1 INTRODUCTION

WSP USA Inc. (WSP), on behalf of Vishay GSI, Inc. (VGSI; a corporate successor of General Instrument Corporation [GIC]), has prepared this combined annual groundwater performance monitoring report and 5-year remedial action review for the former GIC facility in Sherburne, New York (Figure 1). The performance monitoring is the remaining[1,2], portion of a much larger sampling program, begun in the late 1990s, designed to evaluate the efficacy of a permeable reactive barrier (PRB) constructed to treat dissolved chlorinated volatile organic compounds (CVOCs) migrating westward from the site. The program included a network of monitoring wells positioned both upgradient and downgradient of the barrier. Concerns about the performance of the barrier in the early 2000s led to development of an expanded monitoring well network, additional groundwater investigation, and eventually to a supplemental remedial action in 2009 to address CVOCs that remained upgradient of the PRB. That remedial action was effective at addressing the affected groundwater in the treatment areas, except for one location upgradient of the barrier near monitoring well P-8 (Sheet 1). A follow-up investigation was conducted and, based on the results, a second supplemental remedial action (designated as the P-8 supplemental remedial action) was completed in 2014 to address the recalcitrant CVOCs.

This report details of the annual P-8 supplemental remedy performance monitoring program, including the 2020 sampling results and an assessment of the overall efficacy of the treatment. As demonstrated in this report, the P-8 remedial action was successful at treating the recalcitrant CVOCs at the site and has achieved the established remedial goals. WSP proposes to suspend the monitoring program and to meet with the New York State Department of Environmental Conservation (NYSDEC) either in-person (if conditions are appropriate) or via a call in first half of 2021 to discuss the administrative path forward to closure.

All the work at the site is being performed in accordance with the Order on Consent (#A701578810), signed by GIC on August 1, 1989, and a *Record of Decision* (ROD), issued for the site in December 1994 by the NYSDEC. The activities outlined in this report are based on select portions of the approved *Combined Pre-Design Investigation Report and P-8 Area Supplemental Remedial Investigation Work Plan*, dated January 9, 2014; the *Combined June 2015 Semiannual Groundwater Sampling Report and P-8 Supplemental Remedial Action Performance Monitoring Report and 12-Month Review*, dated January 5, 2016; and were conducted in accordance with WSP's standard operating procedures (SOPs; Appendix A).

1.1 REPORT ORGANIZATION

This report is organized into seven sections, including this introduction:

- Section 2 describes the site location and operational history of the facility, provides background on the previous investigation and remedial measures implemented at the site, and summarizes the remedial performance sampling programs, including recent modifications;
- Section 3 outlines the scope of work for the modified P-8 performance monitoring activities that include the sampling of well P-8 within the treatment area and, for 2020, all remaining wells at the site;
- Section 4 presents the findings of the modified performance monitoring program, including the groundwater elevations and analytical results for the remaining monitoring wells;
- Section 5 details the interpretation of the analytical results from samples collected from locations both within and outside the P-8 treatment area;

[1] The performance monitoring program associated with the permeable reactive barrier and the subsequent 2009 remedial action were modified 2017. The changes included an end to the barrier-specific and 2009 supplemental remediation performance monitoring programs, and the subsequent abandoned of all but six groundwater monitoring wells at the site. Sampling of the remaining six wells, which is part of the P-8 supplemental remedial action performance monitoring program, is detailed in this report. See Section 2.2 for additional information.

[2] Initial modifications to the groundwater sampling programs are discussed in the *Combined June 2015 Semiannual Groundwater Sampling Report and P-8 Supplemental Remedial Action Performance Monitoring Report and 12-Month Review*, dated January 5, 2016 (P-8 12-Month Review; WSP 2016).

- Section 6 presents the assessment of the efficacy of the treatment program, the conclusions including evidence that the supplemental treatment has achieved the stated remedial goals, and recommendations for suspending the sampling program;
- Section 7 presents the references cited in the document; and
- Section 8 lists the acronyms used in the text.

It is important to note that this report details the results of the *modified* sampling program, per the NYSDEC's November 7, 2017, response and approval of WSP's October 2017 proposed program modifications. The details of the modified sampling program, which includes sampling the six remaining wells at the site, are presented below.

2 BACKGROUND

The former GIC site is located at 1 Kenyon Press Drive in Sherburne, Chenango County, New York (Figure 1). Originally developed in 1947 for the Technical Appliance Corporation of America, the 5.5-acre site was purchased by Jerrold Electronic Corporation in 1962 and by GIC in 1969. General Instrument used the facility to produce aluminum television antennas, antenna controllers, and other small electronics from 1969 until manufacturing operations ceased in 1983. The facility was decommissioned and subsequently sold in 1989 to Kenyon Press, Inc., a commercial printing company. Kenyon Press, which was in business at the site following their purchase, reportedly ended operations at the former GIC facility in November 2018.

The major physical features of the site include a 75,000-square-foot main building formerly used for manufacturing, warehousing, and administration, and a 4,900-square-foot plating building formerly used for plating, etching, and vapor degreasing (Sheet 1). The site also includes two other buildings, a 1,600-square-foot garage near the southeast corner of the main building that was formerly used as a maintenance shop, and a 2,800-square-foot wooden shed near the western property line that was formerly used to store machinery and materials.

The site is surrounded by a bulk petroleum storage facility, and Mirabito Convenience Store[3] (and gasoline station) to the north; light commercial property to the east and south; the Delaware Lackawanna & Western Railroad (DL&W) Railroad to the west; and further to the west by agricultural fields (Sheet 1). VGSI currently leases a portion of the agricultural fields west of the site to allow access for investigation and remedial activities.

2.1 PREVIOUS INVESTIGATION AND REMEDIATION

General Instrument ceased operations and closed the Sherburne facility in 1983. An investigation conducted as part of the closure activities revealed organic and inorganic compounds in soil samples collected from the northwest corner of the facility near the former plating room (Sheet 1). General Instrument excavated and removed the contaminated onsite soils shortly after the soil evaluation was concluded and, in 1985, initiated a groundwater investigation that included the installation of nine groundwater monitoring wells and six piezometers. The results of the investigation indicated the presence of tetrachloroethene (PCE), trichloroethene (TCE), and several other CVOCs in groundwater along the western (downgradient) edge of the property.

The site was designated by the NYSDEC as a Class 2 inactive hazardous waste site in 1987 and GIC agreed, via a 1989 consent agreement, to perform a remedial investigation/feasibility study (RI/FS). The RI/FS, conducted by Stearns and Wheler, LLC (S&W), of Cazenovia, New York, was completed in 1993. The RI identified CVOCs in the soil beneath the plating building; free-phase petroleum product (fuel oil) floating on the groundwater near the northwest loading dock; and a CVOC-affected groundwater plume in the uppermost water-bearing unit extending west beneath a portion of the adjacent property.

A ROD was issued by the NYSDEC in December 1994 approving remedies S&W developed as part of a remedial design and remedial action plan (RD/RA) to address the issues identified in the RI/FS. The RD/RA included the installation of a soil vapor extraction system to treat the unsaturated soil beneath the plating building and a groundwater recovery and treatment system to address the free-phase petroleum (Sheet 1). Both systems were installed, operated, and eventually decommissioned in the mid to late 1990s by S&W after the NYSDEC agreed that their respective cleanup targets had been achieved.

The remedial action developed by S&W for the dissolved CVOC groundwater plume was a passive *in situ* PRB, which was designed to reductively dechlorinate the affected groundwater. In 1997, based on their interpretation of a funnel-and-gate pilot test, S&W installed a full-scale, granular zero-valent iron (ZVI) PRB consisting of two parallel walls oriented roughly north-south and perpendicular to their interpretation of regional groundwater flow (Sheet 1). The longer of the two walls is approximately 410 feet long and was designed to cover the entire breadth of the CVOC-affected groundwater plume. The second, smaller (120-foot-long) wall was installed approximately 30 feet east of the main wall section to provide additional groundwater treatment where the highest CVOC concentrations were expected (i.e., along the core of the affected groundwater plume). Both walls are comprised of granular ZVI extending through the uppermost water-bearing unit from about 3 feet below

[3] Formerly named the Quickway Convenience Store and Gasoline Station.

ground surface (bgs) to approximately 21 feet bgs where they are keyed into a clay unit that underlies the aquifer. Both walls are approximately 1-foot thick. Stearns and Wheler installed a network of groundwater wells in and around the PRB and monitored the performance of the PRB on a quarterly basis for a period of approximately two years after the installation, and twice per year thereafter.

2.1.1 ADDITIONAL INVESTIGATION

The NYSDEC expressed concerns in 2001 regarding the performance of the PRB, including apparent shifts in the groundwater flow directions and changes in the CVOC distribution. To address these concerns, WSP (at the request of VGSI) completed a technical review and developed a conceptual site model using historical groundwater data (ESC Engineering, 2004a and 2004b). The results indicated a slight groundwater mound located east (upgradient) of the barrier, which appeared to be diverting a portion of the groundwater plume around the ends of the PRB along two flow lines designated as the northern and southern flow lines. Samples from additional wells installed by WSP in 2005 (MW-31 through MW-39) indicated some systematic decrease of CVOC concentrations along the northern and southern flow lines with the concentrations near the ends and further downgradient of the barrier one to two orders of magnitude below those in samples from the area around P-8 and MW-17 (i.e., upgradient of the PRB where the highest concentrations of CVOCs were consistently detected; ESC Engineering, 2006). The data suggested that, while the PRB was not performing exactly as designed, the bulk of the untreated CVOCs had not flowed around the ends of the barrier and instead remained upgradient of the treatment system.

WSP followed the technical review and groundwater well installation with pre-design investigations conducted in 2008. The investigations were intended to refine the extent of the CVOCs and evaluate potential remedial alternatives for the CVOC-affected groundwater bypassing the PRB. The results revealed that the relatively high concentrations of CVOCs at MW-17 and P-8 were limited in extent and indicated that no significant concentrations of CVOCs were present in the former source area on the main site (WSP Engineering of New York, 2009a; Sheet 1). The CVOCs that were detected in and around MW-17 and P-8 were dominated by dechlorination breakdown products, such as 1,2-dichloroethene (1,2-DCE) and vinyl chloride. Analysis of the carbon stable isotope ratios in the CVOCs further indicated that the compounds had biodegraded from TCE. Concurrent biological census data and geochemical data suggested that the intrinsic oxidation-reduction (redox) conditions and indigenous halorespiring microbial population could be sufficiently enhanced through the addition of an electron donor to stimulate reductive dechlorination.

2.1.2 SUPPLEMENTAL REMEDIATION

WSP implemented a supplemental remedial action plan (SRAP) in October 2009 based on the results of the 2008 pre-design investigation. The SRAP was designed to augment the PRB's treatment of the CVOC-affected groundwater that remained upgradient of the barrier (WSP Engineering of New York, 2009b). The bioremediation amendment 3-D MicroEmulsion® (3DMe) was injected into the subsurface to adjust the redox conditions and spur microbial growth within the saturated zone through the introduction of an electron donor source. The 3DMe amendment selected was a low-viscosity formulation that allowed for treatment below surface barriers such as the DL&W Railroad at the site (Sheet 1).

Two supplemental treatment areas, designated the northern and southern treatment areas, were identified based on the pre-design investigation data. The northern treatment area, centered on monitoring wells MW-17 and P-8, was treated with 108 injection points in a 10-foot by 10-foot grid covering approximately 11,800 square feet (ft^2) near the northern terminus of the PRB (i.e., along the northern flow line; Sheet 1). The southern treatment area was treated with 30 injection points (covering approximately 3,000 ft^2) positioned around wells MW-22, MW-31, and MW-32 in a pattern parallel to the southern flow line. Approximately 25,000 gallons (about 170 gallons per injection point) of the 3DMe amendment were injected into the subsurface using temporary direct-push injectors. Performance monitoring activities were conducted for two years after the October 2009 implementation of the SRAP to demonstrate the effectiveness of the injection program.

WSP completed a review of the SRAP performance monitoring data in May 2012 to assess whether the treatment goals had been achieved. As detailed in the *Combined October and December 2011 Semiannual Groundwater Sampling and Supplemental Remedial Action Review Report*, total CVOC concentrations in the northern treatment zone and areas directly downgradient had been reduced to trace concentrations and significant reductions had occurred in the southern treatment zone (WSP Engineering of New York, 2012a; Sheet 1). Bio-assays and monitored natural attenuation (MNA) samples collected over the last two quarters of 2011 showed that the halorespiring microbial populations had stabilized and that redox conditions

remained sufficient to drive ongoing enhanced reductive dechlorination. WSP concluded that the SRAP had achieved its goals in all but one monitoring point, P-8.

Groundwater samples collected from monitoring well P-8 did not exhibit the same level of CVOC mass reduction observed in the samples collected from other northern treatment area wells (Sheet 1). The compound TCE was consistently detected in post-SRAP performance monitoring samples at concentrations (8.3 to 386 micrograms per liter [µg/l]) above the evaluation criteria[4] (5 µg/l). Similarly, the concentration of *cis*-1,2-DCE (75 to 1,430 µg/l) remained above the evaluation criteria (5 µg/l) throughout the same period. The isotopic analyses of both compounds differed from the fractionation trends in the other wells in the surrounding treatment zone. These data indicated that the SRAP treatment did not have the intended effect in the area around the well.

WSP suspected that the recalcitrant CVOCs were related to lithologic differences near well P-8 and the hydraulic variations at the site (Sheet 1). Comparatively fine-grained soils (e.g., silt and silty clay; the surrounding area is silty sand and gravel) were encountered near the water table interface when the well was installed. These finer soils likely contained relatively high concentrations of adsorbed CVOCs from contact with affected groundwater earlier in the history of the plume before the dissolved CVOCs decreased to their current levels. WSP had also observed a correlation between the CVOC concentrations and the seasonal rise and fall of the water table in the post-SRAP performance monitoring data and, after further investigation, in the historical PRB groundwater monitoring results. Increased concentrations of CVOCs were detected in the P-8 samples after these soils were wetted by the rising water table.

WSP hypothesized that the adsorbed CVOCs were being mobilized via contact with the now lower concentration groundwater (via a concentration gradient – also known as back diffusion) resulting in a persistent influx of CVOCs to the groundwater. WSP also theorized that the lower permeability of the soil surrounding the well had limited the distribution and effectiveness of the SRAP injections.

2.1.3 P-8 SUPPLEMENTAL REMEDIAL ACTION PRE-DESIGN

WSP conducted a membrane interface probe (MIP) investigation in November 2012 to delineate the extent of CVOC-affected media around P-8 (Sheet 1). The MIP was selected for its capability of providing a continuous, real-time assessment of the relative level of chlorinated compounds in both saturated and unsaturated soils. The work, which was conducted in accordance with WSP's *Pre-Design Work Plan*, dated September 11, 2012, included the installation of 14 MIP borings, and designated MP-1 through MP-14, in a loose grid around the well (see enlargement of P-8 area on Sheet 2). Additional borings were installed, as necessary (using the real-time data as a guide to steer the investigation), until the extent of CVOCs in both soil and groundwater were fully defined.

The results of the investigations not only revealed elevated MIP responses indicating an area of affected media near well P-8, but outlined a zone of coincident heterogeneous soil (Sheet 2). The affected area, as defined[5] by the elevated MIP responses in borings MP-7, MP-9, MP-4 and MP-10, all contained a significantly higher fraction of fines (e.g., organic silts and clays) in the upper few feet of the soil profile as compared to the surrounding area. Moreover, the highest concentrations of CVOCs were detected within these soils and, when compared to the groundwater monitoring data, appeared to be directly related with the fluctuations in the water table. The results from MIP boring MP-7, for example, showed elevated MIP responses corresponding to a stratigraphic sequence of silt and organic-rich clay in the shallow portion of the soil profile (straddling the water table surface) with the peak MIP responses correlated to the 8-year average groundwater elevation and the historical high stands (based on the PRB and post-SRAP monitoring data for the site). The MIP responses decreased as the sediments coarsened to silty and sandy gravel with depth. Similar responses were noted in the other MIP borings outlining the heterogeneity. These data confirmed WSP's hypothesis that the recalcitrant CVOCs observed in the samples from P-8 were related to the interaction between the water table and the heterogeneous soils within the smear zone of the affected area.

[4] New York State Ambient Water Quality Standards or Guidance for Class GA water provided in the New York State Department of Environmental Conservation Division of Water, Technical, and Operation Guidance Series (1.1.1), dated June 1998, and in the April 2000 Addendum.

[5] The bounds of the heterogeneity were defined by the MIP borings, but are not depicted on Sheet 2 for clarity. See *the Combined Pre-Design Investigation Report and P-8 Supplement Remediation Work Plan*, dated January 9, 2014, for additional information.

The findings of the investigation were presented, along with WSP's proposal for a focused, supplemental remedial action to address the recalcitrant CVOCs (i.e., a polishing treatment), in the *Combined Pre-Design Investigation Report and P-8 Area Supplemental Remediation Work Plan* (P-8 Work Plan), dated January 9, 2014. The NYSDEC approved the scope of work in a letter dated, January 29, 2014.

2.1.4 P-8 SUPPLEMENTAL REMEDIAL ACTION AND 12-MONTH REVIEW

WSP implemented the approved P-8 supplemental remedial action in May 2014. The action included a focused injection program[6] in and around the soil heterogeneity where the elevated CVOC concentrations were detected during the MIP investigation, and pre- and post-treatment performance monitoring of the groundwater within the injection zone to demonstrate the efficacy of the remedy. To maximize efficient delivery of amendment, WSP established a closely-spaced injection grid pattern and used SRS-Z®, a commercial formulation variant of the National Aeronautical and Space Administration's patented EZVI® amendment, manufactured by Terra Systems, Inc., of Claymont, Delaware. The amendment, an *in situ* chemical reductant, contains two remedial technologies proven to be effective at the former GIC site: ZVI and a fermentable carbon food source to enhance anaerobic bioremediation. The SRS-Z® amendment is specifically designed for greater penetration into low-permeability soils than typical grout-style ZVI amendments. In addition, the emulsified ZVI, once injected, is relatively immobile within the subsurface. The iron can remain reactive, depending on the specific conditions, for three to five years allowing continued treatment of the CVOCs, as they diffuse from less permeable locations within the soil matrix.

The treatment zone consisted of 25 injection points within an area of approximately 1,225 ft^2, which encompassed the areal extent of the highest CVOC concentrations in groundwater and the interpreted soil heterogeneity delineated during the pre-design investigation (Sheet 2). The injection points, designated IN-139 through IN-163, were spaced approximately 7 feet apart within the grid. The amendment was introduced from the top of the anticipated water table during seasonal high stands (approximately 1,046 feet above mean sea level [AMSL; 3 to 5 feet bgs]) to the base of the upper water-bearing zone at approximately 1,029 feet AMSL (17 to 19 feet bgs). The treatment was timed to coincide with the relatively high groundwater elevations in the spring to maximize distribution of the amendment. Approximately 1,500 gallons (approximately 60 gallons per point) of pre-mixed SRS-Z® amendment was delivered to the treatment area using temporary injectors. The SRS-Z® application was immediately followed with an application of sodium bicarbonate-buffered potable water (i.e., chase water) to maximize delivery efficiency throughout the treatment zone. Approximately 1,536 gallons of sodium bicarbonate buffer solution containing 650 pounds of total sodium bicarbonate was injected immediately after the SRS-Z® application.

Pre-treatment (baseline) groundwater samples were collected from monitoring wells P-8 and MW-17 in May 2014 immediately before the injections began (Sheet 2). Performance monitoring of the P-8 supplemental remedial action included four quarters of groundwater sampling at these two wells beginning in September 2014 and continuing through June 2016. The samples were analyzed for volatile organic compounds (VOCs), general chemistry parameters (i.e., MNA parameters) indicative of dechlorinating conditions, microbial census, and compound-specific isotope analysis (CSIA) of carbon in site-related CVOCs (i.e., PCE, TCE, *cis*- and trans-1,2-DCE, and vinyl chloride; when present in the samples).

In January 2016, WSP submitted the *Combined Semiannual SRAP Monitoring and P-8 12-Month Review*. The results of the P-8 quarterly performance monitoring showed that the SRS-Z® injection was having the intended effect on the recalcitrant VOCs around P-8, with substantive changes in the dissolved CVOC composition as compared to the May 2014 pre-injection baseline results (Sheet 2). The 2014 and 2015 VOC sampling results indicated mass influx of CVOCs during periods of high groundwater elevations. These findings were expected as CVOCs in the source area become remobilized by the oscillation of the water table. Higher than expected concentrations of CVOCs were observed in nearby well MW-17 due to the migration of remobilized CVOCs from the treatment area.

