XYLENES, TOTAL	vapor

Notes:
Compound list generated from surface and subsurface soil COPCs selected in RAGS 2 Series.
Only volatile organic compounds are considered for the vapor inhalation pathway. All other compound classes are considered for the inhalation of fugitive dust particles.

APPENDIX C
SOIL-TO-AIR VOLATILIZATION FACTORS
CALCULATING Q/Cvol
HONEYWELL, WILLIS AVENUE CHLOROBENZENE SITE, GEDDES, NEW YORK

Exposure Areas for Construction Worker*	Area (acres)	Total Area for receptor	Q/C_{vol} (g/m^2-s per kg/m^3)
Plant Area	14.83	20.95	53.39
Former Chlorination	1.16		
Onsite Ditches	0.04		
Southwest Off-Site/Outfall 006 Area	1.23		
Chlorobenzene Hot Spot Area	1.92		
Petroleum Storage Area	1.77		

$$Q/Cvol = A \times \exp\left[\frac{(\ln A_s - B)^2}{C}\right]$$

t D-3, USEPA 2002

Variable	Value	Units/Rationale/Source
A =	16.8653	unitless, Chicago Zone 7 values, Exhibit D-3, USEPA 2002
B =	18.7848	unitless, Chicago Zone 7 values, Exhibit D-3, USEPA 2002
C =	215.0624	unitless, Chicago Zone 7 values, Exhibit D-3, USEPA 2002

Notes:
* Only those areas that contain soil or sediment are presented.

APPENDIX C
SOIL-TO-AIR VOLATILIZATION FACTORS
VOLATILIZATION FACTOR CALCULATIONS
HONEYWELL, WILLIS AVENUE CHLOROBENZENE SITE, GEDDES, NEW YORK

$$VF(m^3/kg) = Q/C \times \frac{(3.14 \times D_A \times T)^{1/2}}{(2 \times \rho_b \times D_A)} \times 10^{-4}(m^2/cm^2)$$

Constituent	Volatilization Factor (mg^3/kg)
1,2,3-TRICHLOROBENZENE[a]	3.36E+04
1,2,4-TRICHLOROBENZENE	3.36E+04
1,2,4-TRIMETHYLBENZENE[b]	1.21E+04
1,2-DICHLOROBENZENE	1.14E+04
1,3,5-TRIMETHYLBENZENE[b]	1.05E+04
1,3-DICHLOROBENZENE[c]	1.03E+04
1,4-DICHLOROBENZENE	1.01E+04
BENZENE	2.12E+03
CHLOROBENZENE	1.45E+03
ETHYLBENZENE	4.20E+03
SEC-BUTYLBENZENE	NV
TERT-BUTYLBENZENE	NV
TOLUENE	3.09E+03
TRICHLOROETHENE	2.54E+03
XYLENES, TOTAL[d]	6.93E+02

Notes:
Values are from USEPA 2002 unless otherwise noted.
a = 1,2,4-Trichlorobenze used as surrogate.
b = Values taken from Risk Assessment Information System: Chemical Specific Factors Database, Accessed February 2008.
c= Average of values for 1,4-Dichlorobenzene and 1,2-Dichlorobenzene
d = Average values for m-xylene, o-xylene, and p-xylene.

APPENDIX D

Particulate Emissions Factor Calculation

APPENDIX D
PARTICULATE EMISSIONS FACTOR (PEF) CALCULATIONS
PEF TO BE USED FOR CONSTRUCTION WORKER/FUGITIVE DUST SCENARIO
HONEYWELL, WILLIS AVENUE CHLOROBENZENE SITE, GEDDES, NEW YORK

$$Q/C_{sr} = A \times \exp\left[\frac{(\ln A_s - B)^2}{C}\right]$$

Equation E-19, USEPA 2002

Variable		Value	Units	Rationale
A =		12.935	unitless	default as per USEPA 2002
B =		5.738	unitless	default as per USEPA 2002
C =		71.771	unitless	default as per USEPA 2002
A_s =		0.439	acres	area of road that bisects a 20.95 acre square[1].
$Q/C_{sr\ EU1}$ =		**23.5704**	**g/m^2-s per kg/m^3**	

$$F_D = 0.1852 + \frac{5.3537}{t} + \frac{-9.6318}{t^2}$$

Equation E-16, USEPA 2002

Variable		Value	Units	Rationale
t =		48.50	hours	Time vehicles are on the road during the year. (assumes 10 vehicles traversing the length of the road (0.291 km) 4 times per day for 100 days traveling an average of 24 km per hour).
F_D =		**0.2915**	**unitless**	

$$PEF_{const} = Q/C_{sr} \times \frac{1}{F_D} \times \frac{T \times A_R}{556 \times (W/3)^{0.4} \times \left[\frac{(365 - p)}{365}\right] \times \sum VKT}$$

Variable		Value	Units	Rationale
T =		2880000	seconds	Total time of construction (8 hours/day X 100 days X 1 year)
A_R =		1775.10	m2	Area of contaminated road (L_R = 291 meters, W_R = 6.1 meters)
W =		11.5	tons	Mean vehicle weight (average of 5 pickup trucks (3 tons) and 5 dump trucks (20 tons))
ΣVKT =		1164	km	Sum of vehicle km traveled (10 vehicles X 4 trips/day/vehicle X 291 meters/trip X 100 days). 291 is the length of side of a square 20.95 acre area
p =		171	days	Mean number of days with 0.01 inches precipitation or more. Data for Syracuse, NY collected by Cornell University NRCC.
PEF_{const}:		**7.02E+05**	**m^3/kg**	

1. 20.95 acres is the spatial extent of areas visited by the construction worker receptor, as follows:

Exposure Area	Acres	Ft^2
Plant Area	14.83	645,997.02
Former Chlorination Building	1.16	50,427.26
Onsite Ditches	0.04	1,780.76
SW Exposure Area (Outfall-006)	1.23	53,571.24
Chlorobenzene Hot Spot Area	1.92	83,823.20
Petroleum Storage Area	1.77	77,178.99

APPENDIX G1

Honeywell 2007 Response to NYSDEC Comments

September 5, 2007

Mr. Richard A. Mustico
Project Manager
New York State Department of Environmental Conservation
Remedial Bureau B
625 Broadway, 12th Floor
Albany, NY 12233-7016

Re: Willis Avenue Chlorobenzene Site Consent Order #R7-0201-87-08
Human Health Risk Assessment (HHRA)

Dear Mr. Mustico:

This letter provides responses to NYSDEC comments on the October 2004 Revised Human Health Risk Assessment (2004 HHRA) that were submitted to Honeywell in a letter dated March 13, 2007. These responses were originally submitted to NYSDEC on May 17, 2007, but have been revised to reflect discussions between NYSDEC, Honeywell, USEPA, and O'Brien & Gere in the May 30, 2007 conference call.

The May 30, 2007 conference call was to discuss comments G2, G4, S18, S38, S44, T32, and T26. During the conference call and in subsequent email correspondence, the NYSDEC also brought up additional specific notes regarding the following comments: S5, S43, S23, T22, T28, S35, T26, and T29. These responses have been revised to reflect the discussions during the conference call and subsequent email correspondence.

During the phone call, Michael Sivak of the USEPA agreed to provide alternative toxicological values for constituents without approved values in the USEPA IRIS database. A list of constituents with Provisional Peer Reviewed Toxicity Values (PPRTV) was provided by USEPA for review. The PPRTVs will be incorporated into the risk assessment as appropriate.

Responses to the comments listed above are highlighted in yellow in the attachment. We have also enclosed a CD containing the HHRA database. The HHRA database is the same as the Site wide database with the addition of two columns, subsite and medium, which will allow the user to differentiate data subsets used in the risk calculations.

Should you have any additional questions or concerns regarding this matter, please feel free to contact me or Chris Calkins of O'Brien & Gere.

Sincerely,

John P. McAuliffe, P.E.
Program Director, Syracuse

ATTACHMENT: Responses to Comments submitted to Honeywell in a letter from NYSDEC dated March 13, 2007on the October 2004 Human Health Risk Assessment for the Willis Avenue Chlorobenzene Site.

Comment numbers below correspond to the New York State Department of Environmental Conservation (NYSDEC) July 19, 2004 Comments on the June 2002 HHRA and Honeywell's Response to Comments from the December 2, 2004 letter from John P. McAuliffe, P.E. of Honeywell to Richard A. Mustico of the NYSDEC.

Bulleted items represent new comments on the October 2004 HHRA.

General Comments

G1

· *In Honeywell's December 2, 2004 Response to Comments several responses indicate that revisions will be incorporated into the final HHRA to be submitted after NYSDEC review of the October 2004 HHRA (e.g., Response to Comment Nos. 38, 63, 77, 87, 88). Please ensure that these corrections/revisions are made for the final document.*

The corrections/revisions noted in Honeywell's December 2, 2004 Response to Comments will be implemented in the final HHRA.

G2

5. NYSDEC requests a copy of the database in the format required in the consent order, which should include all data generated for the site, including data for the baseline ecological risk assessment and interim remedial measures.

In addition, the data set specific to the HHRA should be presented as an attachment (preferably electronically) in a format that can be used to verify the calculations in the HHRA. Data were not presented in a manner which was conducive to calculations being checked.

A copy of the database and an attachment with the HHRA data set will be presented in advance of the final HHRA. The HHRA data set will contain a "Subsite" and "Medium" field to indicate the exposure area and sample medium for each sample. Site exposure area maps and sample summary tables will also be provided to show which samples are located in which exposure area

G3

· *The adolescent trespasser has not been evaluated as a potentially exposed future population. The revised HHRA does not appear to do this. It is reasonable to assume that, given the expected future land use at the site, the exposure scenarios and parameters used for the current trespasser would be consistent with those for the future receptor as well. Incorporating the future trespasser will only require slight revisions of the text and RAGS tables and is not likely to require new tables or renumbering of existing tables. As an example of what should be done in terms of RAGS tables, please see Table 7.1.CT where the Time Scenario is already labeled "current/future." The future receptor should be added to RAGS 1.1a, b, f, and g (and subsequent affected tables).*

The current adolescent trespasser will be changed to the current/future adolescent trespasser in the RAGS tables and text.

G4

· *The data evaluation section should indicate whether mercury was speciated. If it was not, what assumptions were used to determine the form it might realistically be present in and how was it dealt with in the quantitative assessment? Information on the form of mercury present in the environment is important in understanding the potential for the chemical to migrate into indoor air, as well as for understanding its toxicity. Data in the Table 2 series indicate that at least one sample was analyzed for methylmercury in most areas. For the initial contaminant screening, EPA recommends, in the absence of speciation, mercury should be assumed to be in its most toxic form, methylmercury, and screened against these PRG/RBC values. It is understood that the assumption that not all the mercury at the Willis Chlorobenzene Site is present in the organic form. However, the quantitative assessment must clearly indicate in the text the data and assumptions used to establish any assumptions regarding the form of mercury in specific media and specific locations. In addition, the uncertainty assessment section of the HHRA should include a sensitivity analysis indicating the effect on the risk calculations if the actual fraction methylmercury is higher than the value assumed for risk characterization.*

The data evaluation section will discuss the form of mercury present on Site by evaluating available methylmercury data with respect to total mercury data. In the absence of data regarding speciation, mercury will be screened against methylmercury PRG/RBC values. In the risk characterization, the highest observed fraction of methylmercury from speciated samples will be used to determine mercury toxicity. For Site sediment, this fraction is 7% (rounded up from 6.90%; see table below) and for Site soil, it is 1% (rounded up from 0.61%; see table below). The uncertainty section will include a sensitivity analysis indicating the effect on the risk calculations if the actual fraction of methylmercury is higher than the value assumed for the risk characterization. It should be noted that the adolescent trespasser exposed to On-site Ditch surface soil (0-2 ft) is the only receptor for which the choice of the methylmercury fraction can result in changing the hazard index from less than 1 to greater than 1. This receptor will be discussed in the uncertainty section.

Sample ID	Sample Date	Exposure Area	Sample Depth (ft)	Mercury (µg/kg)	Methyl Mercury (µg/kg)	Methyl Mercury/Mercury Ratio

Specific Comments

Section 2

S1

· *Section 2.2, Page 6. Please provide an explanation of activities that occurred in the Chlorobenzene Hotspot Area so that historic contamination can be better understood. Otherwise, provide a reference to the RI that would provide this information.*

An explanation of activities that occurred in the chlorobenzene hotspot area will be included.

Section 3 – Conceptual Site Model

S2

· *Section 3.2 (Page 10), Footnote 3. The footnote indicates a fire occurred at the chlorination building in 1930. This information should be included in Section 2 on site history since it pertains to historical contamination and is essential to understanding the formation of dioxins, furans, and PAHs at the site.*

The information in the footnote will be included in Section 2.

S3

· *General, Sections 3.2 through 3.9. The individual exposure areas were reorganized (sequence changed) and in some cases were renamed. Are the renamed areas the same as those to which they correspond in the 2002 HHRA, or does the renaming indicate that the definition of the area (and hence the sample data included) has also changed?*

· *General, Sections 3.3 through 3.9. The descriptions of the individual areas were removed. The descriptions are useful to the reader and should be retained. Furthermore, the descriptions should clearly indicated which samples were used for each exposure area. Tables should be used to represent this information and referenced in the text.*

The descriptions of individual areas will be restored and any renamed areas will be described.

S4

· *Section 3.8 (Page 12). This section indicates that in the absence of deep soil samples in some areas, those collected from the General Plant Area were used as substitutes. The effects on the overall assessment from this lack of data should be acknowledged in the uncertainty section and should either be discussed qualitatively or identified as a data gap that may need to be filled at a later stage in the remediation process.*

The effects of using samples from the General Plant Area as substitutes will be discussed in the uncertainty section.

S5

· *Section 3.11.2. This section should discuss the exposure parameters applied to each potentially exposed population, as well as the reference for those values. This is*

especially important for those parameters based on best professional judgement. Simply directing the reader to the tables in Appendix L-C is insufficient.

The rationale and supporting references for each of the exposure parameters in the RAGS D Table 4 Series will be discussed in Section 3.11.2. This Section along with the updated RAGS D Table 4 Series will be submitted to NYSDEC in advance of the full HHRA.

Section 4 – Data Evaluation

S6

· *Section 4.1.3. Although exposure to high levels of mercury may first result in acute health effects, this HHRA should address chronic exposure to elemental mercury in any media or locations where it has been observed or its presence is suspected. Chronic exposure to some concentrations of elemental mercury is associated with adverse health effects. Please make adjustments to the risk assessment appropriately. Acute effects can be addressed as part of the Health and Safety Plan for remediation. The HHRA should indicate, as minimum, whether or not the pathway (exposure to mercury or its vapors) is complete under both current and future scenarios, and address the risks at least qualitatively if it is not possible to do so quantitatively.*

Chronic rather than acute effects of potential exposure to mercury will be addressed, including discussion of complete exposure pathways and corresponding risks.

S7

26, 27, 28. New Table L-3 has been provided to address these comments; Table L-3 should be referenced in Section 4.1.1. However, the areas listed in the table do not appear to match up with the areas listed in the text (e.g., "Northwest Off-Site/Outfall 004" shown as "State Fair Boulevard/Outfall 004" on Table L-3). Please use consistent nomenclature (and also consistent sequence) so that it is apparent which Table L-3 areas match the Section 4.1 areas. For example, it would be helpful to note in the text that the general plant area includes the Plant Area, Former Chlorination Building, and Off-Site Ditches sub-areas (as shown on Table L-3).

Table L-3 will be referenced in Section 4.1.1. and will use consistent nomenclature with the text.

S8

· *It would be clearer if all discussion of the groundwater data was presented in Section 4.1.10. As currently written, the sub-area groundwater data don't appear to always match the discussion (e.g., the last paragraph of Section 4.1.3 appears inconsistent with Table L-3; WA-6, which is evidently included in the count of 11 samples in the text, is included in the 006 area in Table L-3). A table identifiying (listing) all the groundwater samples (including year sampled, well ID, and parameters anlayzed) used for the site-wide drinking water pathway should be provided so that the discrepancy can be resolved. See also comment 37, below.*

All discussion of the groundwater data will be presented in Section 4.1.10, and a table listing all the groundwater samples used for the site-wide drinking water pathway will be provided.

S9

34. In new Table L-3, there is no depth cited for surface soil sample PAS #1. Please provide the depth in the revised table.

PAS#1 is not a surface soil sample. This sample was collected from the pipe bedding material around the P.A. Sewer. The sample was collected at 11 ft below ground surface. The Table will be corrected.

S10

35. *Petroleum Storage Area – second bullet. Based on Table L-3, should this state 4 (rather than 3) additional upper soil samples (i.e., PSA1, PSA2, and two samples from PSA3)?*

The text will be changed to state 4 additional upper soil samples.

S11

36. Chlorobenzene Hot Spot Area – first bullet. Based on Table L-3, should this be 7 (not 6) samples?

The text will be changed to state 7 surface soil samples.

S12

37. Groundwater was treated as one area (as requested), but the number of samples appears inconsistent (29 in the text but 35 in the table). It appears that 35 is the correct number of wells. Please correct the text as appropriate.

In addition, the date range shown appears to be incorrect. As noted in Table L-3 and confirmed in Honeywell's December 2, 2004 response, the only groundwater sample data used were from samples collected in 1992, 1995, and 1997. Therefore, the date range should be 1992 to 1997 (not 1991 to 2002). Please provide a tabulation of all the groundwater data used as noted in the bullet immediately above comment 34, above.

The number of samples and data range will be corrected. A table listing all the groundwater samples used for the site-wide drinking water pathway will be provided.

S13

38. The October 2004 report is incorrect; however, Honeywell's December 2, 2004 letter indicates this will be corrected. Based on the letter, this is provisionally acceptable.

Agreed.

S14

39. The comment was addressed; however, the new text is unclear and perhaps incorrect. It appears that the third sentence was mis-written (should it have meant to state that "analytes were retained as COPCs if the reporting limit was greater than the screening value"?). However, the third sentence of the new text seems to contradict the fourth sentence. Also, what does the phrase "retained as COPCs in the uncertainty analysis" mean? Were these not retained as COPCs in the quantitative assessment, but the impact of not including them is discussed in Section 8? Please re-write this paragraph to address inconsistencies and more clearly describe what was done.

The third sentence will be rewritten as: "For non-detect constituents with reporting limits that were greater than screening values, the constituents were not retained as COPCs in the

quantitative assessment, but the impact of not including them is discussed in the uncertainty analysis (Attachment L-A, Section 8).

S15

· *Section 4.3.1. EPA Region 2 also identifies any Group A (known human) carcinogens as COPCs and retains these chemicals in the quantitative risk assessment. Any chemical that is identified in the IRIS database as a Group A carcinogen should therefore be flagged for inclusion in the baseline human health risk assessment regardless of frequency of detection or if the maximum detected concentration exceeds risk-based limits. This list includes arsenic, benzene, vinyl chloride, and chromium (hexavalent chromium is a known human carcinogen via inhalation). The rationale for inclusion of these chemicals to be used in Table 2 is "TOX." Review of the tables indicates that Honeywell did not screen any of these out based on frequency of detection. Vinyl chloride was not detected, and arsenic was not screened out. However, benzene and chromium were screened out by Honeywell (because concentrations were below the screening level) in the following RAGS series 2 tables: 2.5 (Cr), 2.6 (Cr), 2.9 (benzene), 2.11 (benzene), 2.17 (benzene), 2.18 (benzene), and 2.21 (benzene). These should be included in the quantitative assessment.*

Group A carcinogens will be retained as COPCs in the quantitative assessment.

Section 5 – Exposure Assessment

S16

46. The first two references were added, but the standard default exposure factors (USEPA, 1991) was not. Honeywell's 12/2/04 response indicates that the references have been added, and they are all now in the references. USEPA, 1991 still needs to be added to the text.

USEPA (1991) will be added to the references.

S17

· *Section 5.1.3 (Page 32). Please include the following document in the list of EPA guidance: Calculating the Upper Confidence Limits for Exposure Point Concentrations at Hazardous Waste Sites (USEPA, 2002a).*

This document will be added to the references.

S18

· *Section 5.1.4 (Page 33). Please discuss and provide a statistical reference which provides for a minimum sample number which provides for a meaningful statistical value. Please provide the reference for using the maximum detected concentration as the EPC in cases where there were fewer than 8 samples or the frequency of detection was less than 40 percent (i.e., see RAGS Volume 1, Part A, page 6-22). (Please note that RAGS allows for use of the maximum when there are insufficient data; however, the statistical criteria used for determining when a data set is insufficient need to be documented.)*

The reference for using the maximum detected value as the EPC (instead of the 95% UCL) for frequency of detection less than 50% (corrected from 40% stated above) is USEPA (2006; EPA/240/B-06/003) *Data Quality Assessment: Statistical Methods for Practitioners*. USEPA

(2006) provides guidance on statistical methods for estimating central values (e.g., 95% UCLs) of distributions containing non-detect data (Section 4.7). Methods are provided for data containing less than 15% non-detects and between 15-50% non-detects (Sections 4.7.1 and 4.7.2). However, when the proportion of non-detects exceeds 50%, the guidance recommends switching the parameter of interest from the distribution's center to a parameter to the right of center (using a test of proportions; Section 4.7.3). In sum, we will use 50% frequency of detection as the threshold below which an upper confidence limit on the mean will not be estimated.

Regarding the minimum sample size, the minimum sample size for calculating a 95% UCL using ProUCL 3.0 is 4. Therefore, the maximum detected concentration, instead of the 95% UCLs, will be used as the EPC for data sets with fewer than 4 samples. For data sets with at least 4 samples, non-detect values will be replaced by one-half of the reporting limit, and ProUCL will be used to calculate a 95% UCL, as long as the detection frequency is at least 50%. The calculated 95% UCL will be used as the EPC unless it exceeds the maximum detected concentration, in which case the latter will be used. This approach is consistent with USEPA (1989) RAGS A (p. 6-22),which cautions that if there is great variability in concentration values (due for example to low sample size or low detection frequency), an upper confidence limit may be high and may exceed the maximum detected concentration. In these cases, the maximum detected concentration may be used to estimate the exposure point concentration.

The approach for calculating each exposure point concentration will be documented in the RAGS Table 3 series, which (along with the RAGS Table 2 series) will be submitted in advance of the final HHRA.

S19

The Shapiro-Wilk test is not the only distribution test available in ProUCL and it is typically only used when there are fewer than 50 samples. Please mention other distribution tests, such as the Lilliefors and Empirical Distribution, available in the ProUCL program and whether they were used. [EPA]

The other goodness-of-fit tests available in ProUCL will be discussed.

S20

48. The response is acceptable. However, the typo should be fixed (reference to "Section XX").

The reference to Section XX in section 5.1.3 will be corrected.

S21

· *Section 5.1.5 (Page 34, VOCs) refers to USEPA 2003 Users' Guide but text in Section 4.3.1 refers to the 2002 version of the model. Please correct.*

Consistent references for the vapor intrusion model will be used.

S22

56. The explanation (response) in the 12/2/04 letter should be added to the text here.

The following text will be added to section 5.2.2: "The area containing soils supersaturated with mercury was not evaluated as a hot spot. Since the area is small and will be slated for remediation, an area-specific "hot-spot" evaluation was not undertaken."

S23

· *Section 5.2.1 (Page 36). An adequate explanation of the 10 minutes per day exposure duration for the surveillance worker, along with the rationale for the Fraction Ingested (FI) of 0.1, should be provided. These exposure parameters have not been adequately explained. The document must clearly state why this time was selected (e.g., the surveillance is only a 'windshield survey' and the worker only leaves the vehicle to check the lock on the gate). Additionally, the FI value of 0.1 is lower than EPA's default recommendation (i.e., assuming 100 percent ingested unless site-specific information suggests otherwise).*

Because the surveillance worker surveys the Site from inside a vehicle and only leaves the vehicle to check fence gate locks, it is estimated that the exposure time for the surveillance worker is less than one hour per day. As a result, only a fraction of the surveillance worker's daily soil ingestion rate (50 mg/day) is expected to result from exposure to Site soils. To account for this fractional intake of Site soils, an FI less than 1 is used. This approach is consistent with NYSDEC comment 49 in Honeywell's December 2, 2004 response letter to NYSDEC. For the CT scenario, an FI of 0.02 is used, corresponding to the ratio of 10 minutes on-Site per workday to the 480 minutes for an 8 hour workday. For the RME scenario, an FI of 0.125 is used, corresponding to the ratio of 60 minutes on-Site per workday to the 480 minutes for an 8 hour workday. This explanation will be included in Section 5.2.1.

S24

57. End of Section 5.2.2 (page 37). Please fix the justification of the last sentence in the last paragraph of the subsection (i.e., spacing between "Attachment" and "L-C2").

Agreed.

S25

59. Section 5.4. Terminology changed to "Northwest Off-site/Outfall-4" – is this the same area as the State Fair Boulevard/Outfall 4 area in the 2002 HHRA? Please clarify.

The "State Fair Boulevard/Outfall 4/Niagara Mohawk Area" in the 2002 HHRA is the same as the "Northwest Off-site/Outfall-4 Area" in the 2004 HHRA. These changes reflect only a renaming.

S26

· *Section 5.4.2 (Page 39). This section and those that follow suggest that the maximum detected concentration was used for the EPC to be conservative, rather than because the dataset was small. This implication is incorrect. Please amend the text to explain that the maximum was used because of the "fewer than 8 samples" and "frequency of detection less than 40 percent" criteria stated earlier.*

The correct rationale for why the maximum detected concentration was used for the EPC will be noted.

S27

· *Section 5.7.1 (Page 42). The PA sewer workers would be exposed to surface and subsurface soils as well as deep soils. Honeywell states that the sewer worker could be exposed to soils as deep as 20 ft bgs. The data set used for this receptor should be consistent with this assumption. It appears that the data set in the tables does not always match up with the data set described in the text. For example, RAGS Table 2.18 includes a depth interval from 0-10 feet. Please correct the text, as well as the appropriate RAGS tables, to reflect this.*

The soil depth for the PA sewer workers listed in the text and tables will be made consistent as 0-20 ft.

S28

· *Section 5.8.1 (Page 43). The last paragraph contains text on the General Plant Area rather than the CHSA. Please correct this mistake.*

The last paragraph of section 5.8.1. will discuss the CHSA instead of the General Plant Area.

Section 6 – Toxicity Assessment

S29

· *Section 6.1 (Page 47). The ethyl alcohol example should be deleted. It is not relevant to the HHRA and should be removed.*

The example will be deleted.

S30

· *Section 6.1.2 (Page 48). Please remove the italics from "including sensitive subpopulations" in the first paragraph.*

The italics will be removed.

S31

63. Section 6.2.1, second bullet (Page 49). The footnote was re-numbered as requested, but the actual footnote was deleted. Please replace the footnote.

The footnote will be replaced.

S32

· *Section 6.3 (Page 50): This section does not reflect EPA's current toxicity hierarchy as outlined in the OSWER Directive 9285.7-53, "Human Health Toxicity Values in Superfund Risk Assessments" (December 2003). Please revise using the following hierarchy:*

> ***Tier I:*** *IRIS*
> ***Tier II:*** *EPA's Provisional Peer Reviewed Toxicity Values. (These must be requested from USEPA; consultants do not have direct access to these files.)*
> ***Tier III:*** *Other current toxicity values, which include California EPA, ATSDR and HEAST. Consultation with the Superfund Technical Support Center (STSC) at the National Center for Environmental Assessment (NCEA) is recommended*

before anything in Tier III (including HEAST) is used in a quantitative assessment.

This hierarchy will be used in selection of toxicity factors.

S33

- *Section 6.3.1. Section title should be "elemental" mercury, not "elementary."*

- *This section (6.3.1) should be re-named (e.g., Mercury – other forms) – or perhaps better, a new subsection 6.3.2 should be added – and include not only a discussion of elemental mercury but also methylmercury. The section could be introduced with a brief statement as to where these forms were either detected or may be present on site. See also first bullet on Chapter 4.*

"Elementary" will be changed to "elemental" and a new subsection (6.3.2) discussing methylmercury will be added.

S34

- *Section 6.4.1 (pages 51 and 52). (a) The last two paragraphs of the dioxin/furan discussion are irrelevant to the risk assessment and should be removed (i.e., last two paragraph of this section which occur on page 52). Any legitimate concerns with the toxicological values may be presented in the uncertainty section. A helpful addition would be to include, either in the text or as an appendix, the TEF values from the World Health Organization that were utilized in this assessment. (b) In addition to the oral slope factor of $1.5x10^{5}$ used in this assessment, mention of the draft oral slope factor of $1x10^{6}$ and how use of this new slope factor may affect the assessment should be included in the uncertainty section. The draft review of dioxin can be found at http://www.epa.gov/ncea/pdfs/dioxin/nas-review/.*

The last two paragraphs will be removed. The WHO TEF values are provided in Table L-5. The draft oral slope factor will be discussed in the uncertainty section.

S35

- *Section 6.4.2 (Page 52). Please attribute the toxicity values used for PCBs to the proper source. (a) The CSF of 2.0 $(mg/kg\text{-}day)^{-1}$ for PCBs comes from IRIS, not the Risk Assessment Information System (RAIS). Toxicity values from RAIS are not part of EPA's hierarchy and should not be used unless recommended by NCEA. Additionally, EPA's IRIS database currently recommends using the high risk and persistence oral CSF of 2.0 $(mg/kg\text{-}day)^{-1}$ for inhalation of an aerosol or dust contaminated with PCBs. The dermal CSF should be the same as the oral since according to Exhibit 4-1 of RAGS, Part E, no gastrointestinal absorption efficiency for PCBs should be applied. (b) Aroclors 1242 and 1268 were detected in addition to 1016, 1248, 1254, and 1260 as stated in the text. EPA recommends that for Aroclors with percent chlorine less than or equal to 42 (i.e., Aroclor 1242) the RfD for Aroclor 1016 be used. Alternatively, for Aroclors with percent chlorine greater than 42 (i.e., Aroclor 1248, 1260 and 1268) the RfD for Aroclor 1254 should be used. The reference for this recommendation is a February 25, 2005, email communication with Stanley Barone, Chemical Manager for PCBs and Research Biologist with NCEA/ORD. Please update Table 5.1 to reflect this recommendation.*

The reference to RAIS will be changed to IRIS. The dermal and oral CSF will be the same. Aroclors with percent chlorine less than or equal to 42 (i.e., Aroclor 1242) will use the RfD for

Aroclor 1016. Aroclors with percent chlorine greater than 42 (i.e., Aroclor 1248, 1260 and 1268 will use the RfD for Aroclor 1254.

S36

· *Section 6.4.3 (Page 53): The reference for the TEF (or more correctly, the relative potency) approach to PAHs described in this section should not be attributed to Region 4, but rather to EPA's "Provisional Guidance for Quantitative Risk Assessment of Polycyclic Aromatic Hydrocarbons" (EPA/600/R-93/089, July 1993). Also, RAGS, Part E does not recommend adjusting the oral slope factor for benzo(a)pyrene for the dermal route. Please amend the text appropriately.*

The reference for the relative potency approach to PAHs will be changed as suggested. The oral slope factor for benzo(a)pyrene will not be adjusted for the dermal route.

S37

· *Section 6.4.4 (Page 53). The oral slope factor of $4.2x10^{1}$ $(mg/kg\text{-}day)^{-1}$ for Chromium VI is derived from the inhalation unit risk from IRIS, not RAIS. Please correct the reference.*

The reference will be changed from RAIS to IRIS.

S38

· *Section 6.4.5 (Page 53). EPA suggests that surrogate analysis be performed, or at least approved, by ORD, STSC-NCEA. Currently, RAGS Tables 5 and 6 were not adequately referenced with respect to what surrogates were applied and generally the sources of the toxicity values used. EPA recommends that the tables be revised to more clearly document the origin of the toxicity values. Once these revised tables are submitted for review, the surrogate values listed in Table L-6 will be submitted to NCEA for approval. Due to the time necessary for this review (which also includes identifying COPCs for which current PPRTVs are available), it is recommended that the toxicity tables – with the source of values clearly identified – be submitted for review in advance of the full HHRA.*

RAGS Tables 5 and 6 and will be updated to document use of surrogates and origin of toxicity values. These tables and Table L-6 will be submitted in advance of the full HHRA. O'Brien & Gere will coordinate with USEPA (Michael Sivak, Region 2) to obtain toxicity values that follow the EPA preferred hierarchy of sources (IRIS; PPRTV; other sources including CALEPA, ATSDR, HEAST).

Section 7 – Risk Characterization

S39

68. *In the first sentence, the exponent was fixed. In the second sentence, the comment about the NCP citation was not properly addressed. Honeywell should use the text from the NYSDEC July 19, 2004 comments in the discussion of cancer risk:*

". . . acceptable exposure levels are generally concentration levels that represent an excess upper bound cancer to an individual of between 10^{-4} to 10^{-6} . . . The 10^{-6} risk level shall be used as the point of departure for determining remediation goals . . ." (40 CFR §300.430[e][2][i][A][2]). These target risk levels are also often applied by other agencies responsible for protecting human health (New York State Department of Health [NYSDOH] and Agency for Toxic Substances and Disease Registry [ATSDR]).

The above text will be inserted.

S40

· *Some of the area names have been changed (e.g., in Section 7.2 "Outfall 006" has been added; in Section 7.3 what had been "State Fair Boulevard/Outfall 005/ Nimo" is now "Northwest Off-Site/Outfall 004"). Do these changes reflect only a renaming of the previous (2002) areas, or have the actual areas (including samples and data) associated with these area names also changed?*

The "State Fair Boulevard/Outfall 4/Niagara Mohawk Area" (mislabeled as "State Fair Boulevard/Outfall 5/Niagara Mohawk Area" in Section 7.3) in the 2002 HHRA is the same as the "Northwest Off-site/Outfall-4 Area" in the 2004 HHRA. The "Southwest Off-Site/Outfall 006" Exposure Area (mislabeled as "Southwest Off-Site Exposure Area" in Section 7.2) in the 2002 HHRA is the same as the "Southwest Off-Site/Outfall 006 Exposure Area" in the 2004 HHRA. These changes reflect only a renaming.

