the rivers but, instead leaves almost entirely through pumped wells. Much of the groundwater still originates from local precipitation, but now a large amount infiltrates from the rivers into the aquifer.

Approximately half the water withdrawn from the Clinton Street-Ballpark aquifer is used for municipal supply by Johnson City and its satellite water districts. The other half is used by industrial firms such as the Anitec Corporation for industrial processes [D.14].

2. Site Hydrology

Three borings were drilled at the GAF Dump site to assess the subsurface geology and to emplace monitoring wells. Boring MW-1, located just north of Seymour Street across from the dump site, revealed gravelly sands to 27 feet below the ground surface and compacted silty gravelly sands from 27 feet to 37 feet (bottom of hole). Boring MW-2, located on the southeast corner of the dump site, consisted of fine sand and silt to fifteen feet followed by a nine inch layer of gravelly sandy silts which were underlain by two feet of gray, highly plastic silty clay. Boring MW-3, located on the southwest corner of the dump site, revealed a layer of fine sand and silt to 10 feet, followed by a 10 feet of alternating clay and silty clay layers. Beyond this depth fine sands and silts were uncovered. [B.2]

The sands and gravels detected from the borings are indicative of the previously discussed glacial meltwater outwash material while the clays are indicative of localized glacial lake deposits. Soil samples from downgradient wells (MW-2 and MW-3) were dark grayish brown with significant amounts of silt and some clay, indicative of a swampy environment.

A grain size analysis was conducted on the deepest split spoon sample taken from each boring drilled. The analysis characterized the MW-1 split, spoon sample to be a gravelly sand and silt with a little clay, the MW-2 split spoon sample to be a silty fine sand with a trace of clay, and the MW-3 split spoon sample as silt with a trace of sand and little clay [B.2].

3. Hydraulic Conductivity

The hydraulic conductivity in the saturated zone was determined by a slug test. Results from the slug test show a hydraulic conductivity value of 2×10^{-4} cm/sec for MW-1, 4×10^{-4} cm/sec for MW-2, and 5×10^{-5} cm/sec for MW-3. These results are supported by the determination of hydraulic conductivity from grain size distribution analysis [B.1 and 2].

4. Groundwater Flow

Well data from the vicinity of the site indicate that regional groundwater is moderately close to the surface, within 50 feet, and flows in a south to southeast direction (D.14). The GAF Dump site monitoring well data suggest that localized groundwater flow is to the northeast (Figure

IV-1). However, it is highly unlikely that the local groundwater flow direction is to the northeast. [D.15]. To support this point, water elevation data were requested from Anitec Corporation. The information was used to provide another line of evidence for groundwater flow direction. (Figure 4-2)

The depth to water of five wells on the Anitec property located south of the GAF Dump site ranged from 32 feet to 44.33 feet [D.17]. Relative water elevations are presented in Figure IV-3. Nearby Anitec Corporation wells are being pumped at a rate considerable enough to affect the flow direction at the GAF site (D.15). Therefore, it is predicted that groundwater flow at the GAF site is south to southwest. It is not clear as to why the monitoring wells at the GAF site reflect a northeasterly flow direction. A probable explanation is that wells MW-2 and MW-3 are intercepting a shallow perched water-bearing zone. Clay layers encountered at depths between ten and fifteen feet suggest that the impermeable material is acting as a barrier and creating a local perched groundwater zone. GW-1 on the other hand is probably intercepting a deeper water-bearing zone. It was reported that a silty clay layer separates the groundwater into two water-bearing zones throughout the GAF/Anitec vicinity. This silty clay

lens is not continuous and eventually pinches out. It is possible that the silty clay material encountered during drilling operations is from this lens. The two water-bearing zones are hydraulically connected with the upper zone feeding into the lower one [D.14&15].

A second possible explanation is MW-1 is placed in a highly compacted glacial till material and in an area of restricted groundwater flow. Hydraulic conductivity, due to the nature of the material, is greatly reduced. MW-2 and MW-3 are placed in loosely compacted silty sands where the groundwater flow is far less restricted than at MW-1 and hydraulic conductivity is much higher.

D. SITE CONTAMINATION ASSESSMENT

Potential contamination of the environment within the site boundary was evaluated by a review of the character of wastes suspected at the site and chemical analyses of samples.

The character of wastes suspected at the site was evaluated by a review of information from historical literature assembled in Appendix D.

Groundwater and soil contamination assessment was based on the criteria presented in the Section C.1. Tables IV-1,2&3 summarize the results from the chemical analyses performed at the GAF site. Results of analyses are reported in these tables for every analyte and sample if that analyte was detected in any concentration above Contract Detection Limit (CDL). However, an analyte detected but below CDL is not reported unless it was detected above CDL in another sample or is a contaminant of concern at the site.

1. Waste Characteristics

There is no information available for the original GAF plant process. However, the sensitive surface of photographic films and papers consists of microscopic grains of silver halide suspended in gelatin. Developing agents contain a reducing agent with an accelerator (such as phenolic agents), a preservative (sodium sulfite) and restrainer (potassium chloride). Widely used color sensitizers include cyanine dyes, merocyanines, benzoxazoles, benzothiazoles, cryptocyanine, and diethyl-para-phenylenediamine (D.16). Therefore, given the nature of the industrial production of photochemical products, the monitoring of the site could reveal the presence of metals (such as silver, lead, nickel, zinc,

etc.), phenol, solvents (such as methylene chloride and other chlorinated solvents, acetone, toluene, xylene, benzene, etc.), and some of the chemicals previously mentioned.

2. Groundwater Contamination

Results from the chemical analysis of three groundwater samples and one duplicate are summarized in Tables IV-1 and IV-2. Five volatile organic compounds: methylene chloride (dichloromethane), acetone, 2-butanone, chloroethane (ethyl chloride), and 1,2-dichlorethane were found in the samples of groundwater. Concentrations of methylene chloride in samples GW-2, 3, and 4 are less than ten times the concentration in the trip blank. Concentrations of acetone, another common lab contaminant, in samples GW-2 (87 ug/l) and GW-3 (86 ug/l) are slightly higher than ten times the concentrations in the trip blank (8J ug/l) and approximately five times greater than the background sample concentration (18 ug/l). Methylene chloride and acetone are necessary in making the plastic base for most films; and therefore, their presence in groundwater samples was not surprising. However, we believe that the presence of these two compounds in downgradient samples (GW-2 and GW-3) is due to field or lab contamination.

Concentrations of chloroethane, 1,2-dichloroethane, and 2-butanone are greater than five times the concentrations of these compounds found in the associated blanks. In addition, these compounds were not detected in the upgradient water sample which indicates that the site is the source of this contamination. The concentrations of these compounds are above maximum contamination levels of organic compounds specified by the 10 NYCRR Subpart 5.1 (Table IV-4).

Pesticides/PCBs and semivolatiles were not detected in the groundwater samples.

The metal concentrations detected in the upgradient well (MW-1) were generally above or close to the concentrations detected in the downgradient wells (MW-2 and MW-3). The exception was silver, which exhibited concentrations in the downgradient wells MW-2 and MW-3 at thirty-two and nine times, respectively, above the background concentrations detected in the upgradient well (MW-1) which indicate that the site is the source of this contamination. Barium, cadmium, chromium, iron, lead, manganese, and zinc were detected in the groundwater of both downgradient and upgradient wells at concentrations significantly above the standards specified by the EPA 40 CFR 141 and 143 (Table

IV-4). Lead found in soil samples (in the range of 41.2 to 502 mg/kg) was not detected in high concentrations in groundwater samples. The concentration of lead in the downgradient well GW-2 was approximately two times greater than the concentration of lead in the upgradient well.

3) Soil Contamination

Nine subsurface soil samples were collected, seven from a depth of 3 to 5 feet, including one background off-site sample (SS-1) and two from 8 to 10 feet (SS-8 and SS-9). Sample locations as shown in Figure I-1, and results from the chemical analyses of soil samples are summarized in Table IV-3. The principal toxic contaminant found in soil was lead. The level of lead was thirteen times greater in sample SS-5 than the level detected in the background sample (SS-1). However, the concentration of lead in all other samples was less than ten times the level detected in the background sample. Low concentrations of copper and zinc were also found. The level of copper was eleven times greater in SS-2 and four times greater in SS-5 and SS-6 than the level detected in the background sample. The level of zinc was 5 times greater in SS-2, and two times greater in SS-5, than in the background level. Silver, found in significant concentrations in the groundwater, was in the soil only in concentrations below the background level.

4) Air Survey

Air quality surveys were conducted with a PID during the site reconnaissance, well installation, and sampling activities in accordance with appropriate health and safety precautions. A background level of 0.4 ppm was detected both on and around the site. No detectable levels of organic contaminants above background were registered on the meter.

E. CONCLUSIONS

All tasks of the Phase II investigations for GAF Dump site have been completed. Sufficient data has been collected to prepare final HRS scores.

The groundwater analyses detected three organics - chloroethane, 2-butanone, and 1,2-dichlorethane, released from the site to the groundwater.

The principal TCL metal found in the groundwater is silver (GW-2 only). The only metal which appears to be in a slightly higher concentration than expected in the soil is lead (502 ug/l). Silver, found in the groundwater samples, was not detected in the soil in concentrations above the background concentration.

The results of this Phase II investigation indicate migration of contaminants from the site into the groundwater. Further investigations are recommended to determine the vertical and horizontal extent of contamination and the extent to which migration has occurred. It is also recommended that groundwater samples be collected and analyzed on a regular basis to monitor the migration of contaminants.

[1] If both are present, the total of both concentrations may not exceed 500 ug/l.

[2] For water with hardness greater than 75 ppm. Standard is 11 ug/l for water with hardness less than or equal to 75 ppm.

[3] For water with hardness of 75 ppm. See 6 NYCRR 702 for determination of standard for other hardnesses.

* Maximum Contaminant Level - "maximum permissible level of a contaminant in water which is delivered to the free flowing outlet of the ultimate user of a public water system."

** Secondary Maximum Contaminant Level - same definition as MCL except "not Federally enforceable but intended as guidelines for the States."

*** Primary contact recreation and any other uses except as a source of water supply for drinking, culinary or food processing purposes.

TABLE IV-4

FEDERAL AND STATE STANDARDS AND GOALS

NOTES TO REGULATIONS

- [A] Environmental Protection Agency National Primary Drinking Water Regulations (as of 7/17/89)

Applied to results of all water sample analyses.

- [B] Chapter 1 of Title 10 of the Official Compilation of Codes, Rules and Regulations of the State of New York, Part 5, Drinking Water Supplies, Subpart 5-1, Public Water Supplies (as of 11/28/88)

Applied to results of drinking water sample analyses.

- [C] Chapter 10 of Title 6 of the Official Compilation of Codes, Rules and Regulations of the State of New York, Division of Water Resources, Article 2, Part 702, Appendix 31, Ambient Water Quality Standards - "The standards adopted herein relate to the condition of waters as affected by the discharge of sewage, industrial wastes or other wastes." (as of 7/5/85)

For sources of water for drinking, culinary or food processing purposes and human life protection, unless otherwise noted.

Applied to results of surface water sample analyses for surface water that is not a source of drinking water.

- [D] Chapter 10 of Title 6 of the Official Compilation of Codes, Rules and Regulations of the State of New York, Division of Water Resources, Article 2, Part 703.5(a)(2) and (3), Classes and quality standards for groundwaters - "The purpose of these classes, quality standards, and effluent standards and/or limitations is to prevent pollution of groundwaters and to protect the groundwaters for use as a potable water." (as of 7/5/85)

Applied to results of all groundwater sample analyses regardless of groundwater use.

- [E] Environmental Protection Agency National Secondary Drinking Water Regulations (as of 9/26/88)

Applied to results of all water sample analyses.

- [F] Source: "Review of In-Place Treatment Techniques for Contaminated Surface Soils," Volume 2, EPA-540/2-84-0036, November 1984, except as noted.

Applied to results of soil sample analyses.

- [G] Chapter 360 of Title 6 of the Official Compilation of Codes, Rules and Regulations of the State of New York, Solid Waste Management Facilities, Section 360-4.4(a), "Sewage sludge and septage destined for land application" (as of 12/31/88)

Applied to results of soil and sediment sample analyses.

A. NARRATIVE SUMMARY

A. NARRATIVE SUMMARY

The GAF Dump is located in the City of Binghamton, Broome County, New York. The site is approximately two acres in size and is located in a mixed commercial and residential neighborhood. The site is adjacent to an Anitec Corporation facility which was formerly GAF Manufacturing plant. However, GAF retained ownership of the dump site when the plant was sold. The Johnson City well field, serving 19,600 people, is located 1.8 miles west of the site. The City of Binghamton water intakes are east and south of the site on the Susquehanna River. No fresh water wetland is within a 1-mile radius.

The site allegedly received liquid photochemical wastes from production of photographic material during the time GAF operated the plant. No methods of containment were used during landfill operation.

Contamination of the groundwater and soil was detected during the Phase II investigation. Some analyzed metals were detected in the groundwater of downgradient as well as upgradient wells at concentrations significantly above the NYSDEC drinking water standards. Three organic compounds (chloroethane, 1,2 dichloroethane and 2-butanone) were detected in the groundwater. The results of the soil samples show concentration of iron, lead, manganese, and copper at levels greater than the level of the background samples.

C. UPDATED WORKSHEETS

Facility name: GAF Dump

Location: Charles Street, City of Binghamton, Broome County

EPA Region: II

Person(s) in charge of the facility: GAF Corporation, Wayne, NJ

Name of Reviewer: A. Kostic Date: June 2, 1989

General description of the facility:
 (For example: landfill, surface impoundment, pile, container; types of hazardous substances; location of the facility; contamination route of major concern; types of information needed for rating; agency action, etc.)

Inactive facility was allegedly used as a disposal area
for industrial photochemical waste. No containment
practices are in evidence.

Scores: $S_M = 23.00$ ($S_{gw} = 39.80$ $S_{sw} = 0.00$ $S_a = 0.00$)
 $S_{FE} = N/A$
 $S_{DC} = 0.00$

D. UPDATED DOCUMENTATION RECORDS

DOCUMENTATION RECORDS
FOR
HAZARD RANKING SYSTEM

INSTRUCTIONS: As briefly as possible summarize the information you used to assign the score for each factor (e.g., "Waste quantity = 4,230 drums plus 800 cubic yards of sludges"). The source of information should be provided for each entry and should be a bibliographic-type reference. Include the location of the document.

FACILITY NAME: GAF Dump

LOCATION: City of Binghamton, Broome County

DATE SCORED: June 15, 1989

PERSON SCORING: A. Kostic/A. Longoria

PRIMARY SOURCE(S) OF INFORMATION, Investigation, FIT, etc.):

Groundwater and soil chemical analyses, site visit, site representative interview, NYSDEC file.

FACTORS NOT SCORED DUE TO INSUFFICIENT INFORMATION:

Sa - No air sampling data available.

COMMENTS OR QUALIFICATIONS:

No surface water samples were collected because there is no surface water in the vicinity of the site which would be directly impacted by surface run-off.

GROUNDWATER ROUTE

1 OBSERVED RELEASE

Contaminants detected (5 maximum):

Chloroethane, 1,2 dichloroethane, 2-butanone [6].

Score = 45

Rationale for attributing the contaminants to the facility:

Results of chemical analyses show that these compounds were not detected in the upgradient water sample and were detected in downgradient water samples at more than three times detection limits. The concentrations of these compounds are greater than five times the concentrations found in the associated blanks [6].

* * *

2 ROUTE CHARACTERISTICS

Depth to Aquifer of Concern

Name/description of aquifer(s) of concern:

Clinton Street-Ballpark aquifer. Unconsolidated deposits of sand, gravel and occasional silt and clay lenses, Pleistocene age. The Clinton-Street-Ballpark aquifer is reported to be more than 40 feet at its thickest point [5,7].

Depth(s) from the ground surface to the highest seasonal level of the saturated zone [water table(s)] of the aquifer of concern:

Depths from the ground surface to the water table range from 6.3 to 31.0 feet [5].

Depth from the ground surface to the lowest point of waste disposal/storage:

Wastes poured out on ground surface [4]. The lowest point of waste disposal is unknown. For purpose of scoring, assumed a minimum of 6 feet [1].

Score = 3

Net Precipitation

Mean annual or seasonal precipitation (list months for seasonal):

39 inches [1]

Mean annual lake or seasonal evaporation (list months for seasonal):

27.5 inches [1]

Net precipitation (subtract the above figures):

11.5 inches [1]

Score = 2

Permeability of Unsaturated Zone

Soil type in unsaturated zone:

Sand and gravel with occasional lenses of silt and clay [5].

Permeability associated with soil type:

4×10^{-4} cm/sec. (well MW-2) [8].

Score = 2

Physical State

Physical state of substances at time of disposal (or at present time for generated gases):

Liquids [4]

Score = 3

3 CONTAINMENT

Containment

Method(s) of waste or leachate containment evaluated:

No known containment [4].

Method with highest score:

No liner or leachate control.

Score = 3

4 WASTE CHARACTERISTICS

Toxicity and Persistence

Compound(s) evaluated:

Chloroethane, 1,2-dichloroethane, 2-butanone

Compound with highest score:

1,2-dichloroethane [1]

Score = 12

Hazardous Waste Quantity

Total quantity of hazardous substances at the facility, excluding those with a containment score of 0 (Give a reasonable estimate even if quantity is above maximum):

Total quantity of waste disposed is unknown. For scoring purposes assumed minimum non-zero quantity [4,9].

Basis of estimating and/or computing waste quantity:

Letter, T.H. Teitel. Associate Counsel, GAF Corporation, to Mr. Chen, November 27, 1984 [9].

Score = 1

5 TARGETS

Groundwater Use

Use(s) of aquifer(s) of concern within a 3-mile radius of the facility:

Drinking water (Johnson City Water Works) and industrial (Anitec Corp.). There are no alternative sources of water supply within a 3-mile radius [2,7,10].

Score = 3

Distance to Nearest Well

Location of nearest well drawing from aquifer of concern or occupied building not served by a public water supply:

Johnson City well field is located 1.8 miles northwest of the site [3].

Distance to above well or building:

1.8 miles [3]

Score = 2

Population Served by Groundwater Wells Within a 3-Mile Radius

Identified water-supply well(s) drawing from aquifer(s) of concern within a 3-mile radius and populations served by each:

19,600 [2,10]

Computation of land area irrigated by supply well(s) drawing from aquifer(s) of concern within a 3-mile radius, and conversion to population (1.5 people per acre):

No irrigation being done within a 3-mile radius [11].

Total population served by ground water within a 3-mile radius:

19,600

Score = 5

Matrix Score = 30

SURFACE WATER ROUTE

1 OBSERVED RELEASE

Contaminants detected in surface water at the facility or downhill from it (5 maximum):

None. No surface water analysis has been performed as a part of this Phase II investigation. No surface water was detected on or adjacent to the site. Trout Brook storm sewer cannot be considered surface water [6,3].

Score = 0

Rationale for attributing the contaminants to the facility:

Not applicable.

* * *

2 ROUTE CHARACTERISTICS

Facility Slope and Intervening Terrain

Average slope of facility in percent:

4 percent [3]

Name/description of nearest downslope surface water:

Chenango River [3]

Average slope of terrain between facility and above-cited surface water body in percent:

Less than 1 percent [3]

Is the facility located either totally or partially in surface water?

No [3]

Score = 0

Is the facility completely surrounded by areas of higher elevation

No [3]

1-Year, 24-Hour Rainfall in Inches

2.25 inches [1]

Score = 2

Distance to Nearest Downslope Surface Water

4,500 feet [3]

Score = 2

Physical State of Waste

Liquids [4]

Score = 3

* * *

3 CONTAINMENT

Containment

Method(s) of waste or leachate containment evaluated:

Liquid wastes from production of photographic material were allegedly dumped directly onto the ground of an area depressed below grade. Depression was filled with rubble and presumably covered with soil [13].

Method with highest score:

Landfill has adequate cover material [1].

Score = 0

4 WASTE CHARACTERISTICS

Toxicity and Persistence

Compound(s) evaluated

None. Wastes are not introduced to the surface water route due to adequate cover material.

Compound with highest score:

N/A

Score = 0

Hazardous Waste Quantity

Total quantity of hazardous substances at the facility, excluding those with a containment score of 0 (Give a reasonable estimate even if quantity is above maximum):

Zero.

Basis of estimating and/or computing waste quantity:

Wastes are not introduced to the surface water route due to adequate cover (containment score is zero) [1].