These findings were supported by the geochemical data, which showed an increase in the dissolved organic carbon (DOC) leading to increasingly reducing conditions. Isotopic results reflected enrichment in the daughter products relative to the baseline results at various times; and the biological census results indicated dramatic increases in key microbes, functional genes and total microbial biomass.

[6] The P-8 supplemental remedial action is an extension of the original 2009 SRAP (i.e., a polishing treatment for the northern treatment area) designed to address recalcitrant CVOCs identified near well P-8 and, as such, uses 2009 metrics for success (i.e., 50-percent reduction of the dissolved CVOCs) established by the NYSDEC. See the *Combined Pre-Design Investigation Report and P-8 Area Supplemental Remedial Investigation Work Plan*, dated January 9, 2014, for additional information.

The conclusion of the 12-month review was that the injections were working as designed. The treatment raised the concentrations of organic carbon and ferrous iron, reduced the oxidation-reduction potential, and the abundances of dechlorinating microbes and genes that code for key enzymes needed for complete degradation of TCE to innocuous end products increased. Initial post-treatment groundwater sampling results indicated a concurrent decline in the dissolved concentrations of total CVOCs within the treatment area with the corresponding isotopic results indicated enrichment of both the parent and daughter compounds. These early results provided strong evidence that reductive dechlorination was occurring.

Subsequent data indicated an anticipated rebound in the overall CVOC concentrations in samples from wells P-8 and MW-17 largely due to the demonstrated historical relationship between the seasonal fluctuations in the water table and periodic increases in CVOCs. The geochemical, biologic, and isotopic data continued to indicate that the amendment remained active, despite the influx of CVOCs. WSP concluded that the increases in total CVOC concentrations were transient fluctuations in an expected (overall) downward concentration trend as the CVOC mass in the vadose zone was treated by the *in situ* SRS-Z®. Additional data, however, were necessary to clearly demonstrate the anticipated reductions in the CVOC mass (the results of the additional sampling beyond the 12-month review are presented below).

2.2 MODIFICATIONS TO THE PERFORMANCE MONITORING SCHEDULES

A concurrent analysis of the long-term PRB and SRAP performance monitoring results was completed during the P-8 treatment 12-month review. The long-term trend and distribution of CVOC concentrations were, at the time of the analysis, generally consistent with historical observations and interpretations, including those of the 2012 SRAP review. Groundwater elevation results consistently indicated that the PRB continued to influence the overall groundwater flow pattern by diverting a portion of the flow around both ends of the barrier, regardless of seasonal water table fluctuations. The post-SRAP CVOC concentrations in wells situated along flow lines both north and south of the PRB were consistently lower than at any time before the supplemental treatment.

The monitoring programs were modified, based on these favorable geochemical conditions and observed declines in VOC concentrations, to both discontinue sampling at a subset of the monitoring wells and the reduce the sampling frequency for the remaining wells in the network (see details of historical modifications to the performance monitoring programs in Section 2.2 below). Specifically, the monitoring program was modified as follows:

- The P-8 supplemental treatment performance monitoring program was extended through 2016; the sampling frequency was reduced from four times per year to three times per year (i.e. triannual), occurring in April, August, and December.
- The number of analyses per event was streamlined eliminating unnecessary redox indicators; the remaining analysis focused indicators of active reductive dechlorination and the end products of such reactions.
- The number of biological samples was reduced to focus on active dechlorinating microbes, the necessary functional genes, and indicators of overall microbial health.
- The frequency of the PRB and SRAP performance monitoring program was reduced to annual, and modified to exclude both wells upgradient of the PRB (e.g. MW-08, MW-18) and wells along the central portion of the barrier (e.g. MW-23, MW-26, MW-27, MW-29, MW-30, MW-35, MW-36, P-3 and P-10) where CVOCs had not been detected for nearly a decade.

At the completion of the 2016 sampling period, WSP and VGSI proposed additional modifications to the 2017 groundwater monitoring programs:

- The P-8 supplemental treatment performance monitoring program was extended through 2017 on a triannual basis (i.e., April, August and December).
- Monitoring well MW-17 was removed[7] from the P-8 triannual performance monitoring program.

[7] The concentration of CVOCs in samples collected from MW-17 had attenuated to levels below the evaluation criteria, and the corresponding geochemical and biological data indicated that reductive dechlorination had significantly diminished.

2.2.1 2017 MODIFIED PERFORMANCE MONITORING PROGRAM

The results of the 2017 modified performance monitoring program were generally consistent with historical observations and interpretations, including those of the 2012 SRAP review. Substantive decreases in the dissolved CVOC concentrations around P-8 (following the rebound evident in winter 2014 and 2015) were supported by the isotopic results, which reflected periodic ^{13}C enrichment in the daughter products relative to the parent material, as well as a long term progressive isotopic enrichment of *cis*-1,2-DCE and vinyl chloride through time. The biological census results indicated modest declines abundances of key microbes, functional genes and total microbial biomass at P-8, which were expected based on the observed reductions in VOC concentrations. Taken together, these data were interpreted as strong evidence that the SRS-Z® injection was having the intended effect and additional modifications to the performance monitoring programs were proposed at the end of 2017.

WSP submitted a request to the Department prior to the 3rd triannual sampling event at the end of 2017. That request, subsequently approved[8] by the NYSDEC, included the following modifications:

- The PRB performance monitoring program was discontinued and most of the monitoring wells at the site (i.e., MW-2, MW-8, MW-14, MW-18, MW-20, MW-21, MW-24, MW-25, MW-28, MW-33, MW-35 through MW-39, P-3, P-10 and P-11) were identified for decommissioning (the wells were abandoned in February 2018).
- The frequency of the P-8 area performance monitoring was reduced to an annual basis, beginning in April[9] 2018; three wells (MW-17, MW-31, and P-8) are sampled for CVOCs using the same methods as previous monitoring events (e.g. passive diffusion bag [PDB] sampling); monitoring wells MW-22, MW-32, and MW-34 have been maintained but are not sampled as part of the annual P-8 performance monitoring program.
- The frequency of sampling for select MNA parameters at P-8 was reduced to an annual basis.
- All six remaining wells (i.e., MW-17, MW-22, MW-31, MW-32, MW-34 and P-8) were to be sampled for analysis of VOCs in April 2020 as part of a 5-year review of the P-8 area supplemental treatment performance.

The sections that follow in this report details the sampling of all six remaining wells for VOCs, the P-8 supplemental remedial performance monitoring program results, and a discussion of the overall treatment performance.

[8] WSP submitted a request to discontinue the permeable reactive barrier groundwater monitoring program and modify the P-8 area supplemental treatment performance monitoring program in a letter dated October 23, 2017. The request was approved by the NYSDEC (with some modifications to keep three additional wells, see above) in a letter dated November 7, 2017.

[9] April was chosen, in cooperation with the NYSDEC, as the monitoring period to provide the most conservative evaluation of the data (as indicated by the previous sampling results).

3 PERFORMANCE MONITORING

WSP completed the modified performance monitoring at the site on April 28, 2020. The work included the annual sampling of monitoring well P-8 to determine the current conditions within the P-8 supplemental treatment area, and sampling of the balance of the monitoring wells at the site (MW-17, MW-22, MW-31, MW-32, and MW-34) as part of the NYSDEC-requested assessment of the overall groundwater conditions at the site (Sheet1). Samples for analysis of VOCs were collected from all six wells using PDBs placed in the wells during the previous sampling event in April 2019. The deployment and recovery of the PDBs are detailed below. Additional analytical groundwater samples were collected from monitoring well P-8 (as part of the remedy evaluation) in accordance with low flow sampling techniques specified in the U.S. Environmental Protection Agency's (EPA's) *Low-flow (Minimal Drawdown) Groundwater Sampling Procedures* (EPA 1996) and WSP's SOP 11 (Appendix A). The samples were collected (after the PDB was removed) for the analysis of select monitored MNA parameters, CSIA, and microbial ecology.

The modified groundwater monitoring program, including pre-sampling synoptic depth-to-groundwater measurements at all the wells, was performed following the sampling procedures outlined in Jan 2014 Combined Pre-Design Investigation Report and P-8 Area Supplemental Remediation Work Plan. The methods for each activity are presented below and the results are summarized in Tables 1 through 5. Historical elevations and analytical results are included on Tables 2, 4, and 5 to aid in evaluating the current groundwater data.

3.1 GROUNDWATER ELEVATION MEASUREMENTS

Depth-to-groundwater measurements were collected from the six remaining onsite monitoring wells to determine groundwater elevations for the site. Each well was uncapped and allowed to stand for a minimum of 15 minutes (for equilibration with the atmosphere) and then gauged using an electronic water level indicator. The gauging was conducted in advance of the PDB recovery and the collection of the analytical samples (described below) to ensure static water level conditions before the sampler was removed. Measurements were made to the nearest 0.01-foot with the results recorded in the field notebook.

The depth-to-groundwater measurements are presented in Table 1 and were used to calculate groundwater elevations for each well. Historical groundwater elevations in the remaining six site wells dating back to 2004 are included in Table 2 for comparison.

3.1.1 GROUNDWATER ELEVATION RESULTS

The April 2020 groundwater elevations in the six gauged monitoring wells ranged from a low of 1,044.77 feet AMSL in monitoring well MW-34 near the northern end of the PRB to a high of 1,045.38 feet AMSL at monitoring well MW-31 near the southern end of the barrier (Sheet 1; Table 1). The elevations were up to 0.25 foot lower than those measured in during the previous sampling event in April 2019, but within the historical range of elevations (including the previously-described seasonal trends) for these wells (Table 2).

The existing monitoring well network comprises a transect roughly parallel to the PRB and perpendicular to the historical westerly groundwater flow direction (Sheet 1). The well positions, while good for monitoring the water quality in the areas of interest, do not lend themselves to calculating the hydraulic gradient (*dh/dl*) or generating a meaningful groundwater elevation contour map. No site gradient was calculated or elevation contour map prepared for this report.

3.2 GROUNDWATER ANALYTICAL SAMPLING PROCEDURES

WSP collected groundwater samples for analysis of VOCs from the six remaining wells at the site (P-8, MW-17, MW-22, MW-31, MW-32 and MW-34; Sheet 3). Those samples were collected from each well using PDB samplers obtained from ALS

Environmental, an analytical laboratory in Rochester, New York, that were deployed[10] at the end of the previous sampling event. The PDB samplers used at the site consisted of 24-inch long, 1.25-inch diameter, heat-sealed, low density polyethylene permeable membranes pre-filled with 220 milliliters of laboratory-grade analyte-free, de-ionized water. The samplers were fitted with stainless-steel weights and suspended in each well using dedicated Teflon®-coated steel lift lines secured to the well casing. Each sampler was positioned at the midpoint of the well's screened interval to allow equilibration with the surrounding formation water. The analytical samples were collected from the PDBs by retrieving each sampler, slicing it open at one end using decontaminated field scissors, and pouring the contents into the appropriate laboratory-supplied, pre-cleaned sample vials. The sampling included, as detailed below, the collection of a blind duplicate and matrix-spike/matrix-spike duplicate samples for quality assurance/quality control (QA/QC) purposes, in accordance with WSP's SOP 4 (Appendix A).

Groundwater samples for analysis of select MNA parameters, CSIA, and an assessment of the microbial population were collected from well P-8 (after the PDB was removed from the well for the VOC sampling and the water levels were allowed to stabilize) using low flow sampling techniques (Sheet 1). The well was first purged and, later, sampled using QED Environmental Systems, Inc. (QED) MP15 MicroPurge® Controllers (to adjust the flow rates) and CO2-driven QED Sample Pro® bladder pumps equipped with dedicated polyethylene bladders and tubing. The bladder pump was positioned at the midpoint of the monitoring well screen and purged at a rate between 0.2 and 0.5 liter per minute. Temperature, pH, specific conductance, dissolved oxygen (DO), turbidity, oxidation-reduction potential (ORP), and drawdown were monitored every 5 minutes during the purge process using a Horiba U-52 water quality meter equipped with a flow-through cell. Purging continued until water quality parameters stabilized (±10-percent for temperature, turbidity, DO, and ORP; ±0.1 unit for pH; ±3-percent for specific conductance; and drawdown variance less than 0.3 foot) and the turbidity readings were less than 50 nephelometric units. The analytical samples were collected directly from the pump discharge tubing after the field parameters stabilized. All the low flow sampling work was performed in accordance with WSP's SOP 11 and the EPA's *Low Flow (Minimal Drawdown) Groundwater Sampling Procedures* (EPA 1996; Appendix A). The low flow sampling field form for the monitoring well P-8 is included in Appendix B.

The analytical samples recovered from the PDBs and the low flow sampling of well P-8 were labeled, packed on ice, and shipped by overnight carrier to one of three analytical laboratories, depending on the parameters (Sheet 1). The water quality (VOC) samples recovered from the PDBs were shipped to SGS North America[11], Inc. (SGS), of Dayton, New Jersey, for analysis of VOCs by U.S. Environmental Protection Agency (EPA) Method 8260. The MNA samples were shipped to Pace Analytical Services, LLC, in Greensburg, Pennsylvania, for analysis of ethene, ethane, and methane by Method AM20GAX; DOC (field-filtered with an in-line 0.45-micron filter) by EPA Method number 9060; and CSIA by method number AM-24-DL-C. The microbial samples were shipped to Microbial Insights, Inc., in Knoxville, Tennessee, for assessment by quantitative polymerase chain reaction (qPCR) of the indigenous halorespiring microbes *Dehalobacter spp*. (DHBt) and *Dehalococcoides spp*. (DHC); and, the associated key functional (dechlorination) enzymes, tceA reductase, BAV1 vinyl chloride reductase, and vinyl chloride reductase. The populations of methanogens and total eubacteria abundances were also evaluated by Microbial Insights. All samples were maintained and shipped in accordance with WSP's SOP 3 (Appendix A).

Laboratory results for the VOC analysis are included in Appendix C with results for the MNA and CSIA, and the microbial assays presented in Appendices D, E, and F, respectively.

3.2.1 QUALITY CONTROL PROCEDURES

WSP collected the following QA/QC samples at the rate specified in WSP's SOP 4:

- trip blanks (labeled with the prefix "TB" or as "trip blanks") were submitted with the shipment of samples for VOCs analysis to SGS; the trip blanks were included at a rate of one blank per shipment containing samples for VOC analysis;
- equipment blanks (labeled with the prefix "EB") were collected by pouring laboratory-supplied deionized water over the decontaminated sample equipment; the blanks were collected at a rate of one per day per sampling apparatus (no equipment blanks were collected for the dedicated, single-use PDB samplers);

[10] The PDBs were placed in the wells (and later retrieved and sampled) in accordance with the methods outlined in a letter to the NYSDEC from WSP, dated November 16, 2006; the User's Guide for Polyethylene-Based Passive Diffusion Bag Samplers to Obtain Volatile Organic Compound Concentrations in Wells (Vroblesky, 2001); and in accordance with WSP's SOP 11 (Appendix A).

[11] Formerly known as SGS Accutest, Inc.

- blind duplicates were collected during each sampling event at the rate of one duplicate per 20 samples; and
- matrix spike/matrix spike duplicate (MS/MSD) sample pairs were collected from at a rate of one MS/MSD pair per 20 samples collected.

Data validation was performed by Laboratory Data Consultants, Inc. (LDC), of Carlsbad, California, in accordance with the EPA *Contract Laboratory Program National Functional Guidelines*[12]. Data validation reports for the groundwater monitoring are included in Appendix G.

3.2.2 WASTE MANAGEMENT

Groundwater generated during sampling (i.e., purge water), decontamination rinsate, and other investigation-derived wastes (IDW) generated during the groundwater monitoring activities were contained in appropriately-labeled US Department of Transportation-compliant 55-gallon steel drums. All IDW was managed under existing waste profiles and was disposed of as hazardous waste in accordance with all local, state, and federal requirements and WSP's SOP 5 (Appendix A).

[12] Data validation was not conducted on CSIA or qPCR analysis. National Functional Guidelines are not available for these procedures.

4 MONITORING RESULTS

The groundwater sampling results are detailed below in two sections: the water quality (VOC) data, which discuss the site-related compounds detected in samples from all six remaining wells; and, for the supplemental performance sampling at well P-8, the findings of the additional MNA, CSIA, and microbial ecology analyses. The latter grouping, because of their complex and interrelated nature, are discussed as part of the overall analysis. The CSIA and biological assay (qPCR) data, for example, which are directly related and provide insight into the level and mechanisms of degradation, are presented together rather than in stand-alone sections. The intent is to provide a framework for reference while tracking the progress of the remedy.

The presentation of the results assumes a level of background familiarity with the methodologies and data evaluation approaches and, thus, only brief, in-line descriptions of the significance of the data are included. Detailed explanatory sections for the more complex analyses, such as the isotopic evaluation and microbial essays, are presented in the *2014 Combined Pre-Design Investigation Report and P-8 Supplemental Remediation Work Plan* and previous remedial performance monitoring reports.

4.1 VOLATILE ORGANIC COMPOUND SAMPLING RESULTS

The April 2020 groundwater monitoring results revealed only two site-related[13] CVOCs at concentrations above their respective evaluation criteria (Table 3). Concentrations of the dechlorination daughter products *cis*-1,2-DCE (9.2 to 22.3 µg/l) and vinyl chloride (3.3 to 12.3 µg/l) were detected in the samples from monitoring well P-8 within the remedial treatment area; and, in the samples from monitoring wells MW-22, MW-32, and MW-31, all of which are near the southern end of the PRB (Sheet 3). The highest concentrations of total CVOCs were detected in the P-8 sample; however, the concentration differences between the wells was negligible. The total CVOC concentrations from well P-8 (32.1 µg/l) were only slightly greater than the total CVOCs from well MW-22 (27.1 µg/l) or MW-32 (23.2 µg/l). Notably, the concentrations of all the CVOCs detected, including the vinyl chloride in wells P-8, MW-22, and MW-32, were only slightly greater than the evaluation criteria.

No other site-related CVOCs, including the parent compound TCE, were detected in the samples at concentrations above the evaluation criteria. These findings include the samples from wells MW-17 and MW-34 at the northern end of the PRB (i.e., in the 2009 SRAP northern treatment area) adjacent to and downgradient of the P-8 treatment area (Sheet 3). The significance of the water quality results from well P-8 and the portions of the site beyond the treatment area are discussed in Section 5 below.

4.1.1 NATURAL ATTENUATION, ISOTOPIC, AND BIOLOGICAL SAMPLING RESULTS

The P-8 remedial performance evaluation included *in situ* measurements and analyses of select parameters designed to assess geochemical and thermodynamic conditions, determine if the halorespiring microbes (and their functional genes) are present, and evaluate whether reductive dechlorination is occurring within the treatment zone. The field measurement conducted at well P-8 prior to the analytical sampling indicate a moderately strong reducing environment (ORP value of -87 millivolts [mV]) with nondetectable concentrations of DO (i.e., the groundwater is anaerobic; Sheet 3; Table 5). Temperature and the circumneutral pH measurements (necessary to promote dechlorination) of groundwater at well P-8 were also within the range of values historically observed at the site. These results are comparable with previous post-remediation findings for groundwater within the treatment area (including those detailed in the *2016 Combined Semiannual SRAP Monitoring and P-8 12-Month Review)* and are consistent with the intent of the remedial injections to create suitable conditions for reductive dechlorination.

MICROBIAL CENSUS AND DISSOLVED GASES EVALUATION

The microbial ecology samples from monitoring well P-8 contained a modest population of one of the two previously-detected indigenous halorespiring microorganisms (Sheet 3). The microbe DHC was present in the groundwater at levels of

[13] The April 2020 volatile organic compound were analyzed for several petroleum-related hydrocarbons, including benzene, toluene, and naphthalene. This analysis was conducted for consistency with past sampling events, which focused on evaluating the extent of a petroleum release at the facility that occurred in the 1980s. None of the petroleum-related compounds were detected at concentrations above the method detection limit (Table 4; Appendix B).