S41

73. *Section 7.5.1. Lakeshore Property Area, Current receptors, Adult Trespasser. As it states in Honeywell's Response 73, the recreational fisherman scenario, which evaluates the risk associated with the consumption of fish, was addressed in the Onondaga Lake HHRA. Also in Response 73, it states that the Adult Trespasser scenario considers the potential exposure of a recreational fisherman to surface soil at the Lakeshore Property Area. Since, for this specific scenario, it does not really matter if the Adult Trespasser is a "recreational fisherman" or just a plain adult trespasser, as the exposure is to surface soil, we suggest deleting the term "recreational fisherman" and using "Adult Trespasser" in order to avoid confusion. See also Section 5.6.1.*

The recreational fisherman will be changed to an adult trespasser.

Section 8 – Uncertainty Assessment

S42

77. Section 8.2.1. The comment was not addressed in the October 2004 HHRA. However, based on Honeywell's 12/2/04 letter, this comment has been addressed. See also Comment 38.

Agreed.

S43

· *Section 8.2.2 (Page 69). It is not necessary to have air monitoring data to estimate exposure to fugitive dust and volatile emissions from construction activities. This exposure route could potentially be significant and should be evaluated quantitatively. Consult the "Supplemental Guidance for Developing Soil Screening Levels for Superfund Sites" (OSWER 9355.4-24, December 2002) for the equations to estimate the particulate emission factor (PEF) during hypothetical construction activities. Intake equations can be adapted from the Soil Screening Level equations found on page 23 and 24 of the "Soil Screening Guidance: User's Guide" (OSWER 9355.4-23, July 1996).*

USEPA (2002) Supplemental Guidance for Developing Soil Screening Levels for Superfund Sites will be used to develop a Site-specific particulate emission factor (Equation 5-5), chemical-specific volatilization factors (Equations 5-14 and 5-17), fugitive dust intake equations (Equations 5-3 and 5-4), and volatile intake equations (Equations 5-12 and 5-13) for evaluating

the inhalation exposure route for a construction worker. Site-specific data will be used when available, and literature values will be used when Site-specific data is not available.

S44

· *Section 8.2.3 (Page 69). There are several reasons noted in the text as to why there is a great deal of uncertainty associated with applying the Johnson & Ettinger Model to the site – the main one being the heterogenous nature of the subsurface geology. With such complex subsurface conditions, applying a model that assumes homogeneous soil properties in a horizontal plane may not provide useful information. Other site conditions that question the use of the model are: a) there is no information on how the contaminants may react with the subsurface Solvay Waste, b) NAPL may be present, and c) very shallow groundwater exists at some portions of the site making attenuation difficult to model. Site groundwater data can be compared qualitatively to the generic screening levels in the USEPA Draft Guidance for Evaluating the Vapor Intrusion to Indoor Air Pathway from Groundwater and Soils (EPA 530-F-02-052), Table 2 series for risks at various levels (10^{-4} through 10^{-6}), with the caveat that USEPA Region 2 uses the risk-based value for vapor intrusion screening and does not default to the MCL (as is the case in the cited Vapor Intrusion Guidance).*

The above site conditions that question the use of the J&E model will be included in the text. Site groundwater data will be compared qualitatively to the risk-based generic screening levels for vapor intrusion in the uncertainty analysis. [Note: this response did not require further revision.]

S45

79. *Section 8.2.3. As described in the J&E model manual and USEPA guidance, when models are used to predict exposure a sensitivity analysis should be performed. Given the inherent uncertainties in models and the selection of model parameters, a sensitivity analysis should be conducted to provide a range of upper and lower bound conditions in order to assess the potential for exposure. Sensitivity analyses are particularly appropriate in this case since parameters of the model have been changed from the defaults without much (if any) documentation. In addition, the most recent Johnson and Ettinger model and manual should be used.*

The most recent J&E model/manual will be used and a sensitivity analysis will be conducted using a range of upper and lower bound conditions.

S46

85. *Section 8.3.2. The USEPA recommendation of 330 mg/day is now specifically recommended in "Supplemental Guidance for Developing Soil Screening Levels for Superfund Sites" (USEPA OSWER 9335.4-24, 2002b). This should now be cited in the first sentence of Section 8.4.1 (instead of "as per the NYSDEC's direction"). Also, as the 480 mg/day ingestion rate is no longer used or recommended by USEPA, please delete the second, third, and fifth paragraphs of this section.*

The reference for 330 mg/day will be changed to the USEPA reference, and the second, third, and fifth paragraphs of the section will be deleted.

S47

88. Section 8.4.1. The comment was not addressed in the October 2004 revision; however, the 12/2/04 Honeywell response is acceptable.

Agreed.

S48

90. Section 8.4.2. It does not appear that the comment was adequately addressed. The ATSDR MRLs are now shown, but site data do not appear to be incorporated (i.e., no comparison of site data to the MRLs is presented). With regard to the dioxin reassessment (EPA, 2003), it is acknowledged that the requested citation is a review draft. It is on that basis that values from that document are only to be used in the uncertainty assessment section of the HHRA and are not used quantitatively. The fact that the document is a draft does not preclude its use as a source used in evaluation of the uncertainty associated with dioxin toxicity data. The recent National Academy of Sciences (NAS, 2006) review of the 2003 draft may be cited in the uncertainty section, provided however that use of the NAS review is done in a balanced manner. (For example, the NAS review did not dispute the quantitative values developed by USEPA; but did suggest that carcinogenic potency be assessed by non-linear methods, in addition to the linear manner in which the 2003 draft values were prepared.)

Site dioxin data will be compared qualitatively to ATSDR MRLs and EPA (2003) draft values in the uncertainty section, and the NAS (2006) review of EPA (2003) will be cited.

Section 9 – Conclusions

S49

92. Section 9, first paragraph. Please make the conclusions consistent with changes necessitated by other comments. This comment may also be applicable to the Executive Summary section of the report.

The conclusions section and the Executive Summary section will be revised to address the other changes incorporated into the HHRA.

References

S50

93. The USEPA 2002a (Calculating the Upper Confidence Limits for Exposure Point Concentrations at Hazardous Waste Sites, USEPA, 2002a), 2002b (cited in Comment 85), and 2003 (OSWER Directive 9285.7-53, "Human Health Toxicity Values in Superfund Risk Assessments", December 2003) references should be added. For the ORNL 2004 citation, please provide the full link to where the data used can be found (the existing citation is only to the RAIS home page).

- *Please fix the typo in the spelling of the date in USEPA 2002c.*
- *References should be updated as appropriate.*

The three references will be added, the ORNL 2004 citation will be updated, and the typo in the USEPA 2002c reference will be corrected.

TABLES

T1

· *Table L-1. Gastrointestinal Absorption Factors should come from RAGS, Part E, Exhibit 4-1. Dermal Absorption Factors should come from RAGS, Part E, Exhibit 3-4. Permeability Coefficients should come from RAGS, Part E, Exhibits B-2 and B-3.*

The GI Absorption factors and permeability coefficients will be obtained from RAGS Part E.

Tables L-2 through L-11, Analytical Data Summary Tables

T2

96. Based on Honeywell's 12/2/04 response, this comment appears to have been adequately addressed. Does "Trench areas" in this response mean "On-Site Ditches" as reference in Table L-3?

Yes, trench areas refer to the on-site ditches.

T3

· *Note that Tables L-6 (and documentation of L-5) will require revision to address previous agency comments regarding surrogates and hierarchy of toxicity values. Also, please fix typo in Table L-6, Footnote 2 (replace XXX).*

Tables L-6 and L-5 will be revised in accordance with the surrogate and toxicity value updates. The type in Table L-6, Footnote 2 will be corrected.

T4

98. *The Old Table L-7a had 7 to 10 data points per analyte. The New Table 2.13 only has 4 per analyte, still only MeHg, not Hg, shown; please explain, clarify, or correct as necessary. However, old Table L-7b and new Table 2.14 seem to have the same number of samples.*

Mercury concentrations will be reported in Table 2.13. Table 2.13 will be corrected to have 7 to 10 data points per analyte as were present in the old Table L-7a.

Tables L-12 through L-21, COPC Selection Summary Tables [Now RAGS Tables 2.1 through 2.25]

T5

· *Screening tables – general. The note for "ca*" is not relevant to this HHRA and can be deleted from the table and notes. Screening values for "ca**" (or the analog notation '!' in the Region 3 tables) should be replaced with the nc value divided by 10 to obtain the appropriate conservative screening value (at HI of 0.1).*

The "ca*" note will be removed from the screening tables and "ca**" screening values will be replaced by "nc" values corresponding to an HI of 0.1.

T6

· *As noted in earlier comments, class A carcinogens should not be screened out (i.e., benzene and chromium which were screened out as 'BSL' should be retained – rationale is "TOX").*

Class A carcinogens will be retained for quantitative assessment.

T7

· *General. Please follow the RAGS, Part D, format and include the ARAR/TBC column in the tables, even if ARARs/TBCs have not been established at this time.*

The ARAR/TBC column will be included in the screening tables.

T8

· *General. Please cite the appropriate RBC/PRG value in footnotes 4 and 5. For example, Table 2.1 states that values were taken from the Region 9 PRG table for tap water instead of soil.*

Footnotes 4 and 5 will be corrected.

T9

· *Several of the tables present water pathways but the units on PRGs/RBCs are shown as mg/kg (e.g., 2.7, 2.13, 2.16, 2.19, 2.23, 2.24, 2.25). Please correct the units or provide the correct RBC/PRG values.*

The screening criteria units will be corrected.

T10

· *Table 2.5. Please correct the Exposure Point. It should be FCB instead of CHSA.*

The Exposure Point in Table 2.5. will be corrected.

T11

· *Table 2.7. The maximum concentration of lead in groundwater is high and well above EPA's action level of 15 µg/L. A qualitative discussion of lead in drinking water should be included in the text (e.g., add new section 8.4.3 in text to discuss).*

A new subsection will be added to the uncertainty section to qualitatively discuss lead in drinking water.

T12

· *Table 2.8. The groundwater screen against vapor intrusion values from Table 2c of the EPA's draft Vapor Intrusion Guidance does not follow RAGS, Part D format and therefore should not be in the Table 2 series, but rather a separate appendix. All tables evaluating vapor intrusion should be included in a separate appendix so that they can be evaluated together as a unit.*

All vapor intrusion tables will be moved to a separate appendix.

Tables L-22 through L-33, COPC Exposure Summary Tables *[Now RAGS Tables 3.1 through 3.25]*

T13

- *General, RAGS Table 3 series. The final column in Table 3 should contain the rationale for why the statistic used in calculating the 95% UCL was chosen. For example, if the statistic suggested is the "95% Student's-t," the rationale should be, "The Shapiro-Wilk test for samples <50 suggest data are normally distributed. Analytical process suggests using the Student's-t statistic for normally distributed data." This information can be included in a footnote.*

The rationale in the Table 3 series will be updated and supplemented with descriptive footnotes.

T14

108. *The New Tables 3.1 and 3.2 have more than seven samples, but no values – please explain. There are also problems in some of the tables (specifically 3.1 and 3.2) in the manner in which the entries appear in the columns. For example, in Table 3.1, a value of zero is entered into the 95 percent UCL field. The value is not zero; it should be "NC" (not calculated) if in fact no UCL value was calculated (although for this table we believe a value should have been calculated, as there were 50 general plant area surface soil samples listed on Table L-3). The "Value" column under the Exposure Point Concentration field should not be blank; the actual value used for the EPC should be shown (if that value is the maximum, then the maximum should be shown in this column). EPCs should be identified in Table 3.1 along with the proper rationale even if the 95% UCL cannot be calculated due to lack of data.*

The EPC value column in the Table 3 series will be updated to include the actual EPC value. If a UCL value could not be calculated, the UCL field will be reported as NC.

T15

- *Table 3.3. Please explain how the mean can be greater than the maximum detected concentration (i.e., 2-Hexanone). This is likely due to the fact that ½ the detection limit was used in place of non-detects; however, a footnote explaining this would be helpful. The data as presented also suggest that Honeywell did not remove data points with anomalously high SQLs; this should have been done so that ND values don't drive the EPC calculation (see Guidance in RAGS Volume 1, Part A, Section 5.3.2).*

Data with anomalously high SQLs will be removed, and footnotes will be provided to explain remaining examples of means that exceed maximum detected values.

T16

- *Table 3.7. The EPC for benzene does not appear in this table, yet it is detected at significant concentrations in the groundwater and is listed as a COPC in Tables 2.7/16/19/23/25. Please correct this omission and include all COPCs in the Table 3 series.*

All COPCs identified in the Table 2 series will be included in the Table 3 series, including benzene for Table 3.7.

T17

· *Table 3.8. Please remove this table from the series. It does not follow RAGS Part D format and does not represent indoor air EPCs, but rather those of groundwater. All tables evaluating vapor intrusion should be included in a separate appendix so that they can be evaluated together as a unit.*

Table 3.8 will be moved to a separate appendix for vapor intrusion.

Tables L-34 through L-43, Chronic Exposure Parameter Tables *(Now RAGS series 4).*

T18

· *General comment on RAGS Table 4 series. The "Footnote instructions" and the text following the (1) can be deleted (leave "footnotes" and then list them). Also, the NYSDEC 2004 line has a typo, change "commont" to "comment." Also, as noted in comments elsewhere (see Comments 111 to 116 below), the Region 4 citation should be changed to USEPA 1991 (Risk Assessment Guidance for Superfund Volume 1, Human Health Supplemental Guidance Standard Default Exposure Factors) or USEPA 1997a (Exposure Factors Handbook) as appropriate.*

The footnote line beginning with (1) will be deleted. The typo in the NYSDEC reference will be corrected. The Region 4 citation will be replaced by USEPA 1991.

T19

· *General. The references for the exposure factor values in this series are often not clear and make verification difficult. It is not enough to simply give the title of the reference for the value. Page or exhibit numbers should be provided as well. For example, when citing the 1997 Exposure Factors Handbook, please give the specific page or table number for the value. Also, please indicate whether the exposure parameter represents a mean or upper bound value. For values such as the skin surface area (SA), please include the parts of the body that are included in that calculation. This is especially important since most of the SA values in the series seem high. For example, EPA recommends an SA of 3,300 cm^2 for the industrial worker (RAGS, Part E, exhibit 3-5). This same value (3,300 cm^2) is also recommended for the construction worker, as shown in Table 1-2 of EPA, 2002b. The reference for this is Exhibit 1-2 in the "Supplemental Guidance for Developing Soil Screening Levels for Superfund Sites." (EPA, 2002b). Table 4.1.RME has this value as 5726 cm^2.*

·

Page or exhibit numbers will be added to references. Mean or upper bound values will be documented as will body part-specific values.

T20

· *General. EPA recommends using the soil ingestion rate for both the adolescent and the adult of 100 mg/day. The reference for this is Exhibit 1-2 in the "Supplemental Guidance for Developing Soil Screening Levels for Superfund Sites." (EPA, 2002b). Use of a rate less than 100 needs to be supported clearly and defensibly. The RAGS tables should reference the specific text section in which the rationale for IR of less than 100 is presented. It is recommended that the ingestion rates in the 1991 "Standard Default Exposure Factors" (USEPA, 1991), which are the same as those utilized in Table 1-2 of the cited supplemental guidance (EPA, 2002b) be used for the RME scenario. The 'average' or 'best estimate' values cited in the Exposure Factors Handbook (EPA, 1997; section 4.7) may be used for the CT.*

The IR values in USEPA (2002b) and USEPA (1991) will be used for the RME scenario and the values from USEPA (1997) will be used for the CT scenario.

T21

· *General. Please define the age of the adolescent being evaluated.*

The age of the adolescent will be defined as 7 to <16 years.

T22

· *General. EPA recommends a default RME fraction ingested (FI) of 1.0. Use of a factor less than 1.0 needs to be supported clearly and defensibly. The RAGS tables should reference the specific text section in which the rationale for FI of less than 1.0 is presented.*

The only RME FI values less than 1 in the RAGS Table 4 series are for the surveillance worker, which is discussed in the response to comment S23. However, a number of CT FI values less than 1 are found in the RAGS Table 4 series for other receptors (trespasser, industrial worker, sewer worker). For these other receptors, an FI value of 1 will be used for the CT scenario, to match the value of 1 used for the RME scenario.

T23

· *General. The Skin Surface Area factor is an average rather than an upper-bound value. It should be the same for both the RME and CT exposure scenarios. Please amend the tables in series 4 so that this is the case.*

The RME and CT skin surface area will have the same (50th percentile) value.

T24

· *General. The dermal absorption factors (ABS) should come from RAGS, Part E, not RAIS.*

RAGS E will be the source of ABS values.

T25

111-116. *Reference for adolescent and in some cases adult body weight (USEPA [Region 4], 2000) appears incorrect; a Region 4 reference is cited, but no reference to body weight appears to be located in the cited document. USEPA 1991 or USEPA 1997a should be used for body weight defaults.*

USEPA 1991 or USEPA 1997a will be used for body weight defaults.

T26

· *Table 4.2.RME: The Exposure Assessment portion of the text states that the RME exposure frequency for the industrial worker is 250 days per year, which is the correct value. However, the tables present an EF of 193 days per year, which is also cited as the CT parameter. The CT parameter should be 219 days per year as stated in exhibit 3-5 of RAGS, Part E. If there is reason to believe that these values are too high, a clear and thorough justification for changing them must be provided. Otherwise, this table, and those following it in the series, must be corrected. As noted in RAGS Part E (Final; EPA/540/R/99/005, July 2004), Section 3.2, site-specific values may be used instead of the defaults shown on Exhibit 3-5, but adequate justification must be provided.*

The RME EF of 190 days (correction from 193 days above) assumes 250 work days per year and exposure reduced by 24% due to snow cover. Similarly, for the CT EF, 219 work days per year reduced by 24% due to snow cover yields a CT value of 166 days. These site-specific considerations will be documented in the text.

The snow cover percentage of 24% is derived from a thirty year (1971-2000) temperature and snowfall record for Syracuse, NY from the National Weather Service (Available at: http://www.erh.noaa.gov/bgm/climate/syr/syr_normals.shtml). During the months of December, January, and February, there is on average measurable snowfall (28.6, 33.2, and 24.0 inches, respectively), and average temperatures are below freezing (28.6, 22.7, and 24.5 °F, respectively). Therefore, it can be assumed that snow that falls during these months does not readily melt and provides continuous snow cover. Since the three months include 90 of the 365 days in a year, a snow cover percentage of 24% is derived. This percentage is conservative in that the months of March and November are not included. March and November on average have measurable snowfall (18.8 and 11.1 inches, respectively), but also have average temperatures above freezing (33.6 and 39.7 °F, respectively).

The *Climate of New York* issued by the New York State Climate Office (http://nysc.eas.cornell.edu/) also describes a 3 month period of snow cover for the Syracuse area: "The Southern Plateau, Great Lakes Plain in southern portions of western upstate New York, and the Hudson Valley experience a continuous snow cover from about mid-December to mid-March, with maximum depths usually occurring in February."

T27

- *Table 4.5.RME. The inhalation rate of 1.25 m^3/hr for the Industrial Worker is incorrect. EPA recommends using 1.6 m^3/hr. The reference for this is the worker involved in moderate activity from the 1997 "Exposure Factors Handbook," page 5-24, Table 5-23. It represents a mean value on an upper bound activity.*

The inhalation rate of 1.6 m^3/hr will be used.

T28

- *Table 4.11. RAGS, Part E, Exhibit 3-5 recommends changing the exposure frequency and duration when going from the RME to CT exposure scenarios. Also, the default FI for both the RME and CT should be 1.0. A clear explanation of the rationale for the factors used for the CT should be provided. Using factors other than the EPA default may be acceptable for the CT scenario so long as they are reasonable and documented, and appropriately conservative factors are used for the RME scenario. While previous agency comments agreed to the approach by which a FI for the CT of other than 1.0 may be derived, the underlying assumptions for that approach need to be documented and justified.*

Except for the surveillance worker, an FI value of 1 will be used for all receptors for both the RME and CT scenarios. See response to comment S23 for the surveillance worker.

T29

- *Table 4.14.RME. Please provide more information on the reference for the 0.01 L/day ingestion rate of water for the PA Sewer Worker. This comment also applies to the ingestion rate used for the adolescent trespasser in Table 4.21.RME.*

Section 6.6.1 of USEPA (1989) RAGS A presents an incidental ingestion rate of 0.05 L/hr for a swimmer. For a non-swimmer, the RME incidental ingestion rate has been estimated to be

lower, a value of 0.03 L/hr for 1 hr/day, resulting in an ingestion rate of 0.03 L/day. For the CT scenario, an incidental ingestion rate of 0.01 L/hr for 1 hr/day will be used, based on professional judgment. This information will be provided as a footnote in Table 4.14 and Table 4.21.

T30

· *Table 4.21.RME: The intake equation used to estimate dermal exposure to surface water is incorrect. Please consult RAGS, Part E, page 3-1 for the appropriate method.*

The intake equation will be corrected.

Tables L-44 through L-50, Toxicity Tables *(Now RAGS Tables 5- and 6-series.)*

T31

123. (Re: old Table L-49). The PAH potency values are consistent with the USEPA documented cited, but are from a different source (ORNL). The Honeywell 12/2/04 response uses the USEPA document citation, not ORNL. Please cite the USEPA recommended values when such values are available.

The USEPA recommended values will be cited.

T32

· *Many of the toxicity values listed in this table are improperly referenced or incorrect. For example, 2,6-Dinitrotoluene, 2-Butanone, and 2-Chloronaphthalene have RfD values listed in Table 5.1, but the reference to IRIS is missing. Additionally, 1,1-Dichloroethane and 1,2,4-Trichlorobenzene have extrapolated RfD values in Table 5.2, but no reference is given. The correct reference is HEAST and PPRTV (provisional peer-reviewed toxicity value), respectively. Please reference each value appropriately. It is incorrect to take toxicity values directly from the Region III RBC table published in 2002. This table is out of date (as of the writing of the reviewed HHRA, the most recent was from April 2004; as of December 2005, the October 2004 version is the one posted on the Region 9 website) and also contains values that may not be consistent with EPA's hierarchy outlined in the OSWER Directive 9285.7-53, "Human Health Toxicity Values in Superfund Risk Assessments." (EPA, 2003) EPA submitted the list of chemicals that were missing values to NCEA for review. Additionally, Quantitative Structure Activity Relationship (QSAR) analysis for 1,2,3-trichlorobenzene, 1,2,4-trimethylbenzene, and 2,4,6-trichlorophenol was performed by STSC-NCEA to determine if there are chemicals that are structurally similar enough that their RfDs may be used as surrogates. As PPRTVs have a limited "shelf life" (three years), and new toxicological data is continually being developed, Honeywell should coordinate with NYSDEC to establish communication pathways with EPA so that the appropriate toxicity values and sources are used for RAGS Tables 5 and 6. Available current PPRTVs (as of January 2007) are shown in the attached table from NCEA-STSC. (Note that the table only provides a listing of what is available; the actual PPRTVs and supporting documentation are available only through USEPA.) See also new comment on Section 6.4.5 (page 53), above.*

The toxicity values will be updated and referenced consistent with EPA's hierarchy and will be submitted to NYSDEC prior to submittal of the final HHRA. O'Brien & Gere will coordinate with USEPA (Michael Sivak, Region 2) to obtain toxicity values that follow the EPA preferred hierarchy of sources (IRIS; PPRTV; other sources including CALEPA, ATSDR, HEAST).

Table 7 Series

T33

· *General. The Table 7 series is arranged in a confusing manner. Having all the exposure areas for each receptor included in the same table (i.e., Table 7.1.RME includes every cancer risk and hazard for the adolescent trespasser) suggests cumulative risk from exposure to these separate areas. Please divide up these larger tables by exposure area, consistent with Table 1.*

The Table 7 series will be divided up by exposure area for a given receptor.

T34

- *General. Sitewide risks and hazards for the receptor that may have access to more than one exposure area at this multi-area site have not been assessed. This may be acceptable considering current and expected future land uses. However, there may be a situation where a receptor, such as the adolescent trespasser or the industrial worker, is exposed to multiple areas. It would be helpful to have possibilities for such future scenarios, where receptors are exposed to multiple areas, discussed in the uncertainty section. To illustrate the concept, it may be helpful to have summary tables where all the risks and hazards from individual exposure areas are combined for each receptor. For example, if it is reasonable that the future adolescent trespasser is exposed to the General Plant area, as well as the CHSA and the PSA, the risks and hazards for this individual could be combined and briefly discussed. The use of summary tables would not require any revisions to the RAGS, Part D tables, but would be helpful for discussion in the Risk Characterization section. See, for example, Tables 6-2 and 6-3 of the Geddes Brook/Ninemile Creek HHRA (July 2003).*

Cumulative risks and hazards from exposure to more than one area will shown in summary tables and discussed in the risk characterization section, as appropriate.

T35

- *Table 7.1.RME: The EPCs for surface soil at the General Plant Area do not appear to correspond with the EPC tables. Please verify the origin of these values and that EPCs for other receptors are correct.*

The EPCs in the Table 7 series will match those in the Table 3 series.

T36

- *Table 7.3.CT: Why are there no values in the Intake/Exposure column for some of the exposure routes? Also, on page 14 why is the intake for Aldrin 0.0?*

The missing intake values will be provided and the risk/hazard calculations updated.

Table 9 Series

T37

- *In line with the RAGS, Part D, format, please calculate the HIs for each target organ. This is especially critical for HIs that exceed 1.*

HI will be calculated for each target organ.

Table 10 Series

T38

- *Please provide RAGS Part D, Table 10. In line with RAGS Part D format, this series should follow Table 9. It serves as a summary of the cancer risks and non-cancer hazards that exceed EPA's acceptable levels.*

Table 10 series will be provided.

APPENDIX G2

Honeywell 2008 Response to NYSDEC Comments

Response to "Comments on 'Willis Avenue Chlorobenzene Site HHRA RAGS Tables 1,2, and 4'" prepared by New York State Department of Environmental Conservation, received under cover letter (Richard Mustico [NYSDEC] to John McAuliffe [Honeywell]) dated Sept. 22, 2008.

This submission responds to NYSDEC's Sept. 22, 2008 comment letter, which comments on "Willis Avenue Chlorobenzene Site HHRA RAGS Tables 1,2, and 4" prepared by O'Brien and Gere for Honeywell, submitted March 7, 2008. Reviewer comments are shown in italics.

Review of 2/27/08 Responses to Comments in Appendix C

General Comments

G.2

(5) While Appendix A provides a listing of the samples used in the HHRA, there is no discussion of the analytical parameters, data sets, what each consists of, and why it was included or excluded, and any limitations or concerns regarding the data. (This discussion can also address some of the specific comments below regarding the data and how parameters are grouped and summed.) The scope and content of the text in Appendix A of the Onondaga Lake HHRA (NYSDEC/TAMS, 2002) and Geddes Brook/Ninemile Creek HHRA (NYSDEC/TAMS, 2003) can be used as a guide to the scope and content for this discussion; and see Table 1-1 of both cited HHRAs for a useful overall summary.

A discussion of the data set will be provided in the text of the HHRA.

G.4

(new) This response has been expanded. The proposed assumptions regarding the fraction of mercury assumed to be in organic form (methylmercury) (1 percent in soil and 7 percent in sediment) are acceptable, in that the assumptions are reasonable based on the available data and are at least as conservative as assumptions made for the Onondaga Lake HHRA (NYSDEC/TAMS, 2002).

Honeywell will use these assumptions.

Specific Comments

S.12

37. The original comment is no longer fully applicable, as the groundwater data presented in the (new) Appendix A show more years of data, including some samples from 2007. The HHRA should discuss how the data are used in calculating EPCs – including how multiple samples from the same location (over time) are used, and whether each sample is weighted equally or whether a single value for each point (monitoring well) is developed and then these well-specific

values are used. The uncertainty assessment should include a discussion of the age of the data and its temporal distribution.

Note that several of the subsequent comments which related to the EPC calculations using ProUCL (e.g., S26) are also affected by the release of version 4.

Each sample is treated as a separate data point for development of the UCL. Honeywell will clarify this in the text, and add a discussion of the temporal distribution of the data in the uncertainty section.

S.17

(new) The comment and response are both, to some extent, moot as the current version of ProUCL is now version 4.x. It is assumed that the data processing in ProUCL will be consistent with what was recently agreed to for the Wastebed B/Harbor Brook HHRA.

Data processing using ProUCL V. 4 will be consistent with what was agreed to for the Wastebed B/Harbor Brook HHRA.

S.23

(new) (New response from Honeywell) See comment on page A-8 below, incidental ingestion of soil.

See response to comment on A-8.

S.27

(new) See G.2 (5) above regarding the data presented in Appendix A. The data listing should be edited to remove sample points which are not used in the HHRA; for example, soil samples collected from depths greater than 20 ft bgs (or 10 ft bgs, depending on area/receptor).

Appendix A summarizes all samples in the Site database, regardless of whether they are utilized in the HHRA. A field titled "Utilized in HHRA?" will be added to Appendix A.

S36

(new) Clarification. Consistent with recent agency comments on the Wastebed B/Harbor Brook HHRA, the TEQ should be calculated for each sample; the TEQs should be the values that are then used as input ot ProUCL (not individual congener values).

Honeywell will calculate TEQs for each sample and use TEQs instead of individual congeners in tables and as input to ProUCL.

S43, S44, and S45

(new) Utilization of the approach agreed to for Wastebed B/Harbor Brook is recommended.

The approach to evaluating the vapor intrusion pathway will follow the approach agreed to for Wastebed B/Harbor Brook. Since soil vapor data are not available for Willis Ave, the ground water-to-indoor-air vapor intrusion pathway will be evaluated. For the construction worker receptor, the fugitive dust and volatile emissions pathways will be evaluated following the approach used in Wastebed B/Harbor Brook.

T7

(new) Although the "ARAR/TBC" column was re-instated as per the comment, the field is blank. It is recommended that the approach agreed to for Wastebed B/Harbor Brook be used to complete this column of RAGS Table 2.

Honeywell will complete this column using the restricted residential soil cleanup objectives for protection of public health from NYSDEC Part 375 for soil exposure media. For surface and ground water, Honeywell will use the MCL values from USEPA 2008, National Primary and Secondary Drinking Water Regulations. This follows the approach used in Wastebed B/Harbor Brook.

T19

(new) This submission includes Appendix B, listing the parameters, values, and source of value, thereby addressing the comment.

Agreed.

T26

(new) The response is acceptable. However, the fraction (snow cover) should be 25 percent (not 24 percent) – see most recent (2008) Agency comments on this issue on the Wastebed B/Harbor Brook HHRA.

The fraction snow cover will be changed from 24% to 25%. This leads to an RME EF of 188 days rather than 190 days, and a CT EF of 164 days rather than 166 days.

T29

(new) Note-this is a modified response, it appears that Honeywell has changed the non-swimmer ingestion rate to 0.03 L/d (up from 0.01 L/d in the previously-submitted response). The underlying ingestion rate (30 mL/hr) is sufficiently conservative for the non-swimmer exposure.

Agreed.

NEW COMMENTS SPECIFIC TO THIS SUBMISSION

G.1. The adolescent trespasser is quantitatively evaluated at many of the exposure areas. EPA recommends adding an adult trespasser to these areas. If it is expected that this population would have a significantly lower exposure frequency or duration that the adolescent trespasser, this population can be qualitatively evaluated, as long as the reationale for the lesser intense expousure is clearly explained.

An adult trespasser is already evaluated quantitatively in the Lakeshore Property Area (RAGS Table 1.4) for the purposes of recreational fishing in Onondaga Lake. For the other exposure areas that are unrelated to recreational fishing, an adult trespasser will be added and evaluated quantitatively based on the parameters used at Harbor Brook.

Attachment A, Discussion

1. Page A-1, paragraph at bottom of page (following table). The age ranges for the selected receptors do not include ages 16 and 17. Also, what is the rationale for defining the adolescent as 7 to less than 16 years old? Keeping the same exposure duration, an age range of 9 to less than 18 would be more reasonable (as previously noted and agreed to for comment on Table L-35 in 2004).

The adolescent age range of 7 to <16 yrs corresponds to the age range used for the Age Dependent Adjustment Factor (USEPA, 2005) used to assess child exposure to PAHs operating in mutagenic mode (as these PAHs have been identified as COCs at Willis Ave); The age gap (between 16 and 18 years of age) for which exposure is not calculated will be addressed in the uncertainty section of the HHRA.

2. Page A-2, Paragraph 5 (Outfall 006 Area). This exposure area should include an adult trespasser along with the adolescent trespasser.

A quantitative evaluation of an adult trespasser will be added (see response to G1).

3. Page A-3, "Lakeshore Property": Since fishing on this site would likely be limited to recreators fishing from the lakeshore, it is recommended that the conclusions from the Onondaga Lake HHRA, with respect to fish consumption, be summarized in this HHRA.

Honeywell will summarize the fish consumption conclusions from the Onondaga Lake HHRA.

4. Page A-3, Paragraph 5 (Tributary 5A). The text should state that this exposure area includes an adult trespasser along with the adolescent trespasser, as shown in the table on page A-1. Please clarify why a utility/construction worker (and thus subsurface sediments) are not included.

A quantitative evaluation of an adult trespasser will be added. Since there are utilities present underneath Tributary 5A, a utility worker will also be included.

5. *Page A-3, Paragraph 6 (PSA). This exposure area should include an adult trespasser along with the adolescent trespasser.*

A quantitative evaluation of an adult trespasser will be added.

6. *Page A-4, Paragraph 6 (Chlorobenzene Hot-Spot Area). This exposure area should include an adult trespasser along with the adolescent trespasser.*

A quantitative evaluation of an adult trespasser will be added.

7. *Page A-5, RAGS Table 2, media definitions, surface soil. While the definition provided here is acceptable, the sample summary table (Appendix A) is not consistent with this definition.*

Some soil samples between 0 and 2 feet have the sample code SB in the sample summary table because these samples were collected during soil boring. Soil samples from 0-2 feet are considered surface soil for the HHRA, regardless of the sample code shown in the sample summary table.