Score = 0

* * *

5 TARGETS

Surface Water Use

Use(s) of surface water within 3 miles downstream of the hazardous substance:

Recreation and transportation [2,10,13]

Score = 2

Is there tidal influence?

No

Distance to a Sensitive Environment

Distance to 5-acre (minimum) coastal wetland if 2 miles or less:

N/A

Distance to 5-acre (minimum) freshwater wetland if 1 mile or less:

None present [13]

Distance to critical habitat of an endangered species or national wildlife refuge, if 1 mile or less:

None [12]

Score = 0

Population Served by Surface Water

Location(s) of water-supply intake(s) within 3 miles (free-flowing bodies) or a 1 mile (static water bodies) downstream of the hazardous substances and population served by each intake:

None. (Water supply intake for Binghamton City Water is located upstream on the Susquehanna River above the confluence with the Chenango) [2,10,16].

Score = 0

Computation of Land area irrigated by above-cited intake(s) and conversion of population (1.5 people per acre):

None [11]

Total population served:

N/A

Name/description of nearest of above water bodies:

N/A

Distance to above-cited intakes measured in stream miles:

N/A

AIR ROUTE

1 OBSERVED RELEASE

Contaminants detected:

No documentation of an observed release has been obtained. No air samples have been taken. Field measurements taken with a PID indicated no readings above background levels.

Date and location of detection of contaminants:

N/A

Methods used to detect the contaminants:

N/A

Rationale for attributing the contaminants to the site:

N/A

Score = 0

* * *

2 WASTE CHARACTERISTICS

Reactivity and Incompatibility

Most reactive compound:

N/A

Score = 0

Most incompatible pair of compounds:

N/A

Toxicity

Most toxic compound:

N/A

Score = 0

Hazardous Waste Quantity

Total quantity of hazardous waste:

N/A

Score = 0

Basis of estimating and/or computing waste quantity:

N/A

* * *

3 TARGETS

Population Within 4-Mile Radius

Circle radius used, give population, and indicate how determined:

| | | | |
|-----------|--|----------------|-------------|
| 0 to 4 mi | <input type="text" value="0 to 1 mi"/> | 0 mi to 1/2 mi | 0 to 1/4 mi |
| | 10,817 | 2,287 | 448 |

Population is based on 3.8 persons per house and, in part, on population density for Binghamton (5,371 people/sq. mi.) [14]. The highest score was obtained for 0 to 1 mi radius [14].

Score = 24

Distance to a Sensitive Environment

Distance to 5-acre (minimum) coastal wetland if 2 miles or less:

N/A

Distance to 5-acre (minimal) fresh-water wetland if 1 mile or less:

There is no freshwater wetland within 1 mile radius [13].

Distance to critical habitat of an endangered species if 1 mile or less:

N/A [12]

Score = 0

Land Use

Distance to commercial/industrial area if 1 mile or less:

On-site [3]

Score = 3

Distance to national or state park, forest, or wildlife reserve if 2 miles or less:

N/A [12]

Score = 0

Distance to residential area if 2 miles or less:

40 feet [3]

Score = 3

Distance to agricultural land in production within past 5 years if 1 mile or less:

None [17]

Score = 0

Distance to prime agricultural land in production within past 5 years if 2 miles or less:

None [17]

Score = 0

Is a historic or landmark site (National Register or Historic Places and National Natural Landmarks) within the view of the site?

No [15]

Score = 0

FIRE AND EXPLOSION*

1 CONTAINMENT

Hazardous substances present:

N/A

Type of containment if applicable:

N/A

* * *

2 WASTE CHARACTERISTICS

Direct Evidence

Type of instrument and measurements:

No measurements taken.

Ignitability

Compound used:

N/A

Reactivity

Most reactive compound:

N/A

Incompatibility

Most incompatible pair of compounds:

N/A

*S_{FE} is scored only if a Fire Marshal has certified that the site is a fire and explosion threat or field observation documented a fire and explosion threat. Since neither of these is true, S_{FE} is not scored.

Hazardous Waste Quantity

Total quantity of hazardous substances at the facility:

N/A

Basis of estimating and/or computing waste quantity:

N/A

* * *

3 TARGETS

Distance to Nearest Population

N/A

Distance to Nearest Building

N/A

Distance to Sensitive Environment

Distance to wetlands:

N/A

Distance to critical habitat:

N/A

Land Use

Distance to commercial/industrial area if 1 mile or less:

N/A

Distance to national or state park, forest, or wildlife reserve,
if 2 miles or less:

N/A

Distance to residential area, if 2 miles or less:

N/A

Distance to agricultural land in production within past 5 years,
if 1 mile or less:

N/A

Distance to prime agricultural land in production within past 5
years, if 2 miles or less:

N/A

Is a historic or landmark site (National Register or Historic
Places and National Natural Landmarks) within the view of the
site?

N/A

Population Within 2-Mile Radius

N/A

Buildings Within 2-Mile Radius

N/A

DIRECT CONTACT

1 OBSERVED INCIDENT

Date, location, and pertinent details of incident:

No documentation of direct contact causing injury to humans or animals [4].

Score = 0

2 ACCESSIBILITY

Describe type of barrier(s):

Fencing is present, but accessible along south side.

Score = 3

* * *

3 CONTAINMENT

Type of containment if applicable:

Liquid wastes from production of photographic material were allegedly dumped directly onto the ground of an area depressed below grade. Depression was filled with rubble and presumably covered with soil.

Score = 0

* * *

4 WASTE CHARACTERISTICS

Toxicity

Compounds evaluated:

None

Compound with highest score:

N/A

Score = 0

5 TARGETS

Population within one-mile radius

At least 10,817 persons [14].

Score = 4

Distance to critical habitat (of endangered species)

Not within 1 mile [12].

Score = 0

Re: GAF-Dump ID# 704011
Binghamton/Broome County

BUREAU OF HAZARDOUS SITE CONTROL
DIVISION OF SOLID AND
HAZARDOUS WASTE

Dear Sirs:

GAF has searched its records in response to DEC's September 28 request for information concerning the Binghamton site. GAF has attempted to compile all currently available information consistent with the Environmental Conservation Law (ECL), Section 27-1307.

As provided by Section 27-1307(2), GAF cannot fully comply with DEC's request for information because no records remain. GAF has no knowledge of records or of anyone who can provide information concerning the types or quantities of wastes deposited at Binghamton.

Consequently, GAF is also without information about the period of operation, description of practices, including testing, monitoring or remedial action. There has not been, to GAF's knowledge, any health or environmental problem resulting from disposal of waste at this site.

This response follows a significant effort to locate records which may have provided additional information. Please contact me at (201) 628-4021 if you have any additional questions concerning this matter.

Sincerely yours,

JHT:er

TELEPHONE CONVERSATION MEMORANDUM

CLIENT NYSDEC Phase I Round 3 PROJ. No. 04339 EX

PROJECT GAF Dump DATE May 21, 1986

TIME 2:35 p.m.

CALL TO/FROM Lee Nelson REPRESENTING Cooperative Extension,
Horticulture Division.

PHONE No. (607) 772-8953

SUMMARY OF CONVERSATION:

Lee Nelson is aware of no such irrigation practices being done within a three mile radius from aquifer of concern of the GAF site. Outside of the City, she is aware of strawberry fields being irrigated, but is over a three mile radius.

Norman W. Hinsey
 Gibbs and Hill, Inc.
 11 Penn Plaza
 New York, N.Y. 10001-2059

Dear Mr. Hinsey:

We have reviewed the Significant Habitat Program and the Natural Heritage Program files with respect to fourteen (14) inactive hazardous waste sites in various counties in New York State.

We have identified the following potential concerns:

1. Cardwell Condenser Corp. Site - Bay Shore West quadrangle -
 There is a designated Significant Coastal Fish and Wildlife Habitat (SCFWH) in Great South Bay. The Great South Bay SCFWH has records of Least tern (*Sterna antillarum*), a federally-listed endangered species. A brief report on this site is enclosed. This site is officially designated under the New York State Department of State's Coastal Management Program; coastal consistency requirements have to be met for projects that might adversely impact the habitat, whether or not the project is actually within the designated area. More information regarding this designation and the consistency requirements may be obtained by contacting:

Mr. Thomas Hart, NYS Dept. of State, Coastal Management Program
 162 Washington Ave., Albany, N.Y. 12231 (518) 474-3642

There are four historic records of rare plants in this area.
 (see enclosed list for occurrences on the Bay Shore West quadrangle).
 None of these species are federally-listed.

2. Site 356013, Poughkeepsie quadrangle -
 The Poughkeepsie Deepwater Habitat SCFWH is officially designated under the Coastal Management Program described above. The same Coastal consistency requirements apply to this site. This SCFWH includes habitat for Shortnose sturgeon (*Acipenser brevirostrum*), a federally-listed endangered species. A brief report describing this site is enclosed.

There are three historic records of rare plants in this area
 (see enclosed list for occurrences on the Poughkeepsie quadrangle).
 None of these species are federally-listed.

3. Hercules site, Kingston East quadrangle -
This site is within a deer wintering area (Sig. Hab. #DC56-101), a significant wildlife habitat.
4. Site 344028, Sloatsburg Quad -
There is a 1977 report of bog turtle (Clemmys muhlenbergii), a state-endangered species, within 1 mile of the site (see enclosed list).
5. Cornwall Landfill, site #336011, Cornwall quadrangle -
There are three significant wildlife habitats in the vicinity, a waterfowl concentration area, a raptor concentration area, and an anadromous fish concentration area. (see enclosed list).
6. Site 314062, Copake quadrangle -
There is an occurrence of a rare wetland community, a rich shrub fen, in the vicinity (see enclosed list).
7. C & D Batteries, site #336001, Port Jervis North quadrangle -
There are records of copperhead (Agkistrodon contortrix, Heritage rank of S3) and timber rattlesnake (Crotalus horridus, ranked S3), a state-threatened species in the vicinity. There are also significant occurrences of two communities: Appalachian calcareous rocky summit and hemlock northern hardwood forest (see enclosed list).
8. East Greenbush Landfill, East Greenbush quadrangle -
The Papscanee Marsh and Creek SCFWH is officially designated under the Coastal Management Program described above. The same coastal consistency requirements apply to this site. A brief report describing this site is enclosed.

We did not identify any other potential impacts on endangered, threatened or special concern wildlife species, rare animal or natural community occurrences, or other significant habitats on or adjacent to the other six sites.

Our files are continually growing as new habitats and occurrences of rare species and communities are discovered. In most cases, site-specific or comprehensive surveys for plant and animal occurrences have not been conducted. For these reasons, we can only provide data which have been assembled from our files. We cannot provide a definitive statement on the presence or absence of species, habitats or natural communities. This information should not be substituted for on-site surveys that may be required for environmental assessment.

This response applies only to known occurrences of rare animals, plants and natural communities and/or significant wildlife habitats. You should contact our regional offices(s), Division of Regulatory Affairs, at the address(es) enclosed for information regarding any regulated areas or permits that may be required (e.g., regulated wetlands) under State law.

If this project is still active one year from now we recommend that you contact us again so that we may update this response.

If we can be of further assistance please do not hesitate to contact us.

Sincerely,

Carol Reschke

POTENTIAL HAZARDOUS WASTE SITE
SITE INSPECTION REPORT
PART 3 - DESCRIPTION OF HAZARDOUS CONDITIONS AND INCIDENTS

I. IDENTIFICATION
01 STATE: 02 SITE NUMBER
NYD 002239465

II. HAZARDOUS CONDITIONS AND INCIDENTS

01 A. GROUNDWATER CONTAMINATION 02 OBSERVED (DATE: _____) POTENTIAL ALLEGED
03 POPULATION POTENTIALLY AFFECTED: 19,600 04 NARRATIVE DESCRIPTION

Groundwater analyses detected three organics. Several metals were found to be above NYS Sanitary Code for Drinking Water.

01 B. SURFACE WATER CONTAMINATION 02 OBSERVED (DATE: _____) POTENTIAL ALLEGED
03 POPULATION POTENTIALLY AFFECTED: _____ 04 NARRATIVE DESCRIPTION

Site is 200' uphill from Trout Brook storm sewer (66") which discharges to Chenango River. Site has no leachate control system.

01 C. CONTAMINATION OF AIR 02 OBSERVED (DATE: _____) POTENTIAL ALLEGED
03 POPULATION POTENTIALLY AFFECTED: _____ 04 NARRATIVE DESCRIPTION

No detection of contamination of air using PID during Gibbs & Hill Engineering Site Reconnaissance, August 4, 1988, and well drilling from 10/8/88 to 10/28/88.

01 D. FIRE/EXPLOSIVE CONDITIONS 02 OBSERVED (DATE: _____) POTENTIAL ALLEGED
03 POPULATION POTENTIALLY AFFECTED: _____ 04 NARRATIVE DESCRIPTION

None noted during field activities.

01 E. DIRECT CONTACT 02 OBSERVED (DATE: _____) POTENTIAL ALLEGED
03 POPULATION POTENTIALLY AFFECTED: _____ 04 NARRATIVE DESCRIPTION

No direct contact has been documented, causing injury to humans or animals. No workers on-site. Cover material presumably placed over waste.

01 F. CONTAMINATION OF SOIL 02 OBSERVED (DATE: _____) POTENTIAL ALLEGED
03 AREA POTENTIALLY AFFECTED: unknown 04 NARRATIVE DESCRIPTION
(Acres)

Waste liquids were allegedly spilled out of 55-gallon drums onto soil surface. Soil analyses show silver and lead.

01 G. DRINKING WATER CONTAMINATION 02 OBSERVED (DATE: _____) POTENTIAL ALLEGED
03 POPULATION POTENTIALLY AFFECTED: 19,600 04 NARRATIVE DESCRIPTION

Under certain environmental conditions, potential exists for cone depression to change groundwater flow gradient such that flow is from site towards Johnson City.

01 H. WORKER EXPOSURE/INJURY 02 OBSERVED (DATE: _____) POTENTIAL ALLEGED
03 WORKERS POTENTIALLY AFFECTED: None 04 NARRATIVE DESCRIPTION

No worker exposure/injury has been documented.

01 I. POPULATION EXPOSURE/INJURY 02 OBSERVED (DATE: _____) POTENTIAL ALLEGED
03 POPULATION POTENTIALLY AFFECTED: None 04 NARRATIVE DESCRIPTION

None known. Site is closed.

PART 3 - DESCRIPTION OF HAZARDOUS CONDITIONS AND INCIDENTS

| L IDENTIFICATION | |
|------------------|----------------|
| 01 STATE | 02 SITE NUMBER |
| NYD | 002239465 |

II. HAZARDOUS CONDITIONS AND INCIDENTS (Continued)

01 J. DAMAGE TO FLORA
04 NARRATIVE DESCRIPTION

02 OBSERVED (DATE: _____) POTENTIAL ALLEGED

None noted or reported.

01 K. DAMAGE TO FAUNA
04 NARRATIVE DESCRIPTION (include names of species)

02 OBSERVED (DATE: _____) POTENTIAL ALLEGED

None noted or reported.

01 L. CONTAMINATION OF FOOD CHAIN
04 NARRATIVE DESCRIPTION

02 OBSERVED (DATE: _____) POTENTIAL ALLEGED

None noted or reported.

01 M. UNSTABLE CONTAINMENT OF WASTES
(Soils Runoff, Standing liquids, Leaking drums)
03 POPULATION POTENTIALLY AFFECTED: _____ 04 NARRATIVE DESCRIPTION

02 OBSERVED (DATE: _____) POTENTIAL ALLEGED

Wastes from the plant were allegedly dumped directly onto the ground. Dump area was presumably filled with rubble and covered with soil.

01 N. DAMAGE TO OFFSITE PROPERTY
04 NARRATIVE DESCRIPTION

02 OBSERVED (DATE: _____) POTENTIAL ALLEGED

None noted or reported.

01 O. CONTAMINATION OF SEWERS, STORM DRAINS, WWTPs
04 NARRATIVE DESCRIPTION

02 OBSERVED (DATE: _____) POTENTIAL ALLEGED

None noted or reported.

01 P. ILLEGAL/UNAUTHORIZED DUMPING
04 NARRATIVE DESCRIPTION

02 OBSERVED (DATE: _____) POTENTIAL ALLEGED

None noted or reported.

05 DESCRIPTION OF ANY OTHER KNOWN, POTENTIAL, OR ALLEGED HAZARDS

None noted or reported.

III. TOTAL POPULATION POTENTIALLY AFFECTED: 19,600

IV. COMMENTS

Most obvious threat is to groundwater supply and population utilizing groundwater.

V. SOURCES OF INFORMATION (cite specific references, e. g., state files, sample analyses, reports)

07 COMMENTS
Waste liquids allegedly spilled out of drums onto ground surface.

IV. CONTAINMENT

01 CONTAINMENT OF WASTES (Check one)
 A. ADEQUATE, SECURE B. MODERATE C. INADEQUATE, POOR D. INSECURE, UNSOUND, DANGEROUS

02 DESCRIPTION OF DRUMS, DIKING, LINERS, BARRIERS, ETC.
None. Liquids disposed on soil surface.

V. ACCESSIBILITY

01 WASTE EASILY ACCESSIBLE: YES NO
02 COMMENTS
Site fenced in, but accessible along south side.

14 DESCRIPTION OF SITE IN RELATION TO SURROUNDING TOPOGRAPHY

Site is located in a mixed commercial and residential neighborhood in the north central region of the City of Binghamton. Immediately to the east is Spring Forest Cemetery, to the south is the Anitec Corp. plant facility, and to the immediate west and downhill is Veterans Memorial Park. A residential neighborhood to the north on Prospect Street is uphill and upgradient of the site.

I. DEC WORK PLAN

Phase II Work Plan

GAF Dump

City of Binghamton/Broome County

Site ID #704011

Based on this work plan, the consultant must develop a detailed cost estimate for each task identified on Table 1. The cost estimate and work plan will be incorporated into the cost plus fixed fee contract with a limiting upset figure. Unless it is otherwise stated, work shall conform to the concept of Schedule 4, Exhibits 1 (Generic Work Plan - State Superfund Program - Phase II Investigations) and 3 (Guidelines for Exploratory Boring, Monitoring Well Installation, and Documentation of these Activities) of the contract document.

A copy of this work plan and Exhibits 1 and 3 of the contract must be taken to the field by the consultant during Phase II field activities, since these documents are crucial to proper implementation of Departmental field protocols. Through his actions, the field representative will display familiarity with the provisions of the work plan and exhibits. Failure to provide any of the above documents at the New York State Department of Environmental Conservation (NYSDEC) representative's request, or for the consultant to show inadequate comprehension of their contents are sufficient grounds for NYSDEC to halt Phase II field work.

Introduction

The GAF Dump is a one-acre site located in the City of Binghamton behind the former GAF manufacturing plant, now owned by Anitec Corporation. GAF retained ownership of the dump area when their plant was sold to Anitec.

The site was used for dumping construction debris and there are piles of cinders scattered about. GAF allegedly used the site to dispose of waste liquids from the production of photographic material by dumping 55-gallon drums of liquid directly onto the ground. GAF denies this allegation.

Since the site is located in a populous neighborhood, and Johnson City, located west of the site, draws groundwater from the aquifer of concern, a Phase II investigation will be performed.

A Phase I investigation by Wehran Engineering was completed in April, 1986.

Objective

The objective of this Phase II investigation is to collect the information required to classify the site for further action and to develop a final HRS score. This includes collecting the field data necessary to identify the occurrence and characteristics of contamination and if a release of contaminants from the site has occurred. This information will be used to determine if any imminent and/or significant environmental or health hazard exists. Specifically, these objectives will be accomplished through the drilling of test borings, installation of groundwater monitoring wells, and sampling and analysis of groundwater, surface water, soil, wastes, and sediments (where any or all of these media are applicable).

For the purpose of report preparation, the consultant is to compile all pertinent file information and data obtainable from the NYSDEC and various other agencies.

Site Reconnaissance

Representatives of NYSDEC met with GAF's consultant on November 1, 1985 and inspected the GAF Dump site in order to familiarize staff with the site and to discuss locations for sampling and boring/monitoring well installation.

The site is located at the east corner of Charles and Seymour Streets and abuts Spring Forest Cemetery. Approximately one third of the site consists of a paved parking lot. Based on the topography of the cemetery, it appears that the paved area was probably never filled in. However, a slope from the west side of the site down to a gravel parking area and basketball courts indicates that at least a section of the site may have been filled at one time.

Access to the site will not be difficult since the terrain is flat and it is located adjacent to two roads. A chain link fence surrounds the site and entrance must be made through a gate at the north site of the paved area. GAF Corporation has the key to that gate.