4.24E+03 cells per milliliter (cells/ml; Table 5). This population count, although lower (up to two orders of magnitude) than post-treatment levels measured in 2014 and 2015, is consistent the abundances of DHC detected over the past three years. The continued presence of DHC, while below the 1.0E+04 cells/ml threshold typically indicative of a flourishing microbial community, is important as it is one of the few halorespiring microbes capable of reducing chlorinated compounds like PCE and TCE through vinyl chloride to their innocuous end products of ethene and ethane (these compounds were detected in the dissolved gas analysis; see below). The assay revealed that the population of the second indigenous dechlorinating microbe DHBt, which was present in the pre-treatment samples and was detected at relatively modest abundances (2.13E+02 to 5.65E+03 cells/ml) through the first three years following the remedial injections, was reduced to trace levels (4.63E+0 cells/ml) in the December 2017 samples and to nondetectable levels in the April 2019 and 2020 samples. These reductions in DHBt, a microbe that is capable of dechlorinating PCE or TCE to *cis*-1,2-DCE (but generally not beyond *cis*-1,2-DCE), contrast with the balance of the biological results. The total Eubacteria count, which is a measurement of total bacterial biomass (1.14E+06 cells/ml), remained relatively high (as compared to the baseline) and there was an appreciable population of methanogens (6.31E+03 cells/ml) and dissolved methane (see below). Both are generally seen as proxies of the overall ecological health of the system (the biomass increased after the SRS-Z® injections) and, in the case of the methanogens (obligate anaerobes), support the geochemical measurements detailed above indicating a post-treatment reducing environment suitable for microbial growth.

The ecology samples from monitoring well P-8 were also evaluated for the presence and abundances of key functional genes (e.g., enzymes) necessary for hydrogenolysis (Sheet 3). The results revealed relatively low levels of tceA reductase (5.6E+00 cells/ml), and BAV1 vinyl chloride reductase (1.1E+00 cells/ml) with no detectable vinyl chloride reductase (Table 5). These abundances are lower than that detected during the previous monitoring event in 2019, but remain above the levels detected in the pre-treatment (baseline) samples collected in May 2014. Their presence in the water-bearing zone indicates that CVOC reduction through vinyl chloride remains possible. Moreover, they are an important line of evidence that, along with the dissolved gas and isotopic results, supports the interpretation that microbially-mediated dechlorination is occurring within the treatment area.

The MNA data and dissolved gases analyses for the well P-8 samples exhibited results consistent with the previous post-treatment monitoring data (Sheet 3). The DOC was measured at a concentration of 4.3 milligrams per liter (mg/l), which is approximately the same concentrations detected in the treatment area over the past 4 years (Table 5). This level of DOC, although lower than the concentrations[14] following the injections, remain sufficient to drive the microbial dechlorination process. The dissolved gases analysis likewise revealed a relatively robust concentration of methane (10,000 µg/l), consistent with the presence of methanogens and comparable to previous post-treatment levels; and, more importantly, modest concentrations of the dechlorination end products ethane (17 µg/l) and ethene (9.5 µg/l). The continued presence of ethene and ethane in all the post-treatment monitoring samples, along with the ecology data and the isotopic results presented below, are strong evidence that the reduction through vinyl chloride is occurring (i.e., the reductive pathway is complete).

ISOTOPIC RESULTS

The CSIA results for the sample from monitoring well P-8 show definitive evidence of reductive dechlorination (Sheet 3). The $\delta^{13}C$ value for the two remaining CVOCs, *cis*-1,2-DCE (-3.68 per mil [‰]) and vinyl chloride (-12.97 ‰), are substantially enriched (more positive; generally indicative of sequential dechlorination) than the depleted baseline values of -28.30 ‰ and -38.60 ‰ for *cis*-1,2-DCE and vinyl chloride, respectively (values that are isotopically depleted with respect to the as-manufactured parent compound isotopic range; Table 5). The April 2020 findings not only demonstrate reductive dechlorination, they are part of a post-treatment trend that, when viewed over time, reveals a systematic enrichment corresponding to the CVOC concentrations decreases over the same period (Table 4). The relationship between the VOC and CSIA results, and the overall importance of the isotopic data is discussed further in Section 5 below.

[14] The current concentrations of DOC are lower than those observed immediately after the P-8 treatment. This is likely the result of the bioconsumption of the dissolved, readily-available "quick-burn" fermentable carbon that was introduced as part of the amendment (i.e., the relatively higher levels of DOC were quickly consumed by the microorganisms in the water-bearing zone). The current residual concentrations, which are consistent with the slow-release of longer-chain fatty acids introduced in the injectate, are sufficient (as evidenced by the associated data) to continue to drive the dehalogenation process.

5 INTERPRETATION

The April 2020 remedial performance groundwater sampling confirm earlier findings detailed in the 2016 Combined Semiannual SRAP Monitoring and P-8 12-Month Review and the subsequent groundwater monitoring reports. Specifically, the April 2020 remedial performance groundwater sampling revealed results that indicate the P-8 supplemental remedial action is achieving the remedial goals. The post-treatment groundwater geochemistry within the injection area, the alteration of which was described in previous monitoring reports, remains suitable for reductive dechlorination. The water-bearing zone near well P-8 is anaerobic, as evidenced by the nondetectable levels of DO and the presence of obligate anaerobes; strongly reducing (methanogenesis thermodynamic range), as indicated by the -87 mV ORP values; and, exhibits a pH that is optimum for halorespiring microbes to flourish and effectively mineralize the CVOCs (Sheet 3). The sampling also indicated modest amounts of DOC consistent with the slow-release carbon component in the SRS-Z® amendment; and, notable populations of DHC, a key halorespiring microbe[15], and the functional genes necessary for reductive dechlorination through vinyl chloride. The abundance of this microbe and the enzymes in the April 2020 sample is lower than the peak populations detected in the 2016 performance monitoring samples (the current population is equivalent to the levels detected in the May 2014 baseline sample), but remains sufficiently robust (as indicated by the VOC and isotopic analyses below) to systematically degrade the CVOCs at the site, including TCE, to their innocuous end products. The reduction in DHC abundance correlates, as expected, with the diminishing concentrations of CVOCs remaining in the P-8 treatment area.

The biologic and geochemical changes reflected in the remedial performance groundwater samples from well P-8 following the injections directly impacted the dissolved chlorinated mass at the site (Sheet 3). Those impacts are best visualized by reviewing the current data in the context of the historical results, as presented in Figures 2 and 3. Figure 2 depicts the concentrations of TCE, and the daughter products *cis*-1,2-DCE and vinyl chloride, in the groundwater samples from well P-8 extending from June 2004 through the current monitoring period. The portion of the figure before the 2014 P-8 supplemental remedial treatment highlights the persistence of TCE and *cis*-1,2-DCE (and their relationship to the water levels) even after the 2009 SRAP treatment: decreases in the amount of dissolved chlorinated mass were invariably followed by a rebound in the concentrations. The effective recalcitrance of these compounds, which is detailed in previous reports (and in the background section above), led to the MIP investigation, the identification of the heterogeneity, and the eventual SRS-Z® supplemental treatment.

The performance monitoring following the P-8 treatment revealed definitive changes in concentrations of the individual CVOCs detected in the pre-treatment (baseline) samples that, when combined, show a steady (overall) decline in the amount of dissolved chlorinated mass. Those changes, illustrated in Figure 3, included anticipated decreases in the concentrations of TCE and *cis*-1,2-DCE immediately following the May 2014 SRS-Z® injections, followed by a rebound in the levels of these two compounds observed in March 2015 (Figure 3; Table 4). The rebound is consistent with the dynamics of the water-bearing zone before the injections: untreated, sorbed CVOCs were remobilized to groundwater after the seasonal high stand in the winter and spring of 2014 (Table 2; Figure 2). This interpretation is supported by the corresponding isotopic[16] data, also depicted on Figure 3, which parallels the CVOC results. Specifically, the isotopic data shows the initial enrichment of 13C in TCE, *cis*-1,2-DCE, and vinyl chloride in the groundwater at the time of treatment indicating reductive dechlorination, followed by a reversal of the trend as new source material (i.e., untreated CVOCs) was flushed from the vadose zone into the system.

The magnitude of subsequent rebound sequences within the treatment area lessen over time. The concentrations of TCE in the samples from well P-8, for example, increase following post-treatment seasonal high water stands in late 2015 and 2016, but the amplitude is dampened (Figure 3). The high water stands resulted in rebounds with peaks of just 14.2 µg/l in April 2016 and 17.1 µg/l in December 2016, both of which are order of magnitude decrease from the concentrations in the 2015 samples (Table 4; Figure 2). WSP concluded that the systematically reduced levels of rebound are result of amendment introduction in the smear zone (i.e., the amendment is brought into contact with the capillary fringe via the high water table) and its simultaneous treatment of the TCE (and other CVOCs) that does partition into the groundwater. The concentrations of TCE decline to trace (2017) and eventually nondetectable (2019) concentrations with no apparent rebound after the seasonal

[15] The decline of halorespiring microbe DHBt populations to nondetectable concentrations in the 2019 and 2020 performance monitoring samples tracks the decreasing amounts of dissolved TCE, only trace or nondetectable concentrations of which were detected in samples from 2017 through 2020. These findings are consistent with the documented DHBt reductive dechlorination facilitation of select highly-chlorinated VOCs (i.e., parent compounds TCE) with lower efficacy for less chlorinated daughter products, such as *cis*-1,2-DCE or vinyl chloride.

[16] Note that the δ13C axis in Figure 3 is reversed to aid in visualizing isotopic enrichment (i.e., becoming less negative) as an intuitively destructive process.

groundwater fluctuation, described in previous reports as a decoupling of the two mechanisms. These are important findings as they indicate the remedial injections destroyed the TCE within the P-8 treatment area (i.e., a 100-percent destruction rate), including those compounds that were sorbed to the soil matrix within the capillary fringe.

The *cis*-1,2-DCE concentrations in the post-injection performance samples from well P-8 are relatively high and more variable than the TCE, likely due (in part) to the reductive dechlorination of TCE (i.e., the TCE is being converted to 1,2-DCE; Figure 3). The concentrations nevertheless follow the same overall trend decreasing (with some minor variations) from a post-treatment high of 1,810 µg/l in March 2015 to the current trace concentration of 19.8 µg/l, a 99-percent decrease (Tables 3 and 4; Figure 2). The corresponding CSIA results for *cis*-1,2-DCE shows a systematic fractionation from a δ13C value of -28.30 ‰, consistent with the typical as-manufactured (parent) compound isotopic range of -24 to -30 ‰, to a highly-enriched δ13C value of -3.68 ‰ (Table 5; Figure 3). These data demonstrate that the compound, which persisted through the 2009 SRAP treatment, is being reduced by the 2014 P-8 supplemental remedial injections. That is, the *cis*-1,2-DCE is not migrating out of the treatment zone or being attenuated by some other physical mechanism (e.g., sorption, dilution, etc.), but is, instead, being reductively dechlorinated. These findings are supported by the VOC results from nearby monitoring wells MW-17 and MW-34. Not only were the VOCs detected in the post-treatment samples from well MW-17 (due to displacement of affected groundwater during the injections) mineralized, there was no evidence of the migration of affected groundwater from the P-8 treatment area. Likewise, the post-treatment samples from MW-34 did not reveal any downgradient migration from the treatment area of MW-17.

The vinyl chloride followed a similar, but delayed pattern. The concentrations of vinyl chloride in the P-8 samples increased from 4.3 µg/l in the May 2014 baseline (pre-treatment) samples to a peak[17] of 369 µg/l in December 2015, approximately nine months after the TCE rebound (Sheet 3; Table 4; Figure 3). The later peak is likely due to the time delay in the dechlorination sequence: TCE is first converted to *cis*-1,2-DCE, which in turn, is (later) degraded to vinyl chloride. The concentrations have declined since December 2015 to concentrations (12.3 µg/l) 97-percent lower than the peak and only slightly above the evaluation criteria of 2 µg/l. The vinyl chloride CSIA data for the post-treatment monitoring period is analogous to the isotopic results for *cis*-1,2-DCE. The δ13C value, substantially depleted in the baseline samples (-38.60 ‰) and again in the March 2015 samples (-36.61 ‰), well below the typical as-manufactured (parent) compound isotopic range, is systematically enriched to a of δ13C value of -12.97 ‰. The fractionation of vinyl chloride over time, like that of *cis*-1,2-DCE, is definitive proof that the compound is being systematically dechlorinated. These data are consistent with the VOC and dissolved gas findings from P-8 and are supported by the VOC results from nearby wells MW-17 and MW-34, which contain no evidence of vinyl chloride migration.

5.1 ADDITIONAL VOC SAMPLING

The water quality sample results for the remainder of the onsite wells revealed only minor concentrations of dissolved CVOCs outside of the P-8 supplemental treatment area. The results from wells MW-17 and MW-34 revealed only *cis*-1,2-DCE at trace concentrations below the evaluation criteria: no other CVOCs were detected (Sheet 3). These findings are consistent with the 24-month review of the 2009 SRAP (detailed in the May 2012 Combined *October and December 2011 Sampling and Supplemental Remedial Action Review Report)*, which found that the SRAP injections in the northern treatment area were effective at destroying the dissolved chlorinated mass and that the post-injection geochemical and thermodynamic conditions were suitable for supporting ongoing microbially-mediated treatment, if necessary. That ongoing treatment capacity was necessary following the P-8 supplemental remedial action: affected groundwater was displaced from the treatment area and was detected in the samples from MW-17 immediately following the injections. The concentrations of TCE and *cis*-1,2-DCE (up to 35.4 µg/l and 306 µg/l, respectively, in December 2014), and vinyl chloride (up to 20.6 µg/l in June 2015) in the displaced groundwater were, as detailed in previous reports, subsequently destroyed (i.e., 100-percent reduction rate for all three compounds; Table 4). Importantly, no affected groundwater was detected in the performance monitoring samples from MW-34, which is downgradient (along the northern flow line) of both MW-17 and the P-8 treatment area. These findings, as

[17] The December 2015 groundwater monitoring was conducted during the transition between quarterly and triannual sampling frequencies and included the collection of VOC samples only. Samples for the select MNA parameters, CSIA, and microbial ecology were collected during the first triannual sampling event in April 2016.

noted above, support the interpretation that the CVOC mass was being reductively dechlorinated and was not migrating downgradient.

The samples from wells positioned near the southern end of the PRB, MW-22, MW-31, and MW-32, contained concentrations of just two CVOCs, *cis*-1,2-DCE and vinyl chloride (MW-22 and MW-32), at concentrations only slightly above the ambient water quality standards (Sheet 3; Table 3). The detection of these relatively low levels of CVOCs is comparable with earlier monitoring results, both from samples collected as part of the 2009 SRAP performance monitoring program, and those collected since the 2014 P-8 supplemental treatment was implemented. WSP's interpretations of these detections is consistent with previous analysis: they do not represent a new source but, instead, are post-SRAP treatment residual concentrations. WSP anticipates that the CVOCs in these three wells, all three of which are within the 2009 SRAP southern treatment zone, will continue to attenuate over time.

6 CONCLUSIONS AND ADJUSTMENTS TO THE PERFORMANCE MONITORING PROGRAM

The P-8 supplemental remedial action, based on the groundwater performance monitoring data collected for this and previous sampling events, created the conditions for the attenuation of the affected groundwater. The direct measurements and analytical samples revealed favorable post-treatment geochemical and thermodynamic conditions, and a relatively robust microbial community that includes DHC (and its key dechlorination enzymes). Water quality analyses from well P-8 confirm the previously-described decoupling of the CVOC concentration rebound and seasonal groundwater high stands, and the corresponding isotopic data definitively demonstrate that the compounds are being reductively dechlorinated. The concentrations of CVOCs remaining in the samples from well P-8, and those from select other wells outside the treatment area are only marginally above the evaluation criteria.

Specifically, WSP observed the following findings in the remedial performance monitoring results for the P-8 supplemental treatment area:

- The VOC analysis indicates that samples from monitoring well P-8 contained just only two daughter product CVOCs, *cis*-1,2-DCE and vinyl chloride, at concentrations slightly above the ambient water quality standards; the concentrations of the compounds were reduced by 99 and 97-percent, respectively, from their post-treatment peak levels.
- No concentrations of the parent compound TCE were detected above laboratory reporting limits in the April 2020 P-8 supplemental treatment area samples (i.e., 100-percent destruction rate).
- Samples from wells installed in the 2009 (SRAP) southern treatment zone (MW-22, MW-31, and MW-22) contained *cis*-1,2-DCE and vinyl chloride (MW-22 and MW-32) at concentrations slightly above the evaluation criteria; the concentrations are consistent with historical results and are interpreted (as indicated in earlier reports) to be post-treatment residuals.
- The samples from wells MW-17 contained only trace amounts of *cis*-1,2-DCE at concentrations below the evaluation criteria; the previous concentrations of this compound (and others) interpreted to be the result of affected groundwater displacement during the injections are not present and were determined to be mineralized (100-percent destruction).
- The microbial ecology samples from monitoring well P-8 revealed post-treatment populations of DHC that are consistent with abundances of this microbe detected in monitoring samples collected in 2017 and 2019; these data comport with the VOC, dissolved gas, and isotopic findings and provide evidence that reductive dechlorination is occurring and the degradation pathway is complete.
- The results revealed tceA reductase and BAV1 vinyl chloride reductase at abundances that are lower than that detected in during the previous sampling event in 2019, but remain above the levels detected in the pre-treatment (baseline) samples; Their presence not only indicates that CVOC reduction through vinyl chloride is possible, it provides evidence that, along with the dissolved gas and isotopic results, supports the interpretation that microbially-mediated dechlorination is occurring within the treatment area.
- The census data did not reveal detectable populations of the indigenous halorespiring microbe DHBt in the samples from monitoring well P-8, which corresponds to the nondetectable concentrations of TCE (DHBt is capable of dechlorinating PCE or TCE to *cis*-1,2-DCE, but not is well suited to breakdown beyond the 1,2-DCE step).
- A substantive population of methanogens (obligate anaerobes) is present within the treatment zone confirming the direct measurements indicating reducing conditions are present in the P-8 treatment zone; the presence of methanogens (along with the relatively high abundances of total Eubacteria) are generally indicative of a healthy microbial environment within the water-bearing zone.
- The dissolved solids analyses revealed DOC concentrations consistent with the slow-release phase associated with the SRS-Z® amendment; the levels are lower than those immediately following the injections (during the quick-release phase of the amendment) but remain sufficient to drive the microbial dechlorination process.

- The isotopic analysis of samples collected from well P-8 show a systematic post-treatment enrichment trends in the δ13 values for *cis*-1,2-DCE and vinyl chloride (corresponding to the post-remediation concentration decreases in both compounds detailed in the VOC results) culminating with highly-enriched δ13 values (-3.68 ‰ and vinyl chloride -12.97 ‰, respectively) in the April 2020 results; these findings are a line of evidence indicating that reductive dechlorination in the P-8 treatment area is occurring.
- The samples from well P-8 revealed the presence of the modest concentrations of the innocuous product ethene and ethane; the continued presence of ethene and ethane in all the post-treatment monitoring samples, along with the ecology data and the isotopic results, are strong evidence that the reduction through vinyl chloride is occurring (i.e., the reductive pathway is complete).

6.1 CONCLUSIONS AND RECOMMENDATIONS

The data collected as part of the P-8 supplemental remedial action performance monitoring demonstrate that the treatment addressed the recalcitrant CVOCs. The results show a decoupling of the relationship of the CVOCs to the seasonal water fluctuations and substantive, long-term reductions in the chlorinated mass. The current and historical performance monitoring results indicate that TCE was destroyed and the 97-percent or more decreases of both *cis*-1,2-DCE and vinyl chloride. The concentrations of the latter two compounds remain just marginally above the evaluation criteria. The *cis*-1,2-DCE was detected at concentrations less than 20 µg/l and the vinyl chloride detection was less than 13 µg/l. The magnitude of the reductions exceeds the objectives of the P-8 treatment detailed in the *2014 Combined Pre-Design Investigation Report and P-8 Area Supplemental Remedial Investigation Work Plan*. Specifically, the reductions exceed the (minimum) 50-percent reduction in the amount of dissolved CVOCs, which was established as the metric for success[18] by the NYSDEC as part of the 2009 SRAP treatment (the P-8 supplemental remedial action, as a focused polishing treatment, was an extension of the 2009 remedial action).