8. *RAGS Table 2, Approach to Selection of Constituents of Concern, page A-7, fourth paragraph (regarding TEFs). See S36, above.*

This paragraph will be updated to describe the recommended method of calculating the TEQ of each sample.

9. *Revised RAGS Table 4, page A-7, last paragraph. See T26, above.*

The snow cover will be changed from 24% to 25% to calculate the exposure frequency.

10. *Page A-7, "Revised RAGS Table 4": The second paragraph states that the EF for outdoor exposure is 219 days/year for the RME, while the text that follows this paragraph states that the RME EF is 190 days. Please clarify.*

The first and second paragraph will both be revised to say the RME EF is 188 days, consistent with each other and the 25% snow cover assumption. The CT EF will say 164 days in both paragraphs.

11. *Page A-8, "Incidental Ingestion of Soil": The RME Ingestion Rate of soil for the surveillance worker at the Wastebed B/Harbor Brook subsite is presented in Table 4.2 of the PAR (02/20/2008) at 100 mg/day, with an FI value of 1. This value should also be used for the Willis Ave Chlorobenzene subsite. The overall exposure of this receptor can be modified by changing the exposure frequency, as was done for the Wastebed B/Harbor Brook surveillance worker.*

Honeywell will use the IR of 100 mg/day and FI of 1, and modify the exposure frequency in the text and the Table 4 series.

12. *Page A-8, "Exposure Frequency": The exposure frequency for the adolescent receptor is listed as 39 days/year. It is recommended that the value of 42 days/year be used to be consistent with the adolescent trespasser at the Wastebed B/Harbor Brook and Wastebeds 1-8 sites.*

NYSDEC's 2004 comment letter recommended an exposure frequency of 39 days/year (comment 58) to account for trespassing occurring 3 times per week during the 13 summer weeks. However, the exposure frequency for the adolescent receptor will be changed to 42 days/year in the text and the Table 4 series.

RAGS Table 1 Series
See comments above.

13. *Table 1 Series: Table 1.3 identifies a "transient adult", but this population is called a trespassing adult. Please use consistent language. Also, please clarify the difference between the transient and the trespasser and add this to the spreadsheet.*

The transient adult refers to an adult walking along State Fair Boulevard during the NYS fair. The transient is not a trespasser since walking on the road is legal. This will be clarified in the spreadsheet.

RAGS Table 2 Series

The review of the data in the Table 2 series was limited to key contaminants such as chlorobenzene, dichlorobenzenes, and mercury. Potential discrepancies noted for these contaminants should be checked for other contaminants as necessary.

14. *RAGS Table 2 Series.*
General – Chemical-specific (also affects the subsequent tables relying on the sample data). It is acknowledged that the data used in this HHRA may have come from various sources and the same of similar parameters may have been analyzed by different methods over time. However, these analytical or reporting differences need to be reconciled for the HHRA so that a consistent set of data, oriented toward the parameters likely to be assessed quantitatively in the HHRA, is developed. Specific concerns are as follows:
    - *Xylenes – report all xylene data as "total xylenes" (sample data for which o-xylene and m&p xylenes were reported should have the detections summed and reported as total xylenes, which is the parameter for which screening and IRIS toxicity values are available).*
    - *Chlordane – sum all chlordane constituents for screening against technical chlordane criteria.*

- *PCBs – sum as 'less chlorinated' (Aroclors 1221, 1232, 1016, and 1242) for screening against Aroclor 1016 criteria and subsequent non-cancer hazard calculation; 'highly chlorinated' (Aroclors 1248, 1254, 1260 [and higher if reported]) for screening against Aroclor 1254 criteria and subsequent non-cancer hazard calculation, and 'total PCBs' (sum of all detected Aroclors); screen against Aroclor 1254 criteria and for subsequent use in quantitative HHRA for cancer risk calculation.*
- *Polychlorinated dibenzo-p-dioxins/furans. The TEQ should be calculated for each sample; then these calculated TEQs should be used for screening and completion of the remaining RAGS tables. The approach utilized in this HHRA, taking the highest congener concentration regardless of sample (shown on the RAGS 2.x.b series tables), creates a "max" value that is not associated with any individual sample (and in some cases is higher than the max in any sample) and also precludes completion of the fields in other RAGS tables.*

Xylenes are already reported as total xylenes. Chlordane constituents will be summed and screened against technical chlordane. PCB's will be summed as less chlorinated, highly chlorinated, and total PCB's and evaluated as suggested. For dioxins/furans, the TEQ will be calculated for each sample and the TEQs used for screening and in the RAGS tables.

15. *Please include the NYSDEC Part 375 value/TAGM in the Potential ARAR/TBC column. For groundwater, the appropriate groundwater standard or MCL should be included.*

The ARAR/TBC column will include the NYSDEC Part 375 value/TAGM for soil, as well as the MCL values from USEPA (2008) National Primary and Secondary Drinking Water Regulations for surface and ground water.

16. *Table 2.1a (et al.). Screening criteria for lead do not need to be adjusted for a HI of 0.1, due to differences in the way the lead screening criteria were developed. Therefore, the residential criterion for lead should be 4.0E+02, not 4.0E+01. Similarly, we would suggest that the drinking water "action level" (40 CFR 141) could be used for lead in groundwater and surface water (the value could be entered in the "ARAR/TBC" column).*

The residential criterion for lead will be changed to 4.0E+02. For groundwater and surface water, Honeywell will use the drinking water "action level" in the "ARAR/TBC" column.

17. *Endosulfan II and Endosulfan Sulfate can be screened against the values for Endosulfan.*

Endosulfan II and endosulfan sulfate will be screened against the values for endosulfan.

18. Endrin aldehyde and endrin ketone can be screened against criteria for endrin.

Endrin aldehyde and endrin ketone will be screened against criteria for endrin.

19. RAGS Table 2.1b (et al.). See comment S36, above. The approach specified for the Wastebed B/Harbor Brook HHRA should be used.

The specified approach to TEQs in comment S36 will be used.

20. RAGS Table 2.2a (et al.). 1,2,3-Trichlorobenzene (TCB) can be included as a VOC (not "other"), as was done with 1,2,4-TCB.

1,2,3-Trichlorobenzene will be included as a VOC.

21. Table 2.4, Table 2.18a. Benzoic acid is a SVOC.

Benzoic acid will be listed as an SVOC.

22. Table 2.7a. The USEPA RPG value for soil for 1,2-Dichlorobenzene should be changed from 600 mg/kg to 60 mg/kg to be consistent with the rest of the tables and approach that for noncarcinogenic compounds, guidance values are multiplied by 0.1. Also, when this value is changed, the COPC and Rationale for Selection should be corrected to "Y" and "ASL" for this compound.

The PRG will be multiplied by 0.1. The COPC and Rationale for Selection will be updated as well.

23. Table 2.8a. The data and screening of VOCs are not included. According to the database, there are VOCs detected in this exposure area in surface soil (0 to 2 ft depth). For example, concentrations of 1,4-Dichlorobenzene and 1,3-Dichlorobenzene at location WA-NW DITCH-S (depth interval of 0 to 0.5 ft) are 2.1 mg/kg and 0.073 mg/kg, respectively. Since the corresponding sample from the duplicate pair was reported as non-detect for these VOCs, the detections should be used for the screening table.

The VOC detections noted were from a QC sample (samples with Field Sample ID WA9351) and were therefore excluded. VOC detections from this sample will be included.

24. Tables 2.9a, 2.10a, 2.14a, and 2.25. With the exception of methylmercury, the remaining chemicals listed as "Other" should be grouped as VOCs.

The other chemicals will be grouped as VOCs in these tables.

25. Tables 2.9a and 2.10a. Maximum detected concentrations of 190, 76, and 430 mg/kg are shown for 1,2-, 1,3-, and 1,4-Dichlorobenzene, respectively. However,

according to the database, maximum concentrations for these compounds in the NYSDEC samples are 274.4, 116.2, and 2,098 mg/kg, respectively. Appendix A notes that the NYSDEC results are not included in the HHRA tables. However, since these concentrations are much higher than those reported by Honeywell and these data are included in the database, they should also be included in the HHRA unless justification for excluding them can be provided.

NYSDEC data was excluded because they are usually split samples from the data O'Brien and Gere collected. Consequently, the NYSDEC samples are not independent data, and including them would give excessive weight to those locations. In the new field that will be added to Appendix A titled "Utilized in HHRA?," NYSDEC data will be noted as "No."

26. *Table 2.10a. The USEPA PRG for 1,2-Dichlorobenzene, shown as 2.22E-01 mg/kg, should be changed to 6.00E+01 mg/kg, as in other tables (e.g., Table 2.3a).*

This value will be changed to 6.00E+01.

27. *Table 2.15a. The USEPA RBC and PRG values for mercury should be changed to 7.82E-01 and 6.11E-01 mg/kg, as per note c.*

The values will be changed as suggested.

28. *Table 2.15a. The USEPA RBC and PRG values for 1,2-Dichlorobenzene should be changed to 7.04E+02 and 6.00E+01 mg/kg.*

The values will be changed as suggested.

29. *Table 2.17. "Ammonia" can be removed from the table.*

Ammonia will be removed from the table.

30. *Table 2.26, "Other". Ammonia and nitrogen can be removed from the table and HHRA. Benzoic acid and benzyl alcohol are SVOC's. The remaining chemicals are VOCs.*

Ammonia and nitrogen will be removed from the table and the HHRA. Benzoic acid and benzyl alcohol will be classified as SVOC's. 1,2,3-trichlorobenzene, and 1,2,4- and 1,3,5-trimethylbenzene will be classified as VOC's.

RAGS Table 4 Series

31. *Table 4 Series, General. Where possible, recent agreements on values for exposure parameters for the Wastebed B/Harbor Brook and Wastebeds 1 through 8 sites should be used to finalize this HHRA. Also, there are discrepancies in*

some corresponding values in the Table 4 series and Appendix B (see comments below).

In general, recent agreements on exposure parameters for the Wastebed B/Harbor Brook and Wastebeds 1 through 8 sites will be used. See responses to comments below for specific changes.

32. *The age of the adolescent trespasser is listed as 7-<16 years, for an exposure duration of 9 years. However, this leaves a gap in exposure from 16-18 years, the age typically used for adults. Please clarify why the adolescent was identified up to 16 years. We assume that this was done to correspond to the age range used for the Age Dependent Adjustment Factor (USEPA, 2005), used to assess child exposure to PAHs operating in mutagenic mode (as these PAHs have been identified as COCs at Willis Ave); this explanation should be provided in the HHRA. In addition, the age gap (between 16 and 18 years of age) for which exposure is not calculated should be addressed in the uncertainty section of the HHRA.*

As noted, the adolescent age range of 7 to <16 yrs corresponds to the age range used for the Age Dependent Adjustment Factor (USEPA, 2005) used to assess child exposure to PAHs operating in mutagenic mode. The age gap (between 16 and 18 years of age) for which exposure is not calculated will be addressed in the uncertainty section of the HHRA.

33. *Table 4.1, RME. In the Rationale/Reference column for Skin Surface Area for Dermal Absorption, "USEPA 1997, See Appendix A (Honeywell 2008)" is stated as the reference. However, Appendix A of this document is the Sample Summary Table. It is believed that it should state Appendix B which is the Exposure Parameters Summary. Also, the reference for skin surface area for the adolescent trespasser in Appendix B appears to be USEPA 2004 not 1997. Please correct as appropriate.*

The Skin Surface Area for Dermal Absorption for the adolescent trespasser in Table 4.1 RME will be changed to match the value (4250 cm^2) and reference (USEPA 2004) given in Appendix B. This change will be made for the adolescent trespasser throughout the Table 4 RME series.

34. *Table 4 Series: Table 4.5a RME lists the EF for the transient adult as 2 days/year. According to the text, this population is expected to access the site during visits to the State Fair. Based on the duration of the fair, and the EF utilized for rain attendees in the Wastebeds 1-8 HHRA, a value of 14 days/year should be used.*

To be consistent with the State Fairgrounds Attendee in the Wastebeds 1-8 HHRA, a value of 14 days/year will be used.

35. *Table 4.6a, RME. The exposure frequency for the adult trespasser is listed as 8 days/year with a reference of "NYSDEC, 2004". However, this value could not be found in the NYSDEC letter (nor Honeywell 2004 which is cited for this same value in Appendix B) and is lower than values agreed to for nearby sites. If this value is in the letter, the reference should also cite the comment number (this should be done with all values taken from the NYSDEC or Honeywell letters). This comment also applies to the adult exposure frequency of 2 days/year in Table 4.5a, RME.*

To be consistent with the Wastebed B/Harbor Brook HHRA, the exposure frequency for the adult trespasser will be changed to 42 and 32 days/year for the RME and CT scenarios. This exposure frequency will be used for the adult trespasser in the Lakeshore Area which is evaluated quantitatively. The adult trespasser in other exposure areas will be evaluated qualitatively (see response to Comment G.1).

36. *Table 4 CT series. The parameter codes for Averaging Time-Cancer and Averaging Time-Non-Cancer should be switched.*

The parameter codes will be corrected throughout the Table 4 series.

37. *Table 4.1, CT and others. The skin surface area for both CT and RME should be the same as it is an average rather than upper bound value. The value in the CT table (4,250) is different than the value in the RME table (5,098).*

Throughout the Table 4 series, the RME value will be changed to 4,250, consistent with Appendix B.

38. *Table 4 CT series, adolescent trespasser (4.1, 4.3a, 4.5a, 4.6a, 4.7b, 4.8). The ingestion rate of soil of 50 mg/day for adolescent was determined based on a value recommended for adults. Since the age range for adolescent is defined in this document as 7 through 16 years, the value of ingestion rate of soil recommended for children of 100 mg/day is more appropriate, as was done for the Wastebed B/Harbor Brook site.*

The ingestion rate will be changed to 100 mg/day.

39. *Tables 4.1, 4.2a, 4.4a, 4.11a, CT. The Averaging Time – Non-Cancer (AT-NC) for surveillance worker and industrial worker is the same as in the corresponding RME tables. Since the exposure duration is 25 years for the RME and 9 years for the CT, the AT-NC value for CT should be changed from 9,125 to 3,285 days.*

AT-NC will be changed to 3,285 days for these CT scenarios.

40. *Tables 4.2b, 4.4b, 4.9b, 4.11b, RME and CT. The inhalation rate of 1.6 m^3/hr for construction worker was used for both RME and CT based on Table 5-23 of USEPA, 1997 Exposure Factors Handbook for adult moderate activity. However,*

this table includes inhalation rate for outdoor worker, which is more appropriate to use for a construction worker. Therefore, similar to Wastebed B/Harbor Brook, the inhalation rate should be 3.2 m^3/hr for RME and 1.6 m^3/hr for CT.

An inhalation rate of 3.2 m^3/hr for RME and 1.6 m^3/hr for CT will be used for the construction worker.

41. *Table 4.6a, CT. It appears that there is a typo in the value for ingestion rate of soil; 15,000 mg/day should be changed to 100 mg/day.*

This is a typo and will be corrected to 100 mg/day.

42. *Table 4.6a, RME and CT. Since the exposure duration for the adult trespasser is listed as 24 years, the averaging time – non-cancer value should be changed from 3,285 days to 8,670 days.*

AT-NC will be changed to 10,950 days for the adult trespasser, which is the number of days in 30 years, which is now the exposure duration for the adult trespasser.

43. *Table 4.9a, CT. Since the exposure duration for the industrial worker is listed as 9 years, the averaging time – non-cancer value should be changed from 9,125 to 3,285 days.*

The averaging time will be changed to 3,285 days in the CT scenario.

44. *Table 4 series, CT. The soil-to-skin adherence factor of 0.07 mg/cm^2 is used for the adolescent trespasser even though a value of 0.15 mg/cm^2 was requested by NYSDEC in the comment letter dated July 19, 2004 and agreed to by Honeywell in the response letter (Comment 110, Appendix D of this submission). Please revise.*

The soil-to-skin adherence factor will be revised to 0.15 mg/cm^2.

45. *Table 4.12, CT. The averaging time – non-cancer value for adult resident is the same as in the corresponding RME table. Since the exposure duration is 30 years for RME and 9 years for CT, the AT-NC value for CT should be changed from 10,950 to 3,285 days.*

The AT-NC value will be changed to 3,285 days for CT.

FIGURES AND APPENDICES

46. *Figure L-2. In the legend, the Tributary 5A Exposure Area is shown as pink; however, on the figure, it is shown as blue. The figure should be revised so these are consistent.*

The figure will be revised so that the legend matches the figure.

47. *Appendix A. It does not appear that the list of samples corresponds to the data set which will be used for the HHRA, nor does it appear that the 'sample code' reflects the matrix (exposure medium) consistently.*
    - *Although the greatest depth to which receptors are exposed to subsurface soil is 10 ft or 20 ft, there are numerous soil samples (e.g., from the plant area) for which the start depth is greater than 20 ft.*
    - *There appears to be an inconsistency in terms of which sample are flagged as surface soil (SS) as opposed to soil boring (SB), assumed to be the deeper soil samples. For example, a number of samples from the Chlorobenzene Hot Spot Area from the 0 to 2 ft interval are flagged as "SB" in appendix A, although a number of samples with start depths greater than 0 (typically 0.5 to 0.7 ft) from the Former Chlorination Building are flagged as "SS".*
    - *Page 3 of 8, Location ID WA-WA-02D, sampled 2/7/92, is listed as sample matrix-soil but exposure medium-groundwater. Please revise.*

Appendix A summarizes all samples in the Site database, regardless of whether they are utilized in the HHRA. A field titled "Utilized in HHRA?" will be added to Appendix A. The SB label refers to the soil boring method of sampling, rather than to a specific depth. Samples shallower than 2 feet may be labeled SB if the sample was collected as part of a soil boring effort to collect soil from several depths. Otherwise, samples shallower than 2 feet are labeled SS. For the HHRA, surface soil will be defined based on depth, not the "SB" versus "SS" label. The WA-WA-02D will be revised so that the matrix and exposure medium are consistent.

48. *Appendix B. The age of the non-adult receptors should be indicated on the tables (e.g., Child resident, 0 to <6 years old).*

The tables will indicate the age range of the non-adult receptors.

49. *Appendix B. On page 1, please revise the drinking water ingestion rate for children <6 years to 1 L/day. This value is consistent with the value used for the Harbor Brook HHRA, and is also consistent with the value used for the Harbor Brook HHRA, and is also consistent with the 90th to 95th percentile values presented in Table 4-1 of USEPA (2006).*

The ingestion rate of water will be changed to 1 L/day for both the RME and CT scenarios, and the reference updated. The Table 4 series will also be revised accordingly.

50. *Appendix B. On Page 2, please revise the drinking water ingestion rate for adults > 18 years to 2 L/day. The reference for this is the RAGS Volume I: HHEM Supplement "Standard Default Exposure Factors" (Interim Final, OSWER Directive 9285.6-03, March 1991), and is also consistent with the value used in other Onondaga Lake site HHRAs for adult residents.*

The ingestion rate for adults will be changed to 2 L/day for both CT and RME scenarios, and the suggested reference will be cited. The Table 4 series will also be revised accordingly.

51. Appendix B. The tables should be updated based on comments provided above on the Table 4 series.

Agreed.

APPENDIX H

Honeywell 2004 Response to NYSDEC Comments

December 2, 2004

Mr. Richard A. Mustico
Project Manager
New York State Department of Environmental Conservation
Bureau of Central Remedial Action
625 Broadway, 12th Floor
Albany, NY 12233-7016

Re: Willis Avenue Chlorobenzene Site
Human Health Risk Assessment (HHRA)

File: 1163/34941 #2

Dear Mr. Mustico:

At the request of NYSDEC, this letter provides the responses to NYSDEC comments on the June 2002 Revised Human Health Risk Assessment (2002 HHRA) that were submitted to Honeywell in a letter dated July 19, 2004. The NYSDEC comments were incorporated into the Revised HHRA submitted for your review on October 19, 2004 (2004 HHRA).

The responses provided in the attachment to this letter are reflective of the changes made to the 2004 HHRA. We anticipate that the HHRA report will be finalized following your review. In the attachment, the comments are reprinted along with the responses that were incorporated into the HHRA report. The responses include the current page references of the 2004 HHRA report.

We hope that these responses to NYSDEC comments and the revised HHRA submitted to the agency on October 19, 2004 address the agency concerns regarding potential human health exposures at the site and in the vicinity of the site.

Should you have any additional questions or concerns regarding this matter, please feel free to contact me.

Sincerely,

John P. McAuliffe, P.E.
Program Director, Syracuse

ATTACHMENT:
Responses to Comments on the June 2002 Human Health Risk Assessment for the Willis Avenue Chlorobenzene Site submitted to Honeywell in a letter from NYSDEC dated July 19, 2004.

General Comments
In addition to the General comments provided by NYSDEC the revised HHRA presents the following clarifications over the 2002 HHRA:

- The description of the General Plant Area was clarified to consist of the Plant Area, the former chlorination building and the on-site ditches.
- The area title *Northwest off-site/Outfall 004 area* was adopted as a general description of the area in the vicinity of the State Fair Boulevard, Niagara Mohawk utility line, and the Outfall 004 Area.

Comment 1.
The data that are incorporated into the risk calculations should be more clearly defined. A discussion of what is classified as surface soil needs to be clearly stated and remain consistent throughout the report. It appears as though the 0 to 2 feet interval is considered surface soil (stated on page 19) for the risk estimates, however, in many instances in the text, the 0 to 2 ft interval is also referred to as subsurface soils (e.g., page 9, third paragraph). The surface and subsurface soil classifications should be used consistently throughout the report.

It should be noted that USEPA guidance states that a depth interval of 0 to 6 inches below ground surface (bgs) be used for evaluation of exposure to surface soils; the 0 to 2 ft interval data may be used if there is no other "surface soil" data available. This should be explained in the text.

Additionally, all of the soil samples collected in 1999 and reported in the March 22, 2001 letter to NYSDEC from Honeywell regarding the Willis Ave Chlorobenzene Site Baseline Ecological Risk Assessment (BERA) Screening Tables are classified as surface soils, however, the depth intervals are not reported. A brief summary of these data, as well as other data incorporated in the risk estimates, should be included in the report. Also, the BERA samples referenced in the Human Health Risk Assessment (HHRA) were cross checked against those listed in the BERA, and it was noted that sample WB-9-SS was not included in the HHRA. If this sample was collected in a reference area not applicable to the HHRA then it should be stated.

Response 1.
The data utilized in support of the risk assessment represent a compilation of soil data generated over a seven-year period (1992-1999) consistent with approved sampling plans. To clarify the exposure evaluations of soil depths, three soil intervals were defined:

- Surface soils consist of samples collected from the 0 to 2 ft interval. It is noted in Section 4.1.1 on page 22 that USEPA prefers that surface soil samples be collected from the 0 to 6 inch bgs interval and that for this HHRA, samples were collected from the 0 to 2 ft interval.
- Upper soils consist of surface and subsurface samples of soil collected from the 0 to 10 ft interval.
- Deep soils consist of subsurface samples of soil collected from depths of 10 ft and greater.

Table L-2 presents a summary of the sampling activities including the 1999 sample collection for the BERA.

Comment 2.
The HHRA should include a summary of all the investigations performed which generated data used in this HHRA. The summary should identify the organization doing the investigation, the year, its purpose, its name (e.g., 'referred to hereafter as the Phase 2 RI'), and a summary of the types and

quantities of samples and analyses (e.g., "included about 50 surface and 25 subsurface soil samples from the CHSA and general plant area; all of which were analyzed for total mercury and 15 to 20 analyzed for full TCL/TAL"). Then, in the sections where the characterization of particular exposure areas is discussed (Sections 4.1.3 through 4.1.10) the figures showing the sample locations should be referenced; but more detail should be provided especially since for most if not all of the areas the number of sample locations on the figures does not match the number of samples referenced in the text.

Response 2.
Table L-2 presents a summary of the investigations performed, the year of the investigation and the data generated for the HHRA. O'Brien & Gere completed each of the investigations. Additional references to figures showing the sample locations were added to the report, as requested.

Comment 3.
There were some issues in the comment letter issued by NYSDEC to Honeywell dated January 25, 2002 that were not addressed in the revised version of this report. These include the calculation of CT risk scenarios in cases where RME estimates exceed the acceptable risk limits. These calculations should be performed where necessary and discussions of the results should be incorporated into the report. This, as well as other issues not addressed, are discussed in the Specific Comment section below.

Response 3.
In the revised report, CT risk scenarios are presented where RME estimates exceed the acceptable risk limits and the results are discussed in the report. Further discussion of the calculations and discussion of the results are presented in the report, as indicated in the responses to the specific comments presented below.

Comment 4.
The figures in the revised report are an improvement over those in the draft. The text should be updated to take advantage of these figures and reference them as appropriate. There are a few items that should be addressed or corrected, however; these are discussed in the Specific Comments section.

Response 4.
The report text has been updated to reference the figures, as requested.

Comment 5.
Although an attempt to verify each risk calculation was not made, TAMS was able to duplicate those included in a spot check using the raw data provided with the electronic version of the report. However, there seems to be a question of whether all of the available data were used. There are discrepancies between the number of samples reported in the text and summary tables with those shown on the figures, as discussed below in the Specific Comments section.

Response 5.
All available data were used as identified in Table L-2 of the revised HHRA report, except as noted in the response to Comment #38. The database was reviewed and discrepancies that were identified in the previous HHRA report have been addressed. A copy of the data base can be provided upon request.

Comment 6.
Toxicity data will need to be updated based on the most recent additions to IRIS and the most recent evaluation of provisional data available from EPA/ORD-NCEA.

Response 6.
The toxicity data (presented in RAGS D Tables 5.1, 5.2, 6.1, and 6.2, Attachment C) have been updated based on the most recent additions to IRIS and the most recent evaluation of provisional data available from EPA/ORD-NCEA, including RAIS from the Oak Ridge National Laboratory.

Specific Comments

Executive Summary

Comment 7.
Page xiii, fourth paragraph. It is stated that process-related constituents were detected in subsurface soils and groundwater at the site and related areas of study (AOS). This text should be modified to include surface soils. As discussed above, surface soil, as described on page 19, includes the 0 to 2 ft depth interval. Elevated levels of process-related compounds were detected within this interval (e.g., mercury detected at 4,780 mg/kg in a 0 to 2 ft interval sample as shown on Table L-2a). See also the comment on section 3.1.

Response 7.
Page xvi, first paragraph. The text has been modified to include surface soil. Table L-2a for the surface soils of the General Plant Area was replaced by RAGS Tables 2-1, 2-4, and 2-5 of Attachment C which present surface soil data for the Plant Area, On-site Ditches, and Former Chlorination Building Area, respectively. The mercury concentration of 4,780 mg/kg was detected in the on-site ditches and is reported in RAGS Table 2-4, Attachment C.

Comment 8.
Page xiv, fourth paragraph. The "and" in the fifth line should be changed to "at".

Response 8.
Page xvii, first paragraph, fourth sentence. The requested change has been made.

Comment 9.
Page xiv: The last paragraph should be revised to indicate that the groundwater has been evaluated as a potable water supply due to the State designation of the aquifer.

Response 9.
Page xvii, second paragraph: The requested change has been made.

Comment 10.
Page xv, last paragraph to top of page xvi. It is stated that there is no significant risk to current receptors (trespassers, fisherman, State Fair Boulevard transients, NiMo utility workers, or surveillance workers) because the calculated HIs and cancer risks are less than 1 and 10^{-4}, respectively. However, it should be noted that there were cancer risks that were greater than 10^{-6} (e.g., current trespasser 9.9×10^{-05}).

Also, suggested text which more accurately reflects the National Contingency Plan (NCP) and agency policy follows: "Although the determination of an acceptable risk level is ultimately a decision to be made by risk managers, the findings presented here are compared to levels cited in the National Contingency Plan (NCP) which states " . . . acceptable exposure levels are generally concentration levels that represent an excess upper bound cancer to an individual of between 10^{4} to 10^{6} . . . The 10^{-6} risk level shall be used as the point of departure for determining remediation goals . . ." (40 CFR §300.430(e)(2)(A)(2)). These target risk levels are also often applied by other agencies responsible for protecting human health (NYSDOH and ATSDR, 1995)".

Response 10.
Page xix and elsewhere in the report. Receptors with risks greater than 10^{-6} have been identified in the text of the report.
Page xvi, second paragraph presents the requested NCP text.
Page xix, paragraphs after table present the interpretation of risk for the receptors that were evaluated incorporating the requested changes.

Comment 11.
Page xvi, Future Conditions. The purpose of this section is to summarize the receptors and areas of study with risks that are greater than the acceptable limits. According to the table on page xv (Summary of RME Hazard Indexes and Cancer Risks), all receptors and areas that should be included here are not. For example, the HI for the future industrial worker is 20 for the general plant area and 7 for the ditches in the general plant area, which exceed the acceptable hazard index of 1. There are others that also need to be included. All risks that exceed the acceptable limits should be added to the discussion here.

Response 11.
Page xviii and xix, Future Conditions. The table has been revised to present all receptors and areas evaluated.

Section 2 - Description of Site areas

Comment 12.
Section 2.1, page 3, last paragraph. Comment 2.2 in the NYSDEC comment letter to Honeywell (January 25, 2002) was not addressed adequately. NYSDEC requested a complete description of the physical appearance of the facility. Is there evidence of dumping or trespassing on the site?

Response 12.
Section 2.1, page 3, second paragraph. The last sentence was added to address this comment: "Due to these security measures, there has been no evidence of dumping or trespassing on-site."

Comment 13.
Section 2.2, page 5, last paragraph, third and fourth sentences. A reference should be cited for the "50,000 mg/L" chloride reported in the bedrock aquifer. Also, this concentration is cited both as 50,000 mg/L and 50,000 g/L in different places in this report. Reference to the NYSDEC Class GA criterion for chloride (250,000 g/L) should be inserted in the fourth sentence.

Response 13.
Section 2.2, pages 5 and 6. The reference to the bedrock aquifer was moved from the discussion of the study area (Section 2.2, pages 5 and 6) to the discussion of the site conceptual model (Section 3,page 9, last paragraph). The concentration of chloride reported in the aquifer is approximately

3,000 mg/L chlorides. The revised text includes reference to the chlorides concentration. Previous references to chlorides concentrations were in error.

Comment 14.
This chapter would benefit by referring the reader to the relevant figures (L-3 through L-12) which show the limits of the various areas discussed.

Response 14.
The requested references to relevant figures has been added to the chapter.

Section 3 - Conceptual Site Model
In addition to addressing comments provided by NYSDEC, the subsections of this Section were rearranged to provide a greater level of consistency throughout the report. To avoid duplication of information, references to data that were previously presented in the discussion of the Conceptual Site Model were removed and the discussion of data is presented in Section 4.

Comment 15.
Section 3.1, page 7, fourth paragraph. The text states that process-related compounds were detected in subsurface soil and groundwater. As discussed above, there were elevated concentrations of these constituents detected in the surface soils (*e.g.*, up to 2,600 mg/kg 1,4-dichlorobenzene; 4,780 mg/kg mercury - see Table L-2a), which are defined as 0 to 2 ft. The text should be modified to reflect this.

Response 15.
Section 3.1, page 8, second paragraph. A reference to the detection of process related constituents in surface soil has been added, as requested.

Comment 16.
Section 3.1, page 8, bullet list. Comment 3.3 from the comment letter issued by NYSDEC to Honeywell dated January 25, 2002 was not adequately addressed. The "adolescent trespasser/recreator" should be further defined in order to give an idea of what type of exposure routes may be encountered (*e.g.*, exposure to surface soil via inhalation of dust generated by biking activities).

Response 16.
Section 3.1, pages 8 through 10. Further description of the receptors has been added. The adolescent trespasser/recreator receptor is assumed to be on-foot, as discussed on page 9, first paragraph after the table.

Comment 17.
Section 3.1, page 8, last paragraph. The chlorides units in g/L are not consistent with the units presented in Section 2.2 (mg/L). See comment on Section 2.2 above.

Response 17.
Section 3.1, page 9, last paragraph. The response to Comment #13 (Section 2.2.) addresses the units of chloride concentrations.

Comment 18.
Section 3.2, page 9, third paragraph. In this text, the only constituents reported as being detected in surface soil are dioxins/furans. As discussed above, the use of "surface soil" needs to be consistent throughout the report. As defined on page 19, surface soil is defined as within the 0 to 2 ft interval. Constituents other than PCDD/PCDFs were detected at elevated levels within this interval.

Response 18.
Section 3.2, page 10, second paragraph. The requested text has been added.

Comment 19.
Section 3.2, page 9, fourth paragraph. It is reported that surface soils were not sampled in most areas within the general plant area because it is mostly covered by concrete building foundations, however, later in the report (page 19), surface soil is defined as the 0 to 2 ft interval. There were samples collected within the 0 to 2 ft interval from within the general plant area in areas other than at the former chlorination building and the on-site ditches. The use of "surface soil" and "subsurface soil" needs to be clearly defined and used consistently throughout the entire report.

Response 19.
Section 3.2, page 10, paragraph 3, last sentence. The reference to surface soils has been clarified by the addition of the sentence: "It should be noted that soil samples collected from 0 to 2 bgs are considered surface soil, while samples collected from 0 to 2 ft below concrete building foundations are considered upper soils (0-10 ft).

Comment 20.
Section 3.2, page 9, fifth paragraph. It is reported that groundwater at the general plant area occurs at approximately 25 to 30 ft bls ("bls" was used by O'Brien & Gere in the draft HHRA; believed to be below land surface). On page 8, it is reported that on-site groundwater occurs at a depth of approximately 15 to 20 ft bls. Clarify whether these depths are incorrect / inconsistent, or if they are referring to different specific areas of the site. This paragraph also needs to be modified to reflect that as requested by NYSDEC, on-site groundwater must be evaluated as a potential source of drinking water and a drinking water pathway should be evaluated in the HHRA.