Based on the site inspection, a sketch was prepared showing the proposed monitoring well and sampling locations (see Figure 1).

Field Investigation

This project has been divided into specific tasks, summarized in Table 1. Field efforts to complete this investigation are described in greater detail below.

Geophysics: The goals of the geophysical survey are to characterize the subsurface geology, locate contaminant plumes, define the boundaries of buried waste, and to determine groundwater flow direction. In addition, buried metal objects, such as drums, gas lines, water lines, and metal waste, may also be located.

For the GAF Dump a geophysical survey will be conducted using a grid to sufficiently characterize subsurface conditions of the site and site-related areas (e.g. background and downgradient). The starting point of the grid will be located from an established reference point so that the survey may be repeated if elected. The consultant must determine the best geophysical method to meet the goals of the investigation and submit a work plan for the Bureau's review.

In addition to the geophysical survey, a magnetometer survey will also be conducted on site to locate buried water mains, gas, electric, or telephone lines which may be present. The magnetometer survey will be used to supplement the geophysical data and to investigate proposed monitoring well locations for obstructions.

Since final placement of monitoring wells is contingent on the results of the geophysical investigation, reduced geophysical data and a written interpretation of it shall be present at the site in the field representative's possession, and fully understood by the representative, at the time of drilling and placement of monitoring wells.

Test Borings and Monitoring Wells: Monitoring wells will be installed to provide data pertinent to both water chemistry and characterization of the stratigraphy and groundwater regime at the site.

Well construction shall adhere strictly to the NYSDEC protocols enumerated in Exhibit 3 of the Phase II Generic Work Plan. (This exhibit is also included in the contract). These protocols govern not only well installation and development, but classification and physical testing of soil, containment of drill cuttings and fluids, recording blow counts, etc. They also govern the proper procedures regarding decontamination of drilling equipment, split spoon samplers, and all other downhole materials.

It is anticipated that 2-inch I.D. monitoring wells will be installed at the approximate locations shown in Figure 1, using hollow-stem augers large enough to facilitate placement of downhole materials with a tremie, as required in Schedule 4, Exhibit 3 of the consultant contract.

Finalized well locations will depend on the results of the geophysical study and local conditions. The consultant, in conjunction with NYSDEC representatives, shall determine the final well locations in the field, as necessary. The consultant will provide an experienced engineer, geologist, or other adequately experienced technical staff to be on site at all times during drilling activities and monitoring well construction.

Three test borings/monitoring wells will be installed on the GAF Dump site. Refer to Figure 1 for approximate well locations.

It is anticipated that groundwater will be encountered at approximately thirty to forty feet below ground surface. The site lies over the Clinton Street - Ballpark aquifer, a section of the Endicott-Johnson City valley-fill aquifer that is separated from the Susquehanna River by deposits of till. The site lies on the northern edge of the aquifer, where glacial outwash deposits thin out and the valley wall rises. As a result, the thickness of the aquifer beneath the GAF site is expected to be only 20 to 40 feet.

The area to the east of the Spring Forest Cemetery consists of a kettlehole filled by low permeability peat, muck, silt, and clay deposited over the mixed sand and gravel aquifer to a thickness of twenty feet or more. A tongue of this low permeability deposit reaches to the GAF Dump and ends in the vicinity of Veteran's Memorial Park, immediately to the west of the site. This can be seen in the 1935 topographic map where the area that is now the park was then a swamp.

Groundwater flow in the immediate vicinity of the site appears to flow south, toward Anitec's on-site wells (used for cooling water). Past groundwater pumpage has caused drawdown of the water table to a point that the gradient,

which originally flowed to the east toward the Chenango River, is reversed, causing induced recharge from the Chenango River. In particular, this recharge affects several industrial wells located southeast of the site, between the Chenango and Spring Forest Cemetery, but it may also affect Anitec wells located at the main plant, south of the site. Other sources of aquifer recharge are precipitation, local streams, and inflow from outlying areas. A cone of depression exists around Anitec's on-site wells.

One of Johnson City's drinking water wells draws from a major buried aquifer approximately one and a half miles to the northwest of the site. Though the buried aquifer is separated from the upper aquifer by low permeability deposits of lake silt and fine sand, the potentiometric surface around this well indicates local drawdown conditions. It is, however, unlikely that any potential contamination from the GAF Dump would make its way to this well due to the separation between the sites and the cone of depression caused by Anitec's industrial wells.

The single upgradient well will be located to the north of the site either along the south side of Seymour Street or perhaps across the street in an empty lot. A third option exists just north of the gravel parking lot at the corner of Charles and Seymour Streets.

Two downgradient wells will be located south of the site close to Anitec's plant. There may be some difficulty in well placement, since there is a paved road (approximately fifteen feet wide) along the southern fence line of the site. Since the parking lot is fenced in and no longer used, it may be possible to drill the wells through the pavement in order to take them as far away from the old disposal area as possible. Wells placed on Anitec's property would most likely interfere with plant operation, so this option is not being pursued.

The two downgradient wells will be placed to gain the best information on site stratigraphy and groundwater flow. If a contaminant plume is identified through the geophysical survey, at least one of the wells will be placed to sample from that plume.

If borings are not completed on the same day they are started, a mechanism to ensure their integrity will be devised. The consultant will provide NYSDEC with their plan for this contingency.

During drilling operations, the open hole and split spoon samples will be monitored with an HNU or OVA (or similar instrument). If the site is found or suspected of discharging gases near or above explosive limits, then drilling operations will be monitored with an explosimeter/oxygen meter.

Following construction of the monitoring wells, each well will be developed as soon as it has fully stabilized and as soon as practically possible before or during the drilling operation at the next well. Groundwater elevations will be taken in each well before and immediately following proper development. Each well will be developed to the point that the turbidity of the recovered well water is 50 Nephelometric Turbidity Units (NTU's) or less. A nephelometer shall be brought to the field for the purpose of making this measurement. A signed statement stating that the turbidity in each well was 50 NTU or less immediately after development will be provided to NYSDEC if a Department representative is not present when measurements are made.

Permeability testing of each monitoring well will be performed after well development. The slug test method is preferable, where a known volume of water is introduced to the well and the water level recovery is recorded.

Well locations and elevations for all on-site wells will be surveyed by a licensed surveyor to allow for accurate water level measurements and development of groundwater contour maps. Each well elevation will be determined relative to a USGS datum, if available within 200 feet of the site, or a permanent point set in the field. The top-of-casing measurement for each well will be accurate to the nearest 0.01 foot, and the ground surface adjacent to the well shall be measured to the nearest 0.1 foot. The distance between wells will be measured to a two-foot accuracy.

Prominent surface water levels will also be measured to the nearest 0.01 foot in order to augment groundwater measurements, particularly when the surface water is known or believed to represent an above-ground extension of the water table.

All well locations in Figure 1 are approximate. Final locations will be determined after the geophysical analysis has been performed and data has been reduced and interpreted. Completed well logs shall be prepared and submitted with the Phase II report.

Refer to the Generic Work Plan and Exhibits 3 and 4 for specific monitoring well construction and soil classification requirements.

Sampling and Analysis: Where required by NYSDEC, sampling and chemical analyses will be performed by the consultant. This includes split spoon samples for chemical analysis when it is suspected or confirmed by HNU or OVA that soils are contaminated. During all sampling episodes, the consultant will follow the QA/QC and chain-of-custody protocols as referred to in the Generic Work Plan and as described in the New York State Contract Laboratory Protocols document. NYSDEC's chosen sampling locations (which may be upgraded or modified by the consultant) are indicated in Figure 1, with sampling and chemical analyses summaries specified in Tables 2 and 3, respectively.

Where dilution of any Phase II sample is to be done by the chemical analytical laboratory prior to analysis, NYSDEC is to be advised immediately. The concern is that a component of low concentration, but of significant environmental impact, could become so diluted that its presence in the final extract will not be detected.

During this contract, the NYSDEC chemist will discuss alternatives with the laboratory's chemist on how best to conduct the analysis. NYSDEC chemist is Mr. John Rankin, telephone (518) 457-3252.

Although a method or extra work may be agreed upon by both chemists, clearance for any extra cost must be obtained by the consultant from the NYSDEC contract manager. Such cost will be paid from the contingency amount in the contract, and clearance must be confirmed by NYSDEC in writing.

At least one sample each from the three monitoring wells will be collected for laboratory analysis. Surface water does not exist, per se, at this site. A 66-inch storm sewer line runs underground beneath Anitec's plant to its discharge point at the Chenango River. It is known as the Trout Brook line, perhaps due to incorporation of a stream by the same name. The topographical map shows a small stream which disappears from the map in the vicinity of Wilson School, south of Prospect Street.

It would seem inappropriate to sample this flow as surface water, since any contamination found could not positively be attributed to the GAF Dump. Water from this line was sampled by the Broome County Health Department in 1971 and was found to seriously violate state pollution control laws. The water in the line was determined to represent industrial wastes, cooling water wastes, and storm water from the then GAF plant, plus a small amount of storm water from a portion of Prospect Street.

Since it is not known whether these conditions still exist, it will suffice to say that surface water sampling will not occur at the GAF Dump site.

The alleged waste disposal practice (i.e. dumping liquid on the ground surface) suggests that limited soil sampling should be done in lieu of surface water sampling. Samples shall be taken from various depths by using a hand auger. A total of six soil samples will be taken from a depth of three to four feet at locations spread around the site. In addition, soil samples from the two downgradient locations shall be taken at a depth of ten feet. One additional sample shall be taken from off-site for background information.

These nine soil samples will be analyzed for Hazardous Substance List (HSL) metals. GAF's representative indicated that GAF dumped silver smelting slag on-site in 1964, and sampling of Trout Brook detected silver and zinc. Other heavy metal wastes used by GAF Corp. may be detected in soil samples.

Where determined by NYSDEC or the consultant's field representative that additional chemical analyses are required for soil samples from well drilling activities, the consultant must be prepared to obtain such samples for shipment to a laboratory. Pricing for this activity must be included. For costing purposes, assume one sample per well for analysis.

Water samples will be analyzed for volatile organics (VOA's), pesticides/PCB's, base-neutral-acids (BNA's), and HSL metals. Refer to Table 3 for details on chemical analysis of samples. One trip blank (VOA only) and one field blank will be analyzed with the water samples.

Air monitoring, consisting of a site survey with a detection instrument such as an HNU or OVA, shall occur upon arrival at the site. This air monitoring is separate from monitoring that is part of the health and safety plan. If a source of air contamination is identified, the air will be sampled using appropriate equipment to determine the nature and concentration of the contaminant. Upwind air samples will also be analyzed at the same time. Wind direction must be continuously monitored and documented during any sampling and analysis of air samples.

Health and Safety Plan

The consultant will observe the provisions of the health and safety plan during drilling and sampling activities.

It is anticipated that Level D protection will be necessary on the site. If, during the investigation, it is determined that the level of protection should be upgraded, the consultant shall prepare a site-specific health and safety plan appropriate for the level of protection required.

Report

The report shall follow the format outlined in the Phase II Generic Work Plan, and shall be in accordance with Article 49 of the consultant contract.

Quality Assurance Plan

The Quality Assurance Plan will be submitted as a separate document.

Table 1
Phase II Work Plan - Task Description
GAF Dump

| <u>Tasks</u> | <u>Description of Task</u> |
|--|--|
| II-A Prepare and update work plan | Will be done by NYSDEC. |
| II-B Conduct records search/data compilation | Review Phase I information and any additional information. |
| II-C Site reconnaissance | Has been done by NYSDEC. |
| II-D Conduct geophysical studies | Conduct geophysical survey. Based on the study, revise the location of monitoring wells, if needed, for approval by NYSDEC. |
| II-E Install and develop monitoring wells | Install three wells. The borings will be drilled to a depth of approximately 50 feet. |
| Soil samples during drilling | During drilling, soil samples collected at 5-ft. intervals, and at changes in lithologies. Perform grain size analysis and Atterberg limits. Rock core samples collected continuously. |
| II-F Perform sampling and analysis | Refer to Tables 2, 3 and "Sampling and Analysis". |
| II-G Conduct site assessment | A preliminary site contamination assessment will be conducted to complete the final HRS score and HRS documentation records. |
| II-H Report preparation | Prepare final report containing significant Phase I information, additional field data, final HRS score, HRS documentation records, and site assessments. |
| II-I Project management | Project coordination, administration and reporting. |

Table 2
Phase II Work Plan - Sampling Summary
GAF Dump

| <u>Designation</u> | <u>Location</u> | <u>Aquifer Screened</u> | <u>Approx. Boring Depth (ft)</u> | <u>Length of Screen (ft)</u> |

| <u>Leachate</u> | | | | |
| None | | | | |

NOTE: Locations, aquifer screened, approximately boring depth, length of screen are based on existing data and are the basis of the cost estimate. These criteria may change based on the results of the geophysical surveys and/or field conditions.

TABLE 3
NYSDEC - RECOMMENDED CHEMICAL ANALYSES - GAF Dump

| Type of Sample | Type of Analyses(1) | | | | |
|----------------------------|---------------------|---------------------|------------------------------|-------------------------------|--------------------|
| | HSL(2) Metals | HSL(3) Volatiles | HSL(4) Semi- Volatiles | HSL(5) Pesticides/ PCBs | Spike/Duplicate(6) |
| Groundwater(7) | 4 | 4 | 4 | 4 | 1/1 |
| Surface Water | --- | --- | --- | --- | --- |
| Sediment | --- | --- | --- | --- | --- |
| Soil | 9 | --- | --- | --- | 1/1 |
| Blanks (Trip and Field) | 1 | 2 | 1 | 1 | --- |

- (1) Complete identification per NYSDEC Generic Work Plan, Section 3(b)(ii)(B). Field pH, conductivity and temperature measurements will be conducted on all water samples. Also pH, specific conductance, Chemical Oxygen Demand (COD), Total Dissolved Solids (TDS) and Total Suspended Solids (TSS) measurements will be made at the laboratory for all water samples.
- (2) HSL Metals - Preparation and analysis of the 15 Task 1 and 9 Task 2 inorganic compounds using the specified CLP methods.
- (3) HSL Volatiles - Preparation and analysis using the CLP specified GC/MS method for HSL purgeable organics plus a library search for and the quantification of any additional non-HSL compounds (the CLP requires the library search only for the 10 non-HSL compounds of largest apparent concentration).
- (4) HSL Semi-Volatiles - Preparation and Analysis using the CLP specified GC/MS method for HSL Extractable Base/Neutral and Acid Organic compounds plus a library search for and the quantification of any additional non-HSL compounds (the CLP requires the library search only for the 20 non-HSL compounds of largest apparent concentration).
- (5) HSL Pesticides/PCBs - Preparation and pre-extraction of the HSL organo-chloride pesticides and polychlorinated biphenyls using the CLP specified GC-ECD method
- (6) Superfund and Contract Laboratory Protocol, January 1985, requires at least one spiked sample analysis and one duplicate sample analysis from each group of samples of a similar matrix type for each case of samples or for each 20 samples received, whichever is more frequent.

--- Designates that no samples are to be analyzed.

- (7) The reason for one additional groundwater sample is that a duplicate sample must be obtained from a monitoring well chosen at random. That duplicate sample must not be identified as a duplicate to the laboratory, but must be assigned an identifier similar to other groundwater samples.

The Bureau requires the blind analysis of a duplicate sample for each site by the laboratory, to confirm the integrity of all sampling and analytical activities.

INTRODUCTION

Geophysical surveys were conducted at the GAF Dump site on August 10, 1988 to characterize subsurface conditions. A magnetometer was used at proposed monitoring well locations to detect ferromagnetic objects which might be encountered during drilling. A resistivity survey was performed to determine the depth to the water table and to locate anomalies which could indicate ground-water quality changes resulting from the landfill. A terrain conductivity survey was performed to characterize shallow subsurface conditions.

METHODS OF INVESTIGATION

Magnetometer

The Schonstedt Model GA-52B flux-gate magnetometer used for the survey provides a continuous audio signal which increases from the idling frequency of 40 Hz as surface and/or subsurface ferromagnetic material is approached.

The well locations were furnished by the NYSDEC as shown on Figure 1. At each proposed well location, an area of approximately 300 square feet was screened in detail with the magnetometer. If no detections of ferromagnetic material were made within the survey area, the location center was marked with red spray paint indicating the proposed well number. If detections were made, the surrounding area was screened until a clear location was found. Before leaving the area, distances from permanent site markers were recorded.

Terrain Conductivity

A Geonics Model EM-31D non-contacting terrain conductivity meter was used to locate anomalies in ground conductivity. The instrument has a nominal operational depth of about six meters. Readings, given in millimhos per meter, are influenced by shallow materials more strongly than by those located deeper.