WSP anticipates that, based on the persistence of the geochemical conditions and the presence of the halorespiring organisms, the remaining (trace) amounts of CVOCs within the injection area will continue to be reductively dechlorinated and eventually mineralized. WSP's overall conclusion is that the P-8 remedial action was efficacious at treating the recalcitrant CVOCs at the site.

6.2 CHANGES TO THE MONITORING PROGRAM AND PROPOSED ADMINISTRATIVE CLOSURE MEETING

The P-8 supplemental remedial action performance monitoring program was ultimately scheduled for five years following the treatment. The final sampling event in the planned program was completed in April 2020. WSP proposes, based on the achievement of the objectives and the overall success of the remedial actions, to discontinue the remedial performance monitoring program. The trace concentrations of CVOCs remaining within the treatment area are comparable to post-treatment residual levels in wells around the PRB and, thus, do not warrant further monitoring.

WSP also proposes suspending monitoring at the wells outside of the P-8 treatment area. The samples from wells MW-17 and MW-34 do not contain any CVOCs at concentrations above the evaluation criteria, and the concentrations in wells MW-22, MW-31, and MW-32 are residual concentrations that have been relatively stable for up to 10 years. Continued monitoring of these wells will not provide data useful in the determination of the site future.

WSP will coordinate with the NYSDEC on the administrative closure activities following the suspension of the monitoring programs, if approved. WSP proposes to meet with the Department either in-person (if conditions are appropriate) or via a call in first half of 2021 to discuss the path forward. WSP will develop a schedule for any required deliverables based on the consensus of the meeting.

[18] The objective of the SRAP was the reduction of the overall CVOC mass within the treatment zones by more than 50-percent, as specified in the Condition Approval letter from the NYSDEC to WSP, dated October 2, 2009.

Table 2

Historical Groundwater Elevation Measurements - 2004 to Present
Former General Instrument Corporation Site
Sherburne, New York (a)

Notes:

a/ All measurements are in feet above Mean Sea Level.

b/ The well head at MW-8 was converted to a flush-mount pad on June 8, 2005. The original ground elevation before conversion was 1048.36 feet above Mean Sea Level, and the original reference elevation was 1050.50 above Mean Sea Level.

c/ Monitoring well MW-18 contained 0.11 feet of free-phase product in November 2004, 0.17 feet in June 2005, 0.05 feet in July 2006, an unmeasured thickness in December 2006, and 0.01 feet in June 2007. No measurable free-phase product was observed on December 20, 2007, or during subsequent sampling events.

d/ The depth to water measurement and calculated groundwater elevation at P-8 in December 2014 are considered inaccurate due to the presence of SRS-Z® amendment in the well. See text for explanation.

Notes:

a/ Concentrations highlighted in bold text and gray shading exceed evaluation criteria; ID = identification; VOCs = volatile organic compounds; µg/l = micrograms per liter; U = compound not detected at or above the reporting limit; UJ = the analyte was not detected above the laboratory reporting limit; J = estimated value below the laboratory reporting limit and above the method detection limit.

b/ Evaluation criteria are the New York State Ambient Water Quality Standards or Guidance Values for Class GA groundwater provided in the *New York State Department of Environmental Conservation Division of Water Technical and Operational Guidance Series (1.1.1)* , dated June 1998, and the April 2000 Addendum.

c/ Sample MW-0420 is a blind duplicate of the sample collected from monitoring well MW-17 collected on April 28, 2020.

a/ All results are reported in micrograms per liter (µg/l). Concentrations highlighted in Bold text and gray shading exceed evaluation criteria; U = compound not detected at or above the reporting limit; J = estimated value below the laboratory reporting limit and above the method detection limit; UJ = the analyte was not detected above the laboratory reporting limit; D = compound identified in analysis at the secondary dilution factor; B =

b/ Evaluation criteria are the New York State Ambient Water Quality Standards or Guidance Values for Class GA groundwater provided in the New York State Department of Environmental Conservation Division of Water Technical and Operational Guidance Series (1.1.1), dated June 1998, and the April 2000 Addendum.

c/ No standard or guidance value for groundwater is available for this substance.

d/ All duplicates were originally designated with unique sample identifications in the field for blind laboratory analysis.

APPENDIX

A STANDARD OPERATING PROCEDURES

FIELD STANDARD OPERATING PROCEDURE #3

SAMPLE PACKAGING AND SHIPMENT PROCEDURE

Shipping samples is a basic but important component of field work. The majority of field activities include the collection of environmental samples. Proper packing and preservation of those samples is critical to ensuring the integrity of our work product. The user is advised to read the entire standard operating procedure (SOP) and review the site health and safety plan (HASP) and/or project safety plan (PSP) before beginning any onsite activities. In accordance with the HASP or PSP, proper personal protective equipment (PPE) must be selected and used appropriately.

3.1 ACRONYMS AND ABBREVIATIONS

CFR	Code of Federal Regulations
DOT	U.S. Department of Transportation
IATA	International Air Transport Association
HASP	Health and safety plan
PPE	Personal protective equipment
PSP	Project safety plan
SOP	Standard operating procedure

3.2 MATERIALS

- Suitable shipping container (e.g., plastic cooler)
- Chain-of-custody forms
- Custody seals
- Sample container custody seals (as necessary)
- Mailing address labels (as necessary)
- Shipping form (with account number, as necessary)
- Tape (e.g., strapping, clear packing)
- Permanent marker
- PPE
- Bubble wrap or other packing material

Temperature-preserved samples:

- Large plastic garbage bag
- Wet ice
- Heavy-duty zipper-style plastic bags
- Universal sorbent materials

Note: Some materials will be supplied by the laboratory, while others are must be supplied by the sampler. Confirm supplier of materials prior to mobilizing to the field.

3.3 PRECONDITIONS AND BACKGROUND

This SOP has been prepared as part of the company's Environmental Quality Management Plan and is designed to provide detailed procedures for common field practices. Compliance with the methods presented in this document is mandatory for all field personnel

and will ensure that the tasks are performed in a safe and consistent manner, are in accordance with federal and state guidance, and are technically defensible.

This SOP is written for the sole use of company employees and will be revised periodically to reflect updates to company policies, work practices, and the applicable state and/or federal guidance. Employees must verify that this document is the most recent version of the company SOPs. Employees are also strongly advised to review relevant state and/or federal guidance, which may stipulate program-specific procedures, in advance of task implementation.

WSP requires that all personnel performing specific project assignments be appropriately qualified, including having required certifications or licenses, and properly trained in accordance with the requirements of their assignment, the Environmental Service Line's field standard operating procedures, and the Quality Management System.

This SOP is designed to provide the user with a general outline for shipping samples and assumes the user is familiar with basic field procedures, such as recording field notes (SOP 1), sample collection and quality assurance procedures (SOP 4), and investigation derived waste management procedures (SOP 5).

Most environmental samples are classified non-hazardous materials due to unknown characteristics and hazardous classes, however environmental samples can meet the definition of U.S. Department of Transportation (DOT) hazardous materials when shipped by air, ground, or rail from a project site to the laboratory (e.g., free product, samples preserved with a hazardous material [TerraCore® samplers]). As such, field staff must work with their assigned company compliance professional to determine whether the sample shipment is subject to any specific requirements (e.g., packaging, marking, labeling, and documentation) under the DOT hazardous materials regulations.

3.4 SAMPLE SHIPMENT PROCEDURES

The two major concerns in shipping samples are incidental breakage during shipment and complying with applicable DOT and courier requirements for hazardous materials shipments.

> **NOTE: Many couriers, including Federal Express and United Parcel Service, have requirements that the company register with them before shipping hazard materials. In most cases, it is the sampling location, not the company office address, which needs to be registered. Therefore, each project will likely have unique requirements. Please contact your company compliance professional to determine whether or not you will be required to register for your shipment.**

Protecting the samples from incidental breakage can be achieved using "common sense." Pack all samples in a manner that will prevent them from moving freely about in the cooler or shipping container. Do not allow glass surfaces to contact each other. When possible, repack the sample containers in the same materials that they were originally received in from the laboratory. Cushion each sample container with plastic bubble wrap, styrofoam, or other nonreactive cushioning material. A more detailed procedure for packing environmental samples is presented below.

3.4.1 NON-HAZARDOUS MATERIAL ENVIRONMENTAL SAMPLES

The first step in preparing your samples for shipment is securing an appropriate shipping container. In most cases, the analytical laboratory will supply the appropriate container for bottle shipment, which can be used to return samples once they have been collected. Be sure that the container is large enough to contain the samples plus a sufficient amount of packing materials, and if applicable, enough wet ice to maintain the samples at the preservation temperature (usually 4 degrees Celsius). Use additional shipping containers as needed so that sample containers are protected from breakage due to overcrowding. Do not use lunch-box sized coolers or soft sided coolers, which do not offer sufficient insulation or protection from damage.

3.4.1.1 TEMPERATURE-PRESERVED SAMPLE CONTAINER PREPARATION

Temperature-preserved samples should be shipped to the laboratory in an insulated container (e.g., cooler). If using a plastic cooler with a drain, securely tape the inside of the drain plug with duct tape or other material to ensure that no water leaks from the cooler during shipment. Place universal sorbent materials (e.g., sorbent pads) in the bottom of the insulated container. The amount of sorbent material must be sufficient to absorb any condensation from the wet ice and a reasonable volume of water from melted wet ice (if a bag were to rupture) or a damaged (aqueous) sample container.

The next step is to line the insulated container with a large, heavy-duty plastic garbage bag. If shipping breakable sample containers (e.g., glass), place bubble wrap or other packing materials on the bottom of the container. Place the samples, including a temperature blank, on the packing materials with sufficient space to allow for the addition of more bubble wrap or other packing material between the sample containers. Place large or heavy sample containers on the bottom of the cooler with lighter samples placed on top to minimize the potential for breakage. Place all sample containers in the shipping container right-side up. Do not overfill the cooler with samples; room must be left for a sufficient volume of wet ice. Wet ice must be double-bagged in heavy-duty zipper-style plastic bags (1 gallon-sized, or less); properly seal both bags before placing in the insulated container. Place the bags of ice on top of or between the samples. Place as much ice as possible into the cooler to ensure the samples arrive at the lab at the required preservation temperature, even if the shipment is delayed. Fill any remaining space in the container with bubble wrap or other packing material to limit the airspace and minimize the shifting of the sample containers and in-transit melting of ice. Securely close the top of the heavy-duty plastic bag and knot or seal with tape.

3.4.1.2 NON-TEMPERATURE-PRESERVED SAMPLE CONTAINER PREPARATION

Non-temperature-preserved samples should be shipped to the laboratory in a durable package (e.g., hard plastic container or cardboard box). If shipping breakable sample containers (e.g., glass), place bubble wrap or other packing materials on the bottom of the container. Place the samples on the packing materials with sufficient space to allow for the addition of more bubble wrap or other packing material between and on top of the sample containers. Place large or heavy sample containers on the bottom of the container with lighter samples placed on top to minimize the potential for breakage. Place all sample containers within the shipping container right-side up. Fill any remaining space in the container with bubble wrap or other packing material to limit the airspace and minimize the shifting of the sample containers and in-transit melting of ice.

3.4.1.3 CONTAINER SHIPMENT

Samples in the container should be cross-checked against the chain-of-custory before signing off on the form and sealing the cooler. Place the original chain-of-custody form (i.e., laboratory copy) into a heavy-duty zipper-style plastic bag, affix/tape the bag to the shipping container's inside lid, and then close the shipping container; as required, include return shipping labels for the laboratory to return company-owned coolers. Only one chain-of-custody form is required to accompany one of the shipping containers per sample shipment; the other coolers in the shipment do not need to include chain-of-custody forms, unless required by the project. At this point, sample shipment preparations are complete if using a laboratory courier.

Once the shipping container is sealed, shake test the shipping container to make sure that there are no loose sample containers. If loose sample containers are detected, open the shipping container, repack the contents, and reseal the shipping container. If sending the sample shipment through a commercial shipping vendor, place two signed and dated chain-of-custody seals on alternate sides of the shipping container lid so that it cannot be opened without breaking the seals. Securely fasten the top of the shipping container shut with clear packing tape; carefully tape over the custody seals to prevent damage during shipping.

Affix a mailing label with the ship to and return to addresses to the top of the shipping container using clear shipping tape. Use the pre-printed return mailing label from the laboratory, if provided, or complete a new mailing label from the shipping carrier. Ship environmental samples to the contracted analytical laboratory using an appropriate delivery schedule. **Note: Samples can be shipped for Saturday delivery once the lab has been verified to be open and receiving samples on the weekend.**

Verify whether the shipment cost should be billed to the sender or recipient, and ensure the internal billing reference section on the mailing label includes either the laboratory's billing reference number, if the shipment is billed to the laboratory, or the project billable number, if the shipment is billed to WSP.

Declare the value of samples on the shipping form for insurance purposes, if applicable. When shipping samples to a lab, identify a declared value equal to the carrier's default value ($100); additional fees will be charged based on a higher value declared. Our preferred carrier, Federal Express, will only reimburse for the actual value of the cooler and its contents if a sample shipment is lost; they will not reimburse for the cost of having to re-collect the samples. [Please note: if you are shipping something other than samples, such as field equipment, declare the replacement value of the contents.]

Record the tracking numbers from the shipping company forms (i.e., the airbill number) in the field book and retain a copy of the shipping airbill. On the expected delivery date, confirm sample receipt by contacting the laboratory or tracking the package using the tracking number; provide this confirmation information to the project manager.

> **NOTE: Most shipping carriers adhere to transit schedules with final pickup times each day; these schedules are subject to change and vary by service location. If shipping containers are dropped off at a service location after the final pickup time, transit to the laboratory will not be initiated until the following day, and samples may not be properly preserved. Therefore, confirm transit schedules in advance of each sampling event, and ensure samples are delivered to the carrier before the final pickup time of the day.**

3.4.2 HAZARDOUS MATERIALS SAMPLES

Employees rarely ship hazardous materials due to DOT shipping requirements. If you find that your samples could be considered a DOT hazardous material, first coordinate with the assigned company compliance professional and project manager to make a hazardous material classification and, if necessary, establish the necessary protocols and to receive the appropriate training/certification.

> **NOTE: Employees shipping samples regulated as hazardous materials or exempt hazardous materials by air must have International Air Transport Association (IATA) training. IATA training is a separate training required in addition to DOT hazardous materials training for such shipments. Most of our employees do not have IATA training and therefore, anyone who needs to ship by air MUST consult with a company IATA-trained compliance professional.**

FIELD STANDARD OPERATING PROCEDURE #4

SAMPLE COLLECTION AND QUALITY ASSURANCE PROCEDURE

The purpose of this procedure is to assure that sample volumes and preservatives are sufficient for analytical services required under U.S. Environmental Protection Agency (EPA) or other agency approved protocols. This operating procedure describes sample identification procedures, sampling order for select analytes, quality control and quality assurance (QA/QC) sampling procedures, and custody documentation. The user is advised to read the entire standard operating procedure (SOP) and review the site health and safety plan (HASP) and/or project safety plan (PSP) before beginning any onsite activities. In accordance with the HASP, proper personal protective equipment (PPE) must be selected and used appropriately.

4.1 ACRONYMS AND ABBREVIATIONS

ºC	degrees Celsius
COC	chain-of–custody [form]
DI	laboratory-grade, analyte-free deionized water
DOT	US Department of Transportation
EDD	electronic data deliverable
EPA	US Environmental Protection Agency
HASP	health and safety plan
ID	identification [number]
MS/MSD	matrix spike and matrix spike duplicate
MSA	master services agreement
PPE	personal protective equipment
PSP	project safety plan
QA	quality assurance
QA/QC	quality assurance/quality control
QAPP	quality assurance project plan
SOP	standard operating procedure
VOCs	volatile organic compounds

4.2 MATERIALS

- Field book
- Indelible (waterproof) markers or pens
- PPE
- Sampling containers and labeling/shipping supplies

- Deionized (DI) water
- Cleaned or dedicated sampling equipment

4.3 PRECONDITIONS AND BACKGROUND

This SOP has been prepared as part of the company's Environmental Quality Management Plan and is designed to provide detailed procedures for common field practices. Compliance with the methods presented in this document is mandatory for all field personnel and will ensure that the tasks are performed in a safe and consistent manner, are in accordance with federal and state guidance, and are technically defensible.

This SOP is written for the sole use of employees and will be revised periodically to reflect updates to company policies, work practices, and the applicable state and/or federal guidance. Employees must verify that this document is the most recent version of the company's SOPs. Employees are also strongly advised to review relevant state and federal guidance, which may stipulate program-specific procedures, in advance of task implementation.

WSP requires that all personnel performing specific project assignments be appropriately qualified, including having required certifications or licenses, and properly trained in accordance with the requirements of their assignment, the Environmental Service Line's field SOPs, and the Quality Management System.

This SOP is designed to provide the user with a general outline for collecting environmental and quality assurance samples and assumes the user is familiar with basic field procedures, such as recording field notes (SOP 1), sample shipment procedures (SOP 3), investigation derived waste management procedures (SOP 5), and equipment decontamination (SOP 6). This SOP does not cover investigation planning, nor does it cover the analysis of the analytical results. These topics are more appropriately addressed in a site-specific work plan or a dedicated quality assurance project plan (QAPP). This SOP does not include an special handling requirements for specific parameters such as low-level mercury or per- and polyfluoroalkyl substances. These requirements should be included in the QAPP.

4.4 SAMPLE IDENTIFICATION PROCEDURES

All sample containers (e.g., glass bottles, plastic jars, foil bags, plungers, etc.) should be identified by an affixed sample label. Unless otherwise approved by your project manager or specified in your site-specific work plan/QAPP, information on the sample container labels must include the site/project name, project/task number, unique alpha-numeric sample identification (ID) number, sample collection date, time of collection using the military or 24-hour clock system (i.e., 0000 to 2400 hours), analytical parameters, preservative, and the initials of the sampling personnel. Employees are advised to use pre-printed waterproof mailing labels (e.g., Avery® 5xxx-series Waterproof Address Labels) for all sample identification. Electronic label templates are available.

The sample identification (ID) number must, unless otherwise approved by your project manager or specified in your site-specific work plan/QAPP, follow the company's naming protocol. This protocol was developed to aid in determining the type of sample collected (e.g., soil, groundwater, vapor, etc.), the sample location, and, where appropriate, the sample depth. This protocol was also designed to ensure consistency across the company.

Construct sample IDs in the following format:

SB-10A (4-6)

Where, in this example:

- SB = the first two or three characters will define the sample type (see list of approved prefixes below); in this case, a soil boring
- 10A = the next two or three alpha-numeric digits (separated by a dash from the sample type identifier) indicate the location of the boring on the site; in this case, boring number 10A
- (4-6) = the depth the sample was collected, with the first number (including decimals, if necessary) indicating the top of the sample interval (in feet) and the second number indicating the bottom of the sample interval (in feet); not all sample types will include depth information.

Additional label information may be added after the last character of the sample ID number (e.g., sample date, underground storage tank number, area of concern number, "Area" number, client identifier, etc.). Separate any additional information from the required portion of the sample name by dash(es).

Sample Prefix	Permitted Use
AA	Ambient outdoor air sample
CC	Concrete core/chip sample
CS	Confirmation/verification soil sample collected from an excavation
HA	Soil sample collected with a hand auger
IAB	Indoor air sample – basement
IAC	Indoor air sample – crawl space
IAF	Indoor air sample – first floor
MW	Soil sample collected from a monitoring well borehole or a groundwater sample collected from a monitoring well
PZ	Groundwater sample collected from a piezometer
SB	Soil sample collected from boreholes that will not be converted to monitoring wells
SED	Sediment sample
SG	Soil gas sample other than a sub-slab sample (e.g., sample collected from a temporary or permanent polyvinyl chloride sample point or stainless steel screen implant)
SL	Sludge sample
SS	Surface soil sample collected using hand tools (e.g., trowel, spoon, etc.) and typically at depths less than 2 feet below ground surface
SSV	Sub-slab vapor sample
SW	Surface water sample
TC	Tree core sample
TP	Soil sample collected from a test pit
WC	Waste characterization sample
WP	Wipe sample
WW	Wastewater

4.5 SAMPLE CONTAINERS, PRESERVATIVES, AND HOLDING TIMES

The first step in sample collection is to verify that the correct number and type of sample containers were provided, and that each contains the appropriate preservatives for the proposed project (i.e., check against the sampling plan requirements outlined in the site-specific QAPP or, for those projects without a site-specific QAPP, the laboratory Task Order). Inspect all containers and lids for flaws (cracks, chips, etc.) before use. Do not use any container with visible defects or discoloration. Report non-receipt and any discrepancies of specific types of sample containers to the team leader or project manager immediately. Make arrangements to have missing or additional sampling containers provided on an expedited basis.