Response 20.
Section 3.2, page 10. The reference to ground water has been deleted from this paragraph as this information was previously presented in the discussion of the general conceptual site model (Section 3.1). As presented in Section 3.2, the depth to ground water was identified at approximately 15 to 20 ft bgs under the General Plant area and 4 to 5 ft bgs under the CHSA, PSA , and Lakeshore property area. The previous reference to ground water depths of 25 to 30 ft bls was in error.

Comment 21.
Section 3.4, page 11, fourth paragraph. The Department believes that the reference to Table L-7 which refers to Tributary 5A is incorrect; rather Table L-1 should be referenced.

Response 21.
Section 3.6, page 12. The reference to the table for Tributary 5A was removed from the discussion of the Conceptual Site Model. Data for Tributary 5A is presented in Section 4. 1.6. Samples collected for evaluation of Tributary 5A are summarized in Table L-4. The data for Tributary 5A is presented in RAGS D Tables 2.13 and 2.14, Attachment C. The previous version of the data summary table (Table L-1) was replaced.

Comment 22.
Section 3.6, page 12, fourth full paragraph. Comment 3.9 from the comment letter issued by NYSDEC to Honeywell dated January 25, 2002 was addressed to some extent; however, chlorobenzenes are not the only contaminants detected in the groundwater and surface and subsurface soils in the lakeshore area. Since groundwater is assessed as a separate exposure medium, and groundwater is assessed as a single medium (*i.e.*, overall 95th percentile UCL concentrations), rather than being tied to individual wells in specific soil exposure areas. The discussion should identify the contaminants in soil separately from those in the groundwater. This statement should also include naphthalene and benzene. Also, please be consistent in terminology (*i.e.*, use "subsurface soils" rather than "sub-soils").

Response 22.
Page 11, Section 3.5, first paragraph, Lakeshore property area. The constituents detected in ground water, and surface and subsurface soils in the lakeshore property area are presented separately, as requested.

Comment 23.
Section 3.7, pages 12 and 13, second paragraph. The TPH data are not usable for risk assessment as they provide no information on specific chemicals which can be quantitatively assessed. The discussion should focus on the specific chemicals analyzed for. The TPH data can be used qualitatively for consistency with the TCL data.

Response 23.
Section 3.7, page 12, first paragraph. The reference to TPH data has been deleted and the discussion was revised to focus on specific chemicals that were analyzed.

Comment 24.
Section 3.8, page 13, second paragraph. Monitoring well R-5P does not appear on any of the figures. This monitoring well should be shown on Figure L-11. Additionally, the data for the well could not be found in the database, and it appears that these data were not used in the risk calculations.

Response 24.
Section 3.8, page 13, second paragraph. Monitoring well R-5P was removed from the figure and text. The database does not include this well.

Comment 25.
Section 3.10.2, page 15. Please revise this section using the updated Johnson and Ettinger model. EPA can be contacted for the most recent version of this model.

Response 25.
Section 3.10.2, pages 14 through 16. The section was revised as requested.

Section 4 - Data Evaluation

Comment 26.
Section 4.1.1, page 19, first paragraph in "Data Sources". It is stated that data collected for the RI were used as the input data for the risk assessment. When these data were collected and where they are reported should be included here. Although the reader is referred to the RI report for discussion regarding the incorporated data, the discussion included in the risk assessment is insufficient and should provide more detail about the data. See general comments above.

Response 26.
Section 4.1.1, page 21, first paragraph in "Data Sources" and Table L-2. Table L-2 presents RI data collected by O'Brien & Gere that was utilized in the HHRA.

Comment 27.
Sections 4.1.3 through 4.1.10, pages 20 through 23, discussions of data for specific exposure areas. These data as discussed in this part of the HHRA do not appear to be consistent with the number of sample locations shown in the relevant figures. A better explanation of what data exist and were used, tied to specific samples, should be provided.

Response 27.
Sections 4.1.3 through 4.1.10, pages 22 through 26. Table L-3 was developed to identify (for each exposure area) the specific sample quantities collected and their identifications along with the analyses completed. Throughout Section 4, the text has been revised to identify the samples collected for each area. Revisions were also completed to address inconsistencies were identified between tables and figures.

Comment 28.
Section 4.1.3, pages 20 and 21 , General Plant Area (GPA). The number of sample locations cited in the text does not appear to be consistent with the locations shown on Figure L-5. For example, the text states there were 15 to 18 surface soil samples analyzed. However, there are many more than 18 sample locations shown on Figure L-5, and it seems that there would also be more subsurface soil samples than identified in the text. Sample locations shown include 12 "WA-B" series; 10 "SB" series; 2 "SS" series; 3 "xWMATP" series; 7 monitoring wells at three locations; 14 "MC-B" series (location MC-B-12 was not found); one manhole (PAS UP#), and one BERA (MP-SS). Samples from test pits should be indicated as such. The text also states that groundwater samples were collected from 11 wells, however there are only seven monitoring wells shown on Figure L-5. Please clarify.

Response 28.
Section 4.1.3, pages 22 and 23, General Plant Area (GPA). The text and figures have been updated to address inconsistencies that were identified. Sample locations and analyses are also summarized in Table L-3.

Comment 29.
Section 4.1.3, page 21, Former Chlorination Building (Figure L-4). A total of 14 surface samples and 15 subsurface sample locations are cited in the text, however, Figure L-4 only shows 11 sample points in the FCB area (4 FCB borings [5A, B, C, 08]; five surface soil (FCB-1 through 5); the BERA sample (FCB-SS); and one excavation sample [SS #1]).

Response 29.
Section 4.1.3, page 23, Former Chlorination Building (Figure L-4). The text and figures have been updated to address inconsistencies that were identified. Sample locations and analyses are also summarized in Table L-3.

Comment 30.
Section 4.1.3, page 21, third full paragraph, on-site ditches. Please clarify why the text cites four sample locations and Figure L-3 shows five sample locations.

Response 30.
Section 4.1.3, page 22, second bullet, on-site ditches. The text and figures have been updated to address inconsistencies that were identified. Sample locations and analyses are also summarized in Table L-3.

Comment 31.
Section 4.1.4, page 21, Southwest Off-Site/Outfall 006 area. Figure L-6 shows some test pits but how many is unclear - three are all labeled "006-MATP2"; plus one labeled "006MATP1". There are thee surface soil locations (006MA SS#1, 2, and 3); three samples in "Outfall 6" including the BERA sample; and a pair of monitoring wells. The text should identify which of these were sampled and analyzed.

Response 31.
Section 4.1.4, page 23, Southwest Off-Site/Outfall 006 area. The text and figures have been updated to address inconsistencies that were identified. Sample locations and analyses are also summarized in Table L-3.

Comment 32.
Section 4.1.5, pages 21 and 22, State Fair Blvd/ Outfall 004/ NiMo area. Based on Figure L-7, only two locations in the NiMo area (NiMo #1 and #2) and two in Outfall 004 (004A and 004B) were found. The NiMo samples discussed seem to match the figure, but the text discusses more Outfall 004 samples than could be found. It should also be stated that NAPL was discovered along State Fair Boulevard during excavations around the NiMo gas pipeline.

Response 32.
Section 4.1.5, pages 24, Northwest/Outfall 004 exposure area. The text and figures have been updated to address inconsistencies that were identified. Sample locations and analyses are also summarized in Table L-3. The last sentence in the section addresses the discovery of NAPL.

Comment 33.
Section 4.1.6, page 22, Tributary 5A area. The text does not cite a number of samples. It is unclear from the sample designations used how many samples of what type were collected; although it does seem that there are six locations shown on Figure L-8. In locations where two sample IDs are shown, it was assumed that one is surface water and one is sediment; but in three locations, there are three samples shown. Table L-7a indicates that at least 10 surface water samples were collected from Trib 5A, and seven sediments (Table L-7b). Clarification should be provided.

Response 33.
Section 4.1.6, page 24, Tributary 5A area. The text and figures have been updated to address inconsistencies that were identified. Sample locations and analyses are also summarized in Table L-4.

Comment 34.
Section 4.1.7, page 22, Lakeshore property area. The text cites six samples and this seems to correspond to samples LS-1 through LS-6 as shown on Figure L-9. The figure also includes seven monitoring wells at three locations, and one apparent manhole (L.S.W.I.) that are not discussed in the text and should be.

Response 34.
Section 4.1.7, page 24, Lakeshore property area. The text and figures have been updated to address inconsistencies that were identified. Sample locations and analyses are also summarized in Table L-3.

Comment 35.
Section 4.1.8, page 22, Petroleum storage area. The number of soil samples that are cited does not appear to match what is shown on Figure L-10 (seven borings [3 PSB, 4 PSA] plus one BERA surface soil [PSA-SS]); groundwater samples seem to match the wells shown (four wells at three locations).

Response 35.
Section 4.1.8, page 25, Petroleum storage area. The text and figures have been updated to address inconsistencies that were identified. Sample locations and analyses are also summarized in Table L-3.

Comment 36.
Section 4.1.9, page 22, Chlorobenzene Hot Spots area. Clarification is needed on the sample locations. Sample location CHSA#5 may be mislabeled as a surface soil location on Figure L-11, as all of the other CHSA series samples are shown as boring locations. If this is the case then six total surface and subsurface samples can be accounted for (assuming one per boring). The BERA surface soil sample (CHSA-SS) should be included. There are also eight monitoring wells in this area (5 C-series; MW-111; R-6-MW; and HR-1) and groundwater data are not mentioned. Soil samples collected when the wells were installed should be discussed.

Response 36.
Section 4.1.9, page 25, Chlorobenzene Hot Spots area. The text and figures have been updated to address inconsistencies that were identified. Sample locations and analyses are also summarized in Table L-3.

Comment 37.
Section 4.1.10, page 23, hypothetical drinking water area. There are a total 31 wells at 19 locations shown on Figure L-12; but the text states that 11 wells were used to characterize this area. Of the 31 wells on Figure L-12, there is one triplet (WA-4) that is outside the limits of any of the specific exposure areas discussed previously. The text needs to identify which wells were used and why; and also to discuss the comparability of the scope of the sampling events. If the recent event includes all or almost all the wells and parameters included in the 1991 event, it may be preferable to just use the recent data. (The correlation with the 10-year-old data can be discussed in the uncertainty assessment section). The data summary (Table L-11) shows varying numbers of analyses, typically ranging from 26 or 27 to 53 or 59. This should be explained.

Response 37.
Section 4.1.10, page 25 and 26, hypothetical drinking water area. 29 wells were used for the evaluation of a hypothetical drinking water area. The data are presented in RAGS D Table 2.25, Attachment C. The other 2 wells referenced in the previous HHRA report were historic wells that were identified on the figure. No data was identified for those 2 wells and references to the wells were removed from the current HHRA. Table L-2 identifies the analyses performed and year of sampling for each investigation included in the HHRA. Due to the varied analytical data collected during each sampling event, the HHRA utilized data for the entire monitoring period (1992, 1995, and 1997).

Comment 38.
Section 4.2.2, page 24. The text states that data qualified with "R" were not incorporated into the risk assessment "[i]n most cases." Please clarify the exceptions.

Response 38.
Section 4.2.2, pages 26 and 27. Arsenic "R" qualified data consisted of historic (1991) data for Trib 5A. Since more recent data was collected from Trib 5A for the RI, the historic "R" qualified data were not utilized in the revised HHRA. The text will be revised to reflect this change. This revision will be incorporated into the final HHRA report to be submitted subsequent to NYSDEC review of the October 2004 revised HHRA.

Comment 39.
Section 4.2.3, page 24. Groundwater should be added to the discussion of sensitivity goals.

Response 39.
Section 4.2.3, page 27. Ground water was added to the discussion of sensitivity goals and Table L-A2, which contains ground water sensitivity data, was cited.

Comment 40.
Section 4.2.3, page 25. EPA and NYSDEC agree that anomalously high PQLs can be excluded from the datasets when developing exposure point concentrations. However, these data should be provided, along with other PQLs, so that EPA and NYSDEC can evaluate all PQLs in context to determine if they can be excluded.

Response 40.
Section 4.2.3, page 27. As cited in the subject section of the revised report, tables provided in Attachment A provide a comparison of the reporting limit with the screening values used in the risk assessment.

Comment 41.
Section 4.3.1, page 25, fourth full paragraph. In the previous version of this HHRA report (June 1999), it was reported that the published USEPA Region 3 tap water concentration was applied but not adjusted to an HQ of 0.1. Comment 4.4 from the comment letter issued by NYSDEC to Honeywell dated January 25, 2002, indicates that the concentrations should be adjusted by a factor of 0.1. In the revised report, it was stated that the published groundwater RBCs were applied. It should be specified which published RBCs were used. Additionally, it appears that the Regional (Region 3 and Region 9) risk-based screening criteria ("PRGs" as used by Region 9) non-cancer hazard (which are based on a HQ of 1.0) were correctly multiplied by 0.1 to screen non-cancer hazards at HQ of 0.1. The tap water RBC /PRG is applied to all water pathways (surface water ingestion included), although the intake equation is not the same.

Response 41.
Page 27, Section 4.3.1, second paragraph. The RAGS Table 2 series identify the Region 3 and Region 9 screening values and the screening value applied for the assessment of risk. The tap water RBC/PRG screening values, multiplied by a factor of 0.1, were applied to all water pathways.

Comment 42.
Section 4.3.1, page 26. The section on the Vapor Infiltration Screening Values will need to be revised. The text should reference EPA's guidance, "Evaluating the Vapor Intrusion into Indoor Air" (EPA/530-F-02-053) (November 2002) for appropriate screening values.

Response 42.
Section 4.3.1, page 28 and 29. Vapor Intrusion Screening Values. The section was revised and references the EPA guidance, as requested.

Comment 43.
Section 4.3.1, page 26, evaluation of essential nutrients. We concur with the elimination of calcium, potassium, sodium, and magnesium from the list of contaminants evaluated and recommend that these substances be eliminated from all of the tables.

Response 43.
Section 4.3.1, page 29, evaluation of essential nutrients. No response required.

Comment 44.
Section 4.3.1, page 26. The section on Background will need to be revised based on EPA's background guidance, "Guidance for Characterization Background Chemicals in Soil at Superfund Sites" (EPA/540-R-01-003). This document states that background concentrations cannot be used to screen contaminants for the baseline human health risk assessment. The document also recommends that if background concentrations will be utilized in risk management decisions, then these concentrations should be determined based on a statistical evaluation.

Response 44.
Section 4.3.1, page 29. The section has been revised, as requested.

Section 5 - Exposure Assessment
With the current revision of the HRHA, Section 5.1.3 has been revised to include general procedures for the quantification of exposure that were previously presented in subsequent subsections of the report.

Comment 45.
Section 5.1.2, page 27. It is recommended that a table in the format of RAGS Table 1 be prepared and included to provide assurance that a thorough and systematic review of potentially complete exposure pathways has been made.

Response 45.
Section 5.1.2, page 31. The requested RAGS Table 1 has been prepared and included in Attachment C.

Comment 46.
Section 5.1.3, page 28 The list of EPA guidance documents is not complete. The following documents should be added:

USEPA, 2001. Risk Assessment Guidance for Superfund (RAGS); Volume I, Human Health Evaluation Manual, Part D., OERR, Interim Publication No. 9285.7-47, December 2001.

USEPA, 1992. Supplemental Guidance to RAGS: Calculating the Concentration Term. OSWER 9285.7-081. May 1992.

USEPA, 1991, RAGS Volume I: Human Health Evaluation Manual Supplemental Guidance. Standard Default Exposure Factors. OSWER Directive 9285.6-03. March 25, 1991.

Response 46.
Section 5.1.3, page 32. The requested list of EPA guidance documents have been included.

Comment 47.
Section 5.1.3, page 28, second to last paragraph. "Highly unlikely to exceed" should be changed to "unlikely to exceed", as originally requested in comment 5.2 from the letter issued by NYSDEC to Honeywell dated January 25, 2002.

Response 47.
Section 5.1.3, page 32, second to last paragraph. The requested text change to "unlikely to exceed" has been addressed.

Comment 48.
Section 5.1.3, page 28, last paragraph. As a minimum, CT calculations should also be performed for incremental RME cancer risks greater than 10^{-4} (we would recommend using 10^{-6} as the threshold) and for RME hazard indices greater than one.

Response 48.
Section 5.1.3, page 33, first paragraph. CT calculations have been performed, as requested.

Comment 49.
Section 5.2.1, page 29, Current Land Uses, Surveillance Workers. The manner in which the exposure is calculated for this receptor appears to be incorrect; as well as being inconsistent with the description of site security earlier in the report. If the surveillance worker is on site for 250 days a year, the exposure frequency is 250 days/year, not five. The assumption that this worker is on site for less than a full work day can be accounted for in other ways; for example, by assuming a 'fraction ingested' of less than 1.0. Furthermore, the 10 minutes per day does not appear to be consistent with the claim made earlier in the report that the site is patrolled during business hours. A single 10 minute visit on weekdays during working hours is not likely to be a deterrent to trespassers who in general might be more likely to visit the site after business hours and on weekends. The document should be modified for the Surveillance Worker and/or Adolescent Trespasser scenarios in order to incorporate this comment.

Response 49.
Section 5.2.1, page 36, Current Land Uses, Surveillance Workers. The exposure frequency of 250 day/year is presented for the Surveillance Worker. An FI of 0.1 was applied to account for the assumption of the portion of a shift that the Surveillance Worker is expected to be outside of a vehicle during patrol of the site. A FI of 1 was applied for the adolescent trespasser.

Comment 50.
Section 5.2.1, page 30, *Industrial Workers*. The text in this section begins with "*Industrial Workers* respectively,". Please delete "respectively".

Response 50.
Section 5.2.1, page 36, *Industrial Workers.* The text has been revised, as requested.

Comment 51.
Section 5.2.2, page 30. The text states that the data distribution was determined if datasets contained greater than 8 samples with a frequency of detection of at least 40%. What is the reference for these

criteria? Also, EPA Region 2 recommends using the statistical software package PRO UCL Version 2.1, which uses several different statistical tests to determine data distribution. This software package also provides several nonparametric tests for data which are neither normally nor lognormally distributed. Please contact EPA for a copy of the software package.

Response 51.
Section 5.2.2, pages 36 and 37. The decision to perform a distribution analysis on a data set was based on professional judgement. For data sets with less than 8 samples and a frequency of detection less than 40%, the maximum concentration was conservatively used as the exposure point concentration. Otherwise, exposure point concentrations, based on evaluation of data distributions, were calculated using the current version of the statistical software package ProUCL (Version 3.0), as cited in Section 5.1.4, page 33.

Comment 52.
Page 32, Paragraph 1. The text states that the depth to VOC contamination was estimated to be between 4 and 7 feet. For contamination which is at this shallow depth, the Johnson and Ettinger model may not be appropriate. The model allows for an attenuation or dispersion of contamination from the source to the building, and when contamination is shallow, this attenuation/dispersion may not occur. The revised version of the model will provide more complete information on this phenomenon.

Response 52.
The subject paragraph, previously presented in Section 5.2.2, *Exposure Point Concentrations*, was moved to Section 5.1.5, *Modeling Exposure Point Concentrations in Air* (page 34, last paragraph). The text was changed to clarify that *fill* material was estimated to be at depths of 4 to 7 ft, and not ground water. The depth to ground water contamination varies for each specific area-of-concern and ranges from 5-15 ft. As such, these depths did not violate the assumptions of the Johnson & Ettinger model.

Comment 53.
Indoor Air, page 31. Please revise this section using the updated Johnson and Ettinger model. EPA can be contacted for the most recent version of this model.

Response 53.
Section 5.2.2. *Indoor Air*, page 37. The updated Johnson and Ettinger model has been cited, as requested.

Comment 54.
Section 5.2.2, page 31, bulleted list. Data collected in 1999 as part of the BERA should be included here, as data from this sampling event were included in the risk assessment.

Response 54.
Section 5.1.5, page 34, bulleted list. A reference to the 1999 BERA has been added, as requested.

Comment 55.
Section 5.2.2, page 32, paragraphs 4 and 5 with Table L-C2a. As stated in the text, the air exchange rate chosen is on the higher end, however Table L-C2 describes it as lower end, which appears to be incorrect.

Response 55.
Section 5.2.2, page 35 paragraphs 4 and 5 with Table L-B2a. Table L-B2a has been revised to indicate that the selected air exchange rate is on the higher end of the range. The text in the report incorrectly cites Table L-B2a as L-C2a. The revised table reference will be incorporated into the final HHRA report to be submitted subsequent to NYSDEC review of the October 2004 revised HHRA.

Comment 56.
Section 5.2.2, page 32, last paragraph. The soil module of the J&E spreadsheet does include an entry for mercury. However, in some areas of this site, the mercury is supersaturated and may need to be modeled with the NAPL model.

Response 56.
Section 5.2.2. The area containing soils supersaturated with mercury was not evaluated as a "hot spot." Since the area is small and will be slated for remediation, an area-specific "hot-spot" evaluation was not undertaken.

Comment 57.
Section 5.2.2, page 33, *Estimation of Saturated Mercury Air Concentrations*. The text is confusing. Why is this type of concentration necessary for evaluation exposure to mercury? Please provide additional explanation to support the information present. For example, please provide definitions for the "saturated vapor concentration" and the "saturated vapor pressure." Also, please provide the reason why this concept is referenced to an OSHA document, and not an EPA document.

Response 57.
Section 5.2.2. This approach was not utilized in the revised HHRA, and the referenced discussion related to mercury has been removed from Section 5.2.2.

Comment 58.
Section 5.3.1, page 34. The exposure frequency for the current adolescent receptor is listed as two times per month for the three summer months. This time is very limited. EPA recommends 3 times per week during the 13 summer weeks for an exposure frequency of 39 days per year. This comment also applies to Sections 5.5.1, 5.6.1, 5.7.1 and 5.8.1.

Response 58.
The exposure frequency for the current adolescent trespasser has been revised to 39 days per year, as requested by EPA. This change was incorporated into the subsections listed below:

- Section 5.3, page 37, Southwest off-site/Outfall 006 exposure area
- Section 5.4, page 38, Northwest off-site/Outfall 004 exposure area
- Section 5.5, page 39, Tributary 5A exposure area
- Section 5.6, page 41, Lakeshore property exposure area
- Section 5.7, page 42, Petroleum storage area exposure area
- Section 5.8, page 43, Chlorobenzene hot spot area

Comment 59.
Section 5.4.1, page 35. The current and future land use should consider trespassers.

Response 59.
Section 5.4, page 38, Northwest off-site/Outfall 004 exposure area has been revised to consider trespassers, as noted in the response to Comment #58, above.

Comment 60.
Section 5.4.2, page 35. The text states that the maximum detected concentration was used as the exposure point concentration in soils. Please provide the explanation for not developing a statistical estimate of the average concentration. This comment also applies to Sections 5.6.2, 5.7.2 and 5.8.2.

Response 60.
The maximum concentration was applied as a conservative value using the approach outlined in Section 5.14, which discusses the derivation of exposure point concentrations. RAGS D Tables 3.1 through 3.25 present mean concentrations. This response applies to the Sections cited in the Comment, as outlined below:

- Section 5.4.2, page 39, Northwest off-site/Outfall 004 exposure area
- Section 5.6.2, page 41, Lakeshore property exposure area
- Section 5.7.2, page 42, Petroleum storage area exposure area
- Section 5.8.2, page 43, Chlorobenzene hot spot area

Comment 61.
Section 5.9.1, page 40, first paragraph. As mentioned above in comment 3.6, it is reported that groundwater occurs at approximately 25 to 30 ft bls. Here it is reported to occur at approximately 15 to 20 ft bls. Is one of these incorrect, or is the text referring to different areas? This should be clarified.

Response 61.
Section 5.9.1, page 44. The ground water depths were correctly reported in this section. Section 3.2 (Page 20) was revised, as requested by Comment 10.

Comment 62.
Section 5.9.2, page 40. The text states that the maximum detected concentration was used as the exposure point concentration in groundwater. Please provide the explanation for not developing a statistical estimate of the average concentration.

Response 62.
Section 5.9.2, page 44 has been revised to cite the procedures for deriving exposure point concentrations presented in Section 5.1.4, *Derivation of exposure point concentrations* (page 33). Maximum concentrations were applied due to the limitations in quantities of samples/analyses, as discussed in the response to Comment #37.

Section 6 - Toxicity Assessment

Comment 63.
Section 6.2, page 43, 1st bullet. Please revise the superscript to "2", rather than "6".

Response 63.
Section 6.2, page 49, 1st bullet. The superscript has been revised to "2", as requested. However, the footnote associated with this reference was inadvertently deleted. As cited in the previous revision of

the HHRA, footnote #2 states: "The definition of the terms "sufficient", limited, and adequate are given in USEPA 1986, *Guidelines for Carcinogenic Risk Assessment* (51 FR 33992)."

Comment 64.
Section 6.3, page 45, Toxicity Summaries. The IRIS database is cited as 'USEPA, 1997'. Is this a typo, as it is the HEAST Tables which are 1997? The IRIS database is updated regularly and the HHRA should be revised to reflect the current toxicological data (RfDs, CSFs) in IRIS.

Response 64.
Section 6.3, page 50. Toxicity Summaries. The reference to the IRIS database has been revised to cite the current version (2004).

Comment 65.
Section 6.4, page 46, adjustment for GI absorption. While USEPA dermal guidance has been modified over time, agency guidance more recent than 1989 should be used. (The 1992 USEPA dermal guidance, which is more recent than 1989 but is also superseded, is listed in the 'References' section but not cited here.) As this HHRA was issued in June 2002, the Draft RAGS Part E Supplemental Guidance for Dermal Risk Assessment (USEPA, September 2001) should have been used.

Response 65.
Section 6.5, page 55. The RAGS Part E Supplemental Guidance for Dermal Risk Assessment (USEPA, July 2004) was used for the revised HHRA.

Comment 66.
General. USEPA (IRIS) has published CSFs only for total PCBs; and has a tiered set of CSFs. RfDs are only available for two individual Aroclors. This section should include a discussion of how the available toxicity data were applied to the site Aroclor data. Review of the tables suggest that Aroclors other than 1016 and 1254 were inappropriately deleted from the quantitative assessment of non-cancer hazards.

This section should also describe how the health effects of PAHs are evaluated for which specific toxicity data are not available in IRIS or HEAST. Was the USEPA 1993 guidance for assessing carcinogenic PAHs other than benzo(a)pyrene used? Were non-cancer effects of PAHs assessed (*e.g*, acenaphthylene is identified as a COPC in several media although there are no screening criteria) - if so how? See also comments on Table L-49.

This chapter should address all issues for which there is ambiguity - *i.e*., for which the IRIS values are not used 'out of the box'. The 'surrogate' compounds shown on Table L-49; the dioxin CSF; the determination of how the oral CSF for benzene was selected (IRIS provides a range of values), and similar issues should all be discussed in this section. This chapter should also discuss any assumptions about the data which affect the chosen toxicity values - for example, what valence state of chromium was assumed - all as hexavalent? Or trivalent? Or a 1:6 ratio of hexavalent to trivalent? What form of mercury was assumed to be present in the various media?

Response 66.
Section 6.4, *Evaluation of special constituent classes* (beginning on page 51) has been added to provide clarifications on the information requested in this comment.

- dioxins, Section 6.4.1, pages 51 and 52. The selection of IRIS values for dioxin is discussed in this subsection. Table L-5 presents TEFs that were applied.

- PCBs, Section 6.4.2, pages 52 and 53. Detected Aroclors were evaluated quantitatively for cancer and non-cancer health effects in the attached tables. Aroclors were grouped as low molecular weight PCBs, for which the RfD for Aroclor 1016 was used (Aroclors 1016, 1242, 1248) and high molecular weight PCBs (Aroclor 1254, 1260), for which the RfD for Aroclor1254 was used. This approach is consistent with the recommendation provided by NYSDEC in Comment 119. The attached Tables 1 and 2 provide revised RME and CT estimates to correct PCB risk calculations that were not completely addressed in the revised HHRA report. The HHRA will require revision of RAGS D Table 7 and 9 series, and report text to address this issue. These revisions will be incorporated into the final HHRA report to be submitted subsequent to NYSDEC review of the October 2004 revised HHRA.

- PAHs, Section 6.4.3, page 53. As suggested in Comment #123, the USEPA relative potency factors for carcinogenic PAHs (Provisional Guidance for Quantitative Risk Assessment of Polycyclic Aromatic Hydrocarbons, EPA/600/R-93/089, USEPA 1993) were used to derive appropriate CSFs for benzo(a)anthracene, benzo(b) and (k)fluoranthene, chrysene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene. The values applied to the risk calculations are presented in Table L-5.

- chromium, Section 6.4.4, page 53. As noted in this subsection, chromium was assumed to be hexavalent chromium as a conservative screening measure.

- The selection of the cancer slope factor of 5.5×10^{-2} per mg/kg-day[1] for benzene was applied to the HHRA as the more conservative of the two values presented by IRIS. The other cancer slope factor presented in IRIS is 1.5×10^{-2} per mg/kg-day[1]

- Mercury is discussed in section 6.3.1. For inorganic mercury, the values for mercuric chloride were applied.

Section 7 - Risk Characterization

Comment 67.
General. It was requested in the letter issued by NYSDEC to Honeywell dated January 25, 2002 that the central tendency (CT) risk be calculated in cases where the hazard indices exceed 1 and the carcinogenic risks exceed 10^{-4} under the RME scenario, however this was done for risks greater than 10^{-6} in the HHRA (which is appropriate and more conservative). The results of these CT calculations should be included in this section (either in addition to, or in place of, their presentation in Section 8.6), as well as in the appropriate summary tables.

Response 67.
CT calculations were calculated, as requested, and results are presented in Section 7 and the appropriate RAGS D tables 7 series and 9 series, Attachment C. It should be noted that both RME and CT exposure estimates utilize one set of air model results. In addition to the addition of risk values associated with exposure to Aroclors (cited in the response to Comment #66 above), the attached Tables 1 and 2 include corrections (in **bold** type) to industrial worker scenarios for which air exposures were not included in the CT calculations of total risk in the revised HHRA report. Other revisions included in the attached Tables 1 and 2 (that are identified in **bold** type) are reporting errors

that were identified during review of the revised report. These revisions will be incorporated into the final HHRA report to be submitted subsequent to NYSDEC review of the October 2004 revised HHRA.

Comment 68.
Section 7, page 47, next-to-last paragraph, item number 2. There appears to be an error in the exponent of the cancer risk range, cited as 10^{-4}. This should be changed to 10^{-6}. Furthermore, the discussion does not accurately reflect the text of the NCP. We suggest the following text be used in the discussion of cancer risk:

". . . acceptable exposure levels are generally concentration levels that represent an excess upper bound cancer to an individual of between 10^{4} to 10^{6} . . . The 10^{6} risk level shall be used as the point of departure for determining remediation goals . . ." (40 CFR §300.430[e][2][i][A][2]). These target risk levels are also often applied by other agencies responsible for protecting human health (New York State Department of Health [NYSDOH] and Agency for Toxic Substances and Disease Registry [ATSDR]).

Response 68.
Section 7, page 55, next-to-last paragraph, item number 2. The exponent of the cancer risk range was revised, as requested. In addition, the requested text of the NCP was added to the Executive summary of the report (See response to Comment #9) and referenced in Section 7.

Comment 69.
Section 7.1, page 48. The text states that the maximum detected concentration was used to estimate exposure when a statistical estimate of the mean could not be calculated. However, EPA recommends first trying to develop an EPC using a nonparametric test as provided in the statistical software package PROUCL Version 2. If an EPC cannot be calculated with this program, EPA then recommends estimating risk using both the maximum detected concentration and the statistical estimate of the mean (without the outliers). This provides a more complete picture of potential risks from exposure to possible hot spots as well as exposure to the contamination that may be more representative of site-wide distribution.

Response 69.
Section 7.1, page 56. The development of the UCL is discussed. For specific discussion of the use of ProUCL, please refer to Section 5.1.4.

Comment 70.
Section 7.1, page 48, first paragraph . If there are concerns that the inclusion of certain hot spot areas (e.g. ditches) in the risk calculations may result in an overestimate of the risks associated with the general plant area, the consultant may also calculate risks for the general plant area but excluding data from hot spot areas which are also assessed as discrete exposure areas. This should, however, be done in addition to, not as a substitute for, the risk calculations done for the general plant area using the pooled data.

Response 70.
Section 7.1, page 56, first paragraph. The suggested approach has been incorporated into the HHRA.

Comment 71.
Section 7.1.1, pages 48 and 49, surveillance worker. It is stated that the cancer risk for the surveillance worker at the former chlorination building is related to the maximum TCDD TEQ concentration, however, the estimated risk value is not given. This should be provided here.

Response 71.
Section 7.1.1, pages 56 and 57. The cancer risk value for the surveillance worker is presented, as requested.

Comment 72.
Sections 7.2 through 7.7, pages 50 and 51, general. The characterization of risks less than 1×10^{-4} but greater than 1×10^{-6} as "not significant" is incorrect. As noted earlier, the NCP states risks exceeding 10^{-6} are the point of departure for determining remediation goals.

Response 72.
Sections 7.2 through 7.7, pages 57 through 61. The requested change has been included, as requested.

Comment 73.
Section 7.5, page 51, Lakeshore property area, recreational fisherman. As requested in comment 7.4 in the January 25, 2002 letter issued by NYSDEC to Honeywell, the text summarizing the current recreational fisherman's risk to consumption of fish in the lake should indicate that this risk was evaluated as part of the Onondaga Lake Bottom HHRA.

Response 73.
Section 7.5, page 59, Lakeshore property area, recreational fisherman. The recreational fisherman scenario (which evaluates the risk associated with the consumption of fish) was addressed in the Onondaga Lake Bottom HHRA. The Adult trespasser scenario considers the potential exposure of a recreational fisherman that accesses the lake for fishing via the Lakeshore property area. For that scenario, exposure to surface soil is evaluated.

Comment 74.
Section 7.9.1, page 54, Current Conditions. Please see the comment on Sections 7.2 through 7.7 above regarding description of risks as "not significant".

Response 74.
Section 7.9.1, page 62, Current Conditions. The section has been revised consistent with other sections, as discussed in response to Comment 72.