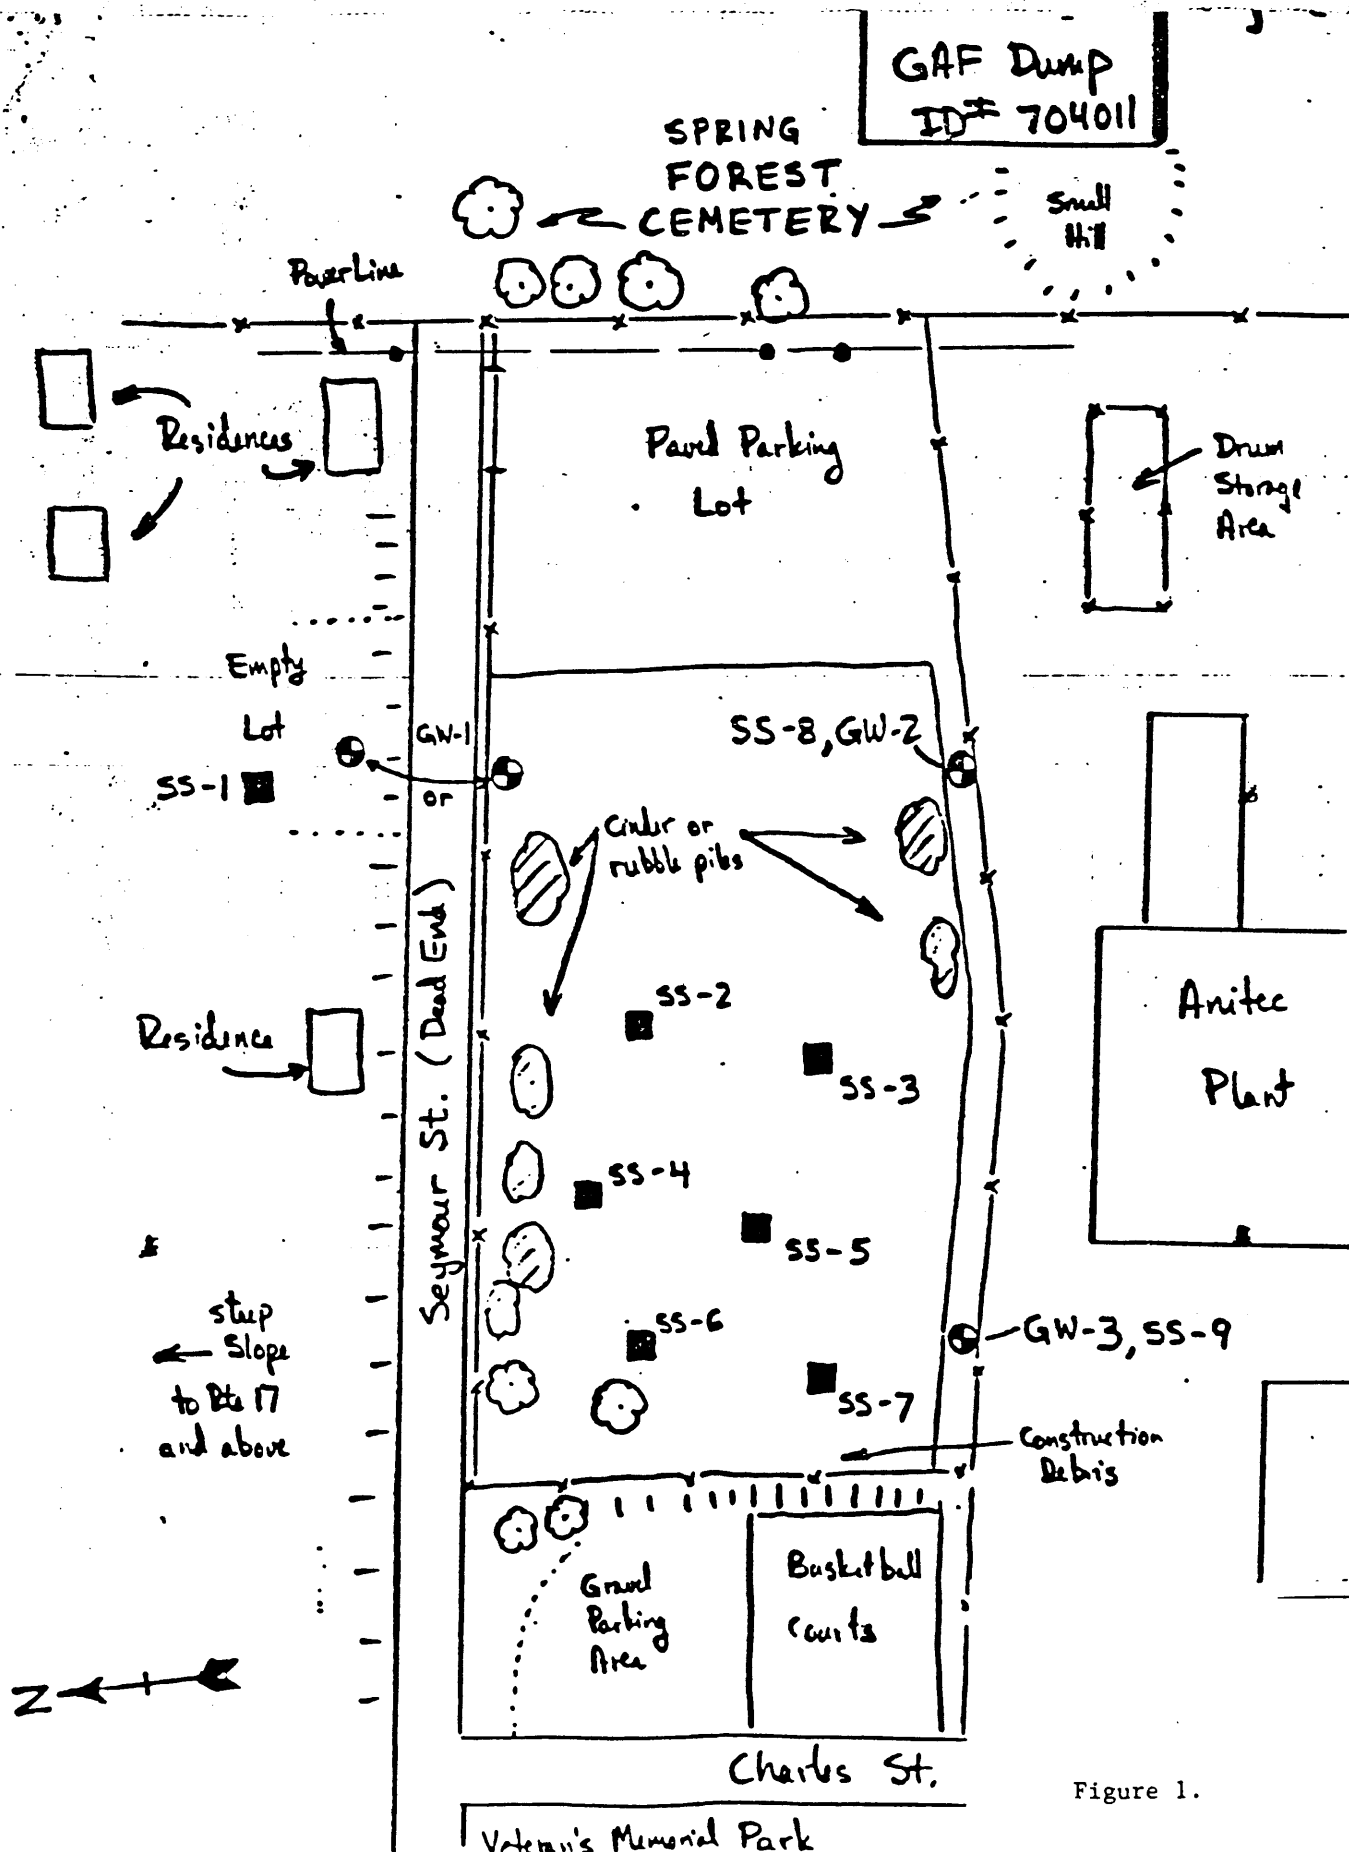

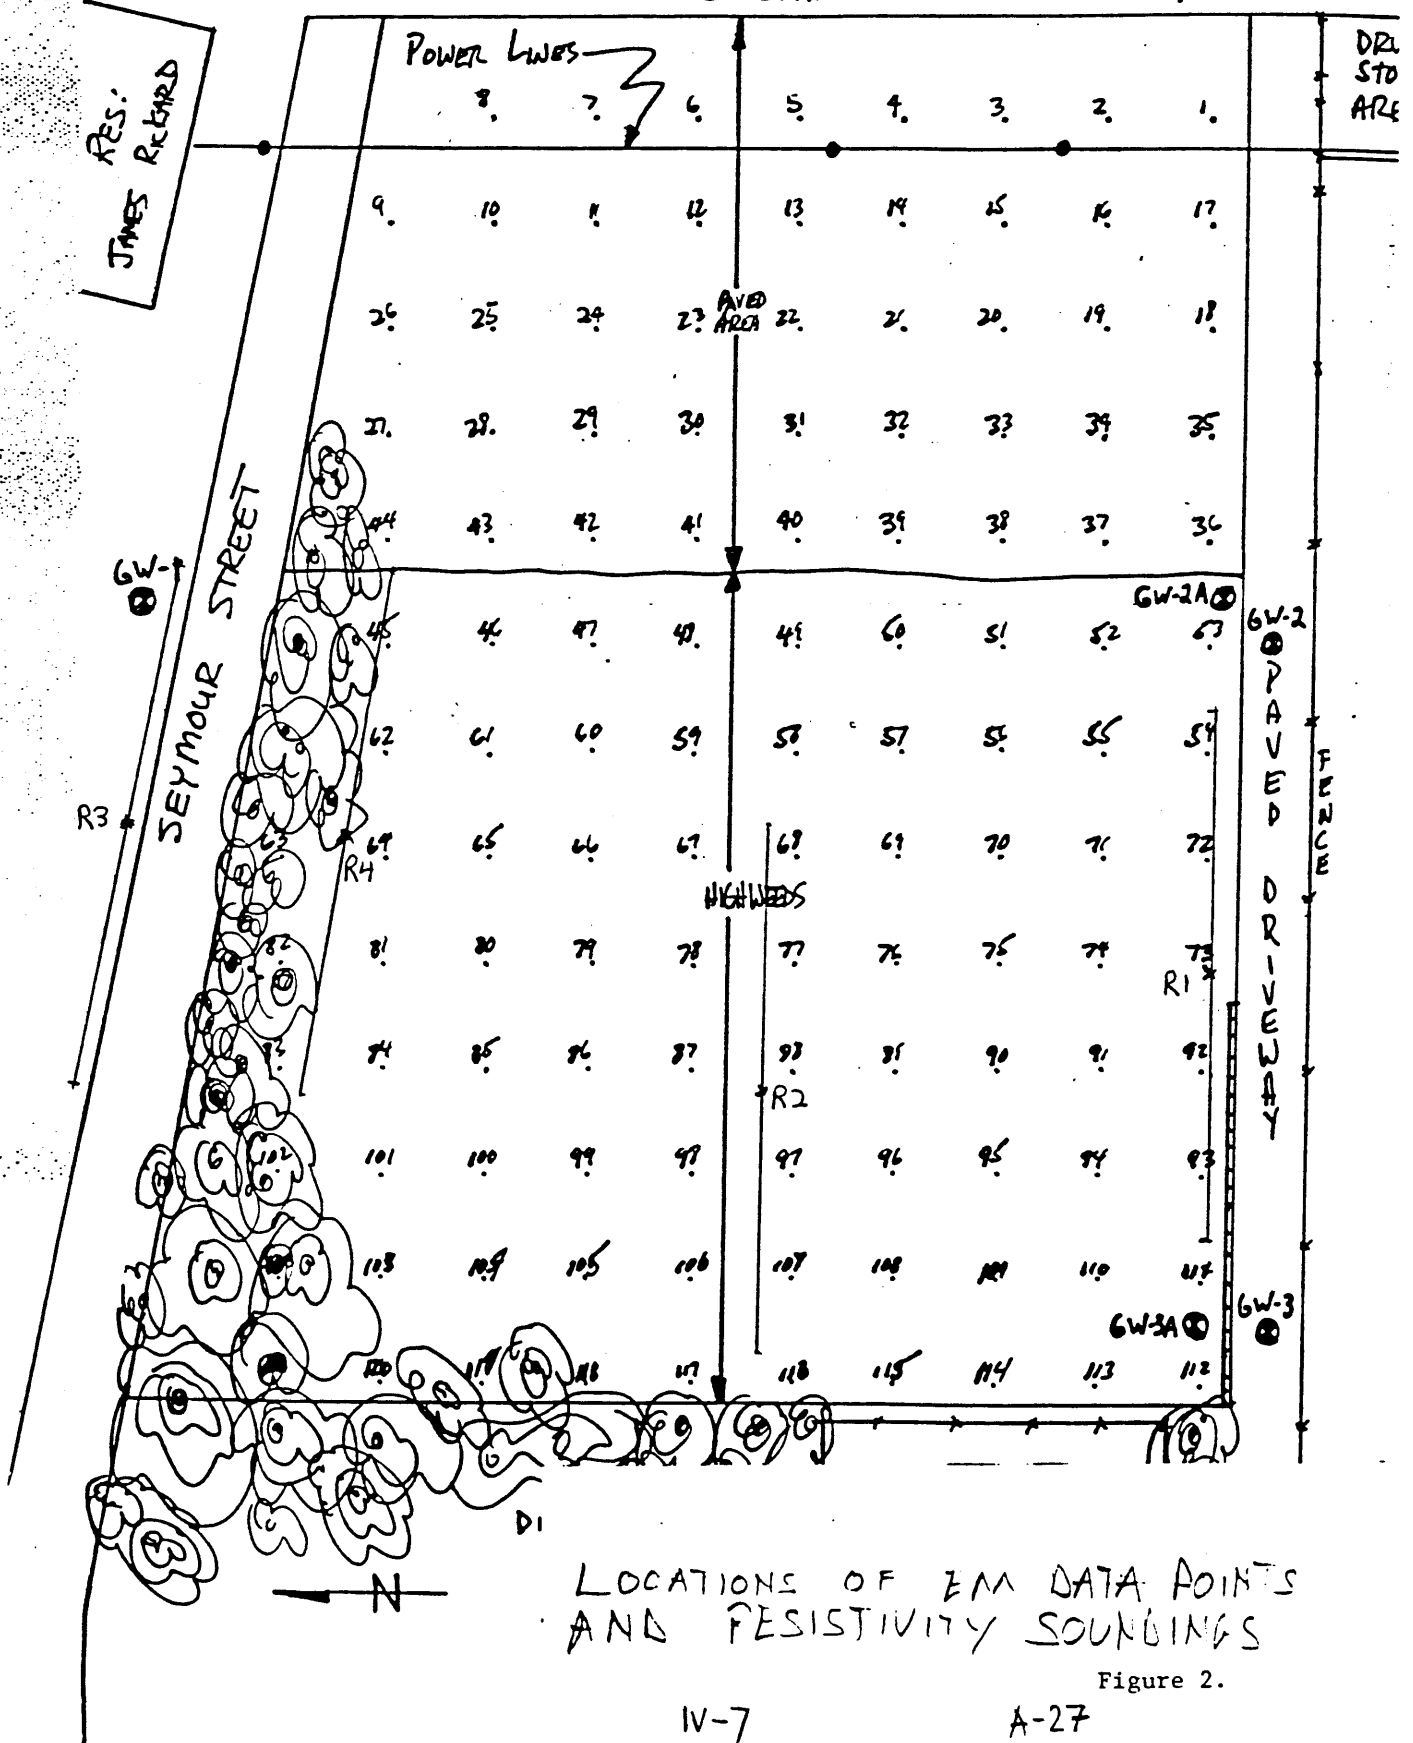

Figure 1.

GAF DUMP SITE
8-10-88

SPRING FOREST CEMETERY

SCALE: 1" = 5'

LOCATIONS OF EM DATA POINTS
AND RESISTIVITY SOUNDINGS

Figure 2.

The survey was conducted with the instrument set up to record the quadrature component of the magnetic field. A 30-by-30 foot grid pattern was referenced to permanent site locations so that the survey may be reproduced if necessary. To detect nearby lateral changes in conductivity, two readings were taken at each grid node, perpendicular to each other. The instrument was calibrated according to the manufacturers specifications prior to the survey.

Resistivity

A Bison 2350B resistivity meter was used to measure earth resistivity. The Lee Electrode Arrangement was used exclusively. The instrument was calibrated according to the manufacturers specifications prior to the survey. Soundings were performed using ten foot electrode spacing increments beginning at ten feet and ending at the fifty foot spacing.

DISCUSSION OF RESULTS

Magnetometer

A magnetometer survey was conducted at the locations of the proposed monitoring wells to detect potential drilling obstructions. No buried ferromagnetic anomalies were detected at the proposed well locations (Figure 2, and Figures 3-5).

Terrain Conductivity

The EM-31 is a geophysical instrument which induces a magnetic field to characterize terrain conductivity. The instrument will respond to changes in geology, ground-water quality and man-made conductive objects to a depth of about six meters. Interpretation of the data is limited because information regarding these factors was not available.

A terrain conductivity survey was conducted using a 30-by-30 foot grid which was keyed into locations of existing monitoring wells so that the survey may be reproduced at some later date if necessary.

Data point locations and readings are shown on Figure 2 and data are presented in Table 1. Figure 6 shows contoured EM-31 data. Higher areally extensive terrain conductivity was recorded at the southwest portion of the site. The area corresponds with that

=====

DATA POINTS 1,2,3 - COULD NOT OBTAIN ACCURATE READINGS FOR THE "t" AXIS ORIENTATION.

- (1) - READING TAKEN WITH INSTRUMENT AXIS IN A NORTH-SOUTH DIRECTION.
- (2) - READING TAKEN WITH INSTRUMENT AXIS IN AN EAST-WEST DIRECTION.

14-18

A-38

projected by the NYSDEC in the Phase II Work Plan to be the downgradient edge of the site. The proposed locations for GW-2 and GW-3 are situated within this area of higher conductivity.

Resistivity

The resistivity survey was conducted using multi depth soundings. Locations and directional orientation of electrode arrays are shown on Figure 2, and data are presented in Tables 2-5 and Figures 7-10.

Depth to groundwater was projected in the Phase II Work Plan to be about 30 to 40 feet below ground surface. The data do not suggest large changes in resistivity at that interval. Also, there are no patterns relating the four soundings. The site is complex geophysically.

At sounding 1, a decrease in apparent resistivity between the 10 and 20 foot electrode spacing was followed by constant readings through 50 feet. The location of sounding 1 corresponds with the area of high conductivity located with the EM-31. Sounding 2 is characterized by a decrease in resistivity through the 40 foot spacing followed by a slight increase to 50 feet. Sounding 3 shows an increase in apparent resistivity through 50 feet while sounding 4 shows consisting apparent resistivity at the 10, 20, 40, 50 foot spacings with a slight increase at 30 feet.

Apparent Resistivity Readings (In Ohm-FT)
Average of 30, 40, 50 foot
Electrode Spacings

A-48

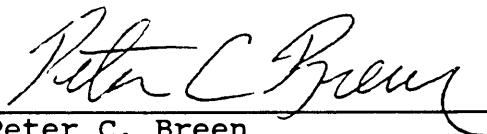

Figure 11

Assuming that the water table is located as estimated by the NYSDEC, an average of the 30, 40, and 50 foot spacings will characterize the resistivity of the saturated zone at each sounding location. Figure 11 shows that the average apparent resistivity for the saturated zone increases toward the north within the site boundaries.

SUMMARY OF FINDINGS

Results of the geophysical survey indicate that there are no buried ferromagnetic objects in the vicinity of the proposed monitoring wells. The terrain conductivity survey located an area of higher readings for the upper 6 meters at the southwest portion of the site. Resistivity data for the estimated saturated zone suggest that there is a general decrease between the projected upgradient and downgradient site boundaries.

V. DRILLING PROTOCOLS

The monitoring wells will be drilled in the following order:

- (1) GW-1
- (2) GW-2
- (3) GW-3

See Appendix A for drilling protocols.

Note: Depth to groundwater was projected in the Phase II Work Plan to be 30 to 40 feet below ground surface. Geophysical data suggests that groundwater depth may be deeper than projected.

GAF DUMP SITE

SPLIT SPOON SAMPLES

One split spoon sample will be taken from GW-2 and GW-3 monitoring wells, (SS-8 and SS-9). The soil samples from the GW-2, and GW-3 wells will be taken from the following depth:

GW-2: 10 ft.
GW-3: 10 ft.

Laboratory analysis of these samples will include a matrix spike and duplicate. The split spoon samples will be taken during the last day of drilling and will be included with other soil samples (SS-1 thru SS-7) in the same matrix.

GRAIN SIZE SAMPLES

One soil sample shall be collected from each monitoring well to be analyzed for grain size distribution. These samples shall be taken from the last split spoon sample of each well.

APPENDIX B

B.1 PROCEDURES

1. Drilling and Well Installation

Monitoring wells were drilled and installed to provide data pertinent to both water chemistry and characterization of the stratigraphy and ground water regime at the site. Drilling was performed by Layne Northern Company.

One well (GW-1) was installed at presumed upgradient locations on the north side of the dumping pit to provide representative samples of the groundwater flowing into the area. This monitoring well was installed by drilling with 6.25-inch hollow-stem augers until refusal (at approximately 25 feet because of boulders), at which time rotary wash method was used to advance the remainder of the boring.

Two additional monitoring wells (GW-2 and GW-3) were drilled to monitor downgradient flow direction and water quality. The monitoring wells were installed by drilling with 6.25-inch hollow-stem augers.

A ten-foot section of #10 slotted PVC screen (2-inch I.D.) was installed at the bottom of each well, and was connected to the surface with a 2-inch, flush joint Sch 40 PVC riser. A sand

pack was extended to approximately two feet above the screen. Bentonite pellets and bentonite slurry seals, each approximately one foot thick, were placed on top of the sand pack. The remaining annular space was filled with a cement/bentonite grout. Steel protective casings (with locking covers) were set over each monitoring well riser and secured into the ground with concrete. See Section B-2 for well schematics.

Split spoon samples were collected at five-foot intervals for the purpose of soil characterization. Soil sample descriptions, sampler blow counts and soil recovery records for all wells are shown in boring logs (Section B.2).

Each well was developed by pumping water with an inertial pump to remove from the screen pack formation the maximum practical quantity of sediment and other fine materials in order to produce a satisfactory amount of sediment-free water. Wells GW-1, GW-2, and GW-3 were developed for more than one hour each. A nephelometer was employed to measure the clarity of groundwater during development. The recommended turbidity of 50 NTU could not be reached [approximately 200 Nephelometric Turbidity Units (NTU) were measured for all wells during and after development] due to the fine-grained nature of the material within the screened interval (silt and clay with some sand and gravel). The well sand pack could not retain small

particles, especially those in the form of colloides, and clear water could not be obtained.

Inertial Pump

The pump is composed of one-piece molded ABS plastic body, foot valve, a flexible polyethylene tubing, and a stainless steel levered handle. A gasoline powered motor drive was used in place of the levered handle where large volumes of water were removed from the wells. The operating principle of the pump is based on the inertia of a column of water contained within a riser tubing. The pump is operated by a continuous up and down movement of the tubing. The water within the tubing will move upward in pulses and ultimately discharge at the surface.

2. Slug Test

A slug test was performed to determine in situ hydraulic conductivity values. A standard method of performing a slug test is to instantaneously drop a clean weight down the well to displace the water and measure the water level as it returns to original level. The weight used was a dedicated teflon bailer with disposable polypropylene disposable cord, filled with distilled water.

The rate of the groundwater level change was recorded by measuring the depth to the water below the top of the casing after the start of the test until the original level of water table was restored.

Groundwater elevation was measured and recorded prior to any testing. All water elevation measurements were performed with an electronic water level indicator.

The Hvorslev method was used to calculate the permeability, K
(cm/sec):

$$K = \frac{r^2 \ln(L/R)}{2 L T_0}$$

Where:

r = radius of a PVC riser, cm

L = length of screen beneath static water level, cm

R = radius of sand pack, cm

T₀ = elapsed time, t, at (H-h)/(H-H₀) = 0.37 sec.