Precautions must be taken to prevent cross-contamination and contamination of the environment when collecting samples. Wear a clean pair of new, disposable gloves each time a different sample is collected and don the gloves immediately prior to collection. This limits the possibility of cross-contamination from accidental contact with gloves soiled during collection of the previous sample. The gloves must not contact the medium being sampled and must be changed any time during sample collection when their cleanliness is compromised. ***In no case should gloved hands be used as a sampling device: always use the appropriate sampler to move the sample from the sampling device to the laboratory-supplied containers.***

Sample collection must follow all appropriate SOPs, state and federal regulations, or guidance, for the collection of environmental samples; the recommended order of sample collection is:

- Geochemical measurements (e.g., temperature, pH, specific conductance)
- Volatile organic compounds (VOCs)
- Extractable organics, petroleum hydrocarbons, aggregate organics, and oil and grease
- Per- and Polyfluoroalkyl substances
- Total metals
- Dissolved metals
- Inorganic non-metallic and physical and aggregate properties
- Microbiological samples
- Radionuclides

Fill the sample bottles to the appropriate level for the parameter analyzed including eliminating head space, as appropriate. Collected samples that require thermal preservation must be immediately (within 15 minutes) placed in a cooler with wet ice and maintained at a preservation temperature of 4° Celsius (ºC).

4.6 FIELD QUALITY ASSURANCE/QUALITY CONTROL SAMPLES

Field quality assurance/quality control (QA/QC) samples may include equipment blanks, trip blanks, temperature blanks, duplicates, matrix spike and matrix spike duplicate samples, field blanks, and split samples. The project manager or QAPP must specify the type and frequency of QA/QC sample collection. The QA/QC sample identification number must, unless otherwise approved by your project manager or specified in your site-specific work plan, follow the company's naming protocol as discussed in the sections below. QA/QC samples must be clearly identified on our copy of the chain-of-custody (COC) form (described below) and in the field book. Failure to properly collect and submit required QA/QC samples can result in invalidation of an entire sampling event.

Several blanks, discussed below, require laboratory-grade analyte-free, deionized water (DI) be used. Only if all options to obtain laboratory-grade DI have been exhausted should store-grade distilled water be used to prepare blanks. If store-grade distilled water is used, be sure to record the source and lot number in the field book.

Collect, preserve, transport and document split samples using the same protocols as the related samples.

4.6.1 EQUIPMENT BLANKS

Equipment blanks, or rinsate blanks, are used to document contamination attributable to using non-dedicated equipment (i.e., equipment that must be decontaminated after each use). Collect equipment blanks in the field at a rate of one per type of sampling equipment per day, unless otherwise specified. If the site-specific work plan or QAPP indicates that an equipment blank is to be collected from dedicated sampling equipment, collect the equipment blank in the field before sampling begins. If field decontamination of sampling equipment is required, prepare the equipment blanks after the equipment has been used and field-decontaminated at least once.

Prepare equipment blanks by filling or rinsing the pre-cleaned equipment with DI and collecting the rinsate in the appropriate sample containers. Record the type of sampling equipment used to prepare the blank and how the equipment blank was generated in the field book. Decontamination of the equipment following equipment blank procurement is not required.

The samples must be labeled, preserved, and filtered (if required) in the same manner as the environmental samples. Have the equipment blanks analyzed for all the analytes for which the environmental samples are being analyzed, unless otherwise specified. Designate equipment blanks using "EB", followed by the date, and in the order of equipment blanks collected that day. For example, the first equipment blank collected on July 4, 2015, would be designated EB070415-1.

4.6.2 TRIP BLANKS

Trip blanks are used to document VOC contamination attributable to shipping and field handling procedures. Trip blanks are only required when analyzing samples for VOCs. The blanks are prepared by the analytical laboratory and shipped along with the empty sample containers. These pre-filled blanks should accompany the environmental sample containers wherever they are stored onsite (i.e., keep the trip blank sample bottles in the same shipping container used to ship and store VOC sample bottles during the sampling event). Never open the laboratory-supplied trip blank sample bottles. Only as a last resort, store-grade distilled water, can be poured into empty VOC sample bottles to generate event-specific trip blanks (or augment the laboratory-supplied ones, if they are provided in insufficient numbers).

The trip blanks, even those provided by the analytical laboratory, should be labeled in the field like other environmental samples collected during the investigation activities. Identify trip blanks using the prefix "TB", followed by the date. For example, the trip blank shipped with a cooler of samples on July 4, 2019, would be designated TB070419-1. If a second trip blank is needed on that same day, the designation would be TB070419-2. A minimum of one trip blank should accompany each shipping container of VOC samples, unless more stringent project requirements are in place. The number of trip blanks needed per shipment can be minimized by shipping all the VOC samples in the same shipping container (if possible).

4.6.3 FIELD BLANKS

The field blank is analogous to the trip blank in that it is designed to assess and document any contamination to the environmental samples that can be attributable to the (ambient) field conditions. Not all projects require the use of field blanks. Their use, if required, and the frequency of collection (often 1 blank per 10 or 20 environmental samples collected) is detailed in the QAPP and the site-specific work plan. The sample is collected by pouring DI water into empty glassware at the site during the sampling event. The intent is to expose the field blank to the same conditions in the atmosphere as those present when the environmental samples were collected.

Identify field blanks using the prefix "FB", followed by the date. For example, the field blank shipped collected on August 22, 2019, would be designated FB082219. If a second field blank is needed on that same day, the designation would be FB082219-2. At least one field blank should be collected for each analytical parameter identified in the sampling event.

4.6.4 TEMPERATURE BLANKS

Temperature blanks are used to determine if the samples are at the appropriate temperature for preservation at the time the sample container (cooler) is received by the analytical laboratory. The temperature is determined by measuring the temperature blank, which provides a proxy for the temperature of the sample container upon arrival at the laboratory. These temperature blanks are typically provided by the laboratory and should be included in each sample cooler used to ship and store the sample bottles during the sampling event. If laboratory-provided temperature blanks are not available, fill a clean, unpreserved sample bottle with potable, DI, or store-grade distilled water and identify the bottle as a temperature blank.

4.6.5 DUPLICATES

Duplicate samples, which are used for measuring the variability and documenting the precision of the sampling process, should be collected at a rate of at least 1 duplicate per 20 environmental samples collected, unless specific project requirements (as detailed in a QAPP) are in place. Be sure that the location selected for duplication has sufficient sample volume and is within the area of contamination, if known. Under no circumstances can equipment or trip blanks be used as duplicates.

Collect each duplicate sample at the same time, from the same sample aliquot, and in the same sampling order (i.e., volatile organic compounds, then semivolatile organic compounds, then inorganics, etc.) as the corresponding environmental sample. Sample bottle aqueous duplicate samples, for example, should be alternately filled with the environmental sample bottles (i.e., the actual sample bottle and the bottle to be used for the duplicate) from the same sampling device. If the sampling device does not hold enough volume to fill the sample containers, fill the first container with equal portions of the sample, and pour the remaining sample into the next

sample containers. Obtain additional sample volume and pour the first portion into the last sample container, and pour the remaining portions into the first containers. Continue with these steps until all containers have been filled.

Duplicate samples will be assigned arbitrary sample ID and a false collection time so that they are not identified as duplicates by the laboratory (i.e., submit the duplicates samples as *blind* to the lab). The blind duplicate sample "location designation" will be left up to the project manager; however, in no case will "Dup" be allowed to appear in the sample name. The duplicate samples should be analyzed for the same analytes as the original environmental sample. Be sure to record the sampling method, duplicate sample ID, the false time, and the actual time of collection in the field notebook. The duplicate should also be indicated in separate documentation, such as on our carbon copy of the chain-of-custody (i.e., the yellow copy), and not on the original chain-of-custody that accompanies the samples to the laboratory.

4.6.5 MATRIX SPIKE AND MATRIX SPIKE DUPLICATES

Matrix spike and matrix spike duplicate samples (i.e., MS/MSD samples) are used to determine the bias (accuracy) and precision of an analytical method for a specific sample matrix. Many of the company's projects require the collection of MS/MSD samples; however, laboratory generated MS/MSD samples are sufficient for some projects (as detailed in the QAPP or site-specific work plan). Collect MS/MSD samples at a rate of 1 MS and 1 MSD (i.e., 2 samples) for every 20 environmental samples, unless more stringent project requirements (as detailed in a QAPP) are in place. Clearly convey the MS/MSD identity to the laboratory by adding "MS" or "MSD" after the sample name (e.g., MW-01MS) and/or in the comments section of the chain-of-custody on the same line as the parent sample. Under no circumstances can equipment or trip blanks be used as MS/MSD samples.

4.6.6 SPLIT SAMPLES

Split samples may be collected as a means of determining compliance or as an added measure of quality control. Split samples measure the variability between laboratories and not the variability of sample collection and laboratory procedures (i.e., they are not equivalent to duplicate samples). The split samples must be subsamples of the same parent material used for the environmental sample: soil should be collected from the same in-place material (for VOCs) or, for non-discrete samples, the same mixing vessel after homogenization. Collect aqueous split samples using the same alternating bottle approach detailed in the duplicate sample description above. These procedures will ensure that the split samples are valid and are representative of the environmental sample collected as part of the investigation.

Collecting split samples of soil, sediment, waste, and sludge is not recommended because the homogenization necessary for a true split sample in these matrices is not possible and the resulting laboratory results would not be comparable.

Spilt samples should have the same sample location designation (e.g., MW-01, SB-03 (4-6), but are differentiated from each other by inserting the laboratory analyzing or the agency/consultant collecting the sample after the sample location (e.g., MW-01-WSP and MW-01-EPA).

4.7 CUSTODY DOCUMENTATION

Sample custody protocols are used to demonstrate that the samples and sample containers were handled and transferred in such a manner as to prevent tampering. Legal COC begins when the pre-cleaned sample containers are dispatched to the field from the laboratory and continues through sample analysis and eventual disposal of the sample and sample containers. Maintaining custody requires that samples must be in the actual possession or view of a person who is authorized to handle the samples (e.g., sample collector, laboratory technician, etc.), secured by the same person to prevent tampering, or stored in a designated secure area.

It is a good idea to limit, to the extent possible, the number of individuals who physically handle the samples. Samples must be placed in locked storage (e.g., locked vehicle, locked storeroom, etc.) when not in the possession or view of authorized personnel. Do not leave samples in unoccupied motel or hotel rooms or other areas where access cannot be controlled by the person(s) responsible for custody without first securing samples and shipping or storage containers with tamper indications in place (i.e., custody seals).

The COC form is used to trace sample possession from the time of collection to receipt at the analytical laboratory. It is recommended that the company's COC be used rather than the laboratory-supplied COC form to ensure that all necessary data are recorded. Submit one COC form per sample shipment, unless more stringent project requirements are in place (as detailed in the QAPP or site-specific work plan). The COC needs to have a unique COC number (pre-printed on the form), accompany all the samples, and include all appropriate project-specific information, such as:

- Project number, name, and location
- Sampler's printed name(s) and signature(s)
- Sample identification number
- Date and time (using the 24-hour clock) of collection
- Sample matrix (e.g., soil, aqueous, solid, etc.)
- Total number of containers per sample
- Parameters requested for analysis including number of containers per analyte.
- Remarks (e.g., irreducible headspace, field filtered sample, expected concentration range, specific turn-around time requested, etc.)
- Signatures of all persons involved in the chain of possession in chronological order
- Requested turn-around-time
- Name and location of analytical laboratory
- Custody seal numbers
- Shipping courier name and tracking information
- Internal temperature of shipping container upon shipment to laboratory, as needed
- Internal temperature of shipping container upon delivery to laboratory
- Employee contact information

Affix custody seals to all storage and shipping container closures when transferring or shipping sample container kits or samples to an off-property party. Place the seal so that the closure cannot be opened without breaking the seal. In the field book, record the time, date and signatures of responsible personnel affixing and breaking all seals for each sample container and shipping container. Affix new custody seals every time a seal is broken until continuation of evidentiary custody is no longer required.

FIELD STANDARD OPERATING PROCEDURE #5

INVESTIGATION DERIVED WASTE MANAGEMENT PROCEDURE

The purpose of this standard operating procedure (SOP) is to provide instructions for handling, storing, and managing investigation derived waste (IDW) pending disposal. All IDW, which includes (but is not limited to) soil cuttings, development water, purge water, drilling fluids, decontamination fluids, personal protective equipment (PPE), and sampling equipment, must be managed in compliance with applicable or relevant and appropriate requirements. The user is advised to read the entire SOP and review the site health and safety plan (HASP) and/or project safety plan (PSP) before beginning any onsite activities. In accordance with the HASP or PSP, proper PPE must be selected and used appropriately.

5.1 ACRONYMS AND ABBREVIATIONS

DOT	U.S. Department of Transportation
EPA	U.S. Environmental Protection Agency
HASP	health and safety plan
IDW	investigation derived waste
PCB	polychlorinated biphenyl
PPE	personal protective equipment
PSP	project safety plan
RCRA	Resource Conservation and Recovery Act
SOP	standard operating procedure
TSCA	Toxic Substances Control Act

5.2 MATERIALS

- Pre-printed weatherproof waste labels (e.g., non-hazardous waste, hazardous waste, polychlorinated biphenyls [PCBs], etc.)
- IDW log (Figure 1)
- Permanent ink marking pen, paint, stick/pen
- Sampling equipment (refer to sampling SOPs)
- Impermeable covers (tarps), as needed
- Duct tape, rope, or other material to secure tarp
- Copy of the waste manifest or bill of lading

5.3 PRECONDITIONS AND BACKGROUND

This SOP has been prepared as part of the company's Environmental Quality Management Plan and is designed to provide detailed procedures for common field practices. Compliance with the methods presented in this document is mandatory for all field personnel and will ensure that the tasks are performed in a safe and consistent manner, are in accordance with federal and state guidance, and are technically defensible.

This SOP is written for the sole use of company employees and will be revised periodically to reflect updates to company policies, work practices, and the applicable state and/or federal guidance. Employees must verify that this document is the most recent version

of the company SOPs. Employees are also strongly advised to review relevant state and/or federal guidance, which may stipulate program-specific procedures, in advance of task implementation.

WSP requires that all personnel performing specific project assignments be appropriately qualified, including having required certifications or licenses, and properly trained in accordance with the requirements of their assignment, the Environmental Service Line's field standard operating procedures, and the Quality Management System.

This SOP is designed to provide the user with a general outline for handling, storing, and managing IDW pending disposal and assumes the user has received current U.S. Department of Transportation (DOT) training, Hazardous Waste Operations and Emergency Response training, and Resource Conservation and Recovery Act (RCRA) training (if required) and is familiar with basic field procedures, such as recording field notes (SOP 1), sample shipment procedures (SOP 3), sample collection and quality assurance procedures (SOP 4), and equipment decontamination (SOP 6). The SOP does not cover investigation planning; DOT, RCRA, and Toxic Substances Control Act (TSCA) regulations; nor does it cover the evaluation of the analytical results. **Consult and involve the company's compliance professionals during all phases of IDW management and disposal.**

It is important to note that information contained in this SOP is based on federal regulations and interpretive guidance provided by the U.S. Environmental Protection Agency (EPA) and other federal regulatory sources; therefore, information provided in this SOP may be superseded by state or local-specific statutes or regulations. Field personnel must plan for and discuss the handling procedures with the project manager and assigned company compliance professional before mobilizing to the field.

5.4 IDW GENERAL PROCEDURES

Nearly all intrusive field activities will generate solid or liquid wastes. Examples include:

Solid Waste

- Soil cuttings
- Drilling mud
- Plastic sheeting
- Spent carbon or filters
- PPE (e.g., Tyvek coveralls, gloves, respirator cartridges)
- Disposable or dedicated sampling equipment (e.g., bailers, hoses, clamps, buckets, cartridge filters)
- Field analytical waste (e.g., HACH kits, Chlor-n-Soil kits, Gastech tubes)
- Compressed gas cylinders (e.g., isopropylene, helium)
-
- Disposable cleaning materials (e.g., wipes or rags)

Liquid Waste

- Decontamination water
- Development water
- Drilling fluids
- Purge water
- Soap or wash solutions
- Reagents (e.g., hexane, nitric acid, methanol)

The specific procedures for dealing with these materials after the field activities have been completed will vary depending on whether the materials are considered to be non-hazardous, RCRA hazardous (characteristic or listed wastes), TSCA-regulated PCB waste, and/or DOT hazardous materials. The characterization of the wastes to be generated should be determined in conjunction with a company compliance professional before the field event occurs, based on previously generated data; however, in some cases, particularly for new sites, the status of the wastes may not be known. In these cases, handle IDW as hazardous waste until the status can be verified. Field personnel must consult their assigned company compliance professionals for assistance in proper waste characterization and to determine waste management requirements applicable to the site.

5.4.1 WASTE MINIMIZATION

As possible, select investigation methods and techniques that will minimize the amount of wastes generated during field activities, particularly if the IDW is hazardous. Examples include using direct-push methods instead of hollow stem augers (to minimize soil cuttings) during a soil investigation, if appropriate, eliminating the use of solvents or solvent-based cleaners for decontamination, if

possible, and limiting contact with the materials to reduce the amount of PPE required. Minimizing the amount of waste generated will reduce handling requirements and overall project costs, and is consistent with the company's corporate goals for sustainability.

5.5 ONSITE IDW MANAGEMENT PROCEDURES

Onsite handling procedures typically involve containerization of the IDW for offsite disposal at a regulated facility or, in the case of certain non-hazardous wastes, onsite disposal. Should more than one waste stream be present onsite, segregate the IDW containers by waste stream to facilitate the future waste disposal. The procedures for each type of waste are presented below.

5.5.1 NON-HAZARDOUS WASTE MANAGEMENT

If the IDW is classified as non-hazardous waste, the following procedures must be implemented only if approved by the applicable regulatory agency and after being discussed and approved by the project manager, project compliance professional, client, and facility personnel:

- Soil can be either:
  - spread around the borehole or other onsite location
  - placed back in the boring or excavated test pit
  - containerized and disposed of offsite
- Groundwater and decontamination fluids can be either:
  - poured onto the ground next to the well to allow infiltration
  - discharged to either the publically-owned treatment works or storm sewer
  - discharged to the onsite wastewater treatment plant
  - containerized and disposed of offsite
- After rendering the IDW unusable (e.g., cutting or tearing material), PPE, plastic sheeting, disposable cleaning materials, and spent bag filters can be double bagged and disposed of as general trash or containerized and disposed of offsite.
- Compressed gas cylinders should be depressurized and disposed of as general trash, recycled as scrap metal, or containerized and disposed of offsite.
- Field analytical waste (e.g., HACH® kits, Chlor-n-Soil® kits) can be disposed of in accordance with the manufacturer's instructions provided the disposal method is approved by the company's project manager and compliance professional.
- Minimize the volume of reagents as much as possible. Consult a company compliance professional to determine the proper disposal of any quantity of unused reagents. Empty reagent containers may be disposed of as general trash after removing all chemical name and warning labels, or may be containerized and disposed of offsite.
- Spent water treatment media (e.g., carbon, resin) should be containerized and disposed of offsite.
- Exploration and production exempt waste derived from material that was downhole at an oil and gas production site.

If the IDW is containerized and is classified as non-hazardous, the following procedures will apply:

- Place the non-hazardous IDW in DOT-compliant containers (e.g., 55-gallon drum, roll-off container, or temporary storage tank). Before placing IDW in the containers, ensure that the containers are in good condition and will not leak.
- Drums used as containers must remain closed except when adding, sampling, or inspecting the waste. The drums cannot be used as a work surface once waste is put in the container.
- Mark the container with the appropriate waterproof, self-adhesive non-hazardous waste label. The label must include a description of the contents of the container (e.g., soil cuttings, purge water) and the generator name (the client or the facility, never the company). **Field personnel must consult the project compliance professional for help in properly completing the labels.**
- Complete the IDW Log (Figure 1) before leaving the site. Present one copy of the log to the site contact and the original to the project manager.
- The IDW containers must be properly closed, wiped clean, and stored in a secure onsite location.