Section 8 - Uncertainty Assessment

Comment 75.
General. As mentioned in comment 8.4 of the January 25, 2002 letter issued by NYSDEC to Honeywell, there should be a discussion of the uncertainties associated with the dermal route in this section. The HHRA should indicate whether or not the dermal assessment was conducted in accordance with the recent (September 2001 Draft RAGS Part E) USEPA Dermal Guidance document (if not, what specific guidance was used); and include a qualitative assessment of how the older version of the USEPA dermal guidance used in this HHRA may differ from the current guidance.

Response 75.
Dermal assessment was conducted in accordance with the recent (July 2004 Final RAGS Part E) USEPA Dermal Guidance document, as cited in Section 6.5. Therefore, a discussion of uncertainty associated with the use of other guidance was not required.

Comment 76.
Section 8.1, page 57, last paragraph. It should be indicated that 100 percent of the PCDD/F data were determined to be useable, as was reported in Section 4 (Data Evaluation).

Response 76.
Section 8.1, page 67, first paragraph. The text was updated, as requested.

Comment 77.
Section 8.1.2, page 58, Rejected data. The compounds for which a high fraction of the data were rejected should be noted here.

Response 77.
Section 8.1.2, page 68, Rejected data. As noted in the response to Comment 38, the "R" qualified arsenic data was not utilized in the revised HHRA; however, the text was not revised to reflect this change. This revision will be incorporated into the final HHRA report to be submitted subsequent to NYSDEC review of the October 2004 revised HHRA.

Comment 78.
Section 8.2.1, page 59, first sentence. The necessary number of data points to conduct statistically valid calculations is dependent upon the amount of data, not the number of detections.

Response 78.
Section 8.2.1, page 68 and 69. The text was revised to cite the number of samples rather than the number of detections. In addition, the inclusion of data with concentrations below the detection limit is explained in this section.

Comment 79.
Section 8.2.3, general. The uncertainty discussion of the model should include model runs with a range of different assumptions, particularly the most sensitive parameters (such as soil type or soil vapor permeability).

Response 79.
Section 8.2.3, general. Model uncertainty is addressed according to the *User's Guide for Evaluating Subsurface Vapor Intrusion into Buildings* Table 5 (USEPA 2003), which has been included in Section 8.2.3. Model-parameter values were selected at the conservative end of the range for Site-specific or default conditions. Therefore, the model derivations are conservative.

Comment 80.
Section 8.2.3, page 61, table. It appears that the table has not been imported correctly from the model guide. Many of the cells appear to have lost their references and superscripts.

Response 80.
Section 8.2.3, page 71, table. The table has been revised based on more recent guidance provided in the *User's Guide for Evaluating Subsurface Vapor Intrusion into Buildings* (USEPA 2003).

Comment 81.
Section 8.2.3, page 61, table. Please revise the table of sensitivity/uncertainty in the Johnson and Ettinger model based on information provided in Appendix G, Table G-2 of EPA's draft vapor intrusion guidance. This guidance is available at: http://www.epa.gov/correctiveaction/eis/vapor.htm

Response 81.
Section 8.2.3, page 71, table. Same as response to Comment 80, above.

Comment 82.
Section 8.2.3, page 62, fourth full paragraph, fifth sentence. It is stated that "Benzene was detected in 22 of 62 samples at concentrations ranging from 0.035 - 16 mg/m^3." Data from the April 12, 2002 package from Honeywell and Appendix K from the June 1999 RI indicate that benzene was detected in 21 of 62 samples at concentrations ranging from 0.01-81.58 ppmv (0.034 to 274 mg/m^3). This should be clarified.

Response 82.
Section 8.2.3, page 72, last paragraph, fifth sentence. The benzene concentration detected in soil vapor samples needs to be revised to present the concentrations from the data in the April 12, 2002 package from Honeywell, and Appendix K from the June 1999 RI. This revision will be incorporated into the final HHRA report to be submitted subsequent to NYSDEC review of the October 2004 revised HHRA.

Comment 83.
Section 8.2.3, page 63, first paragraph. There appear to be some problems with the comparison of the soil gas vapor data (despite the data quality issues associated with them) and the soil/groundwater model results. For benzene, the 95% UCL of the soil gas vapor data is 0.24 ppm by volume (note that the EPC value stated here is based on the data from the April 12, 2002 package from Honeywell and the June 1999 RI Appendix K, since the number used is not indicated in the text) whereas the maximum is approximately 340 times greater at 81.58 ppmv. Honeywell states that the model is too conservative since it generates an indoor concentration using the soil or groundwater (Honeywell doesn't specify; instead, it is referred to as "the simplified conceptual model applied in this assessment") that is 500 times the indoor concentration generated using the 95% UCL from the gas vapor data. Since these data have quality issues, and the soil and groundwater data are more extensive, they do not seem directly comparable. The soil gas vapor data ranges (minimum and maximum which differ by a factor of 8,000) should have been used in the comparison.

Response 83.
Section 8.2.3, page 69, first paragraph. Based on more recent guidance for evaluation of vapor intrusion issues, ground water data was used to develop exposure estimates as opposed to estimating soil vapor concentrations using soil data. The discussion, which compares indoor air screening concentrations derived from measured soil vapor concentrations to those derived from measured ground water concentrations, has been removed.

Comment 84.
Section 8.3.1, page 63, third sentence. As previously noted above, the concentration of chloride reported in the bedrock aquifer is not documented; and is reported at concentrations varying by three orders of magnitude in different parts of this report (50,000 g/L here and on page 8; 50,000 mg/L on pages 5 and 13).

Response 84.
Section 8.3.1, page 73, third sentence. Consistent with other sections of the report (see responses to comments #12 and #17), the chloride concentration was revised as 3,000 mg/l.

Comment 85.
Section 8.3.2, page 63, last paragraph. Region 2 guidance is that the 330 mg/day value be used for the construction soil ingestion rate (for both RME and CT). While the USEPA EFH (1997) does note that there is uncertainty about the way in which the number (480 mg/day) was derived, the EFH does NOT state that 480 mg/day (or the lower value of 330 mg/day currently recommended by USEPA Region 2) significantly overestimates the ingestion rate for the construction worker. If Honeywell wants to suggest that there may be other values (e.g., 82 mg/day) then the place for that discussion is in the uncertainty section.

The following text is suggested:

While not explicitly making a recommendation for construction worker ingestion, the USEPA Exposure Factors Handbook (USEPA, 1997) does cite a study by Hawley (1985) which suggested a 480 mg/day rate. This rate (480 mg/day) has been used in other Onondaga Lake subsite risk assessment documents; however, USEPA Region 2 has re-evaluated the study on which this rate was based and currently recommends a construction worker ingestion rate of 330 mg/day. It is acknowledged that there is an extremely limited data set for these assumptions, especially for the construction worker scenario; however, the direction of the bias is unknown.

Response 85.
Section 8.3.2, page 74, third paragraph. The suggested text has been added as the subject paragraph.

Comment 86.
Section 8.3.2, page 64, 2nd paragraph. The text states that "...soil-skin dermal adherence factors presented in current USEPA guidance indicates that the assumed rates of Hawley exceed the calculated ingestion rates...." Please provide the name or document number for the current USEPA guidance that is referenced in this statement.

Response 86.
Section 8.3.2, page 74, 1st paragraph. The text references the *Exposure Factors Handbook* (USEPA 1997).

Comment 87.
Section 8.3.2, page 64, 3rd paragraph. The text states that "[o]ther assessments have indicated that default incidental ingestion rates in the range of 100 - 200 mg/day are appropriate for high soil contact activities." Please reference these specific assessments, indicate the high contact activities, the ingestion rates, and the number of people included in the studies. The central tendency estimate of 82 mg/day should not be used until this value is more thoroughly evaluated.

Response 87.
Section 8.3.2, page 74, 4th paragraph. The last paragraph in Section 8.3.2 on page 74 no longer applies and will be deleted. The ingestion rate of 82 mg/day was not used, RME values for the soil ingestion rates were also applied as the CT soil ingestion estimates. Differences between the RME and CT exposure calculations were established based on RAGS E values for the soil adherence factor, as summarized below. For RAGS E values, the RME represents the 95th percentile value and the CT generally represents the geometric mean value.

Comparison of adherence factors (mg/cm^2) applied for RME and CT estimates

Receptor	***RAGS E receptor***	***RME***	***CT***
Construction worker	Construction worker	0.3	0.1
Industrial worker	Construction worker (RME)/ commercial grounds keeper (CT)	0.3	0.02
PA Sewer worker	Pipe layer	0.2	0.15
State Fair Blvd transient	Residential grounds keepers	0.06	0.01
Surveillance worker	Construction worker (RME)/ commercial grounds keeper (CT)	0.3	0.03
Trespasser	Residential gardener	0.3	0.15
Utility worker	Utility worker	0.9	0.15

The text in the HHRA report will be expanded to reflect this change in approach. These revisions will be incorporated into the final HHRA report to be submitted subsequent to NYSDEC review of the October 2004 revised HHRA.

Comment 88.
Section 8.4.1, page 64. The text uses magnesium as an example of a chemical for which an RfD is developed "directly from data on human exposures....relating to occupational exposures that are known to have no adverse effects [or] norm0.al dietary levels of certain chemicals...." However, EPA does not recommend an RfD for magnesium, and in fact recommends that it should not be retained for quantitative evaluation in the HHRA. Please revise the text to use a more appropriate example.

Response 88.
Section 8.4.1, page 75. We propose to revise the HHRA to remove the parenthetical references to magnesium, selenium, and silver. These revisions will be incorporated into the final HHRA report to be submitted subsequent to NYSDEC review of the October 2004 revised HHRA.

Comment 89.
Section 8.4.2, pages 66 and 67 general. The discussion of dioxin carcinogenicity should also note that the TEF approach is not a creation of USEPA but is in fact a consensus of international experts; and also that the USEPA draft dioxin reassessment currently available as a peer-review document (EPA/600/P-00/001Bg, September 2000) suggests that the cancer risks from dioxin may in fact be higher than those based on the CSF published in HEAST and used in this HHRA.

Response 89.
Section 8.4.2, pages 76 through 78, general. Based on the *draft – for peer review only* status of the dioxin reassessment, we did not include the preliminary information appearing in it.

Comment 90.
Section 8.5.1, page 67, non-cancer effects. Non-cancer health effects from dioxins should be discussed here or elsewhere in this chapter. ATSDR (1999), USEPA (2000), and the WHO (2000) all have intake numbers for dioxins against which the intakes calculated for site receptors can be compared, at least on a qualitative basis. As no quantitative assessment of non-cancer hazards from dioxins is presented, the HHRA should note that non-cancer hazards may be greater than those calculated for media in which dioxin has been detected.

Response 90.
Section 8.4.2, page 77, last two paragraphs, non-cancer effects. Information on non-cancer effects of dioxins obtained from ATSDR is provided.

Comment 91.
Section 8.6, embedded table on page 68. This table as formatted is difficult to follow. It would be more useful if the RME and CT risks / hazards were in separate columns, not underneath one another and not separated from risks to other receptors at the same exposure area. If necessary, present this information as a free-standing table. Also, this section states that CT risks were calculated where RME risks exceeded 10^{-6}; this appears to be the case and is in fact the approach recommended in previous comments. However, text earlier in this document suggests CT risks were only calculated where the RME risk was greater than 10^{-4}. Please review and make the document consistent and correct.

Response 91.
Section 7.9, pages 62 through 64. The format of the table was revised, as requested.
The table presenting a summary of RME and CT risk/hazards was presented in the executive summary and in Section 7.9.

Section 9 - Conclusions

Comment 92.
The first paragraph needs to be modified in accordance with previous comments (e.g., 7.2). This chapter should be reviewed and re-written as necessary to reflect any other changes necessary to address the comments on this version of the HHRA.

Response 92.
Section 9, page 81. The conclusions section was revised to address changes incorporated into the revised HHRA.

References

Comment 93.
Please proofread (see, for example, apparent typos / internal comments in reference entries for IRIS [also a more recent version should be used] and "Zeisse, ???"). The references section lists the 2002 versions of Region 3 and Region 9 screening criteria; but the 2000 version of the Region 9 screening criteria is cited in Section 4.3.1. This section also lists the 1992 USEPA dermal guidance but the brief discussion of dermal in the text only mentions 1989 USEPA guidance.

Response 93.
References, pages 83 to 87. The references have been proofread and revised, as requested.

Tables

Tables L-2 through L-11, Analytical Data Summary Tables
These tables have been replaced by RAGS D Tables 2.1 through 2.25, Attachment C.

Comment 94.
General. Based on the raw data that were provided with the electronic version of the report, it appears that there may be errors in the reported units for some of the incorporated data. For example, there are mercury data (water) from the chlorobenzene hot spot area that appear to either be reported in the incorrect units, or they are filtered samples and not reported as such. Because the maximum concentrations (rather than 95% UCLs) were used as exposure point concentrations for many of the compounds, errors in the units of detection limits may not have an effect on the risk calculations; however, this should be verified. The units for all detections should also be verified before submitting the revised report.

The notes to Tables L-2 through L-11 state that the column 'site concentration' is the maximum detected for that AOS. Clarify the difference between the concentrations reported in the maximum column under the summary statistics heading and the "Site Concentration".

The arithmetic mean has no significance for human health risk assessment and should not be included.

Response 94
The data base was extensively reviewed to correct errors in the previous report. Table L-2 through L-11 tables have been replaced by RAGS D Tables 2.1 through 2.25, Attachment C.

Comment 95.
Tables L-2e, L-5c, L-9d, and L-10d. These tables are titled "Summary of Detected Analytes (Modeled Indoor Air)", but the analytes are modeled, not detected. Only the parameters that were detected in the soil gas survey in these tables were used, rather than those detected in the soil and groundwater. The groundwater and soil contributions were added, which may not be applicable, since the groundwater models the movement through the soil and assumes equilibrium. If, however, the soil and groundwater contributions are supposed to be added, then the sum of these two effects would need to be considered in the screening tables in the next set of tables.

Response 95.
The subject tables were replaced by RAGS D Tables 3.8, 3.20, and 3.24 for the General Plant Area, Petroleum Storage Area, and Chlorobenzene hot-spot area, respectively. These tables present modeled indoor air concentrations which are based on ground water data.

Comment 96.
Tables L-3 and L-4. A summary appears to be missing for the indoor air for Tables L-3 (FCB) and L-4 (Ditch).

Response 96.
Site data for the overall General Plant area conservatively represents the FCB and Trench areas. Therefore, the indoor air exposure pathway was not evaluated for these areas using location specific data.

Comment 97.
Table L-3b, Former Chlorination Building (0 to 10 ft Soils). The "Frequency of Detection" column should be corrected. Currently, it lists that all COCs were detected in all samples.

Response 97.
The subject table has been replaced by RAGS D Table 2.6, Attachment C. The requested change has been made.

Comment 98.
Table L-7a. There appears to be no entry for mercury (only methylmercury) in this table. Was analysis for mercury performed, but was not detected? If so, what was the detection (reporting) limit? If the standard SW-846 method and reporting limits were used, non-cancer risks from exposure to mercury in Trib 5A may be underestimated. Please address this issue either in a detailed footnote to this table or in the text.

Response 98.
The subject table has been replaced by RAGS D Table 2.13. Mercury concentrations are reported in the table.

Tables L-12 through L-21, COPC Selection Summary Tables
The subject tables have been replaced by RAGS D Tables 3.1 through 3.25, Attachment C.

Comment 99.
These tables compare the soil and groundwater concentrations to the modeled RBCs, when the soil/groundwater concentrations could have been entered into the model and compared to Region 3 and 9 RBC/PRG values for ambient air (this should be appropriate if the model assumptions (slope factors, RfDs, exposure durations and frequencies, *etc.*) are acceptable to the USEPA or mirror those used by USEPA Regions 3 and 9.

Response 99.
After the HHRA report (June 2002) was issued, USEPA published guidance entitled *Draft Guidance for Evaluating the Vapor Intrusion to Indoor Air Pathway from Groundwater and Soils (Soil Vapor Intrusion Guidance* (November 2002). The USEPA draft guidance provides screening-value tables for ground water that are protective of indoor air. Therefore, Site-specific model-derived RBCs were removed from the HHRA screening evaluation. In the initial screening for evaluation of indoor air, Site ground water data were now compared to the USEPA (2002) provided screening values as opposed to modeling of indoor air using soil data. Therefore, subsequent comments (#100 through #106) pertaining to the soil modeling approach do not apply as this approach was not utilized.

Comment 100.
Tables L-12 through L-21, COPC Selection Summary Tables. There does not appear to be a logical progression from these tables to the next set. In the next tables, the model is used to back-calculate the RBC concentrations in the soil or groundwater based on the model assumptions (slope factors, RfDs, exposure frequencies, exposure duration, target cancer risk and target hazard quotient etc.) which are then compared to the soil or groundwater concentrations.

Response 100.
The subject tables have been replaced by RAGS D Tables 2.1 through 2.25, Attachment C.

Comment 101.
It does not appear that the correct units were used for the modeled soil screening RBCs. The model output is g/kg. They compare these values to mg/kg. Therefore it appears that more chemicals should have been retained (*e.g.*, Benzene in L-12e). This is evident in the attachments which have the printouts of the model runs, and are confounded by the fact that the values given for the screening levels do not appear to be shown with units anywhere else (particularly Table L-C1).

Response 101.
This approach was not utilized in the revised HHRA. See response to Comment 99.

Comment 102.
Tables L-12 through L-21 resemble RAGS 2, but they do not have the correct format. The RAGS format does not include a column for 95% UCL, but does include one with the concentration used for screening. As such, with these tables we could not determine which concentrations were used in the screening (max, mean, 95% UCL).

Response 102.
The subject tables have been replaced by RAGS D Tables 3.1 through 3.25, Attachment C. The concentrations used for screening are presented.

Comment 103.
The model was run for soils at 0 to10 ft with a depth to contamination of 13 ft (L_T=400 cm). L_T is directly proportional to the screening value and therefore additional analytes may have been retained if the L_T were reduced.

Response 103.
This approach was not utilized in the revised HHRA. See response to Comment 99.

Comment 104.
The groundwater and the soil screening were not consistent. The L_f (Depth below grade to bottom of enclosed floor) for groundwater was set at 15 cm but for soil it was set at 200 cm. (In both the screening models [groundwater and soil] these are the only two choices, 200 cm always yields a lower screening value.) Although the value will depend on the type of building foundation (15 cm - 6 inches - might be appropriate for slab-on-grade construction; whereas 200 cm [6+ ft] would be more consistent with a building with a basement), the same L_f should be used for both soil and groundwater.

Response 104.
This approach was not utilized in the revised HHRA. See response to Comment 99.

Comment 105.
When using the model to back-calculate a screening value, if the calculated screening value in the soil/groundwater is greater than the saturation/solubility concentration the model labels the value 'NOC' or not of concern. However, this is not always correct since the calculated screening value depends on the model parameters (particularly the temperature, depths, and the target HQ). These screening models were run with a target HQ of 1 and then the concentrations obtained were divided by 10 in the screening tables. The model should have been run with the target HQ at 0.1 due to this saturation issue (the value with target HQ set at 1 is ten times greater than at 0.1 and therefore could be greater than saturation/solubility when the value at HQ=0.1 is not).

Response 105.
This approach was not utilized in the revised HHRA. See response to Comment 99.

Comment 106.
The tables appear misleading to the reader since many of the analytes have "NV" in the "Modeled Toxicity Screening Value" column. There is no note to explain what this means. In many cases (as with the PAHs) the model can be used to provide a screening level; however, it does not appear that the model was used. In addition, there are some analytes that the model is not set up to run. These tables need more than one note to indicate the analytes that were run and resulted in a "NOC" value, those that were not run and those that could not be run. Also an explanation should be given for those that were not run which could have been. As they are, the tables appear misleading since they imply all the analytes listed were screened.

Response 106.
This approach was not utilized in the revised HHRA. See response to Comment 99.

Comment 107.
Table L-15b, page 3 of 5, Offsite Southwest Area/Outfall 006. For endrin aldehyde, the qualifier for the maximum concentration is reported as "0". If this is an error, it should be corrected. If this is not an error, the definition of the qualifier should be reported in the notes for the table.

Response 107.
The subject table was replaced by RAGS D Table 2.10, Offsite Southwest Area/Outfall 006. The error has been corrected.

Tables L-22 through L-33, COPC Exposure Summary Tables
The subject tables have been replaced by RAGS D Tables 3.1 through 3.25, Attachment C.

Comment 108.
Table L-22, List of COPCs by Area of Study and Media. The COPCs listed in this table does not appear to be consistent with those flagged as such in Tables L-12 through L-21. For example, for the surface soils (0 to 2 ft) from the former chlorination building area, there were 17 compounds flagged as COPCs and 23 listed in Table 22. It appears as if the nutrients are included in the listing in Table 22, as well as 2-methylnaphthalene and methylmercury. Clarification is needed.

Response 108.
The subject tables have been replaced by RAGS D Tables 3.1 through 3.25, Attachment C which have addressed the concern that was noted.

Tables L-34 through L-43, Chronic Exposure Parameter Tables
The subject tables have been replaced by RAGS D Tables 4.1 through 4.38, Attachment C.

Comment 109.
Table L-34, Chronic Daily Intake Equations. There appear to be no equations for incidental ingestion or dermal contact with surface water. Because these pathways were evaluated, the equations used in the calculations should be included here. The intake equations for incidental ingestion of surface water and ingestion of drinking water (*e.g.*, groundwater used as a drinking / tap water source) are not the same. The tap water pathway assumes daily (or 350 d/yr) ingestion at a fixed daily rate (2 L/day) to calculate the intake. The surface water pathway first needs to have an assumption about the means

of exposure; then assumptions about the ingestion rate; the duration of the event; and the number of days on which the exposure event occurs.

The equations in this table should be presented in text form, not the form the equation needs to be for spreadsheet or database calculations.

Response 109.
The subject table has been replaced by RAGS D Tables 4.1 through 4.38, Attachment C which present the exposure equations. As shown in RAGS D Table 4.21 (Attachment C), the assumptions for the rate of ingestion, duration of the event, and number of days on which the exposure event occurs are 0.01 L/day, 9 years, 39 days per year, respectively. The surface water pathway assumes that incidental exposures occur for a trespasser that accesses the area for 2 hours each event.

Comment 110.
Table L-35. (a) The soil skin adherence factor (SSAF) appears to be low. Based on values used on other subsites, the adolescent trespasser SSAFs should be at least 0.3 for RME and 0.15 for CT. Table C-3 in RAGS Part E should be reviewed. The value used for the SSAF (0.03) is half the value of the lowest RME value for any receptor shown on the table (0.06 mg/cm^2 for INDOOR children). The RME for children (age 8 to 12) playing in dry soil - also the median RME of the five studies of children - is 0.4 mg/cm^2. The median RME of the three residential adult scenarios is 0.2 mg/cm^2. The median RME for 'miscellaneous activities' is about 0.45 mg/cm^2.
Table L-35. (b)The adolescent is more appropriately defined as 9 to < 18 years old. USEPA considers persons 18 and older in the 'adult' category.

Table L-35. (c) There appears to be a typo in table heading , "ME" should be "RME".

Table L-35. (d) Some of the skin surface area values differ slightly from those in the current RAGS Part E but the differences are minor.

Table L-35. (e) An exposure frequency of 6 d/yr is not necessarily a "conservative" estimate. A lot could be going on at the site on the 23 hours and 50 minutes a day (24 hrs/day on weekends) that the Honeywell surveillance staff is not on site.

Response 110.
The subject table has been replaced by RAGS D Tables 4.1 through 4.38.
a. Adolescent trespasser SSAF for RME and CT are 0.3 and 0.15, as requested.
b. Adolescent is defined as a 9 yr. period spanning 9 to <18 years old.
c. Typo is no longer applicable, the subject table was replaced.
d. Skin surface area values were revised according to the current RAGS E.
e. Comment did not require that a change be made.

Comment 111.
Table L-37, Ingestion of soil. The adult ingestion rate (50 mg/d) is consistent with the mean adult ingestion rate in the EFH (Table 4-23; no 95th percentile value is suggested). The fraction ingested (FI) is then given as 1.0, with a statement that this value assumes 1/4 of daily ingestion occurs at site. If 1/4 of the ingestion is assumed to occur at the site, then the FI is 0.25, not 1.0. As the ingestion rate is a mean, we suggest using a FI of 1.0 as the RME value and 0.25 as the FI for the CT (both using a 'base' ingestion rate of 50 mg/d). The SSAF is also low; RAGS E suggests an RME for industrial workers of 0.2 mg/cm^2, and a CT value of 0.02 mg/cm^2. (The midpoint of the studies cited for commercial/industrial adults has a value of 0.3 for the RME.)

Response 111.

- For adult ingestion rates, the FI is provided as 1.0 and 0.25 for the RME and CT, respectively.
- For dermal contact of industrial workers, the SSAF is provided as 0.3 and 0.02 mg/cm^2 for the RME and CT, respectively, according to more recent RAGS E guidance.

Comment 112.
Table L-38. The numerical fraction ingested is inconsistent with the comment on the FI. Also, the SSAF appears to be too low. Please see the discussions above on Tables L-35 and L-37.

Response 112.
Comment is addressed consistent with the response to Comment 111 above.

Comment 113.
Table L-40. The Soil/Skin Adherence Factor (SSAF) appears to be too low. Please see the discussions above on Tables L-35 and L-37.

Response 113.
Comment is addressed consistent with the response to Comment 111 above.

Comment 114.
Table L-41. The numerical fraction ingested appears to be inconsistent with the comment on the FI. Also, the SSAF appears to be too low. Please see the discussions above on Tables L-35 and L-37. The exposure frequency appears to have been calculated incorrectly; it is 250 d/yr. Account for amount of time on site by using an FI of lower than 1.0.

Response 114.
Comment is addressed consistent with the response to Comment 111 above. Adolescent trespasser and industrial worker exposure frequencies are presented as 250 d/yr, as requested.

Comment 115.
Table L-42.General Exposure Factors, Exposure Frequency. It is unclear what this scenario is addressing and clarification is needed for the comment "1 year of every 25 years". If this is truly a residential scenario [but is that possible in an industrial area?], then the EF of 350 d/yr, 30 yr ingestion would be appropriate.

Response 115.
RAGS D Table 4.38, Attachment C, presents a hypothetical drinking water scenario, as requested by NYSDEC. The EF and ED are presented as 350 d/yr and 30 yr in the revised HHRA.

Comment 116.
Table L-43. Body weight in USEPA 1991 is 15 kg, not 16.

Response 116.
RAGS D Table 4.38, Attachment C, the body weight of a child is presented as 15 kg.

Tables L-44 through L-50, Toxicity Tables
The subject tables have been replaced by RAGS D Tables 5.1, 5.2, 6.1, and 6.2 (Attachment C).

Comment 117.
General note on toxicity data tables (L-45 - L50). Many of the tables contain specific (numerical) values without what appears to be any indication as to the source (*e.g.*, many of the RfDo values in Table L-55a); or do not clarify where an IRIS value for one substance has been applied, either directly or with a factor, to other substances (*e.g.*, carcinogenic PAHs). (Table L-49 addresses this but only in part.)

Response 117.
The subject tables have been replaced by RAGS D Tables 5.1, 5.2, 6.1, and 6.2 (Attachment B) and include references to data sources.

Comment 118.
Table L-45a, Toxicity Values: Potential Non-Carcinogenic Oral Effects for COPCs. The oral reference dose used for mercury in the risk calculations does not appear in the table and should. It was determined that $3x10^{-4}$ mg/kg-day was used ($3x10^{-4}$ mg/m^3 is the reference concentration for chronic inhalation exposure reported by IRIS). This should be verified and included here. For inhalation, please assume elemental mercury (also because there is no RfC for methylmercury or mercuric chloride), which has a RfC of 3×10^{-4} mg/m^3.

Response 118.
- The oral reference dose for mercury, $3x10^{-4}$ mg/kg-day, is presented in RAGS D Table 5.1 (Attachment C).
- The non-cancer RfC of 3×10^{-4} mg/m^3 for mercury inhalation needs to be added the RAGS D Table 5.2. The value was presented as the Extrapolated RfD for mercury.

Comment 119.
Table L-45a only lists an oral RfD for Aroclor 1254. All detected Aroclors should be evaluated quantitatively for non-cancer health effects. Aroclors can be grouped as either low molecular weight PCBs, for which the RfD for Aroclor 1016 should be used; or high molecular weight PCBs, for which the RfD for Aroclor1254 should be used.

Response 119.
As presented in the response to Comment #66 above: Detected Aroclors were evaluated quantitatively for cancer and non-cancer health effects in the attached tables. Aroclors were grouped as low molecular weight PCBs, for which the RfD for Aroclor 1016 was used (Aroclors 1016, 1242, 1248) and high molecular weight PCBs (Aroclor 1254, 1260), for which the RfD for Aroclor1254 was used. This approach is consistent with the recommendation provided by NYSDEC in Comment 119. The RAGS D Table 7 and 9 series correct PCB risk calculations that were not completely addressed in the revised HHRA. As indicated in the response to Comment #66, these data will be presented in a revised HHRA report. Tables 1 and 2, attached, provide a comparison of the risk values presented in the HHRA report and the revised values based on the inclusion of additional Aroclors. In general, the revised risk values do not change the interpretation of risk at the site. These revisions will be incorporated into the final HHRA report to be submitted subsequent to NYSDEC review of the October 2004 revised HHRA.

Comment 120.
Table L-46a. The CSF for 2,3,7,8-TCDD (listed as "TEQ" on the table) is published in HEAST (*i.e.*, source is not "NA").

Response 120.
For the CSF of 2,3,7,8-TCDD (listed as "TEQ" on the table), ASTDR is referenced in the revised HHRA.

Comment 121.
Table L-47 has GI efficiency, dermal absorption factors, and permeability coefficients for about 110 chemicals. Are there really that many dermal COPCs at Willis Ave? Also, there appears to be no explanation of footnote 1 (permeability coefficient table) nor any indication as to what reference "RAIS 2001" is.

Response 121.
In the revised HHRA, Table L-1 presents the GI efficiency, dermal absorption factors and permeability coefficients. A footnote has been added to identify the reference for RAIS 2004 as Oak Ridge National Laboratory.

Comment 122.
Table L-48. This table appears to contain extraneous or irrelevant information. However, non-cancer effects of Aroclors should be quantitated as noted in comments on L-45a. An RfD should be listed for mercury. For chronic exposure (excluding exposure to elemental or free mercury or its vapors) the toxicity of inorganic mercury can be assessed using the RfD for mercuric chloride.

Response 122.
RAGS D Table 5 and 6 series tables, Attachment C, present toxicity data. Non-cancer effects of Aroclors were addressed as discussed in the response to Comment #66, above. Inorganic mercury was addressed using the RfD for mercuric chloride, as requested.

Comment 123.
Table L-49. The USEPA relative potency factors for carcinogenic PAHs (Provisional Guidance for Quantitative Risk Assessment of Polycyclic Aromatic Hydrocarbons, EPA/600/R-93/089, USEPA 1993) should be used to derive appropriate CSFs for benzo(a)anthracene, benzo(b) and (k)fluoranthene, chrysene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene. Appropriate surrogates for Aroclor 1268 would be 'total PCBs' for cancer effects, and 'high molecular weight PCBs' (*i.e.*, RfD for Aroclor 1254) for non-cancer effects (see comment on L-45a).

Response 123.
Table L-5 presents relative potency factors for carcinogenic PAHs, as requested. PCBs were addressed as discussed in the responses to Comments 66 and 119.

Tables L-50a through L-59b, Cancer Risk and Hazard Index Calculation Tables
The subject tables have been replaced by RAGS D Tables 7.1 through 7.10, Attachment C.

Comment 124.
Quantitative risk calculations have been developed at other Onondaga subsites for some compounds that were dropped in this report, even though they had been flagged as COPCs. For example, in Table L-51a, some PAH compounds were dropped, when compared to L-13a, where they were flagged as COPCs.

Response 124.
The requested change has been addressed.

Comment 125.
The RAGS format should be followed to allow for a more logical progression of listing to screening to COPCs for which EPCs are calculated for quantitative assessment. 'Nutrients' may be screened out although there are only a few inorganics for which this is an option. However, it appears that this HHRA omits some other COPCs for which quantitative risks should have been calculated.

Response 125.
The requested change has been addressed.

Tables L-60 through L-69, Cancer Risk and Hazard Index Summary Tables
The subject tables have been replaced by RAGS D Tables 9.1 through 9.10, Attachment C.

Comment 126.
These tables should be modified/updated as needed to reflect changes made elsewhere to the document and calculations.

Response 126.
The requested change has been addressed.

Figures

Comment 127.
General. The figures in general help clarify the exposure areas addressed in this HHRA. However, there a few items that still should be addressed as follows:

- There is no differentiation between former structures and current structures (for example, in the general plant area the extant guardhouse is not differentiated from all the structures which have been demolished).

- For a few structures, there seem to be conflicting outlines and locations, based on partially overlapping outlines. Specifically, the plant area guardhouse and the two General Chemical buildings seem to be affected.

- There is a symbol associated with a number of samples that is typical of a test pit designation, but there is no 'test pit' designation in the sample key. Also, on Figure L-6, there are three of these possible test pits with the same ID (006 MA. TP2); please explain or correct.

- The extent of paved surfaces is discussed in the text but not shown on the figures.

- Figure L-11 - Is the sample type designation for CHSA #5 correct? (It is shown as a 'surface soil' but all the other CHSA samples are shown as 'soil boring'.)

- Manholes are listed in the sample location key (and shown on the figures) but no data from manholes is discussed or presented. Please clarify.

- There are several clarifications required to support the text in Section 4. These clarifications should be provided and the figures should be revised, if necessary.

Response 127.
The requested changes to the figures have been addressed.

Attachment L-C, Subsurface Migration to Indoor Air; Conceptual Scenario and Concentrations

Comment 128.
The model was not used for mercury, even though the model is capable of predicting indoor concentrations for elemental mercury. The model was not used to model many of the other volatile and semivolatile organic contaminants known to be present at the site (e.g., some of the PAHs).