H = reference datum, cm

H₀ = water level at equilibrium, cm

h = water level at time t, cm

t = elapsed time, sec.

(R. Allan Freeze and J.A. Cherry, Groundwater, Prentice
Hall Inc., pp. 339) [D.19]

3. Grain Size Analysis

Grain size distribution analyses were performed by Geo-Tech Associates (Fanwood, New Jersey). Analyses were conducted on the last split spoon samples collected from each overburden well. All analyses were performed in accordance with ASTM Method No. D422. The percentage of each grain size component was determined. Results of these analyses were plotted on a particle size distribution graph.

A hydrometer analysis was not performed on those samples having less than 20 percent silts and clays (i.e., material passing through the number 200 sieve).

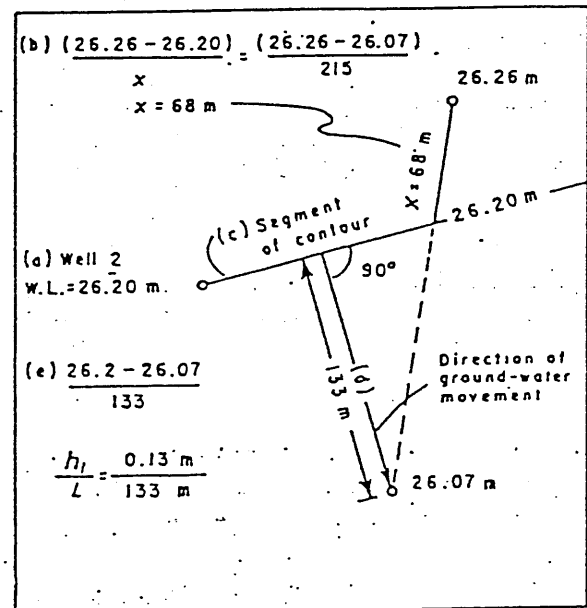

The interrelationship between grain size and hydraulic conductivity can be used for the estimation of conductivity values. An empirical relation based on Morris and Johnson's (1967) Representative Values of Hydraulic Conductivity and Masch and Denny's (1966) determination of saturated hydraulic conductivity from grain-size gradation curves [D.20] was used to estimate conductivity values and correlate them to observed values in the field.

4. Determination of Groundwater Flow Direction

The following diagrams present the triangulation method for determining groundwater flow direction.

(2)

(3)

Both the direction of ground-water movement and the hydraulic gradient can be determined if the following data are available for three wells located in any triangular arrangement such as that shown on sketch 2:

1. The relative geographic position of the wells.
2. The distance between the wells.
3. The total head at each well.

Steps in the solution are outlined below and illustrated in sketch 3:

- a. Identify the well that has the intermediate water level (that is, neither the highest head nor the lowest head).
- b. Calculate the position between the well having the highest head and the well having the lowest head at which the head is the same as that in the intermediate well.
- c. Draw a straight line between the intermediate well and the point identified in step b as being between the well having the highest head and that having the lowest head. This line represents a segment of the water-level contour along which the total head is the same as that in the intermediate well.
- d. Draw a line perpendicular to the water-level contour and through either the well with the highest head or the well with the lowest head. This line parallels the direction of ground-water movement.
- e. Divide the difference between the head of the well and that of the contour by the distance between the well and the contour. The answer is the hydraulic gradient.

B.2 RESULTS

DRILLING SUMMARY REPORT

Site Name: GAF Dump
Site I.D.: 704011
Date(s): 10/17 - 10/28/88
Present: Albert Longoria (G&H)
Larry Alden (NYSDEC)
Driller: Layne Northern Company

Well Summary

1. Relocation of Well

GW-1 - Relocated approximately 30 ft. to the east of original location. Original location was sited incorrectly on someone else's property.

GW-2 - Relocated 10 ft to the north. Permission to install the well on the access road could not be obtained.

GW-3 - Relocated 10 ft to the north. Permission to install the well on the access road could not be obtained.

2. Well Data

| | <u>Boring Depth (ft)</u> | <u>Depth to Water*, (ft)</u> |
|------|--------------------------|------------------------------|
| GW-1 | 40 | 31.02 |
| GW-2 | 18 | 6.27 |
| GW-3 | 20 | 8.25 |

* Depth to water refers to feet below ground surface.

3. Well Development

Each well developed more than one hour by pump (capacity 4.2 gpm). Groundwater turbidity more than 200 NTUs.

4. In-Situ Permeability Test Results

| <u>Well No.</u> | <u>Permeability, cm/sec</u> |
|-----------------|-----------------------------|
| GW-1 | 5.7×10^{-4} |
| GW-2 | 1.3×10^{-3} |
| GW-3 | 1.0×10^{-4} |

HYDRAULIC CONDUCTIVITY VALUES FROM

THE MORRIS AND JOHNSON TABLE

| <u>Well No.</u> | <u>Hydraulic Conductivity</u> <u>cm/sec</u> |
|-----------------|--|
| MW-1 | 5-9 x 10 ⁻⁵ |
| MW-2 | 3 x 10 ⁻³ |
| MW-3 | 9 x 10 ⁻⁵ |

MW-1 has a field hydraulic conductivity of 6×10^{-4} cm/sec while the estimated hydraulic conductivity value from the Morris and Johnson table was taken as a range from coarse sand to silt, 5×10^{-2} to 9×10^{-5} . Using the grain size analysis data it was difficult to narrow the range. The comparison of field and estimated hydraulic conductivities for MW-1 is, therefore, not very strong.

MW-2 had a field hydraulic conductivity of 1×10^{-3} . The estimate, based on grain size analysis data was considered a fine sand with some silt. The hydraulic conductivity chosen from the Morris and Johnson table was 3×10^{-3} cm/sec. and substantiates the slug test field value.

The hydraulic conductivity value for MW-3 was 1×10^{-4} cm/sec. From the grain size analysis data, the MW-3 sample was composed of 80% silt. The hydraulic conductivity of silt, 9.0×10^{-5} cm/sec. was, therefore, chosen from the Morris and Johnson table as a representative estimate for MW-3. As in MW-2, the estimated hydraulic conductivity for MW-3 substantiates the slug test field value.

APPENDIX C
SAMPLING AND ANALYSIS

C.1 PROCEDURES

1. Sampling Methodology

The sampling plan was prepared by Gibbs & Hill as a part of the updated work plan. It identifies the number of each sample type to be collected and describes collection methods to be utilized. The sampling plan specifies each sampling location and gives a sketch with roughly indicated sampling locations for illustrative purpose. The sampling locations were given code numbers for identification.

In order to ensure a smooth and proper sampling process in the field, the following preparations and steps were taken:

- Coordination with the laboratory to ensure adequate number of laboratory cleaned containers were provided, with the necessary preservatives according to the appropriate protocols.
- All instruments to be used in the field were checked to ensure working order. All instruments were calibrated before going to the site.

- Sampling equipment was cleaned in accordance with the cleaning procedure outlined on Page C-4.

During the sampling events, the following elements were implemented:

- Chain of custody procedures were followed.
- Accurate sampling log was maintained.
- No sampling containers other than those provided by the laboratory were used.
- A field blank and a trip blank accompanied aqueous samples.
- Prior to sampling, laboratory supplied deionized water was poured over sampling equipment and collected into field blank bottles.
- Well purging was performed. A minimum of three well volumes of water were evacuated.
- Prior to filling the sample bottles, the groundwater was analyzed for temperature, specific conductance and pH.
- Groundwater sample collection occurred immediately following well development. Samples were collected from the inertial pump except samples for VOA. Dedicated teflon bailers with disposable polypropylene suspension cords were used to collect samples for VOA. Care was

taken to minimize the potential for volatilization during the transfer of the sample from the bailer to the bottle. No headspace or air bubbles were allowed in these samples.

- Samples were capped, labeled (well no., site location, type of sample, collection date and time) and placed in ice filled coolers.
- All samples were stored and maintained at less than 4°C and delivered to the laboratory within 48 hours.

Cleaning Procedure

All sampling equipment was thoroughly cleaned before use in accordance with the following procedure:

1. Non-phosphate detergent and tap water wash
2. Tap water rinse
3. Distilled water rinse
4. Acetone (pesticide grade) rinse
5. Hexane rinse
6. Distilled water rinse
7. Air dry

After this procedure was accomplished, the sampling equipment was wrapped in aluminum foil, placed in a plastic bag, and kept in its wrapping until use.

2. Chemical Analysis

A quality assurance program was developed in the Work Plan to ensure that the precision and accuracy of the groundwater sample analyses were not impacted by sampling, sample handling, and equipment decontamination procedures. This program was based on the collection of the field blank samples for laboratory analysis and the maintenance of a trip blank.

A trip blank determines if sample bottles (empty or full) have been exposed to airborne contaminants in transport or on-site. A trip blank (an aliquot of deionized, analyte-free water which was placed in a container and sealed at the laboratory) accompanied the sampler to each sampling site. The trip blanks were handled, transported, and analyzed (for VOA) in the same manner as the samples acquired that day except that the sample containers themselves were not opened in the field.

A field blank was prepared for each sampling episode. The purpose of a field blank is to provide an additional check on possible sources of contamination beyond those intended for the trip blank. At the field location, in the most contaminated area, the analyte-free water was passed through a sampling device into an empty set of containers. By being opened in the field and transferred over a cleaned sampling device, the field

blank was also indicative of atmospheric conditions and/or equipment conditions that might potentially affect the quality of the associated samples. The field blanks were transported, handled, and analyzed as routine groundwater samples.

All sample analyses were performed by H2M Laboratory following the procedures outlined in the New York State Contract Laboratory Protocol (CLP) of November 1987. The analyses included are the following:

- TCL (Target Compound List) Inorganics - Preparation and analysis of inorganic compounds using the specified CLP methods. The analyses are performed on unfiltered samples. Results of the analyses represent total metals.
- TCL Volatiles - Preparation and analysis using the CLP specified GC/MS (Gas Chromatograph/Mass Spectrometer) method for TCL purgeable organics plus a library search for and the quantification of any additional non-TCL compounds (the CLP requires the library search only for the ten non-TCL compounds of largest apparent concentration).
- TCL Semi-Volatiles - Preparation and analysis using the CLP specified GC/MS method for TCL extractable base/neutral and acid organic compounds plus a library search for and the

quantification of any additional non-TCL compounds (the CLP requires the library search only for the 20 non-TCL compounds of largest apparent concentration).

- TCL Pesticides/PCBs - Preparation and pre-extraction of the organo-chloride pesticides and polychlorinated biphenyls using the CLP specified Gas Chromatograph/Electron Capture Detection (GC/ECD) method.

The CLP used for the analyses specified the quality control measures which were employed including:

- A duplicate sample obtained from a monitoring well chosen at random. That sample was not identified as a duplicate to the laboratory, but was assigned an identifier similar to other groundwater samples. The Bureau of Hazardous Site Control requires the blind analyses of a duplicate groundwater sample for each site by the laboratory to confirm the integrity of all sampling and analytical activities.
- The CLP requires at least one spiked sample analysis and one spiked duplicate sample analysis from each group of samples of a similar matrix type for each case of samples or for each 20 samples received, whichever is more frequent.

- A method blank for each category was used to assess the level of possible laboratory background contamination.

OBG Laboratories, Inc. performed validation of data submitted by H2M Laboratory. For validation of analytical data, the CLP guidelines for validation of laboratory data were followed.

3. Guidelines for Evaluating Chemical Analyses

The assessment of a chemical analysis is made to determine the existence and magnitude of contamination problems and criteria to determine whether or not a quantitative evidence exists of an "observed release" of contaminants to the environment. The following criteria, based on USEPA Laboratory Data Validation, February 1, 1988 [D.18] have been applied for evaluation of any blank associated with the samples:

- For all pollutants the method blank must contain less than Contract Required Quantitation Limits (CRQL) of any single organic pollutant and less than Instrument Detection Limits (IDL) of any single inorganic pollutant. If a method blank exceeds this criterion, the analytical system is considered as "out-of-control".
- Trip and field blank are evaluated as if they are "true" samples. The presence of the analyte in the field/trip blank is an indication of possible field/trip introduced contamination.
- If contaminants are detected in blanks, then sample results are considered "significant" when concentration of the compound in the sample exceeds ten times the amount in any blank for common lab contaminants (methylene chloride, acetone, toluene, 2-butanone and common phthalate esters), or five times the amount for other compounds.

To determine whether or not quantitative evidence exists of an "observed release", the following guidelines have been applied:

- If a contaminant is measured in a sample at a concentration equal to or greater than ten times that of the contaminant in the background sample, then the contaminant is considered to be at a significantly higher level than the background level, and quantitative evidence exists for an observed release.
- If no background concentration is detected (background sample results are below CRQL), then the analytical results for contamination of the sample must be three or more times the CRQL to be considered at a significantly higher level than the background level.

To determine the magnitude of a water body contamination problem, sample results are compared to the following federal and New York State water quality standards or guidelines:

- Environmental Protection Agency National Primary Drinking Water Regulations (as of 7/17/89).

Applied to results of all water sample analyses.

- Chapter 1 of Title 10 of the Official Compilation of Codes, Rules, and Regulations of the State of New York, Part 5, Drinking Water Supplies, Subpart 5-1, Public Water Supplies (as of 11/28/88).

Applied to results of drinking water sample analyses.

- Chapter 10 of Title 6 of the Official Compilation of Codes, Rules, and Regulations of the State of New York, Division of Water Resources, Article 2, Part 702, Appendix 31, Ambient Water Quality Standards - "The standards adopted herein relate to the condition of waters as affected by the discharge of sewage, industrial wastes, or other wastes" (as of 7/5/85).

Applied to results of surface water sample analyses for surface water that is not a source of drinking water.

- Chapter 10 of Title 6 of the Official Compilation of Codes, Rules, and Regulations of the State of New York, Division of Water Resources, Article 2, Part 703.5(a)(2) and (3), Classes and Quality Standards for Groundwaters - "The purpose of these classes, quality standards, and effluent standards and/or limitations is to prevent pollution of groundwaters and to protect the groundwaters for use as a potable water" (as of 7/5/85).

Applied to results of all groundwater sample analyses regardless of groundwater use.

To determine the magnitude of soil and sediment contamination, soil and sediment results are compared to the common range of inorganics in uncontaminated soils as listed in the USEPA publication, Review of In-Place Treatment Techniques for Contaminated Surface Soils (EPA-5400/2-84-0036, November 1984, p. 79).

4. Air Survey

The Photoionization Detector (PID) was used to monitor the presence of volatile organic contaminants in the ambient air at the hazardous waste site. The measurements were evaluated to determine the proper health and safety requirements to be implemented during the site reconnaissance, and during drilling activities. Prior to daily activities, PID measurements were taken along perimeter of the GAF Dump site and readings were logged. Background levels remained at 0.4 ppm.

All split spoon samples were scanned with the PID immediately upon opening of the split spoon samples to assess potential for high levels of volatile organic contamination. The results of these readings are attached with the boring log of each well. No readings were measured in excess of 0.4 ppm.

The meter was calibrated before each day with a benzene standard. Organic vapor emanating from the surface was determined by holding the probe 6"-12" above the surface for 30 seconds. During the drilling procedure, each split-spoon soil sample was tested by holding the probe at approximately 1-inch from the soil sample. Readings were registered when the instrument stabilized. In all monitoring events, the readings were at the background level.

Re: Data Validation
File: 4398-1-517

Dear Mr. Alden:

The purpose of this letter is to comment on the data validated for the Gibbs & Hill Phase II investigation. OBG Laboratories responsibility was to review the data to verify its compliance with NYSDEC CLP requirements. The useability of the data to satisfy the objectives of the investigation is not within our purview, however, we are willing to make a comment as to whether the excursions are major or minor. The ultimate decision lies with the regulatory agency responsible for oversight. The enclosed text provides comments on each site validated. Future packages will include qualitative statements about the overall package.

Should there be any further questions on this matter, please feel free to contact Mr. Norman Hinsey of Gibbs & Hill or myself.

Very truly yours,

OBG Laboratories, Inc.

A handwritten signature in dark ink, appearing to read 'David R. Hill', is written over the typed name.

David R. Hill
Vice President

Mr. Stanley Isaacson, H2M Labs, Inc.
Mr. Iqbal Singh, IMS Engineers, Inc.

Data Validation
Overall Comments

There are major and minor excursions of the CLP deliverables which qualify data. The following comments reflect our experience as analytical chemists reviewing hazardous waste data. Each data package has questions which need to be addressed and are documented in the validation report. Generally, the reports are technically sound and most of the errors are typographical and/or transferring information from one form to another.

- GAF Dump Site - The excursions are minor and the data is useable with qualifiers.
- RCA Rocky Point Site - The excursions are minor, however, the laboratory control sample for inorganics need to be addressed to use the metals data.
- South Montclair Site - There are no major excursions, however, the volatile results should be reviewed to verify that the proper identification was applied.
- Homer Village Site - The excursions are minor and the data is useable with qualifiers.
- Armstrong Site - There was a major excursion in the area of holding times for volatiles and three pesticide samples. The other excursions are minor and should not significantly effect the interpretation.
- Mirabito Site - The comments cited for the Armstrong Site are the same for this site.
- Sealright Site - The data is of good quality with several minor excursions.
- Taylor Site - The comments for this site are the same as the Sealright Site
- Central Suffolk Site - Volatile continuing calibration problems require qualifiers for certain compounds. The other excursions are minor and the data is useable.
- New Scotland Site - The data from this site has no major excursions. However, the high %D on continuing calibration runs for VOA's and BNA's should be addressed.
- East Greenbush Site - One BNA sample required reextraction and was outside the holding time. There are several minor excursions, however, overall the data is useable.

Attn: Norman Hinsey

Dear Mr. Hinsey:

Please find enclosed copies of the lab data reports and case narratives for the samples submitted from the GAF Dump Site. The CLP data package has been forward to O'Brien & Gere and the NYSDEC for review.

Also enclosed are the invoices for both the GAF Dump Site and the RCA Rocky Point (Roux Associates).

If you have any questions regarding this material, please feel free to contact us.

Very truly yours,

H2M Labs, Inc.

ENVIRONMENTAL and INDUSTRIAL ANALYTICAL SERVICES

CASE NARRATIVE FOR PURGEABLE ORGANICS

All quality control criteria were met and no problems were encountered for this data package.

I certify that this data package is in compliance with the terms and conditions of the contract, both technically and for completeness, for other than the conditions detailed above. Release has been authorized by the Laboratory Manager or his designee, as verified by the following signature.

Date Reported: 12/06/88

*
* *J. Molloy* *
*

John J. Molloy, P.E.
Laboratory Director

ENVIRONMENTAL and INDUSTRIAL ANALYTICAL SERVICES

CASE NARRATIVE FOR BASE NEUTRALS/ACID EXTRACTABLES

All Quality Control requirements were met for this group of samples with the exception of the following: the surrogate standard tribromophenol was outside the allowable limits for all samples analyzed. After investigation into the reasons for this unusually high recovery, it appears to be due to a low daily Rf of the continuing calibration. Since the average Rf of the initial calibration was used to quantify the samples the recoveries are on the high side.

The matrix spike and matrix spike duplicate results for pentachlorophenol were both outside the allowable limits, the recoveries were 110% and 126% respectively. The upper allowable range was 103%. The %RPD was slightly outside the allowable for 1,2,4-trichlorobenzene and pyrene.

A dichlorocyclopentane isomer was found in all samples and the method blank. The method blank contained 18J ug/L. The source of this contamination is under investigation.

I certify that this data package is in compliance with the terms and conditions of the contract, both technically and for completeness, for other than the conditions detailed above. Release has been authorized by the Laboratory Manager or his designee, as verified by the following signature.

Date Reported: 12/02/88

John J. Molloy, P.E.
Laboratory Director

ENVIRONMENTAL and INDUSTRIAL ANALYTICAL LABORATORY

CASE NARRATIVE FOR PESTICIDES/PCB'S

The bottles for Pesticide/PCB matrix spike and matrix spike duplicate arrived broken in the laboratory. Therefore, no matrix spike and matrix spike duplicate was performed for the Pesticide/PCB.

The DBC surrogate spike recoveries for sample #4 and the field blank were outside the advisory limits.

All other quality control checks were in compliance with the required limits in the protocol and no problems were encountered with the analyses.

A low level compound eluting at the aldrin retention time was detected on both the primary and confirmatory columns in the method blank (0.13 ug/l); field blank (0.05 ug/l); Sample #3 (0.11 ug/l); and Sample #4 (0.14 ug/l). The cause of this contamination is under investigation.