5.5.2 HAZARDOUS WASTE MANAGEMENT

If site data or generator knowledge indicates that the IDW is RCRA hazardous, the following procedures will apply:

- Place IDW in DOT-compliant containers (e.g., 55-gallon drum, roll-off container, or temporary storage tank). Before placing IDW in the containers, ensure that the containers are appropriate for the type of IDW generated (e.g., solid in containers authorized for transport of solids), in good condition and will not leak.

- Containers must remain closed except when adding, sampling, or inspecting the material. The containers cannot be used as a work surface once waste is put in the container.
- Mark the container with an appropriate waterproof, self-adhesive hazardous or radiological waste label. The label must include the accumulation start date, a description of the contents of the container (e.g., soil cuttings, purge water), the EPA identification number, the generator name (the client or the facility, never the company), and the hazardous waste codes, if known. **Field personnel must consult the project compliance professional for help in properly completing the labels.**
- The IDW containers must be properly closed, wiped clean, and stored in a secure onsite location (i.e., a designated facility hazardous waste storage area) to limit access. At a minimum, place the drums on an impermeable surface (if available) in an area of limited access. If stored outside, cover the containers with a secured tarp at the end of each field day until the containers are picked up for disposal.
- Complete the IDW Log (Figure 1) before leaving the site. Present one copy of the log to the site contact and the original to the project manager.
- If applicable, ensure that weekly inspections are conducted, and the proper inspection forms for documentation are completed during the entire time the waste is stored onsite. **Field personnel must consult the project compliance professional for help to determine if weekly inspections are required.**

If the IDW is presumed to be hazardous and sampling is required to confirm its classification, it must be labeled "Hazardous Waste-Pending Analysis" and sampled for the parameters specified by the project compliance professional or project manager before leaving the site. Any waste confirmation samples must be collected in accordance with the company's SOPs. Treatment, storage, and disposal facilities will usually specify the required analysis for waste profiles.

5.5.3 PCB WASTE MANAGEMENT

If information exists to classify PCB-containing IDW as TSCA-regulated IDW (i.e., PCBs greater than 50 milligrams per kilogram), the following procedures must be implemented:

- Place the PCB-containing IDW in DOT-compliant containers (e.g., 55-gallon drum, roll-off container, or temporary storage tank). Before placing IDW in the containers, ensure that the containers are in good condition and will not leak.
- Containers must remain closed except when adding, sampling, or inspecting the material. The containers cannot be used as a work surface once waste is put in the container.
- Mark the container with an appropriate waterproof, self-adhesive yellow label with the words "Caution Contains PCBs", the "removed from service" date (the accumulation start date), and a description of the contents of the container (e.g., soil cuttings). Complete the label with the name and phone number of the company personnel to contact in the event of an accident or spill. **Field personnel must consult the project compliance professional for help in properly completing the labels.**
- The IDW containers must be properly closed, wiped clean, and stored in a secure PCB storage area onsite. If a PCB storage area is not available, construct a temporary PCB storage area. Cover the containers with a secured tarp at the end of each field day until the drums are picked up for disposal. Place one yellow 6" x 6" "Caution Contains PCBs" label on the outside of the tarp, and note the "Removed from service date" on the label.
- Complete the IDW Log (Figure 1) before leaving the site. Present one copy of the log to the site contact and the original to the project manager.
- If applicable, inspect the area and the containers for leaks once every 30 days in accordance with TSCA requirements during the entire period the waste is stored onsite. **Field personnel must consult the project compliance professional for help to determine if weekly inspections are also required.**

5.6 POST-FIELD IDW MANAGEMENT ACTIVITIES

Field personnel must follow up on the management of the IDW after returning from the field. RCRA hazardous and TSCA-regulated PCB-containing wastes have storage time limits and periodic inspection requirements to remain in compliance with federal, state, or local regulations. Arrangements for proper disposal of wastes must be made within the required time limits and must be consistent with all applicable regulatory requirements, as well as the company's contracting procedures and policies for waste disposal. Copies of waste disposal documentation (e.g., bill of lading, waste manifest, land disposal restriction form, etc.) should be provided to the project manager and saved with the project files.

FIELD STANDARD OPERATING PROCEDURE #11

GROUNDWATER SAMPLING PROCEDURE

Groundwater sampling procedures outlined in this Standard Operating Procedure (SOP) are designed to ensure that collected samples are representative of current site conditions. These procedures can be applied to permanently or temporarily installed monitoring wells, direct-push sample points, water supply wells with installed plumbing, extraction wells for remedial groundwater treatment systems, and excavations where groundwater is present. The user is advised to read the entire SOP and review the site health and safety plan (HASP) and/or project safety plan (PSP) before beginning any onsite activities. In accordance with the HASP, proper personal protective equipment (PPE) must be selected and used appropriately.

11.1 ACRONYMS AND ABBREVIATIONS

ID	inside diameter
DI	deionized
DNAPL	dense non-aqueous phase liquid
DO	dissolved oxygen
DTW	depth-to-water
HASP	health and safety plan
IDW	investigation-derived waste
l/min	liters per minute
LNAPL	light non-aqueous phase liquid
mg/l	milligrams per liter
mV	millivolts
NAPL	non-aqueous phase liquid
NTU	nephelometric turbidity unit
ORP	oxygen reduction potential
PID	photoionization detector
PPE	personal protective equipment
PSP	project safety plan
QAPP	quality assurance project plan
SOP	standard operating procedure
SU	standard units
TD	total depth
TOC	top-of-casing
VOCs	volatile organic compounds

11.2 MATERIALS

- Field book
- PPE
- Air quality monitoring equipment (e.g., photoionization detector [PID]) with calibration reagents and standards, as needed
- Electronic water level indicator or interface probe
- Water quality meter(s) with a flow-through cell, and calibration reagents and standards, as needed
- Field test kits, as needed
- Adjustable wrench or manhole wrench, as needed
- Well key(s), as needed
- Power supply, as needed
- Sampling containers and labeling/shipping supplies
- Deionized (DI) water
- Container(s) for water storage (e.g., bucket, drum)
- Pump or bailers, tubing, and associated lanyard materials
- Filters, as needed
- Decontamination supplies

11.3 PRECONDITIONS AND BACKGROUND

This SOP has been prepared as part of the company's Environmental Quality Management Plan and is designed to provide detailed procedures for common field practices. Compliance with the methods presented in this document is mandatory for all field personnel and will ensure that the tasks are performed in a safe, consistent manner; are in accordance with federal and state guidance; and are technically defensible.

This SOP is written for the sole use of company employees and will be revised periodically to reflect updates to company policies, work practices, and the applicable state and/or federal guidance. Employees must verify that this document is the most recent version of the company SOPs. Employees are also strongly advised to review relevant state and/or federal guidance, which may stipulate program-specific procedures, in advance of task implementation.

WSP requires that all personnel performing specific project assignments be appropriately qualified, including having required certifications or licenses, and properly trained in accordance with the requirements of their assignment, the Environmental Service Line's field SOPs, and the Quality Management System.

This SOP is designed to provide the user with a general outline for conducting groundwater sampling and assumes the user is familiar with basic field procedures, such as recording field notes (SOP 1), utility location (SOP 2), sample shipment procedures (SOP 3), sample collection and quality assurance procedures (SOP 4), investigation derived waste (IDW) management procedures (SOP 5), equipment decontamination (SOP 6), and use and calibration of all sampling and monitoring equipment (SOPs 7 and 8). This SOP does not cover investigation planning, nor does it cover the analysis of the analytical results. These topics are more appropriately addressed in a project-specific work plan. Before groundwater sampling, be sure to review the project-specific work plan or quality assurance project plan (QAPP) and any applicable state and federal guidelines or sampling procedures. All sampling and monitoring references must be available for consultation in the field, including:

- Company SOPs
- Applicable state and federal guidelines or sampling procedures
- Manufacturer's manuals
- Project-specific work plan, PSP and/or HASP, and QAPP

11.4 GENERAL PROCEDURES

Although the techniques used to sample groundwater are varied, most sampling events can be broken down into a three-step sequence:

1. Gauging: The measurement of the water column height (i.e., total well depth less depth-to-water) within the well.

2 Purging: The removal of stagnant water from the well bore to ensure that samples collected are representative of groundwater conditions in the water-bearing zone surrounding the well.
3 Sample Collection: After purging, the collection of aliquots of groundwater in method-specific, preserved (as needed) containers.

The procedures and equipment that are used to accomplish these steps are project-specific and should be discussed by the project team before arriving onsite. All types of groundwater sampling, however, regardless of the equipment used, share common handling and management procedures that are designed to ensure the integrity of the samples collected. These procedures include:

- The use of new, disposable, decontaminated, or dedicated sampling equipment
- The use and rotation of the appropriate PPE
- Selection of a suitable sampling location and staging area

Wear a clean pair of new, disposable gloves each time a different sample is collected and don the gloves immediately prior to collection. This limits the possibility of cross-contamination from accidental contact with gloves soiled during collection of the previous sample. The gloves must not contact the medium being sampled and must be changed any time during sample collection when their cleanliness is compromised. ***Gloved hands should not be used as a sampling device; always use the appropriate equipment to move the sample from the sampling device to the laboratory-supplied containers.***

11.5 EQUIPMENT SELECTION

Collect all samples using either new, disposable equipment or properly decontaminated sampling equipment. Groundwater purging and sampling equipment should be selected based on the analytical requirements of the project and the project-specific conditions (e.g., well diameter, depth to water, dissolved constituents, etc.) likely to be encountered. The equipment should be constructed of non-reactive, non-leachable materials (e.g., stainless steel, Teflon®, Teflon®-coated steel, polyethylene, polypropylene, etc.) that are compatible with the chemical constituents at the site. Note that project or regulatory guidance may limit the type of equipment for groundwater sampling.

Consider the following when choosing groundwater purging and sampling equipment:

- the diameter and depth of the well
- the depth to groundwater
- the volume of water to be withdrawn
- the sampling and purging technique
- the volume of sample required
- the analytes of interest

Select the decontamination procedures based on the types of sampling to be performed and media encountered; decontamination may require multiple steps or differing cleaning methods (see SOP 6 for decontamination procedures). In no case, should disposable, single-use materials be used to collect more than one sample.

11.6 PRE-SAMPLING CONSIDERATIONS

You should perform the following activities in preparing for sampling with all observations and measurements noted in the field book and on the project-specific groundwater monitoring log, if appropriate:

- Perform a quick reconnaissance of the site to identify sampling locations and evaluate the accessibility to the sampling location.
- Record the approximate ambient air temperature, precipitation, wind (direction and speed), tide, and other field conditions. In addition, any site-specific conditions or situations that could potentially affect the samples at the sample locations should be recorded.
- Record temporary sampling locations with respect to approximate distance to and direction from at least one permanent feature.
- Survey the breathing zone around the sampling location with the appropriate air quality meter(s), as necessary (see HASP), to ensure that the level of PPE is appropriate.
- Install the pump, tubing, passive sampler or other appropriate sampling equipment to the depth prescribed in the project-specific work plan or QAPP.

- Containerize and manage purge water in accordance with the project-specific work plan.

It is important to minimize any sources of cross-contamination that could compromise the integrity of the groundwater samples. Consider the following:

- Position fuel-powered equipment away from the sample collection area, such as drill rigs or excavators, and upwind of other site activities (e.g., purging, sampling, decontamination) that could influence the sample. This is particularly important when screening samples in the field for volatile organic compounds with a PID but should not be limited to the active sample collection.
- Establish a secure sample staging area in an uncontaminated area of the site.

11.7 GAUGING PROCEDURES

All wells should be opened to the atmosphere in advance of sampling to allow any pressure differentials, which could artificially raise or depress the water column in the well, to dissipate. The wells should be inspected to ensure that the protective casing is intact and has not been damaged. Remove the well covers and all standing water around the top of the well casing (for flush mounted-protective covers), as necessary, before opening the inner well cap or plug. Unlock and carefully remove well cap and allow the well to stand undisturbed for a minimum of 15 minutes, or as required by the project-specific work plan, before conducting any down-hole testing or measurements. If required by the HASP, survey the open well casing and the breathing zone around the wellhead with a PID to ensure that the level of PPE is appropriate.

11.7.1 GROUNDWATER LEVEL AND TOTAL DEPTH MEASUREMENT PROCEDURES

Depth to water (DTW) and total depth (TD) measurements are collected prior to sampling and are used to determine the volume water to be purged from the well (if using techniques other than no-purge or low flow sampling). The DTW measurements are also used after the field event to establish the groundwater elevation, flow direction, and gradient. Unless otherwise directed, do not place any objects inside the casing of private water wells; accordingly, DTW and TD measurements should not be collected at private water wells. Measurements of TD are not required for low flow and no-purge sampling applications and should not be measured before sampling the well.

Water level measurements must be collected within the shortest interval possible from all the wells to be gauged during the event before beginning any purge and sampling procedures at the site. This will ensure a nearly instantaneous snapshot of the water levels before the formations are disturbed by pumping or acted upon by other outside influences, such as tides, precipitation, barometric pressure, river stage, or intermittent pumping of production, irrigation, or supply wells.

Record the following observations and measurements (and the time when they were collected) in the field book:

- Measure the casing inside diameter (ID) and record in inches
- Measure the DTW with an electronic water level indicator (or an interface meter, if non-aqueous phase liquid [NAPL] is potentially present – see procedures below) from the top-of-casing (TOC) at the surveyor's mark, if present, and record the depth (to the nearest 0.01 foot) in feet below TOC
- If no mark is present, measure from the north side of the casing and mark the measuring point with a knife, metal file (if the inner casing is metal) or indelible marker for future reference
- Measure the TD from TOC at the surveyor's mark or north side of the casing, as appropriate.

Measuring the depth of deep wells with long water columns can be problematic due to tape buoyancy and weight effects or sediment in the bottom of the well casing. Care must be taken, and proper equipment selection must be used in these situations to ensure accurate measurements. Multiple TD measurements in silt-laden wells can provide a more precise assessment of the bottom depth.

11.7.2 GAUGING WELLS WITH NON-AQUEOUS PHASE LIQUID

If NAPL is potentially present at the site, the DTW and NAPL thickness measurements are collected using an interface meter capable of distinguishing between the NAPL and the groundwater, or a weighted tape coated with the appropriate reactive indicator paste for the suspected NAPL. Measuring NAPL thicknesses must be done with care to avoid agitating the liquids and generating an emulsion. This is particularly the case for light NAPL (LNAPL; those having a density less than water), which are typically viscous oils that

cling to the probe. Oil coating the probe can result in thickness measurements that are biased high (i.e., overestimate the thickness of the NAPL).

Conduct the following procedures to ensure an accurate measurement of the NAPL thickness:

- For LNAPL, slowly lower the electronic interface probe in the well casing until the electronic tone indicates the probe is at the top of the LNAPL layer; measure the depth below the TOC to the nearest 0.01 foot.
- To gauge the NAPL thickness, advance the probe slowly through the layer until the electronic tone indicates top of the water column and then slowly bring the probe back up to the bottom of the LNAPL. Repeat this process several times to ensure an accurate measurement of the bottom of the LNAPL layer (which can include bubbles and an emulsion layer).
- For dense NAPL (DNAPL), advance the probe through the water column until the tone indicates the top of the DNAPL layer; record the depth below TOC.
- To gauge the DNAPL thickness, advance the probe through the layer to the bottom of the well.

11.8 GROUNDWATER PURGING PROCEDURES

Purging is a process whereby potentially stagnant water is removed allowing the collection of samples that are representative of groundwater conditions in the water-bearing zone. The water in a well bore that has not been purged may be different than the surrounding formation due to exposure to ambient air. There are several purging (and no-purge) methods that may be used, depending on specific conditions encountered (e.g., DTW, hydraulic conductivity of the formation, etc.) and the sampling requirements. The purge/no purge options are described below.

- *Multiple Volume Purge:* Traditional well purging technique that relies on the withdrawal of the volume of the well bore and the surrounding filter pack (if present); three to five well volumes are typically removed using pumps or bailers. This methodology relies on equipment that is easy to obtain and use and is generally accepted in most states as an appropriate purging method.
- *Temporary Well Purge:* A variation of the multiple volume purge technique that often uses inertia lift pumps, peristaltic pumps, or bailers to remove water from a temporary well or discrete groundwater sampler (e.g., a groundwater profiler or direct-push screen point sampler). This is a less stringent technique that is typically done to minimize the turbidity of the samples, which can be high due to the lack of a well filter pack.
- *Private Water Well or In-Place Plumbing Purge:* A variation on the multiple volume purge technique whereby a tap or faucet is opened on a fixed water supply pipe and is allowed to remain open until the potentially stagnant water within the well casing and other components of the system (e.g., fixed piping, pressure tanks, etc.) has been removed and groundwater representative of the water-bearing zone is discharged at the tap.
- *Low Flow (Minimal Drawdown/Low Stress) Purge (and Sampling):* A modified purging technique that establishes an isolated, discrete, horizontal flow zone directly adjacent to the pump intake; this method requires the pump to be placed within a screened-interval or open borehole. Pumping rates are typically 0.1 to 0.5 liters per minute (l/min) or less to minimize the stress on the surrounding formation and reduce the geochemical alteration of the groundwater caused by pumping.
- *No-Purge/Passive Sampling Techniques:* These techniques use specialized equipment, such as trap-style samplers or permeable diffusion bags, to sample the undisturbed water column within a screened interval or open borehole. This methodology assumes that the water in the well is representative of the surrounding formation. This approach is well suited for some volatile organic compounds (VOCs), metals, and hydrophobic compounds, depending on the sampling device used.

11.8.1 CALCULATING ONE PURGE VOLUME

Multiple volume purging techniques require that a ***minimum*** of three well volumes of water must be removed before sample collection. The actual amount of water removed may be greater than the three volumes, depending on geochemical parameter stabilization (the field measurement of these parameters is discussed below).

Calculate the volume of water in a well or boring using the following equation:

$$\textbf{Volume (gallons)} = (\textbf{TD} - \textbf{DTW}) \times \textbf{ID}^2 \times \textbf{0.041}$$

where:

TD = total depth (feet)

DTW = depth to water (feet)

ID = inner diameter (inches)

Alternately, the volume of water in a well or boring may also be calculated by multiplying the water column height by the gallons per foot of water for the appropriate well or boring diameter:

ID	Gallons per foot of water	Gallons per three water columns
1-inch	0.04	0.12
2-inch	0.16	0.48
3-inch	0.37	1.11
4-inch	0.65	1.98

Calculate the total volume of the pump, associated tubing and container for in situ measurements (flow-through cell), using the following equation:

Volume (in gallons) = P + ((0.0041)*D2*L) + fc

where:

P = volume of pump (gallons)
D = tubing diameter (inches)
L = length of tubing (feet)
fc = volume of flow-through cell (gallons)

11.8.2 MULTIPLE VOLUME PURGE PROCEDURES

Begin purging at a rate that will not cause excessive turbulence and drawdown in the well; commonly less than 1 gallon per minute for a typical 2-inch diameter monitoring well. You may need to observe the water elevation after the pump is started and adjust the flow rate to minimize the amount of drawdown in the well casing. The objective is to remove the stagnant water in the casing and surrounding filter pack or open borehole allowing water from the surrounding water-bearing zone to enter the well for sampling with as little disturbance as possible. Excessive pump rates or well dewatering can result in higher turbidity, potential volatilization, and geochemical alteration of dissolved parameters.

Typically collect geochemical parameters (i.e., pH, specific conductance, dissolved oxygen [DO], oxygen-reduction potential [ORP], and temperature) at a minimum frequency of once for every well volume of water removed during the purge process. Record the measurements in the field book along with any other pertinent details, such as the visual quality of the water (e.g., color, odor, and presence of suspended particulates) and the approximate withdrawal rate (this can be estimated using a calibrated container and stopwatch). Review the geochemical measurements to ensure that readings have stabilized (after the minimum purge volume has been achieved). This is a proxy for determining that you are purging formation water rather than potentially stagnant water in the casing. Stabilization occurs when at least three consecutive measurements are within the following tolerances:

Multiple Volume Purge Stabilization Parameters	
pH	± 0.1 standard units (SU)
Specific Conductance	± 3%
Temperature	± 3%
Dissolved Oxygen (DO)	± 0.2 milligrams per liter (mg/l) or 10% (flow-through cell only)
Turbidity	± 10% for values greater than 10 nephelometric turbidity units (NTU)
Oxygen Reduction Potential (ORP)	± 10 millivolts (mV; flow-through cell only)

Parameter stabilization that does not occur within five well volumes may require you consult your project manager to decide whether to collect a sample or to continue purging. Wells with extremely slow recharge may also be problematic. Purging these wells, in some cases, may result in dewatering the well before the minimum purge can be completed. Allow wells or borings purged dry to recharge to a level of approximately 90% of the static (pre-purge) water elevation and proceed immediately to sample collection. If recovery exceeds 2 hours, sample as soon as sufficient sample volume is available, in accordance with applicable regulations.