Response 128.
The Tables in L-B2 (formerly Tables L-C) have been amended to evaluate indoor air concentrations for applicable COCs.

Comment 129.
Use of Soil Vapor Advanced Models. The soil model run (for the CHSA) contained a concentration error.

Response 129.
The current version of the USEPA spreadsheets for the Johnson & Ettinger Model do not support the bulk soil concentration module for deriving indoor air concentrations. Therefore, model runs based on bulk-soil concentrations have been removed, as discussed in the response to Comment 99.

Advanced Groundwater Model for Benzene at Chlorobenzene Hot Spot Area

Comment 130.
According to the front sheet, the groundwater concentration was 5,500 g/L; however, in the subsequent sheets the concentration used was 25,000 g/L.

Response 130.
The maximum detected ground water concentration of benzene in the General Plant Area was 3,900 g/L. Areas that were evaluated outside of the General Plant Area consisted of the Chlorobenzene Hot-Spot Area and the Petroleum Storage Area. In those areas, the maximum detected concentrations of benzene were 5,500 g/L and 4,400 g/L, respectively. The revised HHRA incorporated those values.

Advanced Groundwater Model for Chlorobenzene at Chlorobenzene Hot Spot Area

Comment 131.
Using all of Honeywell's assumptions, the indoor concentration was modeled to be 2.8 g/m^3. The following default values were changed, and not mentioned any where in the text based on benzene.

Parameter	Relation to Indoor Concentration	Default	Value used	Effect on Indoor Concentration (if default were used)
Depth Below Grade to Bottom of Enclosed Floor	Direct Relationship	15 or 200 cm	10 cm	15 cm yields 2.8 g/m^3 200 yields 5.1 g/m^3
Soil Total Porosity	Direct Relationship	0.43	Layer A - 0.375 Layer B - 0.439*	0.43 yields 5.3 g/m^3

*Layer A is sand and layer B is silt loam

Response 131.
The USEPA spreadsheet Johnson & Ettinger models have been updated since the 2002 HHRA was submitted. The current report reflects the updated J&E model and incorporates site-specific values, where appropriate.

Advanced Soil Model for Benzene at General Plant Area

Comment 132.
Unlike the soil screening tables, these have the correct units for the soil concentrations (g/kg) for the model.

The same two parameters (depth below grade of building, and soil porosity) were also changed from the defaults in this model run, although neither change drastically changes the final concentration. The fraction organic content (f_{oc}) was left at the default model values (the values are set at defaults of 6% and 3%); however, site-specific TOC data (*e.g.*, obtained for the BERA or for groundwater modeling and fate-and-transport assessments) should be used in place of generic defaults where possible.

Response 132.
The current version of the USEPA spreadsheets for the Johnson & Ettinger Model do not support the bulk soil concentration module for deriving indoor air concentrations. Therefore, model runs based on bulk-soil concentrations have been removed, as discussed in the response to Comment 99.

FOREWORD

The purpose of this Toxicological Review is to provide scientific support and rationale for the hazard and dose-response assessment in IRIS pertaining to chronic exposure to 2-hexanone. It is not intended to be a comprehensive treatise on the chemical or toxicological nature of 2-hexanone.

The intent of Section 6, *Major Conclusions in the Characterization of Hazard and Dose Response,* is to present the major conclusions reached in the derivation of the reference dose, reference concentration, and cancer assessment, where applicable, and to characterize the overall confidence in the quantitative and qualitative aspects of hazard and dose response by addressing the quality of data and related uncertainties. The discussion is intended to convey the limitations of the assessment and to aid and guide the risk assessor in the ensuing steps of the risk assessment process.

For other general information about this assessment or other questions relating to IRIS, the reader is referred to EPA's IRIS Hotline at (202) 566-1676 (phone), (202) 566-1749 (fax), or hotline.iris@epa.gov (email address).

1. INTRODUCTION

This document presents background information and justification for the Integrated Risk Information System (IRIS) Summary of the hazard and dose-response assessment of 2-hexanone. IRIS Summaries may include oral reference dose (RfD) and inhalation reference concentration (RfC) values for chronic and less-than-lifetime exposure durations, and a carcinogenicity assessment.

The RfD and RfC, if derived, provide quantitative information for use in risk assessments for health effects known or assumed to be produced through a nonlinear (presumed threshold) mode of action. The RfD (expressed in units of mg/kg-day) is defined as an estimate (with uncertainty spanning perhaps an order of magnitude) of a daily exposure to the human population (including sensitive subgroups) that is likely to be without an appreciable risk of deleterious effects during a lifetime. The inhalation RfC (expressed in units of mg/m^3) is analogous to the oral RfD, but provides a continuous inhalation exposure estimate. The inhalation RfC considers toxic effects for both the respiratory system (portal-of-entry) and for effects peripheral to the respiratory system (extrarespiratory or systemic effects). Reference values are generally derived for chronic exposures (up to a lifetime), but may also be derived for acute (#24 hours), short-term (greater than 24 hours to 30 days), and subchronic (greater than 30 days to 10% of average lifetime) exposure durations, all of which are derived based on an assumption of continuous exposure throughout the duration specified. Unless specified otherwise, the RfD and RfC are derived for chronic exposure duration.

The carcinogenicity assessment provides information on the carcinogenic hazard potential of the substance in question and quantitative estimates of risk from oral and inhalation exposure may be derived. The information includes a weight-of-evidence judgment of the likelihood that the agent is a human carcinogen and the conditions under which the carcinogenic effects may be expressed. Quantitative risk estimates may be derived from the application of a low-dose extrapolation procedure. If derived, the oral slope factor is an upper bound on the estimate of risk per mg/kg-day of oral exposure. Similarly, a unit risk is an upper bound on the estimate of risk per $\mu g/m^3$ air breathed.

Development of these hazard identification and dose-response assessments for 2-hexanone has followed the general guidelines for risk assessment as set forth by the National Research Council (1983). EPA guidelines and technical reports that may have been used in the development of this assessment include the following: *Guidelines for Mutagenicity Risk Assessment* (U.S. EPA, 1986), *Guidelines for Developmental Toxicity Risk Assessment* (U.S. EPA, 1991), *Guidelines for Reproductive Toxicity Risk Assessment* (U.S. EPA, 1996), *Guidelines for Neurotoxicity Risk Assessment* (U.S. EPA, 1998a), *Guidelines for Carcinogen Risk Assessment* (U.S. EPA, 2005a), *Supplemental Guidance for Assessing Susceptibility from Early-*

Life Exposure to Carcinogens (U.S. EPA, 2005b), *Recommendations for and Documentation of Biological Values for Use in Risk Assessment* (U.S. EPA, 1988), *Methods for Derivation of Inhalation Reference Concentrations and Application of Inhalation Dosimetry* (U.S. EPA, 1994), *Use of the Benchmark Dose Approach in Health Risk Assessment* (U.S. EPA, 1995a), *Science Policy Council Handbook: Peer Review* (U.S. EPA, 2006, 2000a, 1998b), *Science Policy Council Handbook*: *Risk Characterization* (U.S. EPA, 2000b), and *Benchmark Dose Technical Guidance Document* (U.S. EPA, 2000c).

The literature search strategy employed for this compound was based on the Chemical Abstracts Registry Service Number (CASRN) and at least one common name. Any pertinent scientific information submitted by the public to the IRIS Submission Desk was also considered in the development of this document. The relevant literature was reviewed through March 2007.

2. CHEMICAL AND PHYSICAL INFORMATION

Structurally, 2-hexanone consists of a keto group flanked by a methyl group and an n-butyl group (Figure 2-1). The compound is a colorless liquid with a characteristic acetone-like odor but more pungent (NLM, 2005). Synonyms for 2-hexanone include the following: methyl butyl ketone, methyl n-butyl ketone, butyl methyl ketone, MnBK, and propylacetone.

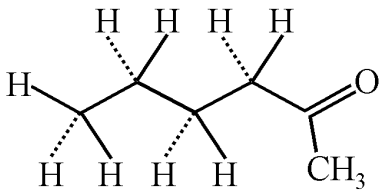

Figure 2-1. Chemical structure of 2-hexanone.

Pertinent physical and chemical properties of 2-hexanone are listed below (NLM, 2005).

Chemical formula	$C_6H_{12}O$
Molecular weight	100.16
Melting point	–55.5°C
Boiling point	127.6°C
Flash point	23°C
Density	0.8113 at 20°C
Water solubility	1.64×10^4 mg/L at 20°C
Log K_{ow}	1.38
Vapor pressure	11.6 mm Hg at 25°C
Conversion factor	1 ppm = 4.1 mg/m^3; 1 mg/m^3 = 0.244 ppm

2-Hexanone is produced commercially by the catalyzed reaction of acetic acid and ethylene under pressure followed by distillation to purify the material (NLM, 2005). The compound has been used as a solvent for lacquers, ink thinners, nitrocellulose, resins, oils, fats, and waxes. It is a medium evaporating solvent for nitrocellulose acrylates, vinyl, and alkyd coatings (polyester coating derived from an alcohol and an acid or acid anhydride).

In 1977, the combined production and import of 2-hexanone in the U.S. was between 453 and 4500 metric tons (NLM, 2005); no breakdown of these figures was provided. The only U.S. producer of 2-hexanone, the Tennessee Eastman Company division of Eastman Kodak, discontinued production of 2-hexanone in 1979 and sold its remaining reserves by 1981 (NLM,

2005). 2-Hexanone is not produced or used in the U.S., and no information on importation is available (ATSDR, 1992).

3. TOXICOKINETICS

3.1. ABSORPTION

3.1.1. Pulmonary Absorption Studies

The available data indicate that 2-hexanone is well absorbed after administration via the inhalation route. DiVincenzo et al. (1978) exposed three healthy male volunteers (ages 22 to 53 years) to 2-hexanone (>97% pure, containing methyl isobutyl ketone [MiBK] and traces of 2-hexanol) at 10 or 50 ppm for 7.5 hours or 100 ppm for 4 hours. The 7.5-hour exposures were interrupted after 4 hours for a 0.5-hour lunch period. The volunteers were sedentary during the exposure. Expired air and venous blood samples were collected before, during, and after exposure. Exposures to 10 and 50 ppm for 7.5 hours produced mean 2-hexanone breath concentrations of 1.4 and 9.3 ppm, respectively. Fifteen minutes after exposure to 10 or 50 ppm, the expired air concentrations of 2-hexanone were 0.1 and 0.5 ppm, respectively. Exposure to 100 ppm for 4 hours produced an average 2-hexanone breath concentration of 22 ppm. These results indicated that between 75 and 92% of the inhaled 2-hexanone vapor was absorbed by the lungs and respiratory tract (DiVincenzo et al., 1978). 2-Hexanone was not detected in the expired air 3 hours after cessation of exposure to 50 or 100 ppm 2-hexanone.

DiVincenzo et al. (1978) exposed four young male beagles to 2-hexanone (>97% pure, containing MiBK and traces of 2-hexanol) for 6 hours at concentrations of 50 or 100 ppm. Over the first 4 hours of the exposure period, the hexanone in exhaled air had time-weighted average concentrations of 16 and 35 ppm for the low and high exposure groups, respectively. Thirty minutes after cessation of exposure to 50 ppm 2-hexanone, the breath concentration of 2-hexanone decreased to 0.7 ppm. 2-Hexanone was below the limit of detection by 3 to 5 hours after the exposure. It was determined that about 65–68% of the inhaled vapor was absorbed by the lungs.

3.1.2. Gastrointestinal Tract Absorption Studies

2-Hexanone appears to be well absorbed after oral administration. DiVincenzo et al. (1978) administered 2 µCi of 1-[^{14}C]-hexanone dissolved in corn oil via a gelatin capsule to human volunteers; the total dose was 0.1 mg/kg. Most of the 2-hexanone-derived radioactivity was exhaled as $^{14}CO_2$, reaching a peak within 4 hours of dosing and then decreasing slowly over the next 3 to 5 days. The major portion of radioactivity excretion in urine occurred during the first 48 hours but continued at measurable levels until 8 days after dosing. The cumulative 8-day elimination of radioactivity in breath and urine averaged 39.5 and 26.3%, respectively. The overall recovery of ^{14}C was 65.8%. The authors presumed that the remainder of the radioactivity was retained in tissue or fat deposits.

Administration of 1-[^{14}C]-2-hexanone at 20 or 200 mg/kg by gavage to rats resulted in excretion of about 1.1% of the administered radioactivity in the feces, about 44% in the breath, and 38% in urine, with about 15% remaining in the carcass after 48 hours and 8% remaining after 6 days (DiVincenzo et al., 1977). The results were similar at either dose level. These findings suggest that about 98% of the administered dose was absorbed via the gastrointestinal tract.

3.1.3. Dermal Absorption Studies

2-Hexanone is also absorbed after dermal application. DiVincenzo et al. (1978) exposed six human volunteers (ages 30–53 years) to radiolabeled 1-[^{14}C]-2-hexanone (>97% purity, contaminants not stated). The labeled compound was applied to the ventral surface of the forearm that had been shaved 24 hours prior to testing. 1-[^{14}C]-2-hexanone was held in contact with the skin for 60 minutes, and precautions were taken to ensure that inhalation exposure did not occur. The surface area of the skin subjected to solvent was 55.6 cm^2. Calculated skin absorption rates were 4.8 and 8.0 µg/cm^2-minute. The quantities of 2-hexanone absorbed by two volunteers were 15.96 and 26.81 mg, respectively. The major respiratory excretion metabolite of 1-[^{14}C]-hexanone was $^{14}CO_2$. A substantial portion of the dose was also excreted in urine; however, the chemical nature of urinary radioactivity was not characterized further.

In a similar set of experiments, DiVincenzo et al. (1978) applied 1-[^{14}C]-2-hexanone (>97% purity, impurities not stated) to the clipped thorax (55.6 cm^2) of beagles. Exposures were carried out for 5 minutes to 1 hour. By 5 minutes, 11 mg of 2-hexanone had penetrated the skin, and there was no apparent change in the absorption of 2-hexanone during the next 15 minutes. However, after 20 minutes the absorption increased markedly so that, by 60 minutes, 77 mg of 2-hexanone had penetrated the skin. The 8-hour cumulative excretion of radioactivity in two dogs dosed with 1-[^{14}C]-2-hexanone was 0.5% of the dose as unchanged 2-hexanone and 9.7% as $^{14}CO_2$ in the breath; urinary radioactivity amounted to 6.5% of the dose. The 8-hour excretion of radioactivity averaged 16.8% of the dose. The fraction of the applied 2-hexanone dose that was absorbed was not calculated.

O'Donoghue and Krasavage (1981) exposed two male beagles (one of which was pretreated with 2-hexanone) to 2-hexanone by tail dipping. Both dogs were exposed to 2-hexanone on an area of 22 cm^2 on the first day of exposure, and then the exposure area was doubled on the second day (44.1 cm^2). It was found that by 8–12 minutes, both dogs had comparable serum levels of 2-hexanone. Doubling the exposed area increased serum levels of 2-hexanone 6 to 20 times. None of the blood samples contained detectable levels of the 2-hexanone metabolites 5-hydroxy-2-hexanone, 2,5-hexanedione, or 2,5-hexanediol. Similar exposures were repeated with three different dogs for 16 minutes followed by two post exposure samples 9 and 19 minutes later (25 and 35 minute samples, respectively). One animal had detectable levels of 2-hexanone in blood within 4 minutes, but the time to detectable levels was

highly variable among the animals. The highest level observed was 3.2 µg/mL. Nineteen minutes post exposure serum levels of 2-hexanone were still detectable. Twenty-four hours later, no 2-hexanone was detected (O'Donoghue and Krasavage, 1981).

To examine the effects of multiple exposures, O'Donoghue and Krasavage (1981) exposed three male dogs as above to 2-hexanone on two occasions 4 hours apart. Samples obtained after the second treatment were not significantly different from the morning samples, indicating the absence of accumulation of detectable 2-hexanone and 2,5-hexanedione levels in the serum.

O'Donoghue and Krasavage (1981) performed comparison studies on percutaneous absorption of 2-hexanone between dog and rabbit skin. Significantly more 2-hexanone was absorbed through rabbit skin compared with dog skin and probably, as a consequence, the metabolite 5-hydroxy-2-hexanone was detected in the serum of rabbits. Overall, the skin studies indicated that 2-hexanone was readily absorbed through the skin; detectable serum levels were present after approximately 10 minutes of exposure to less than 1% of body skin surface; detectable serum levels persisted for approximately 20 minutes post exposure; and, in rabbits, a metabolite (5-hydroxy-2-hexanone) was rapidly formed and detectable in the serum.

3.2. DISTRIBUTION

Duguay and Plaa (1995) treated male Sprague-Dawley rats by gavage with 2-hexanone (>99%, spectrophotometric grade) at 0.5, 1, or 2 mmol/kg (50, 100, or 200 mg/kg) in corn oil (dose volume 10 mL/kg), once daily for 3 days. The animals were sacrificed 1 hour after the last gavage. Dose-dependent increases in plasma and lung 2-hexanone levels were observed, whereas the concentration in the liver increased only with the highest dose (Table 3-1). Calculations for statistically significant differences among dose groups were not performed (Duguay and Plaa 1995).

Table 3-1. Concentrations of 2-hexanone in plasma, liver, and lung of male rats following oral exposure for 3 days

Tissue concentration	Dose		
	0.5 mmol/kg	1 mmol/kg	2 mmol/kg
Plasma (µg/mL)	2.4 ± 1.2	4.7 ± 1.1	8.5 ± 2.0
Liver (µg/g)	1.7 ± 0.5	1.6 ± 0.3	3.8 ± 1.2
Lung (µg/g)	1.1 ± 0.7	4.9 ± 1.1	13.9 ± 4.9

Source: Duguay and Plaa (1995).

In a parallel series of experiments from the same study, Duguay and Plaa (1995) exposed male Sprague-Dawley rats to a total body exposure of 2-hexanone at concentrations of 75, 150, or 300 ppm (307.5, 615, or 1230 mg/m^3). Animals were exposed on 3 consecutive days for 4 hours per day. Animals were sacrificed immediately after the last exposure on the third day.

The concentration of 2-hexanone in plasma, liver, and lung increased in a dose-dependent manner (Table 3-2). It should be noted, however, that because whole body exposures were performed, some oral and dermal absorption may have taken place.

Table 3-2. Concentrations of 2-hexanone in plasma, liver, and lung of male rats following inhalation exposure for 3 days

Tissue concentration	Dose		
	75 ppm	150 ppm	300 ppm
Plasma (µg/mL)	1.2 ± 0.3	2.6 ± 0.7	9.7 ± 0.7
Liver (µg/g)	0.7 ± 0.5	1.2 ± 0.8	2.2 ± 0.4
Lung (µg/g)	0.7 ± 0.2	2.8 ± 0.5	9.3 ± 1.2

Source: Duguay and Plaa (1995).

In male CD/COBS rats administered a single gavage dose of [^{14}C]-2-hexanone at 200 mg/kg, the serum elimination for 2-hexanone was 6 hours; the 2-hexanone metabolites 5-hydroxy-2-hexanone and 2,5-hexanedione were eliminated from serum within 12 and 16 hours, respectively (DiVincenzo et al., 1977). Peak concentrations of 2-hexanone and 5-hydroxy-2-hexanone were reached at 2 hours, whereas the peak concentration of 2,5-hexanone was reached at 6 hours. Radioactivity was detected in most tissues with highest counts in liver > kidney > whole brain. The peak concentration of radiolabel in each of these tissues was observed at 4 hours and was reduced to less than 50% by 24 hours. No quantitative data were given on tissue distribution. An analysis of the subcellular distribution of the ^{14}C-label in liver, brain, and kidney tissue homogenates indicated the highest counts were associated with the protein fraction, with some recovery from DNA and little or none from RNA.

Eben et al. (1979) treated male SPF-Wistar rats with 400 mg/kg 2-hexanone (98% pure, impurities not stated) daily by stomach tube for 40 weeks. The concentrations of 2-hexanone and metabolites in the blood were determined at intervals of 4 or 5 weeks. In the case of 2-hexanone, the maximum concentration was reached 1 hour after administration throughout the study; thereafter, the concentration decreased rapidly. After 7 hours, only trace amounts could be detected. During the first few weeks of the study, 2-hexanone could not be found in the urine. Only during the third week were very small concentrations of the free compound detected in urine, suggesting that the metabolic pathways for 2-hexanone were becoming saturated. A maximum (approximately 20 µg) was reached in the 17th week (Eben et al., 1979).

Granvil et al. (1994) studied the distribution and disappearance of 2-hexanone (purity not stated) from the blood and brain. Male CD-1 mice were treated with 5 mmol/kg (500 mg/kg) 2-hexanone dissolved in corn oil by intraperitoneal (i.p.) injection at a volume of 10 mL/kg. Animals were killed by decapitation, and blood and brain samples were collected at 15, 30, 60, and 90 minutes after treatment. Blood and brain concentrations at 15 minutes were ~182 µg/mL

and ~126 µg/g, respectively. By 90 minutes, the values had dropped in a uniform manner to a blood concentration of ~28 µg/mL and a brain concentration of ~25 µg/mg. The authors noted that the rapid decrease in the concentration of 2-hexanone was due to its active metabolism in these tissues (Granvil et al., 1994).

3.3. METABOLISM

2-Hexanone is hydroxylated to 5-hydroxy-2-hexanone, which is then either oxidized to 2,5-hexanedione or reduced to 2,5-hexanediol and, to a small extent, may be converted to 2,5-dimethyl-2,3-dihydrofuran. The predominant metabolite of 2-hexanone found in blood is 2,5-hexanedione. This can be reduced to 5-hydroxy-2-hexanone and further, but to a lesser extent, to 2,5-hexanediol. The formation of 2,5-hexanedione is favored over that of 5-hydroxy-2-hexanone. 5-Hydroxy-2-hexanone can be metabolized into 4,5-dihydroxy-2-hexanone (not shown in Figure 3-1) before being further converted to 2,5-dimethyl-2,3-dihydrofuran. Additionally, 4,5-dihydroxy-2-hexanone formation may be a result from 2,5-hexanedione metabolism (U.S. EPA, 2005c). Other mechanisms, such as shunting into intermediary metabolism, may accelerate metabolic clearance of 2,5-hexanedione. Reductive metabolism of 2-hexanone results in the formation of 2-hexanol, establishing an equilibrium between the two compounds. 2-Hexanol can be further metabolized to 2,5-hexanediol, 5-hydroxy-2-hexanone, and 2,5-hexanedione. The findings of Abdel-Rahman et al. (1976) that rats, guinea pigs, and rabbits exposed to 2-hexanone vapor excreted glucuronides of 2-hexanol and 2,5-hexanediol in the urine are consistent with the results by DiVincenzo et al. (1976), discussed later in this section (Abdel-Rahman et al., 1976). Although the proportions of metabolites may differ among species, ω-1-oxidation and carbonyl reduction appear to be the initial steps in the metabolism of 2-hexanone in all species tested so far (e.g., rat, cat, dog, guinea pig, and human). The metabolic pathway for 2-hexanone, as proposed by DiVincenzo et al. (1977, 1976), based on 2-hexanone metabolites identified in blood of guinea pigs, mice, and rats, is presented in Figure 3-1.

As discussed in Section 3.2, Duguay and Plaa (1995) conducted studies using male Sprague-Dawley rats exposed to 2-hexanone by gavage (0.5, 1, or 2 mmol/kg) or by inhalation (75, 150, or 300 ppm) and quantified the metabolites in the plasma, liver, and lung. The authors reported that the concentrations of metabolites, such as 2-hexanol, 5-hydroxy-2-hexanone, and 2,5-hexanedione, were readily detectable in serum. After 2-hexanone gavage or inhalation, 2-hexanol was found in low concentrations in plasma and liver (0.5–1.3 µg/mL and 0.3–1.6 µg/g, respectively). In lung, however, concentrations ranged from 2.1 to 5.1 µg/g. However, with both routes of administration, 2-hexanol concentrations did not appear to be dose dependent.

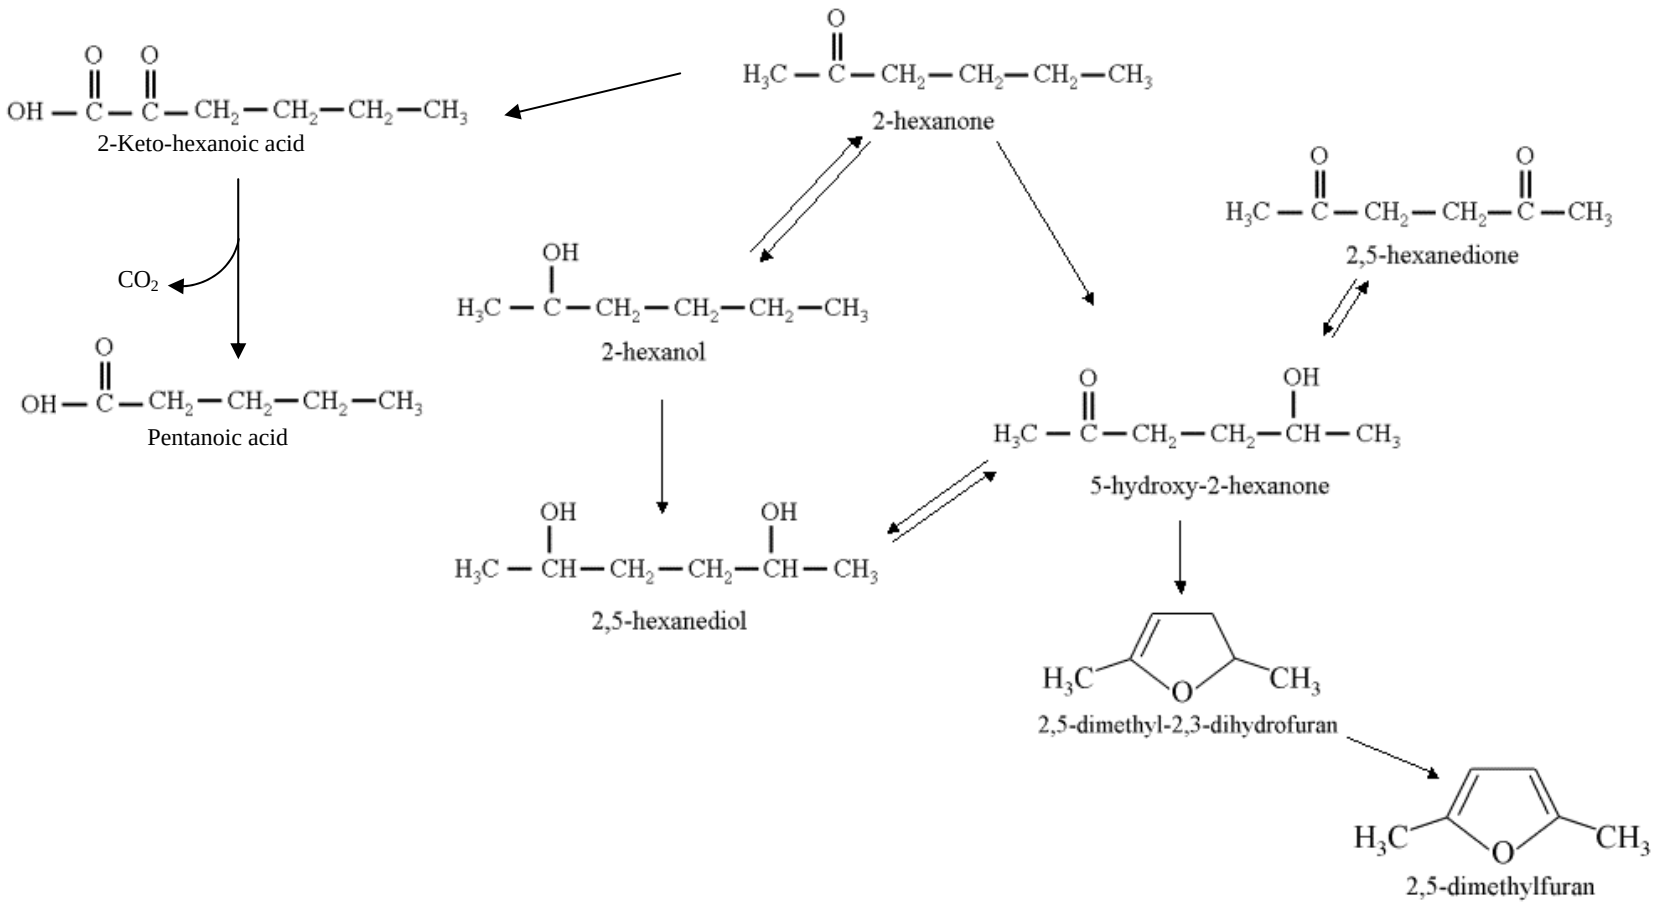

Figure 3-1. Proposed metabolic pathway for 2-hexanone.

Adapted from DiVincenzo et al. (1977, 1976).

The appearance of the 2-hexanone metabolite 2,5-hexanedione in plasma or lung, but not in liver, depended on the route of administration. The highest dose and concentration of 2-hexanone, 2 mmol/kg and 300 ppm, respectively, produced similar plasma 2-hexanone concentrations, 8.5 and 9.7 µg/mL, respectively, but the corresponding plasma 2,5-hexanedione concentrations were 7.7 µg/mL after oral and 25 µg/mL after inhalation administration. 2,5-Hexanedione was not detectable in lungs when 2-hexanone was administered orally, but significant dose-dependent amounts were found following inhalation exposure. The authors concluded that pulmonary 2-hexanone metabolism might contribute to plasma metabolite levels. 2,5-Hexanedione concentrations in liver were dose dependent but independent of the route of administration. A summary of the metabolite levels found in the plasma, liver, and lung following oral and inhalation exposures is presented in Table 3-3.

Eben et al. (1979) administered daily oral doses of 2-hexanone (400 mg/kg) over a 40-week period to male SPF-Wistar rats. The concentrations of 2-hexanone, 2-hexanol, and 2,5-hexanedione were determined in the blood at several intervals every 4 or 5 weeks. 2-Hexanone concentrations in blood peaked at 1 hour after administration then decreased rapidly, and after 7 hours only traces could be detected. The metabolite 2-hexanol was measurable in very small quantities up to 3 hours after administration (<2 µg/mL blood). In contrast, 2,5-hexanedione concentrations were relatively high as early as 1 hour after

administration, and maximum values were recorded after 5 or 7 hours. 2,5-Hexanediol was not detectable in the blood at any time. A summary of the blood concentrations of 2-hexanone, 2-hexanol, and 2,5-hexanedione is presented in Table 3-4.

Granvil et al. (1994) demonstrated the rapid removal of 2-hexanone from blood and brain of male CD-1 mice following a single i.p. injection of the compound at a concentration of 5 mmol/kg. The authors observed that 2-hexanol concentrations found in whole brain at several time intervals (15, 30, and 60 minutes after dosing) were about twice as high as those found in the blood at the same time intervals and interpreted this finding as suggesting that 2-hexanol might be formed in the brain. Furthermore, the authors reported that the appearance of the reduced metabolite 2-hexanol seemed to be considerably faster than the appearance of the oxidized metabolite 2,5-hexanedione.

DiVincenzo et al. (1976) administered a single dose of 2-hexanone (450 mg/kg i.p. in corn oil) to male guinea pigs (strain not stated). Blood was collected by heart puncture from four animals at 1, 2, 4, 6, 8, 12, and 16 hours after dosing. In addition to 2-hexanone, three major metabolites were identified by gas chromatography: 5-hydroxy-2-hexanone, 2,5-hexanedione, and 2-hexanol. 2,5-Dimethyl-2,3-dihydrofuran was also detected, but additional experiments revealed that this was an artifact because 5-hydroxy-2-hexanone underwent dehydration and cyclization in the gas chromatograph. The authors noted that 5-hydroxy-2-hexanone may be

transformed also in vivo to 2,5-dimethyl-2,3-dihydrofuran, but the equilibrium favors the formation of 5-hydroxy-2-hexanone.

DiVincenzo et al. (1976) also conducted follow-up studies to determine the metabolic fate of 2-hexanone metabolites in guinea pigs. Each of the principal metabolites identified in the above study (5-hydroxy-2-hexanone, 2,5-hexanedione, 2,5-hexanediol, and 2-hexanol) was administered individually (450 mg/kg i.p.). 5-Hydroxy-2-hexanone was further metabolized to 2,5-hexanedione and 2,5-hexanediol. The half-life of 5-hydroxy-2-hexanone in serum was 156 minutes. The major metabolite 2,5-hexanedione was formed rapidly, and its concentration in serum was equivalent to or greater than that of the parent compound (5-hydroxy-2-hexanone) in all samples measured. Serum concentrations of 2,5-hexanediol were markedly lower than those of 2,5-hexanedione. 5-Hydroxy-2-hexanone was the only metabolite detected in serum of guinea pigs after an i.p. injection of 2,5-hexanedione. The half-life of 2,5-hexanedione was 100 minutes. Both 5-hydroxy-2-hexanone and 2,5-hexanedione were no longer detectable in serum by 16 hours. The principal metabolites in serum after i.p. injection with 2,5-hexanediol were 5-hydroxy-2-hexanone and 2,5-hexanedione. 2,5-Hexanediol was cleared within 8 hours and had a half-life of 84 minutes in serum. The following metabolites were identified after the administration of 2-hexanol: 2-hexanone, 5-hydroxy-2-hexanone, 2,5-hexanedione, and 2,5-hexanediol. The half-life and clearance time of 2-hexanol were 72 minutes and 6 hours, respectively.

The authors noted that the 2-hexanol was rapidly metabolized to 2-hexanone, which, in turn, was converted to the same metabolites identified above for animals treated with 2-hexanone. They determined that the conversion of 2-hexanol to 2,5-hexanediol seemed to be a minor pathway. The metabolites, 2,5-hexanediol and 2,5-hexanedione, were cleared in 8 and 16 hours, respectively. A summary of the half-life and clearance time of 2-hexanone and metabolites is presented in Table 3-5.