The data file for the converted data (from intergrator to computer file) for capillary run of Sample #1 (871771) could not be accessed. No computer printout for the chromatogram for this run is available. The original chromatogram from the integrator was submitted.

I certify that this data package is in compliance with the terms and conditions of the contract, both technically and for completeness, for other than the conditions detailed above. Release has been authorized by the Laboratory Manager or his designee, as verified by the following signature.

CASE NARRATIVE FOR METALS

ICP analysis was performed on the ARL's 3410 ICP. Furnace analysis was performed on the Zeeman 5100 furnace. Mercury was analyzed using the manual cold vapor method.

Nickel and Cobalt were initially run on the ICP. The CCV's were out of control. These metals were reanalyzed on the Perkin Elmer 2380 Flame A.A.. Lead was initially run on the Zeeman 5100 furnace and had to be reanalyzed on the Perkin Elmer 2380 Flame A.A. due to high concentrations.

The matrix spike recovery for sample #2 is less than 75% for silver. All associated silver results reported flagged with an "N". Matrix spike recoveries for sample #2 are greater than 125% for antimony, barium, cadmium, and manganese. All associated results reported flagged with an "N".

Duplicate analysis of sample #2 is out of control for barium, copper, iron, manganese, and zinc. All associated results reported flagged with an "*".

ICP serial dilution results of vanadium and chromium for sample #8 are not within the contract limit of 10%. All associated results reported flagged with an "E".

I certify that this data package is in compliance with the terms and conditions of the contract, both technically and for completeness, for other than the conditions detailed above. Release has been authorized by the Laboratory Manager or his designee, as verified by the following signature.

Waters Received 11/2/88

CASE NARRATIVE FOR METALS

ICP analysis was performed on ARL's 3410 ICP. Furnace analysis was performed on Zeeman's 5100 furnace. Mercury was analyzed using the manual cold vapor method. Flame analysis was performed on the Perkin Elmer 2380 Flame A.A. .

Sample #4 (871780) was redigested with appropriate spiking levels for sodium, magnesium, calcium, and potassium. These analyses were performed on the flame.

Inadvertently, spiking levels from an earlier protocol were used for arsenic, manganese, antimony, zinc and nickel.

Silver was initially run on the ICP. The ICS-AB result was not within the control limit of +/- 20%. These samples were reanalyzed on the flame and were within the control limits.

The matrix spike recovery for sample #4 is less than 75% for selenium. The matrix spike recovery for sample #4 is greater than 125% for copper. All associated selenium and copper results reported flagged with an "N" as per protocol.

The absorbances for samples #1 (871777) and #3 (871779) for thallium were less than 50% of the spike absorbances. Since the spike recovery was not between 85-115%, the values associated are flagged with a "W". The absorbances for samples #2 (871778) and #4 (871780) for selenium were less than 50% of the spike absorbances. Since the spike recovery was not between 85-115%, the values associated are flagged with a "W".

The lead matrix spike for sample #4 was incalculable due to a required dilution.

ICP serial dilution results of antimony, cadmium, and iron for sample #3 are not within the contract limit of 10%. All associated results reported flagged with an "E".

I certify that this data package is in compliance with the terms and conditions of the contract, both technically and for completeness, for other than the conditions detailed above. Release has been authorized by the Laboratory Manager or his designee, as verified by the following signature.

for the
Broome County Environmental Management Council

Introduction

In 1979, Broome County's Environmental Management Council published the Broome County Toxic Waste Inventory, its first effort to identify hazardous waste dump sites in the County. This report, representing the Council's second effort, goes beyond the 1979 report by including environmental variables related to the dump sites' potential effect on human health. These variables include soil types at the site, a measure of permeability of those soils, average population density in adjacent areas, and land use. The Register also contains data (where available) on the location of wells and test borings drilled near the dump sites.

Each entry lists information sources used to identify the sites, their users, and materials dumped there. These include published sources and/or information provided by local citizens as a result of an information-gathering campaign initiated by the Council. Other sources include the Soil Survey, Broome County, New York (U.S. Dept. of Agriculture, March 1971) for soil data, and the Broome County Land Use Plan (Broome County Planning Department, June 1977) for population and land use data. Wells and test borings information was obtained from Records of Wells and Test Borings in the Susquehanna River Basin, New York (N.Y.S. Dept. of Environmental Conservation, Bulletin 69, 1972).

Maps showing dump sites, wells, and test borings locations appear to the left of each entry in the Register. Base maps are portions of the Council's Natural Resource Inventory map series.

This effort is not considered a definitive register of all hazardous waste dump sites in Broome County. The Council will update the Register whenever information on any site (whether active or closed) becomes available. Local citizens and government officials are encouraged to call the Environmental Management Council at 772-2116 if they have any further information on hazardous waste dump sites documented in this report or information on suspected sites not included here.

only - not
GAF Dump site*

1. 5 Drums/month Solid Waste - dye saturated filter media, dye scrappings, possible traces of mercury or cyanide. Fe, Zn, Al, Sn traces.
2. 10 drums/month Aqueous colored dye wastes.
3. 10 drums/month organic solvent mixtures - includes benzene, cyclohexane, acetone, IPA, methanol, ethanol, n-hexane, toluene, xylene, methyl cellosolve, chlorinated solvents, and diethyl ether.
4. 10 drums/month mixed chemical solvents - includes IPA, methanol, methylene chloride, acetone, and other hydrocarbons and oxygenated solvents.
5. 1 drum/month Lead Iodide Solid
6. 1 drum/month Lead Bromide Solid
7. 5 drums/month - 1. Cadmium, 2. Ammonium salts, 3. Silver, 4. Iron, 5. Zink, 6. Calcium, 7. Magnesium, 8. Copper, 9. Nickel, 10. Sodium, 11. Potassium, 12. Nitrate, 13. Chloride, 14. Sulfate.

WATER SAMPLE ANALYSIS: 2/4/75

| <u>Element</u> | <u>Embankment West Side of Landfill</u> | <u>Downstream from Landfill</u> |
|----------------|---|-------------------------------------|
| Iron | 17.0 Mg/L | .33 Mg/L |
| Arsenic | .01 Mg/L | .01 Mg/L |
| Cadmium | .02 Mg/L | .02 Mg/L |
| Chromium | .1 Mg/L | .1 Mg/L |
| Lead | ND Mg/L | .1 Mg/L |

Compounds found in near by private wells:
Methylene chloride, toluene, 1,1,1 trichloroethane, trichloroethene, T-1,2 dichloroethene, Chloroform, carbon tetrachloride, 1,1,2 trichloroethane

Extensive sampling has been done in 1983 by Melonie Sviatyla and Broome County Health Department.

LEACHATE HISTORY:

4/70 - 5/73 Leachate observed flowing into a small pond on adjacent property. This pond is the headwaters of a small brook flowing into the Susquehanna Rv.

5/73 Dam and Diversion channel constructed and leachate was landlocked on site.

12/73 Leachate flow into pond resumed.

ROBINTECH INC.

LOCATION: 3421 Old Vestal Rd., Vestal

NUMBER ON MAP: 32
WASTE MATERIAL: Acids, solvents, electro-plating, materials & other various industrial waste. Trichloroethylene & Tetrachloroethylene

GAF DUMP

LOCATION: Charles & Grace Streets, Binghamton
USGS COORDINATES: 42°6'43" 75°55'42"
NUMBER ON MAP: 33.
WASTE MATERIAL: Industrial, photo chemical by-products (silver, cadmium, organics - t-1,2 dichloroethylene, trichloroethylene, phenols, intermediate dyestuffs).

SERVICE MERCHANDISE

LOCATION: 220 Reynolds Rd., N. of Harry L. Drive, Johnson City
USGS Coordinates: 42°7'36" 75°58'14"
STATUS: Closed, developed
NUMBER ON MAP: 34
WASTE MATERIAL: Commercial, J.C. municipal, E.J. industrials, Wilson Hospital Wastes

JENNIE F. SNAPP MIDDLE SCHOOL

LOCATION: Loder Ave. (between North St. & Main St.), Endicott
USGS COORDINATES: 42°5'50" 76°3'39"
NUMBER ON MAP: 35
STATUS: Closed, developed
WASTE MATERIALS: Tanning acids (E.J.), animal hides, municipal wastes, and sludge.

TELEPHONE CONVERSATION MEMORANDUM

CLIENT NYSDEC Phase I Round 3 PROJ. No. 04339 EX
 PROJECT GAF Dump DATE May 20, 1985
 TIME 11:50 a.m.
 CALL TO/FROM Melanie Sviatyla REPRESENTING Engineer, Broome Co.
 PHONE No. 607-772-2887 Health Department

SUMMARY OF CONVERSATION:

Previous employee of GAF. Reported that 55 gallon drums of waste materials were just dumped out on the site.

GAF probably stopped using site 10 years ago.

Site currently fenced and some areas are tarred over and are now used as a parking lot.

Trout Brook was sampled in 1971; will send final report on results.

Re: GAF-Dump ID# 704011
Binghamton/Broome County

BUREAU OF HAZARDOUS SITE CONTROL
DIVISION OF SOLID AND
HAZARDOUS WASTE

Dear Sirs:

GAF has searched its records in response to DEC's September 28 request for information concerning the Binghamton site. GAF has attempted to compile all currently available information consistent with the Environmental Conservation Law (ECL), Section 27-1307.

As provided by Section 27-1307(2), GAF cannot fully comply with DEC's request for information because no records remain. GAF has no knowledge of records or of anyone who can provide information concerning the types or quantities of wastes deposited at Binghamton.

Consequently, GAF is also without information about the period of operation, description of practices, including testing, monitoring or remedial action. There has not been, to GAF's knowledge, any health or environmental problem resulting from disposal of waste at this site.

This response follows a significant effort to locate records which may have provided additional information. Please contact me at (201) 628-4021 if you have any additional questions concerning this matter.

Sincerely yours,

JHT:er

TELEPHONE CONVERSATION RECORD

Date: 10/3/88

Time: 9:30 AM

Call By: A. Longoria of Gibbs & Hill, Inc.
(Name) (Company)

Answer By: Peter Breen of Roux Associates
(Name) (Company)

Contract No.: GAF #704011

Subject Discussed: Clarification and adjustments
to geophysical report

Summary of Discussion, Decisions and Commitments

Resistivity: Regarding the discussion on page 5, paragraph 3, of the geophysical report, the absence of large changes in resistivity at the 30 to 40 feet interval implies that a conductant leachate plume has not been detected at this depth.

Summary of Findings: Peter Breen will elaborate on the geophysical complexities and provide us with a more detailed interpretation of the data. However, according to Peter Breen, the geophysical study needs to key in on monitoring well information in order to provide a more complete conclusion.

D. G

Broome County
Memorandum

To: Ron Tramontano, NYSHD
From: Melonie M. Sviatyla, Robert W. Denz, BCHD
Date: December 15, 1983
Subject: Comments on the "Assessment of Health Problems" for the State Superfund List

The following are comments from the Broome County Health Department (BCHD), regarding local landfill sites selected for the State Superfund listing:

(1) Robintech Inc.:

The BCHD has been involved with the installation of a backflow preventor on the water service to the plant. National Pipe (present owners) have drilled four (4) wells on site for cooling water production. These wells may offer a sampling point to check the groundwater quality.

The BCHD has the following concerns:

- 1) Proximity of the site to the Town of Vestal Well #4-2. This well has already been contaminated with volatile organics.
- 2) There are a number of private residences nearby who have not connected to municipal water, which have their own wells.

(2) Colesville Landfill:

The BCHD has been involved with the sampling of private resident wells in the vicinity of the landfill. Of the twenty (20) water sources sampled, four (4) have contained levels of volatile organics which exceed New York State Health Department (NYSHD) guidelines. Those organics found in the resident water supplies were also present in the leachate from the landfill. At the present time, these residences are receiving bottled water for drinking and cooking, supplied by the Broome County Dept of Public Works (BCDPW). Bottled water is also being supplied to those residences who may be located in the "contaminated groundwater plume" as presented in a report prepared by the County Engineering consultants. Additional monitoring of residences will commence in January 1984. At that time, the County consultants Phase II report will be presented.

The BCHD has the following concerns:

- 1) Long term effects of contamination on other wells not presently contaminated (i.e., down-gradient, bedrock).

(3) BEC Trucking:

The BCHD has been involved with the initial inspection of the area used for dumping. Files indicate that a number of 55-gallon drums containing Methanol and Dizco reducer were leaking and saturating the surrounding soil.

The BCHD has the following concerns:

1) Possible groundwater contamination of Vestal wells in Water District #4 and private wells in the area not connected to Municipal water.

(4) Village of Endicott Well (Ranney Well):

The BCHD was involved initially with the New York State Department of Environmental Conservation (NYSDEC) in collecting monitoring samples from the well. This well contains elevated levels of vinyl chloride, a known human carcinogen. Guidelines set by the NYSDH for vinyl chloride is 5 ug/l (ppb) in drinking water. Other volatile organics have also been found in the well.

The BCHD has the following concerns:

1) The long term trends in concentrations, as alternate sources of water will be difficult to develop.

(5) Tri-Cities Barrel Company:

The BCHD has been involved in the SPDES review only under SEQR.

The BCHD has the following concerns:

- 1) Possible groundwater contamination of private wells in the area as there is no public water.
- 2) Surface water contamination of Osborne Creek which flows into the Chenango River.

(6) Keytronics:

The BCHD has been involved with sampling at the South Street Well field down-gradient from site. Samples showed that methylene chloride was not present from past dumping practices at this site.

The BCHD has the following concerns:

1) Possible contamination of groundwater in the vicinity of the dumpsite.

(7) GAF Dump:

The BCHD has been involved in the sampling of two (2) wells on Anitec property down-gradient. Both wells sampled showed trace levels of volatile organics.

The BCHD has the following concerns:

- 1) Possibility of groundwater and surface water contamination.
- 2) Proximity of the dump to the Veteran's Memorial Park (across the street from the dump site).

(8) Conklin dumps:

One private well directly east of the landfill was sampled on 3/30/83 for the priority pollutants by the BCHD (and Water Resources Commission). Results found trace levels of trichloethylene (TCE) and some metals. Leachate wells on site indicate trace TCE contamination and elevated manganese levels in lower dump. The BCHD and Broome County Industrial Development Agency (BCIDA) sampled additional residents in the vicinity on 11/15/83. Results are pending.

The BCHD has the following concerns:

- 1) Possible groundwater contamination of private wells in the area.
- 2) Possibility of connecting local residents to the Town of Conklin public water supply, if a problem develops.

(9) Endicott Village Landfill:

The BCHD has been involved in the past site inspections of the landfill. Complete reports are on file in the Environmental Health Division of the BCHD.

The BCHD has the following concerns:

- 1) Possible contamination of ground and surface waters.
- 2) BCHD files confirms the dumping of industrial sludge containing various metals on site.
- 3) Dumping was done on the banks of the Susquehanna River, resulting most likely in the runoff of landfill leachate into the river.
- 4) Possible impacts on Village of Endicott Ranney Well.

REPORT ON TROUT BROOK SAMPLING SURVEY

FILE
D 8

CAF

Tributary SR - 44

October 18 - 22 1971

Broome County Health Department - Division of Environmental Health Services

An intensive sampling survey was carried out by personnel of the Division of Environmental Health Services, beginning at 9:00 AM October 18, and extending through 5:00 PM October 22. Hourly samples were taken and visual observations and physical measurements and chemical analyses performed on most samples collected. A total of 104 samples were collected from the 66" storm sewer line known as Trout Brook. At least five determinations were made for every sample collected. These being color, odor, temperature and PH, while three other determinations, namely DO, COD, and conductivity were run for approximately 60 samples. Finally, MBAS determinations and metals were measured on about 30 samples. Therefore a total of 760 determinations were made.

The permanent sampling station was established in the back of a van truck owned by the Department for storage of equipment, chemicals, glassware, and providing space necessary for running the dissolved oxygen determinations in the field. The location was at manhole #2 (see accompanying map) in Spring Forest Cemetery, near the corner of Elm and Mygatt Streets. This manhole is about 600 feet downstream from the GAF Sampling manhole, and the sampling was therefore essentially the total storm water discharge of GAF. Observations were made throughout the period of the flow of manhole #1, located just upstream from the GAF Plant, and also at the manhole located at Colfax Avenue. The observations showed that no storm water flow was found at these points, and therefore the total flow at manhole #2 was due to a combination of industrial wastes, cooling water wastes, and any storm water waste coming from GAF property, plus whatever storm water may have been coming from the 18 inch line which drains a portion of Prospect Street. However, since there was no measurable flow at the Colfax Avenue point which drains a much larger area, there is good reason to assume there was little or no flow coming from the Prospect Street line. It should also be mentioned that the sampling program was preceded by a long stretch of rather dry weather.

Flows

Estimates of flow were made at manhole #2 by measuring the conduit at a cross-section of the stream within the manhole structure, and taking measurements of the flow velocity. Estimates of flow based on hourly measurements ranged from 3.5 to 5.1 MGD. This corresponds to flow rates of 2,000 gallons per minute to 3,500 gallons per minute.

Violations of Water Pollution Laws

Violations were found of Parts 701.3 of Chapter 10, Title 6 - Official Rules, and Regulations. According to these standards, and reports on the Susquehanna River drainage basin which was assigned the standard of D to Trout Brook (see page 38, Table 1) violations exist in the following respects:

Colored Wastes

The standards require "none alone or in a combination with other substances in sufficient amounts to impair the waters for any class." Since the waters of Trout Brook discharge as a tributary into the Chenango River, and since the Chenango River is classified B from its mouth to tributary 61, colored wastes make the waters unsuitable for fishing, boating or any other recreational use.

Highly colored wastes were observed in nineteen samples. These colors ranged from milky white to blues, pinks, yellow and brown. By color is meant apparent color which includes not only the color due to substances in solution, but also that due to suspended matter, and was determined on the original sample without filtration or centrifugation. The following color scale was used:

- 0 - none
- 1 - trace
- 2 - faint
- 3 - pronounced
- 4 - intense

PH

Values for class B water range from 6.5 and 8.5 and for class D waters, from 6.0 and 9.5. Samples exceeded PH range both on low part and high part of the scale on a number of cases.

Settleable Solids

Under the requirements of Part 701.4, Title 6, Chapter 10 of the Official Rules, and Regulations, no settleable solids are allowed. Considerable settleable matter was measured in at least three samples during the sampling period.

Suspended Solids

There is no mention of suspended solids in the Quality Standards for Class D waters, however, we regard the presence of suspended solids in amounts greater than 25 PPM as having a deleterious effect upon the waters of the Chenango River into which Trout Brook discharges downstream. Irrespective of any possible toxic effects contained in these solids due to substances leached out by water, suspended solids are considered injurious to fish by causing abrasive injuries, clogging gills and respiratory passages of fish and other aquatic organisms. Such solids also have been observed blanketing the stream bottom. This is destructive to food organisms as well as the eggs and young, and destroys spawning beds. Suspended solids in these amounts also screen out light, (a condition known as turbidity) and therefore create conditions inimical to aquatic life and thus reducing the quality of water.

Dissolved Oxygen

D.O.'s of less than 3.0 PPM (for Class D waters) were measured in 63 cases. Every 24 hour period showed numerous violations of the dissolved oxygen standard. It must be remembered that these DO levels were measured in great volumes, since up to 5 MGD of wastes are discharged daily from the GAF plant. These low DO's in the volumes found impose a serious deleterious impact upon the receiving stream.

Toxic Wastes

The principle toxic waste found during the sampling period was silver. Ten samples taken during the test period showed values of greater than 1.0 PPM. We are not fully acquainted with the toxic effect of silver in this amount, but note that the toxic threshold for silver nitrate for stickleback fish is as low as 0.0048 PPM. Since the plant above our sampling point is engaged in the production and processing of photographic film, it is believed that the silver detected is the result of amounts of silver nitrate being discharged from the plant. If necessary, supplementary data can be obtained, more precisely defining this substance.

Zinc was also found, and since concentrations of 0.1 to 1.0 PPM have been reported to be lethal to fish, we feel that the amount of zinc pollution is unacceptable. Thirteen samples were found to contain zinc in excess of 0.1 PPM. One sample was as high as 1.66 PPM.

Conclusion

The data collected during the sampling period of October 18 through October 22 demonstrates without question that despite efforts made by GAF to control waste water discharges, serious violations of State pollution control laws occur on a daily basis.