11.8.3 LOW FLOW PURGE PROCEDURES

Low flow purging and sampling is used to obtain representative groundwater samples without removing all the water within the well. The protocol uses relatively low pumping rates (i.e., less than 0.5 l/min) to establish an isolated zone around the inlet of the pump where flow is horizontal (i.e., from the water bearing zone) rather than from the stagnant water in the well casing above and below the pump. Selection of an appropriate pump is critical to establishing the flow zone: it must be well suited for both low pumping rates and the analytes being sampled. Bailers are not appropriate for low flow sampling.

The set-up for low flow sampling includes positioning the pump at the appropriate depth within the casing such that the pump inlet is within the screened section of the well. Slowly lower the pump, where appropriate, and tubing into the water column to avoid agitating the water column; use of a lanyard is recommended (i.e., do not use the extraction tubing to lift or lower the pump). Secure the pump and/or tubing at the wellhead once the specified sampling depth has been achieved and record the depth in the field book. Avoid contacting the bottom of the well by using pre-cut tubing at the appropriate length or by lowering the pump/tubing simultaneously with an electronic water level indicator. Once the pump/tubing has been inserted and secured, allow the water levels to return to static conditions before initiating the purge.

The discharge tubing must be connected to an in-line flow-through cell equipped with a multi-parameter real-time water quality meter. The flow-through cell minimizes the exposure of the groundwater to ambient air, which can influence DO and ORP measurements.

Start the pump and maintain a steady flow rate that results in a stabilized water level (less than 0.3 feet of drawdown or as specified in the project-specific work plan). The pumping rate may need to be adjusted depending on the response of the water levels in the well. Record each adjustment made to the pumping rate and the water level measured immediately after each adjustment. Purging should not exceed 0.5 l/min.

During purging, monitor and record the flow rate and geochemical parameters at 30 seconds to 5-minute intervals (depending on the hydraulic conductivity of the aquifer, diameter of the well, and pumping rate). Stabilization occurs once the following criteria have been met over three successive measurements made at least three minutes apart:

Low Flow Purge Stabilization Parameters	
Water Level Drawdown	<0.3 feet
pH	± 0.1 SU
Specific Conductance	± 3%
Temperature	± 3%
DO	± 0.2 mg/l or 10% (flow-through cell only)
Turbidity	± 10% for values greater than 10 NTU
ORP	± 10 mV (flow-through cell only)

Record any other notable observations in the field book (e.g., groundwater color).

11.8.4 NO-PURGE SAMPLING TECHNIQUES

Several alternate sampling devices are available, such as equilibrated grab samplers, passive diffusion samplers, and other in situ sampling devices, that will allow sample collection without purging the well. These devices may be particularly useful for sampling low permeability geologic materials, assuming the device is made of materials compatible with the analytical parameters, meets data quality objectives, and has been properly evaluated.

No-purge grab or trap samplers are placed in the well before sampling and typically remain closed (i.e., no water is allowed into the sampler during insertion) until the sampler is activated. This allows the sampler device to equilibrate with the surrounding groundwater (to prevent adsorption to the sampler materials) and for the groundwater to recover and re-establish the natural flow after the disturbance caused by the sampler insertion into the well. Typical equilibration times depend on the well recovery rates and the type of sampler used. Samples recovered using the no-purge devices are either transferred to containers at the well head or the sampler itself is shipped to the laboratory for analysis. Examples of equilibrated grab samplers include HydraSleeve™, Snap Sampler™, and Kemmerer samplers.

Equilibration time for diffusion samplers are generally dictated by the diffusion rate through the permeable membrane and, thus, are less sensitive to changes induced within the well during deployment. Most diffusion bag samplers have a minimum equilibration time of 14 days prior to sample collection. The samplers may be deployed for an extended period (e.g., three months or longer), although the continuous exchange between the sampler and the well water means that the sampler will likely reflect only the conditions in the few days preceding the sample collection.

11.8.5 TEMPORARY WELL PURGE PROCEDURES

Procedures used to purge temporary groundwater monitoring wells differ from permanent wells because temporary wells are installed for immediate sample acquisition. Wells of this type may include open bedrock boreholes, standard polyvinyl chloride well screen and riser placed in open boreholes, or drilling rod-based sampling devices (e.g., Wellpoint®, Geoprobe® screen point or Hydropunch® samplers). Purging temporary wells of this type may not be necessary because stagnant water is typically not present. However, if water is used in the drilling process, purging would be necessary. Purging can minimize the turbidity in the sample, which can be significant due to the disturbance caused by the sampler installation and to rinse the sampling system with groundwater. The exception is for groundwater profiling applications (e.g., using a Waterloo Profiler®) where a more rigorous purge is used (using the multiple volume purge techniques described above) to limit the potential for cross-contamination between sample intervals.

11.8.6 PRIVATE WATER WELL OR IN-PLACE PLUMBING PURGE PROCEDURES

The configuration and construction of private water wells varies widely and access points for obtaining groundwater samples may be limited. WSP personnel should coordinate with the property owner or site representative to access functioning ports and valves to avoid causing any inadvertent damage.

Collect the groundwater sample as close to the well as possible (e.g., from a sample port at the well head) to ensure the sample is representative. Ideally, the sample should be collected upstream of the piping and treatment equipment (e.g., particulate filter, water softener, carbon filters, ultra-violet lights), heating unit, or storage tanks. The following potential sampling locations are presented in order of preference:

- Sampling port or spigot near the well head or piping system prior to entry into the storage tank
- Sampling port or spigot at storage tank
- Sampling port or spigot downstream of the pressure tank or holding tank but upstream of any water treatment equipment
- Tap or faucet

If purging from a tap or faucet, try to remove any aerators, filters, or other devices from the tap before purging and work with the property owner or site representative to bypass any water treatment systems. Document where the sample was collected and any steps that were taken to minimize the potential alteration of the water sample in the field book.

Purge the system by opening the tap or spigot and allowing the water to run for several minutes. Observe and record the purge rate for the system. The minimum purge volume must be more than the combined volume of the pump, tanks, piping, etc. Review the geochemical measurements (after the minimum purge volume has been removed) to ensure that readings have stabilized using the same procedures as those used for the multiple volume purge detailed above. Purge the system for a minimum of 15 minutes if the minimum volume is unknown. Sample only after the geochemistry parameters have stabilized and no there are no suspended particles (e.g., iron or rust) visible. Record the final purge volume in the field book and any water quality observations.

11.9 GROUNDWATER SAMPLE COLLECTION PROCEDURES

Collect groundwater samples as soon as possible after the geochemical parameters indicate representative groundwater is present. As practically possible, reduce the pump flow rate, but maintain a flow rate high enough to deliver a smooth stream of water without splashing or undue agitation. Collect samples directly from the tubing as it exits the well bore; do not sample on the downstream side of flow-through cells or any other instrumentation. If using a bailer for sample collection, lower and raise the bailer slowly and smoothly to minimize the disturbance to the water within the well.

Collect groundwater samples in order of volatilization sensitivity with organic compounds sampled first followed by inorganic compounds:

- VOCs
- Extractable organics, petroleum hydrocarbons, aggregate organics, and oil and grease
- Per- and Polyfluoroalkyl substances
- Total metals
- Dissolved metals (see filtering procedures below)
- Inorganic non-metallic and physical and aggregate properties
- Microbiological samples
- Radionuclides

Collect quality assurance/quality control samples in accordance with SOP 4 and the project-specific work plan or QAPP.

As necessary, conduct field tests or screening in accordance with the project-specific work plan and manufacturer's specifications for field testing equipment. Field samples must be directly transferred from the sampling equipment to the container that has been specifically prepared for that given parameter; intermediate containers should be avoided. If field chemical preservation is required, check the pH preservation by pouring a small portion of sample onto a pH test strip Adjust pH with additional preservative, if necessary.

Record the sample depth interval, if applicable, in the field book. Note the volume, phases, odor, and color of the groundwater.

11.9.1 GROUNDWATER FILTRATION PROCEDURES

Filtered groundwater samples are sometimes used for field kit analyses and should only be collected for laboratory analysis after approval from the appropriate regulatory agency or project manager. The filtered samples can be collected by attaching the in-line filter directly to the outlet tubing for a pressurized bailer, a submersible pump or a peristaltic pump. Intermediate containers can be used with a peristaltic pump if the well is too deep to use the pump to recover the sample directly. The intermediate container should be unpreserved laboratory-supplied glassware to avoid any cross-contamination during the filtering process.

Filtered samples using pumps should use the following procedures:

- Use a variable speed peristaltic pump with the in-line filter fitted on the outlet end of the tubing and the pump inlet tubing into the intermediate container holding the unpreserved groundwater sample; or,
- If a submersible pump is used to collect the groundwater sample, attached the in-line filter to the outlet end of the tubing (do not allow the groundwater to pass through flow-through cells or any other instrumentation while sampling)

Once the filter is connected:

- Turn on the pump and maintain a flow rate high enough to deliver a smooth stream of water without splashing or undue agitation. Hold the filter upright with the inlet and outlet in the vertical position and pump groundwater through the filter until all atmospheric oxygen has been removed and the minimum volume of water has been flushed through the filter, in accordance with the manufacturer's specifications
- Collect the filtered samples by placing the filtered output directly into the sample container
- If sediment is visible in the sample container after filtration, filter break-through has occurred and the sampling and filtering process should be repeated
- Discard the tubing and filter appropriately

Record sample filtration in the field book.

11.9.2 NON-AQUEOUS PHASE LIQUID SAMPLING PROCEDURES

Non-aqueous phase liquid is typically sampled to identify the compound, usually through an analytical "fingerprint" analysis. If samples are to be collected, the sampling options and techniques should be discussed with the assigned WSP compliance professional and project manager to ensure that the NAPL is either not considered to be a hazardous material for shipping to the laboratory or is properly shipped by qualified personnel using appropriate shipping containers (SOP 3). Samples of NAPL should be collected using the same procedures as above and placed in the appropriate laboratory-supplied containers, packed on ice, and shipped to the analytical laboratory using procedures outlined in SOP 3.

11.9.3 SAMPLE LABELING AND PREPARATION FOR SHIPMENT

Groundwater samples for offsite laboratory analysis should be prepared as follows:

1. Clean the outside of the sample container, if necessary
2. Affix a sample tag or label to each sample container and complete all required information (sample number, date, time, sampler's initials, analysis, preservatives, place of collection)
3. Place clear tape over the tag or label (if non-waterproof labels are used), as needed
4. If needed, preserve samples immediately after collection by placing them into an insulated cooler filled with bagged wet ice to maintain a temperature of approximately 4°Celcius
5. Record the sample designation, date, time, and the sampler's initials in the field book and on a sample tracking form, if appropriate
6. Complete the chain-of-custody forms with appropriate sampling information, including:
   - location
   - sample name
   - sample collection date and time
   - number of sample containers

- analytical method
- field filtration status

7 Secure the sample packing and shipping in accordance with proper procedures

Do not ship hazardous waste samples without first consulting a WSP compliance professional.

11.10 CLOSING NOTES

Secure and restore the site once sampling is completed. This may include locking permanent monitoring wells, staging the IDW, and disposing of (in conformance with applicable regulations) sampling expendables, such as plastic sheeting, tubing, and PPE. All locations where temporary wells or other sampling devices (e.g., profilers or direct-push equipment) should be marked with spray paint, stakes, or other appropriate method for future reference or survey, including collecting Global Positioning System coordinates and photographs, in accordance with the project-specific work plan. Decontaminate all equipment prior to departure and properly manage all PPE and investigation-derived wastes in conformance with SOP 6, the project-specific work plan, and applicable regulations.

CASE NARRATIVE / CONFORMANCE SUMMARY

Client:	WSP Environment & Energy	**Job No**	JD6583
Site:	Former General Instrument Site (GIC), Sherburne, NY	**Report Date**	5/4/2020 11:04:51 AM

On 04/29/2020, 7 Sample(s), 1 Trip Blank(s) and 0 Field Blank(s) were received at SGS North America Inc. at a maximum corrected temperature of 3.3 C. Samples were intact and chemically preserved, unless noted below. A SGS North America Inc. Job Number of JD6583 was assigned to the project. Laboratory sample ID, client sample ID and dates of sample collection are detailed in the report's Results Summary Section.

Specified quality control criteria were achieved for this job except as noted below. For more information, please refer to the analytical results and QC summary pages.

Compounds qualified as out of range in the continuing calibration summary report are acceptable as per method requirements when there is a high bias but the sample result is non-detect.

MS Volatiles By Method SW846 8260C

Matrix: AQ **Batch ID:** V1A8656

- All samples were analyzed within the recommended method holding time.
- Sample(s) JD6583-7MS, JD6583-7MSD were used as the QC samples indicated.
- All method blanks for this batch meet method specific criteria.
- Matrix Spike Recovery(s) for Bromomethane are outside control limits. Outside in house control limits.
- RPD(s) for MSD for Bromomethane are outside control limits for sample JD6583-7MSD. Outside in house control limits.
- V1A8656-MB for Vinyl chloride: MDL from current instrument.
- JD6583-7 for Chloroethane: Associated CCV outside of control limits high, sample was ND.
- JD6583-7 for Bromomethane: Associated CCV outside of control limits low.
- JD6583-1 for Chloroethane: Associated CCV outside of control limits high, sample was ND.
- JD6583-8 for Bromomethane: Associated CCV outside of control limits low.
- JD6583-6 for Bromomethane: Associated CCV outside of control limits low.
- JD6583-1 for Bromomethane: Associated CCV outside of control limits low.
- JD6583-2 for Chloroethane: Associated CCV outside of control limits high, sample was ND.
- JD6583-2 for Bromomethane: Associated CCV outside of control limits low.
- JD6583-3 for Chloroethane: Associated CCV outside of control limits high, sample was ND.
- JD6583-3 for Bromomethane: Associated CCV outside of control limits low.
- JD6583-4 for Chloroethane: Associated CCV outside of control limits high, sample was ND.
- JD6583-4 for Bromomethane: Associated CCV outside of control limits low.
- JD6583-5 for Chloroethane: Associated CCV outside of control limits high, sample was ND.
- JD6583-5 for Bromomethane: Associated CCV outside of control limits low.
- JD6583-6 for Chloroethane: Associated CCV outside of control limits high, sample was ND.
- JD6583-8 for Chloroethane: Associated CCV outside of control limits high, sample was ND.

SGS North America Inc. certifies that data reported for samples received, listed on the associated custody chain or analytical task order, were produced to specifications meeting the Quality System precision, accuracy and completeness objectives except as noted.

Estimated non-standard method measurement uncertainty data is available on request, based on quality control bias and implicit for standard methods. Acceptable uncertainty requires tested parameter quality control data to meet method criteria.

SGS North America Inc. is not responsible for data quality assumptions if partial reports are used and recommends that this report be used in its entirety. Data release is authorized by SGS North America Inc indicated via signature on the report cover

CAS No.	Surrogate Recoveries	Run# 1	Run# 2	Limits
1868-53-7	Dibromofluoromethane	106%		80-120%
17060-07-0	1,2-Dichloroethane-D4	97%		81-124%
2037-26-5	Toluene-D8	98%		80-120%
460-00-4	4-Bromofluorobenzene	93%		80-120%

(a) Associated CCV outside of control limits low.
(b) Associated CCV outside of control limits high, sample was ND.

ND = Not detected MDL = Method Detection Limit
RL = Reporting Limit
E = Indicates value exceeds calibration range
J = Indicates an estimated value
B = Indicates analyte found in associated method blank
N = Indicates presumptive evidence of a compound

SGS Sample Receipt Summary

Job Number: JD6583 **Client:** WSP ENVIRONMENT & ENERGY **Project:** FORMER GENERAL INSTRUMENT SITE (GIC),

Date / Time Received: 4/29/2020 10:40:00 AM **Delivery Method:** **Airbill #'s:**

Cooler Temps (Raw Measured) °C: Cooler 1: (3.6);

Cooler Temps (Corrected) °C: Cooler 1: (3.3);

Cooler Security	Y	or	N		Y	or	N
1. Custody Seals Present:	☑		☐	3. COC Present:	☑		☐
2. Custody Seals Intact:	☑		☐	4. Smpl Dates/Time OK	☑		☐

Cooler Temperature	Y	or	N
1. Temp criteria achieved:	☑		☐
2. Cooler temp verification:	IR Gun		
3. Cooler media:	Ice (Bag)		
4. No. Coolers:	1		

Quality Control Preservation	Y	or	N	N/A
1. Trip Blank present / cooler:	☑		☐	☐
2. Trip Blank listed on COC:	☑		☐	☐
3. Samples preserved properly:	☑		☐	
4. VOCs headspace free:	☑		☐	☐

Sample Integrity - Documentation	Y	or	N
1. Sample labels present on bottles:	☑		☐
2. Container labeling complete:	☑		☐
3. Sample container label / COC agree:	☑		☐

Sample Integrity - Condition	Y	or	N
1. Sample recvd within HT:	☑		☐
2. All containers accounted for:	☑		☐
3. Condition of sample:	Intact		

Sample Integrity - Instructions	Y	or	N	N/A
1. Analysis requested is clear:	☑		☐	
2. Bottles received for unspecified tests	☐		☑	
3. Sufficient volume recvd for analysis:	☑		☐	
4. Compositing instructions clear:	☐		☐	☑
5. Filtering instructions clear:	☐		☐	☑

RE: **31401203.42**

Pace Workorder: 33590

Dear Dave Bouchard:

Enclosed are the analytical results for sample(s) received by the laboratory on Wednesday, April 29, 2020. Results reported herein conform to the most current NELAC standards, where applicable, unless otherwise narrated in the body of the report.

If you have any questions concerning this report, please feel free to contact me.

Sincerely,

Ruth Welsh 05/12/2020

SUBJECT: Former General Instrument Site, Sherburne, NY, Data Validation

Dear Mr. Reinert,

Enclosed are the final validation reports for the fractions listed below. These SDGs were received on May 28, 2020. Attachment 1 is a summary of the samples that were reviewed for each analysis.

LDC Project #48168:

SDG #	Fraction
JD6583 33590	Volatiles, Dissolved Organic Carbons, Methane, Ethane & Ethene

The data validation was performed under Category B guidelines. The analyses were validated using the following documents, as applicable to each method:

- USEPA Region 2 Standard Operating Procedure for Validating Volatile Organic Compounds By Gas Chromatography/Mass Spectrometry, SOP HW-24, Revision 4; October 2014
- USEPA Contract Laboratory Program National Functional Guidelines for Superfund Organic Methods Data Review, EPA 540-R-2017-002, January 2017
- USEPA Contract Laboratory Program National Functional Guidelines for Inorganic Superfund Data Review, EPA 540-R-2017-001; January 2017
- EPA SW 846, Third Edition, Test Methods for Evaluating Solid Waste, update 1, July 1992; update IIA, August 1993; update II, September 1994; update IIB, January 1995; update III, December 1996; update IIIA, April 1998; IIIB, November 2004; update IV, February 2007; update V, July 2014

Please feel free to contact us if you have any questions.

Sincerely,

Christina Rink

Samples Reviewed and Evaluation Summary

FIELD ID	LAB ID	FRACTIONS VALIDATED
MW-32	JD6583-1	VOC
MW-31	JD6583-2	VOC
MW-22	JD6583-3	VOC
MW-34	JD6583-4	VOC
MW-17	JD6583-5	VOC
MW-0420	JD6583-6	VOC
P-8	JD6583-7	VOC
TRIP BLANK	JD6583-8	VOC
P-8MS	JD6583-7MS	VOC
P-8MSD	JD6583-7MSD	VOC

Associated QC Samples(s):
Field/Trip Blanks: TRIP BLANK
Field Duplicate pair: MW-17 and MW-0420

The above-listed water samples were collected on April 28, 2020 and were analyzed for volatile organic compounds (VOC) by SW-846 method 8260C. The data validation was performed in accordance with the USEPA Region 2 *Standard Operating Procedure for Validating Volatile Organic Compounds By Gas Chromatography/Mass Spectrometry,* SOP HW-24, Revision 4 (October 2014) and the USEPA *Contract Laboratory Program National Functional Guidelines for Superfund Organic Methods Data Review,* EPA 540-R-2017-002 (January 2017), modified as necessary to accommodate the non-CLP methodologies used.