Table 3-5. Serum half-lives and clearance times of 2-hexanone and its metabolites in guinea pigs

Compound administered	Half-life (minutes)[a]	Clearance time (hours)
2-Hexanone	78	6
2-Hexanol	72	6
5-Hydroxy-2-hexanone	156	8[b]
2,5-Hexanedione	100	16
2,5-Hexanediol	84	8

Bus et al. (1981) presented metabolism data for n-hexane that provide some insight on the metabolism of 2-hexanone. In the study, the authors exposed male F344 rats for 1 or 5 days, 6 hours/day, to 1000 ppm n-hexane. Animals were sacrificed immediately after exposure or at increasing time intervals for up to 24 hours after the end of exposure, and concentrations of the parent compound and two of its metabolites, 2-hexanone and 2,5-hexanedione, were measured in blood, liver, kidney, brain, and sciatic nerve. Kinetics of all three compounds were similar after 1 and 5 days of exposure, with tissue levels of the metabolites frequently exceeding those of the parent compound even immediately after the end of exposure. Tissue levels of n-hexane and 2-hexanone were always lower after 5 days of repeated exposures, compared with levels after a single exposure, consistent with self-induction of some metabolizing enzymes. On the other hand, tissue levels of 2,5-hexanedione were always slightly higher after 5 days of exposure, compared with single exposure. A compilation of the data for 2-hexanone and 2,5-hexanedione after 5 days of exposure to n-hexane is given in Table 3-6 (sciatic nerve data not included).

This experiment, although conducted with n-hexane as the parent compound, provides some insight into the metabolism of 2-hexanone. The data shown in Table 3-6 indicate that the metabolism of 2-hexanone to 2,5-hexanedione (intermediates not considered) proceeds rapidly, while the further metabolism of 2,5-hexanedione and its elimination appear to proceed much more slowly. Both the resurgence of 2-hexanone levels in kidney between 8 and 12 hours and the precipitous drop of 2,5-hexanedione levels in kidney between 8 and 12 hours occurred in the same fashion with single exposure, suggesting rather complex compartmentalization and

toxicokinetics that, to some extent, may be governed by the lipophilic characteristics of the compounds. The authors (Bus et al., 1981) suggested that the high levels observed in kidney for both metabolites, but not the parent compound, reflect the fact that the metabolites of n-hexane, and thus 2-hexanone, are mostly eliminated via urine.

Cytochrome P450 (CYP450) enzymes catalyze the initial steps (either detoxification or bioactivation) of 2-hexanone, but their identities have not been investigated to any great detail. Oral administration of 1-[^{14}C]-2-hexanone to humans or rats resulted in the appearance of $^{14}CO_2$ in the exhaled breath, indicating removal of the α-carbon (DiVincenzo et al., 1978, 1977). Administration of SKF525A (a mixed function oxidase inhibitor) to rats before oral administration of 2-hexanone resulted in marked decrease in the respiratory excretion of $^{14}CO_2$ for the first 4 hours after administration, followed by a marked increase at 4–8 and 12–24 hours. This suggests that this oxidative step is mediated by a microsomal mixed-function oxidase system (DiVincenzo et al., 1977).

Because inhalation exposure of humans to 1-[^{14}C]-2-hexanone resulted in the appearance of labeled carbon dioxide in expired air and 2,5-hexanedione in serum, DiVincenzo et al. (1978) hypothesized that the metabolic pathway for 2-hexanone is similar in humans and experimental animals. Metabolically, aliphatic ketones generally are in equilibrium with the corresponding secondary alcohols, which explains the presence of 2-hexanol. An alternate pathway is oxidation of the 5-methylene group to the corresponding alcohol, 5-hydroxy-2-hexanone. Another possibility in the metabolism of 2-hexanone is the cyclization of 5-hydroxy-2-hexanone to the corresponding dihydrofuran and oxidation to 2,5-dimethylfuran (DiVincenzo et al., 1977). However, the formation of these furan moieties may be an artifact resulting from thermal dehydration and cyclization during gas chromatography (DiVincenzo et al., 1977). In addition, the γ-valerolactone found in the urine was hypothesized to result from α-oxidation of 5-hydroxy-2-hexanone to 2-keto-5-hydroxyhexanoic acid, decarboxylation and oxidation to 4-hydroxypentanoic acid, and lactonization to γ-valerolactone (not shown in Figure 3-1) (DiVincenzo et al., 1977).

Although the specific isoforms of CYP450 that catalyze the metabolism of 2-hexanone have not been fully characterized, Nakajima et al. (1991) provided some insight into the effects of 2-hexanone on CYP450 induction. The authors treated male Wistar rats with 2-hexanone at 5 mmol/kg (500 mg/kg) i.p. for 4 days and demonstrated that various CYP450 isozyme activities were induced. 2-Hexanone was effective in inducing several CYP450 isoforms as indicated by the increase in activities of benzene aromatic hydroxylase (CYP2E1) and toluene side chain oxidation (CYP2C6/11) two- to threefold and pentoxyresorufin O-dependentylase (PROD; CYP2B1/2) about 30-fold but barely induced ethoxyresorufin O-deethylase activity (EROD; CYP1A1/2) (Nakajima et al., 1991). Imaoka and Funae (1991) also showed that 2-hexanone induced the immunologically measured levels of several CYP450 isozymes, foremost CYPs 2B1, 2B2, 2C6, and 2E1. Minimal or equivocal induction was observed for CYPs 1A1, 1A2,

2C7, and 4A3. The levels of CYPs 2C11 and 2C13 were slightly reduced (Imaoka and Funae, 1991). However, it is not evident to what extent 2-hexanone might affect its own metabolism via enzyme induction. Similarly, the enzymes that synthesize the glucuronides of 2-hexanone metabolites, which were identified by Abdel-Rahman et al. (1976) in the urine of 2-hexanone-exposed rats, guinea pigs, and rabbits, have not been characterized further.

3.4. ELIMINATION

In humans exposed to 2-hexanone via inhalation at 10 or 50 ppm for 7.5 hours or to 100 ppm for 4 hours, unchanged 2-hexanone (but none of its metabolites) was found in expired air, and neither 2-hexanone nor any of its metabolites was found in urine during or after exposure (DiVincenzo et al., 1978). 2-Hexanone was no longer detected in expired air 3 hours after exposure to 50 or 100 ppm. In two humans who received a single oral dose of 1-[^{14}C]-2-hexanone, breath excretion of $^{14}CO_2$ reached a peak within 4 hours then decreased slowly over the next 3 to 5 days. Average overall recovery of the ^{14}C-label in 8 days was 40% in breath and 26% in urine. Feces were not analyzed (DiVincenzo et al., 1978). These results suggest slow clearance and possibly retention of 2-hexanone in humans exposed by this route.

In beagles exposed to 2-hexanone via inhalation at 50 or 100 ppm for 6 hours, 32 and 35%, respectively, of the inhaled vapor was excreted in the expired breath (DiVincenzo et al., 1978). By 3 to 5 hours after exposure, 2-hexanone was no longer detected in expired air. Excretion via other routes was not addressed.

In rats administered a single oral dose of 1-^{14}C-2-hexanone, DiVincenzo et al. (1977) observed similar results as the above findings in humans. Radioactivity in breath accounted for about 45% of the administered dose (5% was in unchanged 2-hexanone; 40% was in $^{14}CO_2$); 38% was found in urine; 1.1% was recovered in the feces; and about 15% remained in the carcass. In male rats that received daily gavage doses of 2-hexanone at 400 mg/kg-day for 40 weeks, very low concentrations of free 2-hexanone were detected in the urine from the third week on. A maximum concentration of approximately 20 µg was reached in the 17th week (Eben et al., 1979). Similarly, free 2,5-hexanediol was found in the urine after 3 weeks and peaked in the 17th week. Free and conjugated 2,5-hexanedione were present in the 7th week, whereas excretion levels of the free form were consistent throughout the study. A strong correlation was observed in this study between the onset of neuropathy and the urinary concentration of 2,5-hexanedione when 2-hexanone, 2,5-hexanedione, or 2,5-hexanediol was administered orally to rats at 400 mg/kg-day.

Radiolabeled ^{14}C from 1-^{14}C-2-hexanone applied to the forearms of two human volunteers was found in the breath and urine (DiVincenzo et al., 1978). In one subject, eliminated amounts in urine and breath were similar, while, in the other subject, the levels in breath were about three times higher than in urine. Fecal elimination was not measured.

3.5. PHYSIOLOGICALLY BASED TOXICOKINETIC MODELS

2-Hexanone was considered as a metabolite in two physiologically based toxicokinetic (PBTK) models for n-hexane that focus on its neurotoxic metabolite, 2,5-hexanedione (Hamelin et al., 2005; Perbellini et al., 1990). PBTK models that deal specifically with 2-hexanone were not identified. A blood/air partition coefficient of 127 for 2-hexanone measured using preserved human blood has been reported (Sato and Nakajima, 1979).

4. HAZARD IDENTIFICATION

4.1. STUDIES IN HUMANS—CASE REPORTS, EPIDEMIOLOGICAL STUDIES, AND OBSERVATIONAL STUDIES

In humans, 2-hexanone vapor caused irritation of the eyes and respiratory tract during acute exposure to relatively high concentrations. Men exposed to 0.23, 0.65, or 2% 2-hexanone in air (9422, 26,600, or 81,900 mg/m^3) for 1 minute or less reported strong eye and nasal irritation (Schrenk et al., 1936). Moderate eye and nasal irritation was reported after a brief exposure to 0.1% (4100 mg/m^3). Peripheral neuropathy was reported in printers, furniture finishers, and spray painters occupationally exposed to 2-hexanone (Davenport et al., 1976; Mallov 1976; Allen et al., 1974; Billmaier et al., 1974). Several studies have described the occurrence of neurological effects after the introduction of 2-hexanone into products used in the occupational setting.

Davenport et al. (1976) reported the occurrence of symmetrical polyneuropathy in a 35-year-old male who was occupationally exposed to 2-hexanone among other compounds. The patient had worked as a furniture finisher for several years, most recently spraying lacquer compounds, sometimes without using a face mask. Initially, according to the manufacturer, MiBK was present at a concentration of 20% in the finish, 12% in the thinner, and 7% in the sealer. Toluene, xylene, n-butyl alcohol, and acetone were also present in various proportions. After repeated inquiries, the manufacturer disclosed that, for the 6-month period before the onset of the man's illness, 2-hexanone had been substituted for MiBK on a volume-for-volume basis in the formulations of lacquers and solvents because of MiBK supply limitations. The patient first noticed tingling in the soles of his feet and mild clumsiness of gait. Weakness progressed rapidly to the upper extremities, resulting in a wheelchair-bound condition. Three months after the onset of the first symptoms, routine hematology, blood chemistry, urinalysis, spinal fluid, and analysis for heavy metals and porphyrins were normal. A biopsy of the sural nerve[1] at the level of the lateral malleolus revealed diffuse fibrosis and loss of nerve fibers. Several enlarged axons, with and without myelin sheaths, with neurofibrillary tangles were evident. A clinical evaluation 3 months later indicated improved strength and ability to walk unassisted, though with some residual unsteadiness of gait. Tendon reflexes distal to the elbows and knees were still absent. The case report noted that a similar progressive distal extremity weakness developed in a 19-year-old coworker of the patient. This condition also improved following removal from contact with lacquer products.

One probable and two definite cases of 2-hexanone-induced peripheral neuropathy were found during an investigation of 26 painters who worked at Cannelton or nearby Newburgh dams

[1] A sensory nerve that innervates the skin of the back of the leg, and skin and joints on the lateral side of the heel and foot.

on the Ohio River (Mallov, 1976). Two formulations of paint were used. The older formulation contained 22% (weight/weight [w/w]) MiBK and 22% (w/w) methyl isoamyl ketone. In the newer otherwise identical formulation, these solvents were replaced by 44% (w/w) 2-hexanone. While both paint formulations were reported to contain 3.1% (w/w) of the known neurotoxicant triorthocresyl phosphate, this substance was not found in two bulk samples of the 2-hexanone paint formulation. One definite case of peripheral neuropathy was that of a 42-year-old man, a painter for 10 years, who had been painting Cannelton Dam from September 1972 until August 1973. His initial signs, including weight loss, numbness and tingling of feet, and progressive weakness in both lower extremities that progressed to his upper extremities as well, began in July 1973. Weakness progressed until he could no longer stand without assistance. Lower extremity reflexes became absent and an electromyogram was abnormal. Blood and urine lead analysis indicated slightly elevated levels but not sufficient to cause effects. The second case was that of a 35-year-old man who had been painting since he was 14 years old. He painted at Cannelton Dam from April to October 1973. He felt well until about 4 weeks prior to the termination of painting at Cannelton but eventually became unable to rise from a sitting position without help. Urine lead levels were in the lower normal range. The third painter had worked at either Cannelton or Newburgh dam from September 1970 until November 1973. He also felt well until about 4 weeks prior to termination of painting. While he experienced weakness in his extremities, he remained able to walk but reported above-normal episodes of falling and dropping things. He was not examined by a physician until 3.5 months after the onset of symptoms, at which time absent ankle reflex, foot weakness, and diminished sensation were noted. None of the three patients had a history of alcoholism or family history of neurological disease or took medications.

A cross-sectional study of peripheral neuropathy among employees at a coated fabrics plant in Ohio was started when it was noted that six workers from the print department had developed severe peripheral neuropathy (five hospitalized, one seen as outpatient) between April and August 1973 (Allen et al., 1974; Billmaier et al., 1974). The plant produced plastic-coated printed fabrics that were used mainly for wall coverings and automobile interiors. Processing steps included mixing, calendering, laminating, coating, printing, embossing, inspecting, and shipping. Starting in September 1973, all 1157 employees of the plant (including the original six cases) were screened using electromyography and nerve conduction testing. A total of 192 employees were referred for detailed neurological evaluation. On the basis of these examinations, it was concluded that 68 employees had definite signs, symptoms, and electrodiagnostic findings of peripheral neuropathy. Severity ranged from mild (electrodiagnostic findings but no physical symptoms) to moderate (distal sensory loss) to severe (distal muscle weakness and sensory loss). There were a total of nine severe cases, including the original six cases. Cases with possible causes other than a toxic chemical (e.g., diabetes) were

not included in the analysis but were identified in the presentation of results. The distribution of cases within the plant is shown in Table 4-1.

Table 4-1. Prevalence of peripheral neuropathy among employees of a coated fabrics plant

Workplace	Number of cases	Number of employees examined	Prevalence (%)
Non-print departments	30[a]	984	3
Print department (total)	38[b]	173	22[c]
Operators	27	69	39[c]
Helpers	10	59	17[c]
Foreman	0	21	0
Service helper	1	16	6
Not known	0	8	0
Total	68	1157	6

[a]Includes 18 persons with diabetes or other conditions that can cause or contribute to neuropathy.
[b]Includes one person with diabetes and one person on isoniazid therapy.
[c]Significantly elevated compared with non-print departments ($p < 0.001$) using the chi-square test.

Source: Billmaier et al. (1974).

The prevalence of peripheral neuropathy was significantly higher among print department employees than among employees from other departments (22 vs. 3%, $p < 0.001$). All nine severe cases were print department workers. Within this department, prevalence was highest among printer operators (39%, $p < 0.001$ compared with non-print department employees), who spent almost 100% of their time near the printing machines. Prevalence among helpers (17%) who spent roughly 50% of their time near the printing machines was also significantly elevated compared with non-print department employees ($p < 0.001$). There was a 6% prevalence among service helpers who were in and out of the premises (one case among service helpers was a pan washer who used the solvent for cleaning). Among manufacturing departments other than the print department, the prevalence of neuropathy ranged from 0 to 6.7%. No cases of peripheral neuropathy were observed in supervisory personnel who remained at a distance from the machines or in office personnel.

In addition to job category, incidence of neuropathy was also associated with working overtime (print operators with definite neuropathy averaged 47.2 hours/week versus 42.0 hours/week for those without neuropathy [$p < 0.01$]) and with eating on the job (data not shown). Each employee generally worked on the same machine all the time. No differences in neuropathy incidence were found based on the type of printing machine or the area in which the machine was located; data were insufficient to correlate illness with individual machines. Among print department employees, there were no significant differences in neuropathy incidence related to age or tenure in the department; 90% of cases had presented within the previous year, and only 5% of the cases were known to have medical conditions that could cause

or contribute to neuropathy. Among non-print department employees, cases were clustered in older (40+) employees ($p < 0.001$); only 53% had onset within the previous year, and 60% of these cases were known to have diabetes or other medical conditions that could cause or contribute to neuropathy unrelated to compound exposure.

In the search for the etiologic agent, other chemicals known to cause peripheral neuropathy were ruled out, either by clinical tests on workers or because they were not used in the plant. Based on an investigation into the relationship between the cases of peripheral neuropathy and the distribution of the roughly 275 chemicals used in the plant, the most likely agent appeared to be contained in the solvents used as ink thinners and cleaners. These had previously consisted of methyl ethyl ketone (MEK) and MiBK, but, starting in August 1972, the latter was phased out and gradually replaced by 2-hexanone, which reached maximal usage in December 1972. Substitution of 2-hexanone for MiBK was the only major change in the production process in the previous 7 years. In September 1973, the print department was closed for a month and 2-hexanone was removed from production materials. Thus, there was a 13-month window of exposure to 2-hexanone.

In addition to exposure to 2-hexanone, affected workers were also exposed to high concentrations of MEK that sometimes vastly exceeded threshold limit values (TLVs). MEK by itself does not produce this type of neuropathy in animal studies but can potentiate the effects produced by 2-hexanone (Saida et al., 1976). Thus, the presence of MEK in the coated fabrics plant study could contribute to an overestimation of the risk associated with exposure to 2-hexanone itself. Workplace levels for 2-hexanone and MEK from this study are presented in Table 4-2.

Table 4-2. Results of area atmospheric sampling for MEK and 2-hexanone in a coated fabrics plant

	Front of print machine[a]		Back of print machine[a]		Wind-up area[a]	
	MEK[b]	2-Hexanone[c]	MEK	MEK[b]	2-Hexanone[c]	MEK

[c]TLV = 100 ppm.

Source: Billmaier et al. (1974).

Another confounding factor for this study is that exposure may not have been limited to the inhalation route. Poor work practices documented at the plant included washing hands in solvent, using solvent-soaked rags to clean equipment, and eating in work areas. Dermal and even oral exposure is likely to have occurred. The significance of exposure by these routes is suggested by the observations that eating on the job was associated with the development of neuropathy and that a worker whose job involved washing pans with the solvent was the only afflicted print department worker other than the print operators and their helpers. As discussed in Sections 3.1.2 and 3.1.3, 2-hexanone is absorbed readily through the skin and gut and can produce neuropathy by both routes in animals.

The researchers reported that patients removed from 2-hexanone exposure showed significant and consistent improvements. They also performed a study of workers at a comparable coated fabrics plant in California that produced the same products as the one in Ohio but without the use of 2-hexanone. Electrodiagnostic studies were conducted on 21 solvent-exposed workers at the California plant, but no peripheral neuropathy was found.

4.2. ACUTE, SUBCHRONIC, AND CHRONIC STUDIES IN ANIMALS

4.2.1. Oral Exposure

4.2.1.1. *Acute and Short-Term Oral Exposure*

Range-finding toxicity data by Smyth et al. (1954) list an oral median lethal dose (LD_{50}) of 2.59 g/kg of 2-hexanone for rats, while Tanii et al. (1986) provide an oral LD_{50} of 2.43 g/kg for mice. Details for either study are limited (Tanii et al., 1986; Smyth et al., 1954).

4.2.1.2. *Subchronic Toxicity Studies*

16-Week study: female Wistar rats

Homan et al. (1977) conducted a 120-day drinking water study with female Wistar rats. 2-Hexanone (purity not stated) was administered in drinking water at 0, 0.65, or 1.3% (0, 480, or 1010 mg/kg-day). A dose-dependent decrease in food consumption was observed in exposed animals versus controls. Water consumption in exposed animals was reduced to about half that of controls. Animals exposed to 0.65 or 1.3% 2-hexanone experienced a 45.5 and 68.8% reduction in body weight gain, respectively. A dose-dependent decrease in absolute liver weight was observed in exposed animals. Absolute kidney weights were increased, and there was a dose-dependent increase in relative kidney weights. A summary of the data for diet and water consumption, body weight gain, and organ weights is provided in Table 4-3. Neurotoxicity outcomes among the treated animals are outlined in Section 4.4.1.

Table 4-3. Gross observations in rats exposed to 2-hexanone in drinking water for 120 days

Dose (mg/kg-day)	Food intake (g/day)	Water intake (mL/day)	Body weight gain (g)	Liver weight		Kidney weight	
				Absolute (g)	Relative	Absolute (g)	Relative
0	17.99	32.29	110.2	10.30	3.10	1.97	0.60
480	16.90	17.98	60.0[a]	9.01	3.35	2.21	0.82[a]
1010	12.90	17.33	34.3[a]	7.80[a]	3.38	2.10	0.92[a]

[a]Significantly different from controls, $p < 0.01$.

Source: Homan et al. (1977).

40-Week study: male Wistar rats

Eben et al. (1979) gavaged male SPF-Wistar rats daily with 400 mg/kg 2-hexanone (98% pure) for 40 weeks. Body weight gain in treated animals was less than in controls; a decrease in body weights was observed from the 17th to the 25th weeks, followed by a slight increase until study completion. There were also symptoms of neurotoxicity in the treated animals (see Section 4.4.1).

4.2.1.3. *Chronic Toxicity Study*

13-Month study: CD/COBS(SD) rats

O'Donoghue et al. (1978)[2] conducted a 13-month study in male CD/COBS(SD) rats. The animals' drinking water contained 0, 0.25, 0.5, or 1.0% (0, 143, 266, or 560 mg/kg-day) 2-hexanone (96% pure, containing 3.2% MiBK and 0.7% unknown contaminants). 2-Hexanone produced a dose-dependent reduction in body weight at all doses tested. The effect was present by the second week in the two highest dose levels and by the third week in the low-dose group. A statistically significant increase in liver weight was found in the highest dose group compared with all groups except the 0.5% group. The 0.5% and 0.25% groups showed dose-dependent increases in relative liver weights compared with controls. A statistically significant increase in relative kidney weights was present between the 1.0% 2-hexanone group and all other groups and between the 0.5% group and all other groups. Similarly, a statistically significant increase in relative testes weight was found between the 1.0% group and all other groups. A summary of the body weight and organ weight data is present in Table 4-4 (O'Donoghue et al., 1978).

Clinical neurological deficits were noted in animals exposed to either 0.5 or 1.0% 2-hexanone. Severe deficits including decreased extension of the hind limb, hind-limb weakness, and muscular atrophy of the hind-limb musculature were noted among animals treated with 1% 2-hexanone. Deficits among animals exposed to 0.5% 2-hexanone were slight and did not result in clinical progression. Evidence of axonal swelling was noted at all dosing levels of

[2]This study is an unpublished study; accordingly, it was externally peer reviewed by EPA in December 2007.

2-hexanone. Neurological effects are discussed in further detail in Section 4.4.1.1. Other than neural effects and changes in body weight, no nonneural clinical signs related to 2-hexanone exposure were found.

Table 4-4. Pathological changes in rats exposed for 13 months to 2-hexanone

	Body weight[a]	Liver[b]		Kidney[b]		Testes[b]	
		Absolute	Relative	Absolute	Relative	Absolute	Relative
Control	710	26.71 ± 2.02	3.64 ± 0.41	4.66 ± 0.53	0.63 ± 0.87	2.99 ± 0.81	0.40 ± 0.11
2-Hexanone (0.25% or 143 mg/kg-day)	685	24.99 ± 4.33	3.97 ± 0.43	4.58 ± 0.69	0.73 ± 0.05	3.24 ± 0.38	0.52 ± 0.08
2-Hexanone (0.5% or 266 mg/kg-day)	612	25.06 ± 2.04	4.22 ± 0.43	5.33 ± 0.31	0.90 ± 0.12[c]	3.16 ± 1.04	0.54 ± 0.19
2-Hexanone (1.0% or 560 mg/kg-day)	448	20.73 ± 2.95	4.62 ± 0.32[c]	4.86 ± 0.38	1.10 ± 0.23[c]	3.29 ± 0.26	0.75 ± 0.17[c]

Source: O'Donoghue et al. (1978).

To determine whether the concentration of MiBK, a CYP450 inducer, a contaminant in the 2-hexanone formulation used by O'Donoghue et al. (1978) may have altered the observed toxicity of 2-hexanone, other studies were evaluated that used MiBK as a test article. In a 13-week gavage study, 30 male and female Sprague-Dawley rats were treated daily with 0, 50, 250, or 1,000 mg MiBK/kg-bw (MAI, 1986). At the middle and high doses, adverse effects were observed in the liver and kidney, which progressed in severity in the high dose animals. No treatment-related effects of any kind were observed at 50 mg/kg-day. The Carnegie-Mellon Institute of Research (1977) conducted a 120-day drinking water study with 1.3% MiBK using female HLA Wistar rats. The authors estimated the dosage to be 1040 mg/kg-day. The only statistically significant finding was increased mean absolute and relative kidney weights in treated rats compared with controls. Histopathological examination revealed renal tubular cell hyperplasia in only one of five of the treated rats. No exposure-related histopathological changes were found in other organs. Based on the foregoing, it can be concluded that the dosage of MiBK received as an impurity in the study by O'Donoghue et al. (1978) did not contribute to the observed 2-hexanone related effects. O'Donoghue et al. (1978) did not observe adverse effects in the kidney or liver of treated animals, despite these organs being the target organs of toxicity in experimental studies with MiBK from both the oral and inhalation routes (U.S. EPA, 2003a).

4.2.2. Inhalation Exposures

4.2.2.1. *Acute and Short-Term Toxicity Studies*

No acute inhalation toxicity studies of 2-hexanone were identified. The National Library of Medicine's Hazardous Substances Data Bank states that a 4-hour exposure of rats to 4000 ppm 2-hexanone did not kill all animals, while exposure to 8000 ppm for 4 hours was an LD_{100} (NLM, 2005). Abdo et al. (1982) reported the death of one out of five hens exposed continuously to 200 ppm 2-hexanone (70% purity). No deaths were reported in hens exposed to 100 ppm or lower (Abdo et al., 1982).

4.2.2.2. *Subchronic Toxicity Study*

11-Week study: male rats

Groups of five male rats (Crl:COBS/CD[SD]BR) were exposed to 0 or 700 ppm (0 or 2870 mg/m^3) 2-hexanone (purity 96.1%) 72 hours/week for 11 weeks (Katz et al., 1980). The exposure schedule was as follows: two 20-hour periods and two 16-hour periods, Monday through Friday, separated by 8-hour nonexposure periods. Total white blood cell counts of treated animals were significantly ($p < 0.05$) lower than those of controls; no other differences were noted in clinical chemistry or hematological values. Gross examination of treated animals revealed marked atrophy of the hind-limb musculature, depletion of adipose tissue, and significantly decreased absolute and relative testicular weight ($p < 0.05$). Histopathological examination was performed on selected tissues, including lung and trachea (but not nasal cavities), eye, digestive tract, pancreas, thyroid, parathyroid, testes, epididymides, spleen, bone marrow, mesenteric lymph nodes, thymus, and nervous system. Atrophy of testicular germinal epithelium and grossly enlarged axons in the brain stem and cerebellum were observed in treated animals. No damage to bone marrow was evident despite the low white blood cell count. Although no discussion of findings in the lung or trachea was presented, the implication is that there were no treatment-related changes in these tissues. The treatment group developed signs of neurotoxicity (weakened hind- and forelimb grasp) by the second week of exposure, progressing to severe hind-limb weakness by 71 days, and showed decreased weight gain. Neurological effects are discussed in further detail in Section 4.4.1.2.

4.2.2.3. *Chronic Toxicity Study*

72-Week study: male Sprague-Dawley rats

Krasavage and O'Donoghue (1977) exposed groups of male Sprague-Dawley rats (18/group) to 0, 100, or 330 ppm (0, 410, or 1353 mg/m^3) 2-hexanone (purity not specified) 6 hours/day, 5 days/week for 72 weeks. Clinical signs (observed daily and examined weekly), body weight (recorded weekly), and water consumption (at 15, 22, 32, and 44 weeks of exposure) were monitored. Beginning at 4 weeks and continuing at approximately 6-week intervals for the first 52 weeks, unspecified numbers of animals were killed for microscopic

examination of an extensive list of tissues, including the trachea and lung. Body weights and weight gain were comparable among groups until the 20th week. Thereafter, body weights of the high-concentration animals fell behind those of controls (data presented graphically without statistical analysis); a visual estimate of the graphic presentation suggested that the body weights of high-concentration animals were at least 10% less than those of controls. After 36 weeks of exposure, body weight gain in the low-concentration group also began to lag behind controls. Water intake was comparable among groups.

Gross postmortem findings revealed no compound-related changes. Low-concentration animals did not develop clinical signs attributed to 2-hexanone exposure or morphologic lesions of neuropathy. Histopathologic evidence for neuropathy in high-concentration rats was equivocal. Neurological effects are discussed in further detail in Section 4.4.1.2. Spontaneous lesions were present in the urogenital, cardiovascular, and endocrine systems of both treated and control animals and were therefore not attributed to 2-hexanone exposure by the study authors (Krasavage and O'Donoghue 1977).

2-Year study: cats

Groups of four domestic shorthair cats were exposed by inhalation to 0, 100, or 330 ppm (0, 410, or 1353 mg/m^3) 2-hexanone (purity not specified) for 6 hours/day, 5 days/week for 2 years (O'Donoghue and Krasavage 1979). Clinical signs and body weights were monitored. Serum was sampled after 30, 90, and 128 exposures to determine the levels of 2-hexanone and two of its metabolites, 5-hydroxy-2-hexanone and 2,5-hexanedione. Each sample set involved collection serum on a Monday prior to daily exposure, the following Tuesday prior to daily exposure, the following Friday prior to daily exposure, immediately after daily exposure and one and three quarter hours after daily exposure. Sera from high-dose and control animals were also analyzed for sodium, potassium, chloride, and calcium levels. Cats were sacrificed at the end of the treatment and were subjected to necropsy and histopathologic examinations.

No clinical neurological effects attributed to exposure to 2-hexanone were identified except that cats anesthetized with sodium pentobarbital following a 6-hour exposure had prolonged sleeping times (O'Donoghue and Krasavage, 1979). No compound-related changes of body weight or serum electrolyte values were found. Serum levels of 2-hexanone and the two metabolites, 5-hydroxy-2-hexanone and 2,5-hexanedione, were below the detection limit on Monday morning following a two-day non-exposure period. With the exception of 2,5-hexanedione in the 330 ppm group (1353 mg/m^3), serum levels on Tuesday morning following a 6-hour exposure after 30 days of exposure remained below the detection level. Of the three substances measured, 2-hexanone cleared the serum more quickly than 5-hydroxy-2-hexanone, which cleared more quickly than 2,5-hexanedione. Biopsy examinations through the first 9 months of exposure were unremarkable and did not serve as an early detection method for neuropathy. Gross postmortem findings revealed no compound-related changes. General

histopathologic examinations showed no compound-related changes other than in the nervous system and musculature. Neurological effects are discussed in further detail in Section 4.4.1.2.

4.2.3. Dermal Exposure

90-Day study: hens

Abou-Donia et al. (1985b) treated leghorn laying hens (n = 5) with 2-hexanone (99% pure; topical application, 1 mmol/kg-bw). The chemical was applied daily with a micropipette over an area of 10 cm^2 on the unprotected back of the neck for 90 days. All hens developed gross ataxia. At sacrifice, no changes were observed in treated versus control animals when compared for size, shape, weight, or color. Equivocal histopathologic changes were present in the spinal cord of two hens. These histopathologic changes were characterized by swollen axons without obvious fragmentation of the axon or myelin sheath. No precautions against licking were mentioned in the study, so ingestion of 2-hexanone may have taken place.

4.3. REPRODUCTIVE/DEVELOPMENTAL STUDIES—ORAL AND INHALATION

4.3.1. Oral Exposure

No standard two-generation studies or other studies of reproductive and developmental effects following oral administration of 2-hexanone were identified.

4.3.2. Inhalation Exposure

In a developmental study, Peters et al. (1981) exposed groups of 25 pregnant F344 rats to 0, 500, 1000, or 2000 ppm (0, 2048, 4096, or 8193 mg/m^3) 2-hexanone (purity not stated), 6 hours/day on gestational days (GDs) 1–21. A separate control group was maintained for each exposure group and the high-concentration controls were pair fed. Respective controls were exposed to ambient air in similar chambers to those of their exposed counterparts. Sexually mature female rats were impregnated and placed in exposure chambers 6 hours/day throughout gestation. Four weeks postdelivery, the dam was separated from the pups. The maternal 500 ppm group along with its control was terminated before 3 weeks because of an apparent lapse in care during which offspring were "unable to reach food and water," resulting in reduced weight gain in this group. The pups in the control, 1000, and 2000 ppm groups were observed over a lifetime. At 4 (weaning), 8 (puberty), and 14 weeks (adult) and at 18–20 months of age (geriatric), five males and five females were taken, one per litter, for gross and histopathology studies and for measurement of organ/body weight ratios. At different periods of development (weaning, puberty, and adult), offspring underwent behavioral testing. Pentobarbital sleeping time was also measured in pubescent and geriatric animals in the high-dose and control groups.

Survival in the 2000 ppm and 1000 ppm dams was not affected by treatment. High-dose dams appeared sluggish after exposure but seemed to have recovered by the next exposure. Hair loss, lack of muscular coordination, and weakness were observed in "several" dams at the

highest concentration after 20 days of exposure. Abnormal sniffing in the air was reported for dams in the 1000 ppm group. Maternal gestational body weight gain was decreased by 14 and 10% in the dams exposed to 2000 and 1000 ppm, respectively. Rats in the 2000 ppm exposure group were observed to eat less than the controls. No unusual behavior or change in maternal gestational growth was reported for the 500 ppm dams. Histopathology and neurotoxicity evaluations were not performed in the dams.