It is recommended that consultation be arranged with officials of GAF and that initial remedial steps be taken immediately by the company to provide necessary industrial waste water treatment required to bring these discharges into compliance with State and County laws.

CLIENT NYSDEC Phase I Round 3 PROJ. No. 04339 EX

PROJECT GAF Dump DATE June 6, 1985

TIME 1:30 p.m.

CALL TO/FROM Melanie Sviatyla REPRESENTING Broome County

Health Department

PHONE No. 607-772-2887

SUMMARY OF CONVERSATION:

1971 Trout Brook sampling survey is of questionable value in terms of assessing toxicity of leachate. The alleged dump site is immediately adjacent to the industrial discharge point. At time of survey, Anatech (now GAF) had primitive treatment facilities. Therefore, cannot assign contaminants to dump site - metals may well have been from process wastes.

EXPLANATION

Aquifers composed of sand and gravel. Darker tone, more than 40 feet of saturated sand and gravel, locally overlapped by silt and clay. Lighter tone, generally less than 40 feet of saturated sand and gravel, overlying a thick section of silt and clay or overlying bedrock; thin sand and gravel aquifers locally beneath the silt and clay

GEOLOGIC FRAMEWORK

The Clinton Street-Ballpark aquifer was formed about 17,000 years ago (Cadwell, 1973) as the last glacier retreated from south-central New York. Deep valleys, originally carved by streams, had been widened and deepened by tongues of ice (Coates, 1966). While the glacier was melting, lakes continually formed between the remaining ice and older sediment downvalley. Turbulent rivers of meltwater built deltas of sand and gravel where they entered these lakes, and the silt, clay, and very fine sand they carried in suspension settled to the lake bottoms. Much of the sediment that was deposited west of the Chenango River in Binghamton and in Johnson City is permeable sand and gravel that today forms the Clinton Street-Ballpark aquifer.

The successive geologic units that compose and border the aquifer are described in table 1; the diagram in figure 2 illustrates the arrangement of these units.

Glacial deposits in the Susquehanna River basin range from "bright" to "drab" (Denny and Lyford, 1963; Moss and Ritter, 1962). The bright deposits contain fragments of many different rock types from remote locations and thus have a colorful appearance; the drab deposits are derived almost entirely from local shale bedrock. Near Binghamton, the drab glacial sand or gravel deposits are slightly older than the bright ones; that is, the bright overlies the drab wherever both types are present (Randall, in press). The change is commonly gradational over many feet if no fine-grained beds intervene. Because small tributary streams continued to bring drab gravel into the major valleys after the retreat of the ice, thin postglacial drab gravel may overlie bright glacial gravel near such streams. Geologists may find these relationships useful in tracing units from one borehole to another.

Distribution of the various geologic units at land surface is shown in a surficial geologic map (plate 6). Their structure and position below land surface are illustrated in figure 3.

ABILITY OF THE AQUIFER TO TRANSMIT WATER TO WELLS

The concept of transmissivity is used by hydrologists to express in quantitative terms the ability of aquifers to transmit water. Transmissivity is a measure of the rate at which water would flow through a vertical strip of specified width extending from the top to the bottom of the aquifer, assuming a 1/1 hydraulic gradient. A 1/1 gradient, which means a 1-foot decline in water level for each foot of water movement, is steeper than gradients usually observed in aquifers but serves as a standard for comparison. However, even though transmissivity is defined exactly and expressed numerically, it is difficult to measure precisely in most glacial aquifers because it varies widely from place to place.

The Clinton Street-Ballpark aquifer is composed mostly of permeable materials. Transmissivity in the central part of the aquifer generally exceeds 10,000 feet squared per day and locally may reach 100,000 feet squared per day (900 to 9,000 meters squared per day).

Table 1.--Geologic units in and near the Clinton Street-Ballpark aquifer

| Geologic unit (youngest to oldest) | Number in figures 2 and 3 | Lithology (materials composing unit) | Distribution, thickness, and position | Hydrologic significance |
|--|---------------------------------|--|---|--|
| Fill | 8 | Chiefly trash and ashes; some sand, gravel, and other materials | Moat natural depressions in Binghamton and Johnson City have been raised 5 to 20 feet by fill; some are now unrecognizable. | Not tapped by wells. Increases dissolved-solids concentration and acidity of infiltrating water, but effect decreases as age of fill increases. |
| Flood-plain silt | 7 | Brown silt and very fine sand with roots and a little fine organic matter. | Mantles lowlands inundated during major floods; typically 5 to 15 feet thick. May rest on all older units (1-5). | Not tapped by wells. Poorly permeable; limits recharge of underlying aquifers from floodwater and possibly from heavy rainfall. |
| Alluvial fan deposits | 6 | Gravel, moderately sandy and in general moderately silty. Most stones are flat pieces of local shale or siltstone. | Deposited by small streams where they enter the Susquehanna valley. May rest on all older units (1-5). | Permeable, but too thin to supply large-capacity wells. Water from small streams infiltrates through alluvial fan deposits to stratified glacial deposits. |
| Older river alluvium | 5 | Sand and gravel, bright but leached partially to completely free of limestone. | Interfingers with and overlies late-glacial lakebeds near Chenango River; as much as 35 feet thick. Relation to other units uncertain. May cap stratified glacial deposits beneath flood-plain silt elsewhere, but is not recognized or mapped. | Highly permeable and in good hydraulic contact with Chenango River. Could be tapped by large-capacity wells. |
| Late-glacial lakebeds | 4 | Silt and very fine sand with some clay and scattered tiny plant fragments; commonly grades into peat or highly organic silt at top. | Fills irregular depressions left when ice blocks melted, chiefly in a narrow east-west zone near deepest part of bedrock valley; as much as 80 feet thick. Generally overlies bright gravel. | A significant barrier to infiltration and ground-water flow in many places. |
| Stratified glacial deposits | 3 | | | |
| Bright gravel | 3c | Sandy gravel and pebbly sand containing variable amounts of silt; highly calcareous. Upper part very bright (35 to 75 percent of the pebbles are limestone and other rock types not derived from local bedrock). Lower part moderately bright (15 to 30 percent exotic pebbles). | Present over much of the valley as broad terraces or underlying younger units; thickness varies widely, locally exceeds 100 feet. | Highly permeable, tapped by several large-capacity wells, but locally above water table. The abundant limestone in this unit causes water that migrates through it to have high hardness (250-400 milligrams per liter). |
| Lake beds | 3b | Silt to fine sand, some clay, no plant fragments. | Lenses may occur anywhere within unit 3, but seem to be most common between the bright and drab gravels. | A significant barrier to infiltration and ground-water flow in places. |
| Drab gravel | 3a | Sandy gravel and pebbly sand with variable amounts of silt; weakly calcareous. Pebbles are almost entirely local. | Present at land surface along north and south sides of valley; commonly underlies bright gravel (directly or | Highly permeable; tapped by several large-capacity wells. |

D-38

6

| | | | | |
|--------------|----|--|---|---|
| Lake beds | 3b | Silt to fine sand, some clay, no plant fragments. | Lenses may occur anywhere within unit 3, but seem to be most common between the bright and drab gravels. | A significant barrier to infiltration and ground-water flow in places. |
| Drab gravel | 3a | Sandy gravel and pebbly sand with variable amounts of silt; weakly calcareous. Pebbles are almost entirely local shale and siltstone, with 10 percent or less exotic rock types. | Present at land surface along north and south sides of valley; commonly underlies bright gravel (directly or with intervening lake beds) in central part of valley; varies widely in thickness. | Highly permeable; tapped by several large-capacity wells. |
| Glacial till | 2 | Mixture of silt, clay, gravel, and sand, tough and compact; commonly called hardpan. May contain minor sand and gravel lenses. | Immediately overlies bedrock. Only about 1 foot thick in places, but forms low hills in southern part of Susquehanna valley. | Very poorly permeable. Low hills of till prevent movement of water between aquifer and Susquehanna River for 3 miles west from Chenango River |
| Bedrock | 1 | Interbedded shale and siltstone. | Present everywhere beneath other units. | Poorly permeable; serves as north, and part of south, aquifer boundary, but yields 100 to 300 gallons per minute of salty water to wells several hundred feet deep. |

Figure 2.--Idealized diagram illustrating arrangement of geologic units numbered and described in table 1. Note that diagram would appear much flatter if drawn to same scale vertically and horizontally.

Call by: Albert Longoria of G&H
 (Name) (Company)

Answer by: Allan Randall of USGS
 (Name) (Company)

Contract No: 5583-157

Subject discussed: Groundwater Geologic Units and Groundwater Flow
Direction In and Near the GAF Site

 SUMMARY OF DISCUSSION, DECISIONS AND COMMITMENTS

The discussion was about the disparity between the groundwater flow direction observed by the data attained from the recently completed monitoring wells and that which has been published by the USGS. Mr. Randall explained that the Anitec Corporation's production wells are influencing the entire vicinity's groundwater flow. It has been documented by the USGS that Anitec's core of influence will direct groundwater flow, at or near the GAF site, in a south by southwest course. A. Longoria discussed the possibility of GAF's GW-1 easterly flow pattern. Mr. Randall stated that this is highly plausible because a silty clay layer exists in the GAF site vicinity. This silty clay layer separates the water bearing zones from each other, subsequently establishing a perched water bearing layer throughout the vicinity. The silty clay layer is discontinuous, allowing for the water bearing layers to be hydraulically connected.

TENTH EDITION

Revised by

GESSNER G. HAWLEY

VAN NOSTRAND REINHOLD COMPANY
NEW YORK CINCINNATI TORONTO LONDON MELBOURNE

D-45

Grades: Technical; 99.9%.

Containers: Carboys; cylinders; tank cars.

Hazard: Highly toxic; corrosive to skin and tissue.

Reacts with water to form HCl. Tolerance, 0.5 ppm in air. Store in tightly closed containers.

Uses: Making phosphorus oxychloride; intermediate for organophosphorus pesticides, surfactants, phosphites (reaction with alcohols and phenols), gasoline additives, plasticizers, dyestuffs; chlorinating agent; catalyst; preparing rubber surfaces for electrodeposition of metal; ingredient of textile finishing agents. Shipping regulations: (Rail, Air) Corrosive label. Not accepted passenger.

phosphorus triiodide - PI_3 .

Properties: Red crystals; hygroscopic. Soluble in alcohol, carbon disulfide, water (dec). M.p. $61^\circ C$ (dec); sp. gr. 4.18.

Grades: Technical; reagent.

Hazard: Toxic and flammable; reacts with water.

Irritant to skin and eyes.

Use: Organic synthesis.

phosphorus trisulfide (phosphorus sulfide; tetraphosphorus hexasulfide; thiophosphorous anhydride) P_2S_3 , or P_4S_6 .

Properties: Grayish-yellow mass; tasteless; odorless. Keep well stoppered! Decomposes in moist air. Soluble in alcohol, carbon disulfide, ether. B.p. $490^\circ C$; m.p. $290^\circ C$.

Hazard: Highly toxic; flammable, dangerous fire risk; reacts with water.

Use: Organic chemistry (reagent).

Shipping regulations: (Rail, Air) Flammable Solid label. Not acceptable passenger.

phosphorylase. An enzyme occurring in muscle and liver which catalyzes the conversion of glycogen into glucose-1-phosphate.

phosphorylation. A reaction in which phosphorus combines with an organic compound, usually in the form of the trivalent phosphoryl group $=P=O$. It occurs naturally in cellular metabolism and is of particular importance in vitamin activity and enzyme formation. It is also used to produce a modified cellulose (P-cellulose) for cation exchange in chromatographic separations.

phosphoryl chloride. See phosphorus oxychloride.

phosphotungstic acid (phospho-12-tungstic acid; phosphowolframic acid; 12-tungstophosphoric acid) $H_3PW_{12}O_{40} \cdot xH_2O$.

Properties: Yellowish-white solid; m.p. (for $24H_2O$ hydrate) $89^\circ C$. Soluble in water, acetone, and diethyl ether. Relatively insoluble in nonpolar organic solvents. Strong oxidizing agent in aqueous solution; strong acid in the free acid form.

Derivation: Addition of phosphates to sodium tungstate in the presence of hydrochloric acid.

Grades: Reagent; technical.

Hazard: Strong irritant to skin and eyes.

Uses: Reagent in analytical chemistry and biology;

manufacture of organic pigments; additive in plating industry; imparts water resistance to plastics, adhesives and cement; catalyst for organic reactions; photographic fixing agent; textile antistatic agent.

phosphotungstic acid, sodium salt. See sodium 12-tungstophosphate.

phosphotungstic pigment (tungsten lake). A green or blue pigment manufactured by precipitating basic dyestuffs such as malachite green or Victoria blue with solutions of phosphotungstic acid, or phosphomolybdic acid, or mixtures of both. See also phosphomolybdic pigment.

Uses: Printing inks; paper; paints and enamels.

photochemistry. The branch of chemistry concerned with the effect of absorption of radiant energy (light) in inducing or modifying chemical changes. Photosynthesis is the most important example of a photochemical reaction; others are the photosensitization of solids, applied in photography, photocells, photovoltaic cells, and the formation of visual pigments; photochemical decomposition (photolysis); photo-induced polymerization, oxidation, and ionization; fluorescence and phosphorescence; and the reaction of chlorine with organic compounds. Free-radical chain mechanisms are usually involved. See also free radical.

photochromism. The ability of a transparent material to darken reversibly when exposed to light. See also glass, photochromic.

Plastics can be made light-sensitive by certain aromatic organic nitro compounds such as 2-(2,4-dinitrobenzyl)pyridine. Such chemicals are compatible with most transparent plastics and are either blended with the base resin or applied as coatings.

photo-glycin. See para-hydroxyphenylglycine.

photographic chemistry. In photographic films and papers the sensitive surface consists of microscopic grains of a silver halide, suspended in gelatin. Exposure to light renders the halide particles susceptible to reduction to metallic silver by developing agents (q.v.) containing a reducing agent, as well as an accelerator, preservative, and restrainer. The accelerator increases the activity of the reducing agent (due principally to ionization of the phenolic agents to their active form) and is usually an alkaline compound. The preservative, usually sodium sulfite, minimizes air oxidation. The restrainer helps to prevent "fog" (reduction of silver halide grains which have not been exposed to light) and is almost always potassium bromide.

Color sensitizers are dyes added to silver halide emulsions to broaden their response to various wavelengths. Unsensitized emulsions are most responsive in the blue region of the spectrum and thus do not correctly represent the light spectrum striking them. Widely used sensitizers include the cyanine dyes (q.v.), the merocyanines, the benzoxazoles, and the benzothiazoles. Cryptocyanine sensitizes the extreme red and infrared.

isms. Most fos

In color photography diethyl-para-phenylenediamine is an important developer, since its oxidation product readily couples with a large number of phenol and reactive methylene compounds to form indophenol and indoaniline dyes, which are the basis of most of the current color processes.

photolysis. Decomposition of a compound into simpler units as a result of absorbing one or more quanta of radiation; examples are splitting of hydrogen iodide by the reaction $2\text{HI} + h\nu \rightarrow \text{H}_2 + \text{I}_2$, and of ketene ($\text{H}_2\text{C}=\text{CO}$) into carbon monoxide and carbene (methylene) ($:\text{CH}_2$). Photodecomposition may also occur with aldehydes, ketones, azo compounds, and organometallic compounds. Continuous generation of hydrogen by photolysis of water has been achieved experimentally, using platinum catalyst in conjunction with ruthenium and rhodium. See also flash photolysis; photochemistry.

photometric analysis. Chemical analysis by means of absorption or emission of radiation, primarily in the near ultraviolet, visible, and infrared portions of the electromagnetic spectrum. It includes such techniques as spectrophotometry, spectrochemical analysis, Raman spectroscopy, colorimetry and fluorescence measurements. See also spectroscopy.

photon. The unit (quantum) of electromagnetic radiation. Light waves, gamma rays, x-rays, etc., consist of photons. Photons are discrete concentrations of energy that have no rest mass and move at the speed of light. Their nature can be described only in mathematical terms. Photons are emitted when electrons move from one energy state to another, as in an excited atom. See also radiation.

phosphor. See calcium phosphide.

photopolymer. A polymer or plastic so made that it undergoes a change on exposure to light. Such materials can be used for printing and lithography plates, for photographic prints and microfilm copying. The effect of the light may be to cause further polymerization or crosslinking, or may cause degradation. One application involves the use of esters of polyvinyl alcohol which crosslink and so become insoluble, whereas unexposed portions of the material remain soluble.

photosynthesis. The utilization of sunlight by plants as well as by bacteria to convert two inorganic substances (carbon dioxide and water) into carbohydrates. Chlorophyll (q.v.) acts as the energy-converter in this reaction, which is perhaps the most important on earth. The generalized reaction is: $6\text{CO}_2 + 6\text{H}_2\text{O} + 672 \text{ kcal} \rightarrow \text{C}_6\text{H}_{12}\text{O}_6 + 6\text{O}_2$. This significance of this process lies in the conversion of energy from radiant to chemical form. The chemical energy a green plant stores by photosynthesis provides the total energy requirement of the plant. Directly or indirectly plants supply the primary organic nutrient for most other living organisms. Most fossil fuels are storehouses of the radiant

energy transformed by photosynthesis in earlier geologic eras.

Photosynthesis is the principal source of atmospheric oxygen. At least two-thirds of the total photosynthetic activity of the earth takes place in the oceans (see algae). Its exact chemical mechanism is extremely complex. Essential features are the reduction of carbon dioxide and utilization of the hydrogen of water to form carbohydrates, the oxygen being liberated; the nucleotides nicotinamide and adenosine triphosphate are involved in this conversion. Sugar (sucrose) is formed in the cytoplasm surrounding the chloroplasts.

Photosynthesis has been suggested as a possible source of fuels by the development of "energy plantations" (intensive growth of crops) and conversion of a small fraction of the solar energy to generation of electric power. See also biomass.

photovoltaic cell. See solar cell.

"Photox."²⁶⁶ Trademark for photoconductive lead-free zinc oxides manufactured by the French process produced from zinc metal. Used in electrophotography.

"PH 990 Resin."⁴⁶⁹ Trademark for a phosphonitrilic-modified phenolic resin. Stable, off-white, free-flowing powder. Soluble in most organic solvents. Flame retardant and retains electrical and structural properties up to 260–426°C.

"Phthalamaquin."³⁴² Trademark for an aureoquin preparation, described as 4-(2-dimethylaminoethylamino)-6-methoxyquinoline diethylaminotetrahydrophthalate. Used in medicine.

phthalamide $\text{C}_6\text{H}_4(\text{CONH}_2)_2$. The double acid amide of phthalic acid.

Properties: Colorless crystals; m.p. 220°C (decomposes into phthalimide and ammonia). Very slightly soluble in water and alcohol; insoluble in ether.

Derivation: By stirring phthalamide with cold concentrated ammonia solution; by the reaction of phthalyl chloride and ammonia; or from the addition of ammonia to phthalic anhydride under pressure.

Use: Intermediate in organic synthesis; laboratory reagent.

phthalic acid (ortho-phthalic acid; ortho-benzene dicarboxylic acid) $\text{C}_6\text{H}_4(\text{COOH})_2$.

Properties: Colorless crystals; soluble in alcohol; sparingly soluble in water and ether. Sp. gr. 1.585; m.p., decomposes at 191°C.

Derivation: Catalytic oxidation of o-toluic acid and oxidation of xylene.

Grades: Technical; reagent.

Uses: Dyes; phenolphthalein; phthalamide; anthranilic acid; synthetic perfumes; laboratory reagent.

para-phthalic acid. See terephthalic acid.

phthalic anhydride $\text{C}_6\text{H}_4(\text{CO})_2\text{O}$.

Properties: White, crystalline needles; sublimes below b.p.; mild odor. Sp. gr. 1.527 (4°C); m.p. 131.16°C;

- 1) Flag all positive results for that compound as estimated (J).
 - 2) Non-detects may be qualified using professional judgment.

IV. BLANKS

A. Objective

The assessment of blank analysis results is to determine the existence and magnitude of contamination problems. The criteria for evaluation of blanks apply to any blank associated with the samples. If problems with any blank exist, all data associated with the Case must be carefully evaluated to determine whether or not there is an inherent variability in the data for the Case, or if the problem is an isolated occurrence not affecting other data.

B. Criteria

No contaminants should be present in the blank(s).

C. Evaluation Procedure

1. Review the results of all associated blank(s), Form I(s) and raw data (chromatograms, reconstructed ion chromatograms, quantitation reports or data system printouts).
2. Verify that Method Blank analysis has been reported per matrix, per concentration level, for each GC/MS system used to analyze VOA samples, and for each extraction batch for semivolatiles. The reviewer can use the Method Blank Summary (Form IV) to assist in identifying samples associated with each Method Blank.