The organic data were evaluated based on the following parameters:

- Data Completeness
- Holding Times and Sample Preservation
- Gas Chromatography/Mass Spectrometry (GC/MS) Tunes
- Initial and Continuing Calibrations
- Blanks
- Surrogate Recoveries
- Matrix Spike/Matrix Spike Duplicate (MS/MSD) Results
- Laboratory Control Sample (LCS) Results
- Internal Standards
- Field Duplicate Results
- Quantitation Limits and Data Assessment
- Sample Quantitation and Compound Identification

Overall Evaluation of Data and Potential Usability Issues

All results are usable as reported or usable with minor qualification due to sample matrix or laboratory quality control outliers.

The validation findings were based on the following information.

Data Completeness

The data package was complete as defined under the requirements for the NYSDEC ASP category B laboratory deliverables.

Holding Times and Sample Preservation

All criteria were met.

GC/MS Tunes

All criteria were met.

Initial and Continuing Calibrations

Initial calibration:

All criteria were met.

Continuing calibration:

Compounds that did not meet criteria are summarized in the following table.

Date	Instrument ID	Compound	CC %D	Associated Samples		Validation Action
04/30/20	1a200837	Bromomethane	37.9	MW-32	XX	UJ nondetects
		Chloroethane	22.0	MW-31		UJ nondetects
				MW-22		
				MW-34		
				MW-17		
				MW-0420		
				P-8		
				TRIP BLANK		

X = Initial calibration (IC) relative standard deviation (%RSD) > 20; estimate (J/UJ) positive and nondetect results.
XX = Continuing calibration (CC) percent difference (%D) > 20; estimate (J/UJ) positive and nondetect results.
SS = Second source verification percent difference (%D) > 30; estimate (J/UJ) positive and nondetect results.
+ = Response factor (RRF) < validation criteria; estimate (J/UJ) positive and nondetect results.

The bromomethane and chloroethane results were estimated due to continuing calibration exceedances. The bias cannot be determined. The results can be used for project objectives as nondetects with estimated quantitation limits (UJ) which may have a minor impact on the data usability.

Blanks

Contamination was not detected in the method blanks.

No positive results were found in the trip blank sample TRIP BLANK for VOC analysis.

Surrogate Recoveries

All criteria were met.

MS/MSD Results

MS/MSD analyses were performed on sample P-8 for VOC analysis. The following table lists the MS/MSD percent recoveries (%R) outside of control limits in the VOC analysis and the resulting validation actions.

MS ID	Compound	MS %R (Limits)	MS/D %R (Limits)	Affected Sample	Validation Action
P-8MS/MSD	Bromomethane	52 (53-142)	-	P-8	UJ nondetects

- Within control limits

The bromomethane result may be biased low due to low MS/MSD percent recoveries. The result can be used for project objectives as nondetects with estimated quantitation limits (UJ) which may have a minor impact on the data usability.

The following table lists the MS/MSD relative percent differences (RPD) outside of control limits in the VOC analysis and the resulting validation actions.

MS ID	Compound	RPD (Limits)	Affected Sample	Validation Action
P-8MS/MSD	Bromomethane	25 (≤14)	P-8	None

Validation action was not required for bromomethane due to MS/MSD relative percent difference exceedances as positive results only are affected and this compound was not detected in the associated sample.

LCS Results

All criteria were met.

Internal Standards

All criteria were met.

Field Duplicate Results

Samples MW-17 and MW-0420 were submitted as the field duplicate pair with this sample group. The following table summarizes the concentrations.

Compound	Concentration (ug/L)		RPD
	MW-17	MW-0420	
cis-1,2-Dichloroethene	1.5	1.6	6

Quantitation Limits and Data Assessment

No results were reported below the reporting limit (RL) and above the method detection limit (MDL) in the VOC analysis.

Dilutions were not required for VOC analysis.

Sample Quantitation and Compound Identification

Calculations were spot-checked; no discrepancies were noted.

DATA VALIDATION QUALIFIERS

U - The analyte was analyzed for, but due to blank contamination was flagged as nondetect (U). The result is usable as a nondetect.

J - Data are flagged (J) when a QC analysis fails outside the primary acceptance limits. The qualified "J" data are not excluded from further review or consideration. However, only one flag (J) is applied to a sample result, even though several associated QC analyses may fail. The 'J' data may be biased high or low or the direction of the bias may be indeterminable.

UJ - The analyte was not detected above the reported sample quantitation limit. Data are flagged (UJ) when a QC analysis fails outside the primary acceptance limits. The qualified "UJ" data are not excluded from further review or consideration. However, only one flag is applied to a sample result, even though several associated QC analyses may fail. The 'UJ' data may be biased low.

JN - The analysis indicates the presence of a compound that has been "tentatively identified" (N) and the associated numerical value represents its approximate (J) concentration.

R - Data rejected (R) on the basis of an unacceptable QC analysis should be excluded from further review or consideration. Data are rejected when associated QC analysis results exceed the expanded control limits of the QC criteria. The rejected data are known to contain significant errors based on documented information. The data user must not use the rejected data to make environmental decisions. The presence or absence of the analyte cannot be verified.

VALIDATION FINDINGS CHECKLIST

Reviewer: JVG
2nd Reviewer:

Method: Volatiles (EPA SW 846 Method 8260C)

Validation Area	Yes	No	NA	Findings/Comments
I. Technical holding times				
Were all technical holding times met?	✓			
Was cooler temperature criteria met?	✓			
II. GC/MS Instrument performance check				
Were the BFB performance results reviewed and found to be within the specified criteria?	✓			
Were all samples analyzed within the 12 hour clock criteria?	✓			
IIIa. Initial calibration				
Did the laboratory perform a 5 point calibration prior to sample analysis?	✓			
Were all percent relative standard deviations (%RSD) ≤ 20% and relative response factors (RRF) within method criteria?	✓			
Was a curve fit used for evaluation? If yes, did the initial calibration meet the curve fit acceptance criteria of > 0.990?			✓	
IIIb. Initial Calibration Verification				
Was an initial calibration verification standard analyzed after each initial calibration for each instrument?	✓			
Were all percent differences (%D) ≤ 30%?	✓			
IV. Continuing calibration				
Was a continuing calibration standard analyzed at least once every 12 hours for each instrument?	✓			
Were all percent differences (%D) ≤ 20% and relative response factors (RRF) within method criteria?		✓		
V. Laboratory Blanks				
Was a laboratory blank associated with every sample in this SDG?	✓			
Was a laboratory blank analyzed at least once every 12 hours for each matrix and concentration?			✓	
Was there contamination in the laboratory blanks?			✓	
VI. Field blanks				
Were field blanks were identified in this SDG?	✓			
Were target compounds detected in the field blanks?		✓		
VII. Surrogate spikes				
Were all surrogate percent recovery (%R) within QC limits?	✓			
If the percent recovery (%R) for one or more surrogates was out of QC limits, was a reanalysis performed to confirm samples with %R outside of criteria?			✓	
VIII. Matrix spike/Matrix spike duplicates				
Were matrix spike (MS) and matrix spike duplicate (MSD) analyzed in this SDG?	✓			
Were the MS/MSD percent recoveries (%R) and the relative percent differences (RPD) within the QC limits?		✓		

Validation Area	Yes	No	NA	Findings/Comments
IX. Laboratory control samples				
Was an LCS analyzed per analytical batch?	✓			
Were the LCS percent recoveries (%R) and relative percent difference (RPD) within the QC limits?	✓			
X. Field duplicates				
Were field duplicate pairs identified in this SDG?	✓			
Were target compounds detected in the field duplicates?	✓			
XI. Internal standards				
Were internal standard area counts within -50% to +100% of the associated calibration standard?	✓			
Were retention times within ± 30 seconds of the associated calibration standard?	✓			
XII. Compound quantitation				
Did the laboratory LOQs/RLs meet the QAPP LOQs/RLs?	✓			
Were the correct internal standard (IS), quantitation ion and relative response factor (RRF) used to quantitate the compound?	✓			
Were compound quantitation and RLs adjusted to reflect all sample dilutions and dry weight factors applicable to level IV validation?	✓			
XIII. Target compound identification				
Were relative retention times (RRT's) within ± 0.06 RRT units of the standard?	✓			
Did compound spectra meet specified EPA "Functional Guidelines" criteria?	✓			
Were chromatogram peaks verified and accounted for?	✓			
XIV. System performance				
System performance was found to be acceptable.	✓			
XV. Overall assessment of data				
Overall assessment of data was found to be acceptable.	✓

Samples Reviewed and Evaluation Summary

FIELD ID	LAB ID	FRACTIONS VALIDATED
P-8	335900001	Dissolved Organic Carbon
P-8MS	335900001MS	Dissolved Organic Carbon
P-8DUP	335900001DUP	Dissolved Organic Carbon

Associated QC Samples(s):

Field/Trip Blanks: None Associated
Field Duplicate pair: None Associated

The above-listed water samples were collected on April 28, 2020 and were analyzed for dissolved organic carbon by standard method 5310C. The data validation was performed in accordance with the *USEPA Contract Laboratory Program National Functional Guidelines for Inorganic Superfund Data Review,* EPA 540-R-2017-001 (January 2017), modified as necessary to accommodate the non-CLP methodologies used.

The inorganic data were evaluated based on the following parameters:

- Overall Evaluation of Data and Potential Usability Issues
- Data Completeness
- Holding Times and Sample Preservation
- Initial Calibration and Calibration Verification
- Blank Analysis Results
- Matrix Spike (MS) Results
- Laboratory Duplicate Results
- Field Duplicate Results
- Laboratory Control Sample (LCS) Results
- Detection Limits Results
- Sample Quantitation Results

Overall Evaluation of Data and Potential Usability Issues

All results are usable as reported.

The validation findings were based on the following information.

Data Completeness

The data package was complete as defined under the requirements for the NYSDEC ASP category B laboratory deliverables.

Holding Times and Sample Preservation

All criteria were met.

Initial Calibration and Calibration Verification

All criteria were met.

Blank Results

Contamination was not detected in the laboratory blank samples.

A field blank was not associated with this sample set. Validation action was not required on this basis.

MS Results

MS analyses were performed on sample P-8 for dissolved organic carbon analysis. All criteria were met.

Laboratory Duplicate Results

Laboratory duplicates were performed on sample P-8 for dissolved organic carbon analysis. All criteria were met.

LCS Results

All criteria were met.

Field Duplicate Results

A field duplicate pair was not associated with this sample set. Validation action was not required on this basis.

Detection Limits Results

No results were reported below the reporting limit (RL) and above the method detection limit (MDL) in the dissolved organic carbon analysis.

Dilutions were not required for dissolved organic carbon analysis.

Sample Quantitation Results

Calculations were spot-checked; no discrepancies were noted.

DATA VALIDATION QUALIFIERS

U - The analyte was analyzed for, but due to blank contamination was flagged as nondetect (U). The result is usable as a nondetect.

J - Data are flagged (J) when a QC analysis fails outside the primary acceptance limits. The qualified "J" data are not excluded from further review or consideration. However, only one flag (J) is applied to a sample result, even though several associated QC analyses may fail. The 'J' data may be biased high or low or the direction of the bias may be indeterminable.

UJ - The analyte was not detected above the reported sample quantitation limit. Data are flagged (UJ) when a QC analysis fails outside the primary acceptance limits. The qualified "UJ" data are not excluded from further review or consideration. However, only one flag is applied to a sample result, even though several associated QC analyses may fail. The 'UJ' data may be biased low.

R - Data rejected (R) on the basis of an unacceptable QC analysis should be excluded from further review or consideration. Data are rejected when associated QC analysis results exceed the expanded control limits of the QC criteria. The rejected data are known to contain significant errors based on documented information. The data user must not use the rejected data to make environmental decisions. The presence or absence of the analyte cannot be verified.

Validation Findings Worksheet
Initial and Continuing Calibration Calculation Verification

Reviewer: ATL
2nd Reviewer: [signature]

Method: Inorganics, Method See Cover

The correlation coefficient (r) for the calibration of DOC was recalculated. Calibration date: 4/3/20

An initial or continuing calibration verification percent recovery (%R) was recalculated for each type of analysis using the following formula:

%R = Found X 100 / True

Where, Found = concentration of each analyte measured in the analysis of the ICV or CCV solution

True = concentration of each analyte in the ICV or CCV source

Type of analysis	Analyte	Standard	Conc. (mg/L)	Area	Recalculated r or r^2	Reported r or r^2	Acceptable (Y/N)
Initial calibration	DOC	s1	0.2	8450	*0.99988*	*0.99980*	Y
		s2	0.5	11850			
		s3	1	20390			
		s4	5	77401			
		s5	20	282920			
		s6	40	549609			
ICV Calibration verification	DOC	FOUND 26.357	TRUE 25.000		105	106	Y
CCV Calibration verification	DOC	25.599	25.000		102	103	Y
CCV Calibration verification	DOC	24.886	25.000		99.5	99.9	Y

Comments: Refer to Calibration Verification findings worksheet for list of qualifications and associated samples when reported results do not agree within 10.0% of the recalculated results.

LDC #: 48168B6

VALIDATION FINDINGS WORKSHEET
Level IV Recalculation Worksheet

Reviewer: ATL
2nd Reviewer:

METHOD: Inorganics, Method See cover

Percent recoveries (%R) for a laboratory control sample and a matrix spike sample were recalculated using the following formula:

$\%R = \frac{Found}{True} \times 100$ Where, Found = concentration of each analyte measured in the analysis of the sample. For the matrix spike calculation, Found = SSR (spiked sample result) - SR (sample result).
True = concentration of each analyte in the source.

A sample and duplicate relative percent difference (RPD) was recalculated using the following formula:

$RPD = \frac{|S-D|}{(S+D)/2} \times 100$ Where, S = Original sample concentration
D = Duplicate sample concentration

Sample ID	Type of Analysis	Element	mg/L Found / S (units)	mg/L True / D (units)	Recalculated %R / RPD	Reported %R / RPD	Acceptable (Y/N)
LCS	Laboratory control sample	DOC	13.529	13	104	104	Y
2	Matrix spike sample	DOC	(SSR-SR) 19.789	20	99	99	Y
3	Duplicate sample	DOC	4.5	4.3	3.8	3.8	Y

FIELD ID	LAB ID	FRACTIONS VALIDATED
P-8	335900001	Methane, Ethane, and Ethene
TRIP BLANK	335900002	Methane, Ethane, and Ethene

Associated QC Samples(s):
Field/Trip Blanks: TRIP BLANK
Field Duplicate pair: None Associated

The above-listed water samples were collected on April 28, 2020 and were analyzed for methane, ethane, and ethene by AM20GAX. The data validation was performed in accordance with the USEPA *Contract Laboratory Program National Functional Guidelines for Superfund Organic Methods Data Review,* EPA 540-R-2017-002 (January 2017), modified as necessary to accommodate the non-CLP methodologies used.

The organic data were evaluated based on the following parameters:

- Data Completeness
- Holding Times and Sample Preservation
- Initial and Continuing Calibrations
- Blanks
- Matrix Spike/Matrix Spike Duplicate (MS/MSD) Results
- Laboratory Control Sample (LCS) Results
- Field Duplicate Results
- Quantitation Limits and Data Assessment
- Sample Quantitation and Compound Identification

Overall Evaluation of Data and Potential Usability Issues

All results are usable as reported.

The validation findings were based on the following information.

Data Completeness

The data package was complete as defined under the requirements for the NYSDEC ASP category B laboratory deliverables.

Holding Times and Sample Preservation

All criteria were met.

Initial and Continuing Calibrations

All criteria were met.

Blanks

Contamination was not detected in the method blanks.

No positive results were found in the trip blank sample TRIP BLANK for methane, ethane, and ethene analysis.

MS/MSD Results

MS/MSD analyses were not associated with this sample set. Validation action was not required on this basis.

LCS/LCSD Results

All criteria were met.

Field Duplicate Results

A field duplicate pair was not associated with this sample set. Validation action was not required on this basis.

Quantitation Limits and Data Assessment

No results were reported below the reporting limit (RL) and above the method detection limit (MDL) in the methane, ethane, and ethene analysis.

Dilutions were not required for methane, ethane, and ethene analysis.

Sample Quantitation and Compound Identification

Calculations were spot-checked; no discrepancies were noted.

DATA VALIDATION QUALIFIERS

U - The analyte was analyzed for, but due to blank contamination was flagged as nondetect (U). The result is usable as a nondetect.

J - Data are flagged (J) when a QC analysis fails outside the primary acceptance limits. The qualified "J" data are not excluded from further review or consideration. However, only one flag (J) is applied to a sample result, even though several associated QC analyses may fail. The 'J' data may be biased high or low or the direction of the bias may be indeterminable.

UJ - The analyte was not detected above the reported sample quantitation limit. Data are flagged (UJ) when a QC analysis fails outside the primary acceptance limits. The qualified "UJ" data are not excluded from further review or consideration. However, only one flag is applied to a sample result, even though several associated QC analyses may fail. The 'UJ' data may be biased low.

JN - The analysis indicates the presence of a compound that has been "tentatively identified" (N) and the associated numerical value represents its approximate (J) concentration.

R - Data rejected (R) on the basis of an unacceptable QC analysis should be excluded from further review or consideration. Data are rejected when associated QC analysis results exceed the expanded control limits of the QC criteria. The rejected data are known to contain significant errors based on documented information. The data user must not use the rejected data to make environmental decisions. The presence or absence of the analyte cannot be verified.

The percent recoveries (%R) and relative percent differences (RPD) of the laboratory control sample and laboratory control sample duplicate were recalculated for the compounds identified below using the following calculation:

%Recovery = 100 * (SSC/SA)
RPD =(({SSCLCS - SSCLCSD} * 2) / (SSCLCS + SSCLCSD))*100

Where SSC = Spiked sample concentration; SA = Spike added
LCS = Laboratory Control Sample; LCSD = Laboratory Control Sample duplicate

LCS/LCSD samples: 670301 LCS/D

Compound	Spike Added (ug/L)		Spike Sample Concentration (ug/L)		LCS Percent Recovery		LCSD Percent Recovery		LCS/LCSD RPD	
	LCS	LCSD	LCS	LCSD	Reported	Recalc.	Reported	Recalc.	Reported	Recalc.
Gasoline (8015)										
Diesel (8015)										
Benzene (8021B)										
Methane AM20GAX (~~RSK-175~~)	750	750	752	751	101	101	100	100	0.19	0.13
2,4-D (8151)										
Dinoseb (8151)										
Naphthalene (8310)										
Anthracene (8310)										
HMX (8330)										
2,4,6-Trinitrotoluene (8330)										
Phorate (8141A)										
Malathion (8141A)										
Formaldehyde (8315A)										

Comments: Refer to Laboratory Control Sample/Laboratory Control Sample Duplicate findings worksheet for list of qualifications and associated samples when reported results do not agree within 10.0% of the recalculated results.

METHOD: /GC __ HPLC

Y N N/A Were all reported results recalculated and verified for all level IV samples?
Y N N/A Were all recalculated results for detected target compounds within 10% of the reported results?

Concentration= $\frac{(A)(Fv)(Df)}{(RF)(Vs \text{ or } Ws)(\%S/100)}$

A= Area or height of the compound to be measured
Fv= Final Volume of extract
Df= Dilution Factor
RF= Average response factor of the compound In the initial calibration
Vs= Initial volume of the sample
Ws= Initial weight of the sample
%S= Percent Solid

Example:

Sample ID. 1 Compound Name Methane

Concentration = $\frac{(11.999)}{(0.00113)}$ = 10578.2

≈ 10000 ug/L

#	Sample ID	Compound	Reported Concentrations (ug/L)	Recalculated Results Concentrations (ug/L)	Qualifications
	1	Methane	10000	10000	—
		on-col	10563.8	10578.2	—