D. Action

Action in the case of unsuitable blank results depends on the circumstances and origin of the blank. No positive sample results should be reported unless the concentration of the compound in the sample exceeds 10 times the amount in any blank for the common contaminants listed below, or 5 times the amount for other compounds. In instances where more than one blank is associated with a given sample, qualification should be based upon a comparison with the associated blank having the highest concentration of a contaminant. The results must not be corrected by subtracting any blank value. Specific actions are as follows:

1. If a compound is found in a blank but not found in the sample, no action is taken.

2. Any compound (other than the five listed below) detected in the sample, which was also detected in any associated blank, must be qualified when the sample concentration is less than five times the blank concentration. For the following five compounds, the results are qualified by elevating the limit of detection when the sample concentration is less than 10 times the blank concentration.

Common lab contaminants:

- a. Methylene chloride
- b. Acetone
- c. Toluene
- d. 2-butanone
- e. Common phthalate esters

The reviewer should note that the blank analyses may not involve the same weights, volumes, or dilution factors as the associated samples. These factors must be taken into consideration when applying the 5x and 10x criteria, such that a comparison of the total amount of contamination is actually made.

Additionally, there may be instances where little or no contamination was present in the associated blanks, but qualification of the sample was deemed necessary. Contamination introduced through dilution water is one example. Although it is not always possible to determine, instances of this occurring can be detected when contaminants are found in the diluted sample result, but are absent in the undiluted sample result. Since both results are not routinely reported, it may be impossible to verify this source of contamination. However, if the reviewer determines that the contamination is from a source other than the sample, he/she should qualify the data. In this case, the 5x or 10x rule does not apply; the sample value should be reported as a non-detect.

3. The following are examples of applying the blank qualification guidelines. Certain circumstances may warrant deviations from these guidelines.

Case 1: Sample result is greater than the Contract Required Quantitation Limit (CRQL), but is less than the required amount (5x or 10x) from the blank result.

| | Rule | |
|-------------------------|------|-----|
| | 10x | 5x |
| Blank Result | 7 | 7 |
| CRQL | 5 | 5 |
| Sample Result | 60 | 30 |
| Qualified Sample Result | 60U | 30U |

In the example for the 10x rule, sample results less than 70 (or 10 x 7) would be qualified as non-detects. In the case of the 5x rule, sample results less than 35 (or 5 x 7) would be qualified as non-detects.

Case 2: Sample result is less than CRQL, and is also less than the required amount (5x or 10x) from the blank result.

| | Rule | |
|-------------------------|------|----|
| | 10x | 5x |
| Blank Result | 6 | 6 |
| CRQL | 5 | 5 |
| Sample Result | 4J | 4J |
| Qualified Sample Result | 5U | 5U |

Note that data are not reported as 4U, as this would be reported as a detection limit below the CRQL.

Case 3: Sample result is greater than the required amount (5x or 10x) from the blank result.

| | Rule | |
|-------------------------|------|------|
| | 10x | 5x |
| Blank Result | 10 | 10 |
| CRQL | 5 | 5 |
| Sample Result | 120 | 60 |
| Qualified Sample Result | 120 | 60 ← |

For both the 10x and 5x rules, sample results exceeded the adjusted blank results of 100 (or 10x10) and 50 (or 5x10), respectively.

4. If gross contamination exists (i.e., saturated peaks by GC/MS), all compounds affected should be flagged as unusable (R), due to interference, in all samples affected.
5. If inordinate amounts of other TCL compounds are found at low levels in the blank(s), it may be indicative of a problem at the laboratory and should be noted in the data review comments which are forwarded to the DPO.
6. Similar consideration should be given to TIC compounds which are found in both the sample and associated blank(s). (See Section XI for TIC guidance.)

V. SURROGATE RECOVERY

A. Objective

Laboratory performance on individual samples is established by means of spiking activities. All samples are spiked with surrogate compounds prior to sample preparation. The evaluation of the results of these surrogate spikes is not necessarily straightforward. The sample itself may produce effects due to such factors as interferences and high concentrations of analytes. Since the effects of the sample matrix are frequently outside the control of the laboratory and may present relatively unique problems, the review and validation of data based on specific sample results is

D.20

GROUNDWATER

R. Allan Freeze / John A. Cherry

D-53

the use of the pumping-test approach is usually inappropriate. It is our opinion that the method is widely overused. Piezometer tests are simpler and cheaper, and they can provide adequate data in many cases where pumping tests are not justified.

8.7 Estimation of Saturated Hydraulic Conductivity

It has long been recognized that hydraulic conductivity is related to the grain-size distribution of granular porous media. In the early stages of aquifer exploration or in regional studies where direct permeability data are sparse, this interrelationship can prove useful for the estimation of conductivity values. In this section, we will examine estimation techniques based on grain-size analyses and porosity determinations. These types of data are often widely available in geological reports, agricultural soil surveys, or reports of soil mechanics testing at engineering sites.

The determination of a relation between conductivity and soil texture requires the choice of a representative grain-size diameter. A simple and apparently durable empirical relation, due to Hazen in the latter part of the last century, relies on the effective grain size, d_{10} , and predicts a power-law relation with K :

$$K = Ad_{10}^2 \quad (8.47)$$

The d_{10} value can be taken directly from a grain-size gradation curve as determined by sieve analysis. It is the grain-size diameter at which 10% by weight of the soil particles are finer and 90% are coarser. For K in cm/s and d_{10} in mm, the coefficient A in Eq. (8.47) is equal to 1.0. Hazen's approximation was originally determined for uniformly graded sands, but it can provide rough but useful estimates for most soils in the fine sand to gravel range.

Textural determination of hydraulic conductivity becomes more powerful when some measure of the spread of the gradation curve is taken into account. When this is done, the *median grain size*, d_{50} , is usually taken as the representative diameter. Masch and Denny (1966) recommend plotting the gradation curve [Figure 8.25(a)] using Krumbein's ϕ units, where $\phi = -\log_2 d$, d being the grain-size diameter (in mm). As a measure of spread, they use the *inclusive standard deviation*, σ_I , where

$$\sigma_I = \frac{d_{16} - d_{84}}{4} + \frac{d_5 - d_{95}}{6.6} \quad (8.48)$$

For the example shown in Figure 8.25(a), $d_{50} = 2.0$ and $\sigma_I = 0.8$. The curves shown in Figure 8.25(b) were developed experimentally in the laboratory on prepared samples of unconsolidated sand. From them, one can determine K , knowing d_{50} and σ_I .

For a fluid of density, ρ , and viscosity, μ , we have seen in Section 2.3 [Eq. (2.26)] that the hydraulic conductivity of a porous medium consisting of uniform

Figure 8.25 Determination of saturated hydraulic conductivity from grain-size gradation curves for unconsolidated sands (after Masch and Denny, 1966).

spherical grains of diameter, d , is given by

$$K = \left(\frac{\rho g}{\mu}\right) C d^2 \quad (8.49)$$

For a nonuniform soil, we might expect the d in Eq. (8.49) to become d_m , where d_m is some representative grain size, and we would expect the coefficient C to be dependent on the shape and packing of the soil grains. The fact that the porosity, n , represents an integrated measure of the packing arrangement has led many investigators to carry out experimental studies of the relationship between C and n . The best known of the resulting predictive equations for hydraulic conductivity is the *Kozeny-Carmen equation* (Bear, 1972), which takes the form

$$K = \left(\frac{\rho g}{\mu}\right) \left[\frac{n^3}{(1-n)^2}\right] \left(\frac{d_m^2}{180}\right) \quad (8.50)$$

In most formulas of this type, the porosity term is identical to the central element of Eq. (8.50), but the grain-size term can take many forms. For example, the *Fair-Hatch equation*, as reported by Todd (1959), take the form

$$K = \left(\frac{\rho g}{\mu}\right) \left[\frac{n^3}{(1-n)^2}\right] \left[\frac{1}{m \left(\frac{\theta}{100} \sum \frac{P}{d_m}\right)^2}\right] \quad (8.51)$$

where m is a packing factor, found experimentally to be about 5; θ is a sand shape factor, varying from 6.0 for spherical grains to 7.7 for angular grains; P is the

percentage of sand held between adjacent sieves; and d_m is the geometric mean of the rated sizes of adjacent sieves.

Both Eqs. (8.50) and (8.51) are dimensionally correct. They are suitable for application with any consistent set of units.

8.8 Prediction of Aquifer Yield by Numerical Simulation

The analytical methods that were presented in Section 8.3 for the prediction of drawdown in multiple-well systems are not sophisticated enough to handle the heterogeneous aquifers of irregular shape that are often encountered in the field. The analysis and prediction of aquifer performance in such situations is normally carried out by numerical simulation on a digital computer.

There are two basic approaches: those that involve a *finite-difference* formulation, and those that involve a *finite-element* formulation. We will look at finite-difference methods in moderate detail, but our treatment of finite-element methods will be very brief.

Finite-Difference Methods

As with the steady-state finite-difference methods that were described in Section 5.3, transient simulation requires a discretization of the continuum that makes up the region of flow. Consider a two-dimensional, horizontal, confined aquifer of constant thickness, b ; and let it be discretized into a finite number of blocks, each with its own hydrogeologic properties, and each having a node at the center at which the hydraulic head is defined for the entire block. As shown in Figure 8.26(a), some of these blocks may be the site of pumping wells that are removing water from the aquifer.

Let us now examine the flow regime in one of the interior nodal blocks and its four surrounding neighbors. The equation of continuity for transient, saturated flow states that the net rate of flow into any nodal block must be equal to the time rate of change of storage within the nodal block. With reference to Figure 8.26(b), and following the developments of Section 2.11, we have

$$Q_{15} + Q_{25} + Q_{35} + Q_{45} = S_{11} \Delta x \Delta y b \frac{\partial h_5}{\partial t} \quad (8.52)$$

where S_{11} is the specific storage of nodal block 5. From Darcy's law,

$$Q_{15} = K_{15} \frac{h_1 - h_5}{\Delta y} \Delta x b \quad (8.53)$$

where K_{15} is a representative hydraulic conductivity between nodes 1 and 5. Similar expressions can be written for Q_{25} , Q_{35} , and Q_{45} .

Section 2.9, α is a function of the sample's loading history. The most common methods of measurement are the fixed-ring and the floating-ring container methods. In the fixed-ring method, the sample is downward toward the midline. The effect of friction in the fixed-ring method is usually neglected. For expansive clays must

consolidation, c_v , which is defined as

$$c_v = \frac{K}{\rho g \alpha} \quad (8.30)$$

At each loading level in a consolidation test, the sample undergoes a transient drainage process (fast for sands, slow for clays) that controls the rate of consolidation of the sample. If the rate of decline in sample thickness is recorded for each loading increment, such measurements can be used in the manner described by Lambe (1951) to determine the coefficient of consolidation, c_v , and the hydraulic conductivity, K , of the soil.

In Section 8.12, we will further examine the mechanism of one-dimensional consolidation in connection with the analysis of land subsidence.

Unsaturated Characteristic Curves

The characteristic curves, $K(\psi)$ and $\theta(\psi)$, that relate the moisture content, θ , and the hydraulic conductivity, K , to the pressure head, ψ , in unsaturated soils were described in Section 2.6. Figure 2.13 provided a visual example of the hysteretic relationships that are commonly observed. The methods used for the laboratory determination of these curves have been developed exclusively by soil scientists. It is not within the scope of this text to outline the wide variety of sophisticated laboratory instrumentation that is available. Rather, the reader is directed to the soil science literature, in particular to the review articles by L. A. Richards (1965), Klute (1965b), Klute (1965c), and Bouwer and Jackson (1974).

8.5 Measurement of Parameters: Piezometer Tests

It is possible to determine *in situ* hydraulic conductivity values by means of tests carried out in a single piezometer. We will look at two such tests, one suitable for point piezometers that are open only over a short interval at their base, and one suitable for screened or slotted piezometers that are open over the entire thickness of a confined aquifer. Both tests are initiated by causing an instantaneous change in the water level in a piezometer through a sudden introduction or removal of a known volume of water. The recovery of the water level with time is then observed. When water is removed, the tests are often called *bail tests*; when it is added, they are known as *slug tests*. It is also possible to create the same effect by suddenly introducing or removing a solid cylinder of known volume.

The method of interpreting the water level versus time data that arise from bail tests or slug tests depends on which of the two test configurations is felt to be most representative. The method of Hvorslev (1951) is for a point piezometer, while that of Cooper et al. (1967) is for a confined aquifer. We will now describe each in turn.

The simplest interpretation of piezometer-recovery data is that of Hvorslev (1951). His initial analysis assumed a homogeneous, isotropic, infinite medium in which both soil and water are incompressible. With reference to the bail test of Figure 8.20(a), Hvorslev reasoned that the rate of inflow, q , at the piezometer tip at any time t is proportional to the hydraulic conductivity, K , of the soil and to the unrecovered head difference, $H - h$, so that

$$q(t) = \pi r^2 \frac{dh}{dt} = FK(H - h) \tag{8.31}$$

where F is a factor that depends on the shape and dimensions of the piezometer intake. If $q = q_0$ at $t = 0$, it is clear that $q(t)$ will decrease asymptotically toward zero as time goes on.

Handwritten notes:
 $H_0 - H_0$
 $H - H_0$
 $h - H_0$
 dh
 $H - h$

Figure 8.20 Hvorslev piezometer test. (a) Geometry; (b) method of analysis.

Hvorslev defined the *basic time lag*, T_0 , as

$$T_0 = \frac{\pi r^2}{FK} \tag{8.32}$$

When this parameter is substituted in Eq. (8.31), the solution to the resulting ordinary differential equation, with the initial condition, $h = H_0$ at $t = 0$, is

$$\frac{H - h}{H - H_0} = e^{-t/T_0} \tag{8.33}$$

(8.32)

the resulting
= 0, is

(8.33)

A plot of field recovery data, $H - h$ versus t , should therefore show an exponential decline in recovery rate with time. If, as shown on Figure 8.20(b), the recovery is normalized to $H - H_0$ and plotted on a logarithmic scale, a straight-line plot results. Note that for $H - h/H - H_0 = 0.37$, $\ln(H - h/H - H_0) = -1$, and from Eq. (8.33), $T_0 = t$. The basic time lag, T_0 , can be defined by this relation; or if a more physical definition is desired, it can be seen, by multiplying both top and bottom of Eq. (8.32) by $H - H_0$, that T_0 is the time that would be required for the complete equalization of the head difference if the original rate of inflow were maintained. That is, $T_0 = V/q_0$, where V is the volume of water removed or added.

To interpret a set of field recovery data, the data are plotted in the form of Figure 8.20(b). The value of T_0 is measured graphically, and K is determined from Eq. (8.32). For a piezometer intake of length L and radius R [Figure 8.20(a)], with $L/R > 8$, Hvorslev (1951) has evaluated the shape factor, F . The resulting expression for K is

$$K = \frac{r^2 \ln(L/R)}{2LT_0} \quad (8.34)$$

Hvorslev also presents formulas for anisotropic conditions and for a wide variety of shape factors that treat such cases as a piezometer open only at its basal cross section and a piezometer that just encounters a permeable formation underlying an impermeable one. Cedergren (1967) also lists these formulas.

In the field of agricultural hydrology, several *in situ* techniques, similar in principle to the Hvorslev method but differing in detail, have been developed for the measurement of saturated hydraulic conductivity. Boersma (1965) and Bouwer and Jackson (1974) review those methods that involve auger holes and piezometers.

For bail tests of slug tests run in piezometers that are open over the entire thickness of a confined aquifer, Cooper et al. (1967) and Papadopoulos et al. (1973) have evolved a test-interpretation procedure. Their analysis is subject to the same assumptions as the Theis solution for pumpage from a confined aquifer. Contrary to the Hvorslev method of analysis, it includes consideration of both formation and water compressibilities. It utilizes a curve-matching procedure to determine the aquifer coefficients T and S . The hydraulic conductivity K can then be determined on the basis of the relation, $K = T/b$. Like the Theis solution, the method is based on the solution to a boundary-value problem that involves the transient equation of groundwater flow, Eq. (2.77). The mathematics will not be described here.

For the bail-test geometry shown in Figure 8.21(a), the method involves the preparation of a plot of recovery data in the form $H - h/H - H_0$ versus t . The plot is prepared on semilogarithmic paper with the reverse format to that of the Hvorslev test; the $H - h/H - H_0$ scale is linear, while the t scale is logarithmic. The field curve is then superimposed on the type curves shown in Figure 8.21(b). With the axes coincident, the data plot is translated horizontally into a position where the data best fit one of the type curves. A matchpoint is chosen (or rather, a vertical axis is matched) and values of t and W are read off the horizontal scales

Figure 8.21 Piezometer test in a confined aquifer. (a) Geometry; (b) type curves (after Papadopoulos et al., 1973).

at the matched axis of the field plot and the type plot, respectively. For ease of calculation it is common to choose a matched axis at $W = 1.0$. The transmissivity T is then given by

$$T = \frac{Wr^2}{t} \quad (8.35)$$

where the parameters are expressed in any consistent set of units.

In principle, the storativity, S , can be determined from the a value of the matched curve and the expression shown on Figure 8.21(b). In practice, since the slopes of the various a lines are very similar, the determination of S by this method is unreliable.

The main limitation on slug tests and bail tests is that they are heavily dependent on a high-quality piezometer intake. If the wellpoint or screen is corroded or clogged, measured values may be highly inaccurate. On the other hand, if a piezometer is developed by surging or backwashing prior to testing, the measured values may reflect the increased conductivities in the artificially induced gravel pack around the intake.

It is also possible to determine hydraulic conductivity in a piezometer or single well by the introduction of a tracer into the well bore. The tracer concentration decreases with time under the influence of the natural hydraulic gradient that exists in the vicinity of the well. This approach is known as the *borehole dilution method*, and it is described more fully in Section 9.4.

E. UPDATED REGISTRY

NEW YORK STATE DEPARTMENT OF ENVIRONMENTAL CONSERVATION
DIVISION OF SOLID AND HAZARDOUS WASTE
INACTIVE HAZARDOUS WASTE DISPOSAL REPORT

CLASSIFICATION CODE: 2a REGION: 3 SITE CODE: 704011
EPA ID: NYD002239465

NAME OF SITE: GAF Dump
STREET ADDRESS: Charles & Grace Street
TOWN/CITY: Binghamton COUNTY: Broome ZIP: 13905

SITE TYPE: Open Dump Structure Lagoon
Landfill Treatment Pond

ESTIMATED SIZE: 1 acre

SITE OWNER/OPERATOR INFORMATION:

CURRENT OWNER NAME: GAF Corporation
CURRENT OWNER ADDRESS: 1362 Alps Road, Wayne, New Jersey
OWNER(S) DURING USE: GAF Corp.
OPERATOR DURING USE: GAF Corporation
OPERATOR ADDRESS:
PERIOD ASSOCIATED WITH HAZARDOUS WASTE: From to

SITE DESCRIPTION:

The GAF dump site is a 2-acre inactive disposal area, adjacent to an Anitec Co. facility, which was formerly a GAF manufacturing plant. An abandoned paved parking lot makes up the eastern half of the site, while the remaining western portion of the site is ungraded and covered with weeds. Liquids from production of photographic material were allegedly dumped (from 1945-1975) directly onto the ground. The dump area was presumably filled with rubble and covered with soil. The site is fenced in, but accessible along the south side.

RECOMMEND:

HAZARDOUS WASTE DISPOSED: Confirmed Suspected

| <u>TYPE</u> | <u>QUANTITY (units)</u> |

LEGAL ACTION:

TYPE: State ___ Federal ___
STATUS: Progress ___ Order Signed ___

REMEDIAL ACTION:

Proposed ___ Under Design ___ In Progress Completed ___

NATURE OF ACTION:

GEOTECHNICAL INFORMATION:
SOIL TYPE: Fine sand and silt
GROUNDWATER DEPTH: 8 feet

ASSESSMENT OF ENVIRONMENTAL PROBLEMS:

A Phase II investigation report was completed in November 1989. The groundwater analyses detected three organics released from the site into the groundwater. The principal TCL metal found in the groundwater is silver. Lead was found in soil samples in a slightly high elevation.

ASSESSMENT OF HEALTH PROBLEMS:

| <u>Medium</u> | <u>Contaminants Available</u> | <u>Migration Potential</u> | <u>Potentially Exposed Population</u> | <u>Need for Investigation</u> |