2-Hexanone exposure was found to result in statistically significant decreases (*p* value not reported) in litter size and pup weight observed at the highest exposure level (Peters et al., 1981). However, maternal toxicity, manifested as decreased maternal body weight during gestation, was also evident in high-dose dams, suggesting that maternal toxicity might have affected fetal growth. There was a significant decrease in the number and weight of live offspring of dams in the 2000 ppm exposure group. A lifelong, statistically significant, concentration-related reduction in growth was observed in male offspring. Only a slight treatment-related effect on body weight was seen in female offspring. Organ weights in weanling, pubescent, and geriatric offspring were unaffected by treatment, but brain weight in adult 1000 ppm offspring was significantly increased compared to that of control. Organ weights were not measured in high-dose adult offspring. The authors did not report any gross skeletal alterations. Beginning at 40 weeks of age, offspring of dams treated with 1000 or 2000 ppm showed a 3–5% decrease in survival relative to controls. The incidence of pathological lesions and the types of lesions contributory to death were not significantly different in treated and control groups (Table 4-5).

Table 4-5. Summary of pathological lesions in offspring of rats exposed to 2-hexanone during gestation

	Control				1000 ppm				2000 ppm			
	Male	**Female**	**Total**	**%**	**Male**	**Female**	**Total**	**%**	**Male**	**Female**	**Total**	**%**

Source: Peters et al. (1981)

Standard hematological tests (hemoglobin, red blood cell count, white blood cell count, lymphocytes, mean corpuscular hemoglobin, packed cell volume) showed no significant

treatment effect on the processes involved in blood cell formation and function (Peters et al., 1981). Clinical chemistry findings were limited to a concentration-related decrease in creatinine phosphokinase activity in pubescent offspring, with values in the 1000 ppm and 2000 ppm groups significantly lower ($p < 0.05$) than controls. In geriatric offspring, there were significant increases ($p < 0.05$) in serum alanine aminotransferase activity in the 1000 ppm and 2000 ppm groups and sodium in the 2000 ppm group. The only lesions showing a significant concentration-response relationship ($p < 0.05$, Fisher's exact test conducted for this assessment) at the time of geriatric sacrifice were ovarian cysts that had 4% (2/57), 21% (7/34), and 36% (8/22) incidences in the control, 1000 ppm, and 2000 ppm females, respectively.

In pubescent high-dose male offspring, pentobarbital sleep time was significantly increased ($p < 0.05$) compared with controls. No significant changes in pentobarbital sleep time were noted in pubescent females or geriatric offspring of either sex. Behavioral alterations were reported in the offspring of pregnant rats exposed to 1000 ppm or 2000 ppm 2-hexanone. These effects consisted of reduced activity in the open field, increased activity in the running wheel, and deficits in avoidance conditioning. Offspring of treated dams (both dose levels) clung to an inclined screen longer than offspring of controls at all ages (newborn, weanling, puberty, and adult) except geriatric in which results were similar to those of controls. For offspring in the puberty and adult categories, pronounced sex differences were noted; females in all exposure categories (including controls) were clinging from 24–100% longer than males. However, the biological significance of this observation is unknown. There was a decreased rate of avoidance learning in puberty-aged females of treated dams and increased random movement in both puberty-aged and adult offspring of treated dams. Behavioral tests in most cases indicated that maternal exposure to 2-hexanone was associated with hyperactivity in the young and decreased activity in the geriatric stage, which the authors (Peters et al., 1981) speculated to be due to premature aging resulting from the earlier hyperactivity. It is not clear whether these effects are the result of transplacental exposure to 2-hexanone or of postnatal exposure to 2-hexanone and/or its metabolites via the milk of the exposed dams.

4.4. OTHER ENDPOINT-SPECIFIC STUDIES

4.4.1. Neurotoxicity Studies

4.4.1.1. *Oral Exposures*

90-Day study: hens

In hens that received a single gavage dose of 2-hexanone (technical grade 2-hexanone, 70% pure, containing 30% methyl isobutyl ketone) at 2000 mg/kg, mild weakness was observed on the day of administration, followed by apparent recovery in 4–5 days. Hens that received 100 mg/kg showed no signs of neurotoxicity (Abou-Donia et al., 1982). In a subchronic (90-day) phase of the same study, hens (n = 3) administered 2-hexanone at 100 mg/kg-day or higher developed

severe ataxia or near paralysis. There was also evidence of histopathological changes, including swelling or degeneration of thoracic and lumbar regions of the spinal cord.

90-Day study: rats

Krasavage et al. (1980) administered 660 mg/kg 2-hexanone (96% pure) by gavage to male CD/COBS(SD) rats for up to 90 days. The authors considered severe hind-limb weakness or paralysis, as exhibited by "dragging" of at least one hind foot, to be clear indication of neuropathy. When this endpoint was reached, the treatment was terminated and the animal was processed for histological examination. There was a time- and dose-dependent depression in body weight gain and feed consumption. Treated animals consumed an average of 21 grams/day versus 28 grams/day for controls. The body weights of experimental and control animals at study completion were approximately 400 and 600 grams, respectively. Histologic examination of nerve tissue collected at termination revealed morphologic changes indicative of giant axonal neuropathy, which included multifocal axonal swellings, myelin infoldings, and paranodal myelin retraction. In this study, atrophy of the germinal epithelium of the testes was also observed, but the statistical significance of this observation was not addressed (Krasavage et al., 1980).

120-Day study: female Wistar rats

Homan et al. (1977) conducted a 120-day drinking water study with female Wistar rats (five/group). 2-Hexanone (purity not stated) was administered in drinking water at 0, 0.65, or 1.3% (0, 480, or 1010 mg/kg-day) (for further experimental details see Section 4.2.1.2). Neurological evaluations were conducted to assess balance, strength, coordination, and behavior. Performance was scored for each of the following 10 criteria: posture, gait, palpebral reflex, startle reflex, flexor reflex, extensor reflex, placing reflex, hopping reaction, righting reflex, and clinging reaction. Score ranged from 0 to 2 with 0 indicating normal and 2 being clearly deficient. The net score for each rat was calculated as the sum of the individual test scores. Scores were tabulated, ranked, and analyzed using the Kruskal-Wallis ranks sum test. The rank values (statistics generated from the Kruskal-Wallis test) for each treatment group for a given day of analysis were then averaged to generate a mean rank and standard deviation. A summary of the mean rank (mean of the values generated from the Kruskal-Wallis test) and standard deviation is provided in Table 4-6. Gross pathological evaluation revealed mild atrophy affecting skeletal muscles of the hind limbs in two of five animals in the 0.65% group and slight to severe atrophy of skeletal muscles (most pronounced in muscles of the hind limbs) affecting four of five animals in the 1.3% group (Homan et al., 1977).

Table 4-6. Time course of neuropathy scores following exposure of rats to 2-hexanone in drinking water

Treatment	Analysis after number of treatment days			
	46	57	80	110
	Mean rank value			
Control	26.1 ± 9.1	15.0 ± 0.0	22.1 ± 12.8	17.5 ± 0.0
0.65% 2-hexanone	32.0 ± 14.9	30.6 ± 12.7	30.9 ± 9.2	21.5 ± 8.0
1.3% 2-hexanone	37.5 ± 12.6	41.0 ± 5.7	40.0 ± 13.7	47.2 ± 2.8a

24-Week study: guinea pigs

Abdel-Rahman et al. (1978) administered 2-hexanone (purity not stated) in drinking water to guinea pigs (five/group, sex not stated) at 0, 0.1, or 0.25% (approximately 0, 97, or 243 mg/kg-day) for 24 weeks. Bibs were used to prevent dermal absorption by inadvertent contact of the animals' bodies with the solvent. The body weight of the guinea pigs was monitored each week up to the eighth week of the study. At the end of the seventh week, animals exposed to 0.25% 2-hexanone weighed an average of 600 grams versus 440 grams in controls. Similarly, animals exposed to 0.1% 2-hexanone weighed 618 grams by the eighth week compared with 490 grams in controls. Decreased locomotor activity may have contributed to increased body weights. The average motor activity counts in animals exposed to 0.25% 2-hexanone were 714 ± 130 compared to 1173 ± 201 in controls. Pupillary response to light (measured by change in pupillary diameter in response to an intense 2-second light stimulus) was abnormal in high-dose animals for the first 5 weeks of treatment as shown in Table 4-7 (data not provided for 0.1% 2-hexanone). The authors reported that by the 24th week of the study, a greatly impaired pupillary response was observed for all treatment groups (data not provided in the report) (Abdel-Rahman et al., 1978).

Table 4-7. Effect of 2-hexanone on guinea pig pupillary response of both eyes

Treatment	Week							
	1		2		3		5	
	Right[a]	Left[a]	Right	Left	Right	Left	Right	Left

40-Week study: rats

Eben et al. (1979) gavaged male SPF-Wistar rats daily with 400 mg/kg 2-hexanone (98% pure) for 40 weeks. The authors stated that this treatment did not cause neuropathic symptoms; however, from the 17th week the authors noted that the animals exhibited weakness of the hind limbs, which continued until the 28th week. Thereafter, an improvement was observed. No further details were provided.

13-Month study: rats

As previously mentioned in Section 4.2.1.3, O'Donoghue et al. (1978) conducted a 13-month study in male CD/COBS(SD) rats. Each group of 10 rats was exposed to drinking water containing 0, 0.25, 0.5, or 1.0% (0, 143, 266, or 560 mg/kg-day) 2-hexanone (96% pure, containing 3.2% MiBK and 0.7% unknown contaminants). Body weight and neurological examinations were performed weekly. At the end of the study, a dose-dependent reduction in body weight was noted among all dose groups. All but one animal was found to have some evidence of neurotoxicity. Other than neural effects and body weight changes, no compound-related clinical signs were found.

Clinical neurological deficits were found only in animals receiving 0.5 or 1.0% 2-hexanone. Deficits were recorded as slight if there was incomplete extension of the hind limb and just detectable widening of the hind limb stance; moderate if there was obvious weakness, incomplete extension of the hind limbs, and waddling; and severe if there was dragging of at least one hind paw. In the 1.0% group, all the animals exhibited severe deficits. Gross pathological examination revealed observable muscle atrophy of hind-limb and lumbar muscles at this high-dose level. Progression of the clinical findings to a more severe state did not occur with time in the 0.5% group. In addition to the aforementioned changes, animals receiving 1% hexanone in their drinking water displayed loss of tone with grossly observable atrophy of the hind-limb musculature and axial muscles of the lumbar area. Weakness of the forelimbs with some muscle atrophy was observable in three of nine rats at the end of the study. Pain sensation, as judged by toe pinch, remained intact, but motor response such as flexor response was easily overcome. It was noted that tactile placing in the hind limbs could be elicited even in rats with severe weakness. Bowel and bladder functions remained normal. The clinical course was highly variable with improvements in the clinical symptoms being very common; thus, while all animals showed slight deficits on at least two of the weekly examinations, they showed improvements during other weeks.

Evidence of neuropathy was most common in the giant axons of animals of each dose level. In peripheral nerves from the 1.0% group, swelling of giant and other axons was common. Myelin infoldings into the axoplasm were more common than in controls. Myelin ovoids were

frequently found along with degenerating axons. The second most common site of neural degeneration was in the spinal cord, particularly in the ventral and ventromedial funiculi of the thoracolumbar segments. The changes were similar to those found in peripheral nerves. In plastic embedded sections, an additional early change was noted, which consisted of clumping of axonal organelles in otherwise normal peripheral or central axons. Examination of the dorsal root ganglia did not reveal any effect on cell bodies, but in three animals single swollen axons were found in adjacent roots, indicating a very minimal effect. Axonal swelling was also very rare in the brain. No neuropathologic effects were found rostral to the pons. Small numbers of swollen axons were located in the ventromedial medulla. Rare single swollen axons were located in the ventral spino-cerebellar tracts, cerebellar peduncles, and deep cerebellar white matter.

Neurogenic skeletal muscle atrophy occurred in both proximal and distal hind-limb musculature. Myofibrillar atrophy was multifocal with foci overlapping in severe cases to produce large diffuse areas of atrophy with fatty replacement. Intramuscular nerves frequently showed an obvious loss of axons and rarely a swollen axon. No difference in the severity or frequency of atrophic foci was seen between proximal and distal muscles.

In the 0.5% group, peripheral nerve changes were identical in morphology and in the number of animals affected compared with the higher-dose animals but were reduced in severity. Swollen axons were generally few in number but were found in all animals. Myelin ovoids and frankly degenerating axons were also reduced in number. In some nerve bundles, there was obvious loss of axons. Spinal effects were reduced to a few swollen axons and rare degenerating axons in the ventromedial fasciculi of the thoracolumbar cord. Effects on the brainstem and cerebellum were minimal, consisting of only single or small numbers of swollen axons and single degenerating axons in half of the animals examined. Neurogenic skeletal muscle atrophy consisted of infrequent multifocal areas of myofibrillar atrophy that were generally regarded as minor. Two animals without myofibrillar atrophy were considered normal. Three samples from the quadriceps and two from the calf muscles, while not demonstrating myofibrillar atrophy, did have early myopathic effects consisting of foci of increased numbers of angular myofibers and increased numbers of myofibers with central or internal nuclei. In one of these animals, intramuscular axonal swelling was found.

At the 0.25% level, peripheral nerve changes were less severe than at higher doses and axonal swelling was found in 8 of 10 animals examined. In these eight rats, the number of swollen axons was very low, but additional changes, such as myelin infoldings into axons, myelin ovoids, and degenerating axons, were more common. In one animal, while no axonal swelling was observed, numerous degenerating axons were found. Another rat was indistinguishable from controls. Spinal lesions were minimal, consisting of a single or very few swollen axons. A few instances of axonal swelling were found in the medullae of two rats. Neurogenic myofibrillar atrophy was also minimal, occurring as a single or very few foci in two

animals. Foci of angular myofibers were found in four additional animals but were of minimal severity. In control animals, the peripheral and central nervous system (CNS) contained a few degenerating axons and myelin ovoids, but these were minimal. A summary of animals found to have axonal swelling and the areas in which these axons or myopathic changes were found is presented in Table 4-8.

Table 4-8. Summary of neuropathologic findings in male rats administered 2-hexanone in drinking water for 13 months

	Incidence of axonal swelling				Incidence of myofibrillar atrophy	
Treatment	**Brain**	**Spinal cord**	**Dorsal root ganglia**	**Peripheral nerve**	**Quadriceps muscle**	**Calf muscle**
Control	0/10	0/5	0/5	0/10	0/10	0/10
0.25% 2-hexanone	2/10	7/10	0/7	8/10	1/10	2/10
0.5% 2-hexanone	4/10	5/5	0/5	10/10	5/10	6/10

4.4.1.2. *Inhalation Exposures*

6-Week study: rats

In a short communication, Duckett et al. (1974) reported the results of a study in which groups of nine rats (strain and sex not reported) were exposed to 200 ppm (819 mg/m^3) 2-hexanone (purity unspecified) 8 hours/day, 5 days/week for 6 weeks. Four rats served as controls. Animals presented with muscular weakness of all limbs that persisted for a few hours after exposure termination each day. Only the sciatic nerve was examined histologically. Axonal hypertrophy, beading, and degeneration associated with perinodal and segmental breakdown of myelin were observed in the sciatic nerve of all treated rats.

13-Week study: rats

In the same short communication discussed above, Duckett et al. (1974) discussed results of an unpublished subchronic experiment with 2-hexanone. In this experiment, groups of 20 Wistar rats of unspecified sex were exposed to 2-hexanone for 8 hours/day, 5 days/week at 40 ppm (164 mg/m^3) for 22–88 days or at 50 ppm (205 mg/m^3) for 13 weeks. Similar numbers of control rats were sham exposed. No overt signs or "pathological manifestations" of peripheral or central neuropathy were seen in exposed rats, except for demyelination of the sciatic nerve in 3 of the 20 rats exposed to 50 ppm for 13 weeks. Additional details were not provided. The results at 50 ppm for 13 weeks, when compared with the results at 50 ppm for 6 months, indicate that the incidence of neuropathy increases with increasing duration of exposure.

12-Week study: cats, rats, chickens

Mendell et al. (1974) continuously exposed groups of animals of unspecified sex (four Sprague-Dawley rats, four domestic shorthair cats, and five domestic chickens) to 2-hexanone (purity not stated) for 24 hours per day, 7 days per week for up to 12 weeks. Concentrations of 2-hexanone were initially 200 ppm (820 mg/m^3) for chickens and 600 ppm (2,460 mg/m^3) for cats and rats but were adjusted at an unspecified time to 100 and 400 ppm (410 and 1640 mg/m^3), respectively, to minimize complications from inanition and weight loss. Pair-fed controls were sacrificed when the exposed animals were sacrificed. After 5–8 weeks of exposure, the cats developed hind-limb and forelimb weakness. Focal swelling of the axon along the sciatic nerve, often associated with loss of neurotubules and denudation of myelin beginning at the nodes of Ranvier, and areas of demyelination were observed. Abnormal electromyograms were also observed in the cats exposed for 9–10 weeks; electromyograms were not measured in chickens or rats (Mendell et al., 1974).

90-Day study: hens

Abdo et al. (1982) exposed adult leghorn laying hens (*Gallus gallus domesticus*), 5 per group, to varying concentrations of 2-hexanone (10, 50, 100, 200, and 400 ppm; technical grade 2-hexanone containing 70% 2-hexanone and 30% methyl isobutyl ketone) for 90 days. Body weights were monitored weekly, and hens were examined every other day for neurological signs of 2-hexanone neurotoxicity. A 30-day observation period followed the final exposure. Clinical assessment of neurotoxicity was graded by classifying the degree of ataxia before paralysis as follows: T_1, mild ataxia, characterized by diminished leg movement and reluctance to walk, with hens tending to slide on the floor or fly; T_2, gross ataxia, characterized by a change in gait and disturbance of leg movement; T_3, severe ataxia, with severe leg weakness manifested by unsteadiness and occasional falling on the floor; T_4, ataxia, with near paralysis, marked by inability to walk (Abdo et al., 1982).

The spinal cord and the sciatic, peroneal, and tibial nerves were excised from hens that died during the experiment or were killed by heart puncture and exsanguinations. Severity of lesions was defined by the following criteria: (1) rare swollen axons without fragmentation, phagocytosis, or loss of myelin staining were designated as equivocal histological changes; (2) occasional degenerative changes of axons and myelin in peripheral nerve or within the spinal cord, which may contain nests of phagocytic cells, were termed mild to moderate degeneration; and (3) lesions were considered severe when there was almost complete destruction of axons and myelin in a given tract such as the anterior columns or within extensive areas of peripheral nerve.

Only hens exposed to one of the highest two concentrations of 2-hexanone, 400 or 200 ppm, lost significant weight at the onset of ataxia; weight loss for these two groups continued, and the hens exposed to 400 and 200 ppm 2-hexanone weighed 48.0 $\pm$ 7.4 and 63.1 $\pm$ 5.5% (mean $\pm$ SE) of the initial weights, respectively, at the onset of paralysis. Although the group

exposed to 100 ppm 2-hexanone gained some weight at the onset of ataxia, they lost 24.4% of their initial weight after 69 days of exposure. This weight loss coincided with the development of severe ataxia. This treatment group, however, regained all lost weight by the end of the 30-day observation period. No appreciable change in weight was observed in hens exposed to 50 or 10 ppm 2-hexanone.

None of the hens continually exposed to 2-hexanone vapor showed any signs of acute toxicity that are attributed to the narcotizing effects of 2-hexanone on the CNS. All hens continually exposed to 50–400 ppm 2-hexanone developed ataxia after a latent period of 6–30 days, depending on 2-hexanone concentrations. Those exposed to 400 ppm progressed to paralysis, and two died 27 days after the beginning of exposure. The remaining three chickens were in a distressed condition and were sacrificed at 31 days. The number of days of exposure to 2-hexanone vapors before the onset of ataxia was dependent on and inversely proportional to the concentration of 2-hexanone.

All hens exposed to 200 ppm 2-hexanone developed paralysis 64–72 days after the beginning of the exposure; one of these hens died at day 72 and the other four were sacrificed on day 73. Four of the hens inhaling 100 ppm 2-hexanone developed severe ataxia (T_3), while the fifth bird progressed to ataxia with near paralysis (T_4). Three hens of the group exposed to 50 ppm 2-hexanone showed severe ataxia (T_3), while the other two developed only gross ataxia (T_2). The clinical condition of all hens in this group was gross ataxia (T_2) at termination. All hens exposed to 10 ppm 2-hexanone remained normal.

Histopathological lesions in the spinal cord were dependent on concentration, duration of exposure, and duration of intoxication. Two of the hens exposed to 400 ppm did not exhibit any histopathological alterations, while another two showed equivocal changes. Hens exposed to 100 ppm 2-hexanone exhibited clinical signs of neurotoxicity for 99 $\pm$ 2 days, and all hens showed unequivocal changes in the spinal cord. Although hens exposed to 50 ppm 2-hexanone were exposed for a mean of 97 days, only four of these hens had unequivocal changes in the spinal cord. Similarly, the presence of histopathological lesions in peripheral nerves was a function of both the level of 2-hexanone inhaled and, particularly, the total dose inhaled. Although all five hens exposed to 100 ppm for 90 days survived until termination on day 120, they showed gross to severe ataxia and each had unequivocal lesions in peripheral nerves. Hens given high doses became paralyzed and thus could not be kept alive as long as those given 100 ppm 2-hexanone.

4-Month study: rats

Groups of six young adult rats (strain and sex not specified) were exposed to 1300 ppm (5325 mg/m^3) of 2-hexanone 6 hours/day, 5 days/week for up to 4 months (Spencer et al., 1975). Three rats were exposed to air only. Animals were observed for neurological signs, and histopathological examinations of several peripheral nerves, regions of the spinal cord, medulla,

and cerebellum were completed. In the exposed rats, narcosis, loss of coordination, weight loss (data not presented), foot drop, and proximal hind-limb and forelimb weakness were observed. Pathological alterations included nerve fiber degeneration in the peripheral nerves, spinal cord, medulla, and cerebellum; axonal dilatation with localized fiber swelling; and secondary paranodal myelin retraction.

6-Month study: male rats

Duckett et al. (1979) exposed groups of Wistar rats (sex not specified) to 0 (n = 20) or 50 ppm (n = 40) 2-hexanone (0 or 205 mg/m^3) 8 hours/day, 5 days/week for 6 months. No overt signs of toxicity were observed during the study. Electrophysiological evaluations were performed on 5 treated and 10 control rats at the end of the experiment. The mean sciatic motor conduction velocity (MCV) in the exposed group was significantly lower (p = 0.005) than in the controls. No effect on the amplitude of the evoked muscle action potential (MAP) was observed. Widespread demyelination of the sciatic nerve was reported in 32 rats from the exposed group; two of the rats also had axonal hypertrophy and beading. No abnormalities were seen in the sciatic nerves of control rats. The study authors reported that the histopathology of the CNS, liver, and kidney of all rats was normal (details were not provided) (Duckett et al., 1979).

72-Week study: male rats

Krasavage and O'Donoghue (1977) exposed male Sprague-Dawley rats (18/group) to 0, 100, or 330 ppm (0, 410, or 1353 mg/m^3) 2-hexanone (purity not specified) 6 hours/day, 5 days/week for 72 weeks (for further experimental detail, see Section 4.2.2.2). Exposure to 100 ppm did not cause clinical or pathologic evidence of neurological damage. One rat exposed to the high concentration developed progressive hind-limb weakness; another three high concentration animals showed slight weakness that was not progressive. One animal in the high concentration group developed a severe polyradiculoneuritis of the nerve roots in the lumbar and sacral spinal nerves and in the sciatic and tibial nerves. The authors concluded that chronic exposure to 100 ppm 2-hexanone was not neurotoxic, while findings at 330 ppm were equivocal (Krasavage and O'Donoghue 1977).

6-Month study: male rats

Male Sprague-Dawley rats (six/group) were exposed to 0 or 100 ppm (0 or 410 mg/m^3) 2-hexanone (purity 96.66%, 2.9% MiBK) 22 hours/day, 7 days/week for 6 months (Egan et al., 1980). Two animals from each group underwent microscopic examination for neuropathologic changes following 2, 4, and 6 months of exposure. No treated or control animals displayed clinical signs of neurotoxicity during the exposure period. After four months of exposure, a typical pattern of 2-hexanone-induced neuropathology began to appear in the CNS and peripheral nervous system (PNS). At this time, PNS specimens revealed giant axonal swellings

and secondary demyelination in a few large diameter fibers in the tibial nerve branches to the calf muscles. In the CNS, isolated giant axonal swellings were found in the medulla oblongata and cerebellum. By six months, more advanced degeneration was presented in teased fibers in calf muscle branches and giant axonal swelling had ascended to the level of the sciatic notch. The spinal cord revealed scattered fiber degeneration in the ventral portion of the gracile tract and the caudal portion of descending fiber tracts in the lumbar region.

10-Month study: male rats, male monkeys

Johnson et al. (1977) exposed male Sprague-Dawley rats (10/per group) and male monkeys (*Macaca fascicularis*) (8/group) to 0, 100, or 1000 ppm (0, 410, or 4100 mg/m^3) commercial grade 2-hexanone (purity not stated) for 6 hours per day, 5 days per week for up to 10 months. Rats in the 1000-ppm exposure group exhibited progressive body weight loss beginning at 16 weeks and reaching statistical significance at 20 weeks ($p < 0.01$). Monkeys in the 1000-ppm group progressively lost body weight beginning at 8 weeks. No significant effect of 2-hexanone on body weight of rats or monkeys was found in the low-dose exposure groups.

Four neurological tests were conducted on both rats and monkeys: MCV of right sciatic-tibial nerves, MCV of the right ulnar nerve, absolute refractory period of these nerves, and MAP recorded in response to both sciatic and ulnar stimulation. In addition, electroencephalograms and visual evoked potentials were recorded from monkeys. All animals were administered an anesthetic prior to neurological testing: rats received an i.p. injection of 35 mg/kg of sodium pentobarbital, and monkeys were given 15 mg/kg of ketamine hydrochloride intramuscularly.

After 25 weeks, all rats and monkeys in the high-dose exposure group were removed from further exposure because neuropathy (hind-limb drag) apparently had developed. All eight monkeys in the 100 ppm group were exposed for a total of 41 weeks. Rats in the low-dose group were removed from 2-hexanone exposures after 29 weeks. Beginning at 3 months of exposure, monkeys in the 1000 ppm group showed a progressive decrease in the MCV of the sciatic-tibial nerves. After 6 months, the mean MCV of this group was 63% of the mean of control animals. Commencing at 9 months, the MCV for the sciatic-tibial nerves in monkeys in the 100 ppm group was significantly different from control values ($p = 0.05$). At the termination of the study, the MCV of monkeys from the 100 ppm group was 12% less than in the corresponding controls ($p < 0.05$).

A similar pattern of sciatic-tibial neuropathy developed in rats exposed to the higher concentration of 2-hexanone. A significant decrease in MCV was observed at approximately 3 months (13 weeks) of exposure ($p = 0.05$). A significant difference at 8 weeks between MCVs of control and 1000 ppm rats was considered spurious. In the 100 ppm group, a significant difference in MCVs between controls and treated rats occurred at 29 weeks ($p < 0.001$).

A neuropathy similar to that observed for the sciatic-tibial nerves was noted in the ulnar nerve of both the monkeys and rats. When compared with controls, commencing at 4 months,

monkeys showed a progressive decrease in the MCV of the ulnar nerve. At the end of 6 months' exposure to 1000 ppm, monkeys showed a significant decrease in ulnar MCV with values approximately 64% of those of controls ($p < 0.01$). Ulnar MCVs in the 100 ppm group showed a similar decreasing trend at about 6 months; however, these values were not statistically different from controls. In rats, ulnar MCVs were significantly decreased compared with control values ($p < 0.05$), beginning at about 17 weeks in both exposed groups.

Both monkeys and rats exposed to 1000 ppm 2-hexanone showed a continuous decrease in MAP amplitude in response to sciatic stimulation that became statistically significant in monkeys at 6 months ($p < 0.01$). This effect was not noted in the low-dose group of monkeys. Rats in the 100 ppm group had reduced MAP amplitudes for sciatic stimulation, beginning at 12 weeks. No effects of 2-hexanone on scalp-recorded electroencephalograms (EEGs) of monkeys were observed. Amplitude measures of the EEG were not affected at either exposure concentration. Visual examination of the EEG records did not reveal any abnormal patterns (e.g., spikes or abnormal waves).

Evidence of 2-hexanone-induced effects on average visual evoked potential (AVEP) was obtained in monkeys exposed to 1000 ppm. Specifically, latencies of certain AVEP components were increased beginning at 4 months. No effects on these latencies occurred as a result of the low-dose 2-hexanone exposure. The refractory time (i.e., the time that must elapse between two consecutive stimuli of a nerve in order for the second stimulus to also excite the nerve) was not affected by 2-hexanone at either level of exposure.

Only rats were examined for effects of 2-hexanone on operant behavior at 10 and 19 weeks of exposure to 100 and 1000 ppm, respectively. For operant behavior, animals were trained on a multiple fixed ratio of 5, fixed interval 3-minute (multi-FR5FI3) schedule for 20–40 days after shaping the bar press response. Once behavior was stable, animals were placed in exposure chambers and tested after exposure. A reduction in response rate in the 1000 ppm group developed by the second week of exposure; however, no effects of 2-hexanone on operant behavior were found with the 100 ppm group (Johnson et al., 1977).

2-Year study: cats

Groups of four domestic shorthair cats were exposed by inhalation to 0, 100, or 330 ppm (0, 410, or 1353 mg/m^3) 2-hexanone (purity not specified) for 6 hours/day, 5 days/week for 2 years (O'Donoghue and Krasavage, 1979). Clinical signs and body weights were monitored (for details, see Section 4.2.2.2). To follow the onset of neuropathy, biopsy specimens were collected from two randomly selected cats in each group at six intervals for the first 9 months of the exposure period. All specimens were taken from alternate hind paws and included 5–6 Pacinian corpuscles and plantar interosseous muscles. Cats were sacrificed at the end of the treatment and underwent gross and histopathologic examinations, and the nervous system was examined microscopically in detail.

No clinical neurological effects attributed to exposure to 2-hexanone were identified. Neuropathologic examination results for the control and low-dose groups were comparable. All cats in the high-dose group showed evidence of neuropathologic changes in the CNS and the PNS at and below the level of the cerebellum and pons (O'Donoghue and Krasavage, 1979). In the PNS, the highest incidences of change occurred in the tibial motor nerve branches to the musculature of the lower leg and then in the tibial nerve itself. In the branches, endoneural space was enlarged with clear fluid. Swelling of giant axons with myelin retraction was evident, and degenerating axons were found infrequently. No changes were found in the dorsal root ganglion cells. In the distal portion of the PNS in the high-dose animals, unusually large preterminal axonal processes were evident, a condition not seen in controls. Examinations of tibial nerve fibers indicated comparable percentages of the four fiber pathology categories (i.e., demyelination, remyelination, swelling, and degenerative fibers) in the control and low-dose groups, but the high-dose group had notable changes in each fiber pathology category except degenerative fibers. Demyelination, remyelination, swelling, and degeneration occurred in 12.3, 3.4, 6.3, and 0.4% of high-dose axons examined (average number of high-dose axons examined = 158), compared with 0, 0.3, 0, and 0.6% of control axons (average number of control axons examined = 84). In the CNS, swollen terminals were found in the posterior cerebellar peduncles, folial white matter, nucleus gracilis, fasciculis gracilis, spino-cerebellar tracts, medullary reticular formation, and all levels of the spinal cord.

4.4.1.3. *Other Routes of Exposure*

11-Month study: dogs (subcutaneous injections)

O'Donoghue and Krasavage (1981) administered 2-hexanone (>97% pure, with 2.9% MiBK and trace quantities of 2-hexanol) by daily subcutaneous (s.c.) injection to purebred male beagles (n = 4) for 11 months. Each dog received 300 mg/kg of the test compound or saline at first once daily and later (time not stated) divided into two equal doses 6 hours apart. All animals developed signs of neurotoxicity to varying degrees. The patellar reflex was lost unilaterally in two of the four dogs receiving 133 grams of 2-hexanone over a period of 96 days. One month later, the patellar reflex was lost bilaterally in both dogs, and clinical signs of neurotoxicity progressed with observations of muscle weakness and difficulty walking. The condition of both dogs gradually reversed during the course of the study, following an unspecified cessation of exposure. In the remaining two dogs, the clinical signs of neurotoxicity appeared later in the study or were apparent at study completion. In one dog, the patellar reflex could not be elicited after it had received 243 grams of 2-hexanone over a period of 156 days. Following cessation of exposure, the dog returned to apparent normality in approximately 56 days. In the remaining dog, no clear neuropathic abnormality was produced, but, although the patellar reflex was present, the response appeared sluggish. There was occasional evidence of hind-limb weakness.

Mean body weights of treated animals were comparable with those of controls, but individual animals showed weight loss or decreased weight gain. Hematology, clinical chemistry, and cerebrospinal fluid analysis were not affected by the treatment. Repeated biopsy examinations of distal peripheral nerves showed typical giant axonal swelling. The biopsy findings paralleled the clinical course except during a recovery phase, where the biopsy continued to be abnormal while the clinical course improved. Electromyographic examination of the treated dogs showed the persistence of abnormalities in two recovering dogs, no abnormalities in one recovering dog, and no abnormalities in the one dog that had appeared clinically normal throughout the study (O'Donoghue and Krasavage, 1981).

90-Day study: hens (intraperitoneal injections)

Abou-Donia et al. (1982) treated five groups of leghorn laying hens (*Gallus gallus domesticus*, n = 3) with daily injections of 2-hexanone (70% 2-hexanone and 30% methyl isobutyl ketone, i.p.) at 100 or 200 mg/kg for 90 days. Hens given a daily 100 mg/kg i.p. injection of 2-hexanone progressed through all successive stages of ataxia; the clinical conditions of two of them improved after treatment was stopped, while the third hen progressed to paralysis and died after 30 days of administration. Daily i.p. injection of 200 mg/kg 2-hexanone produced ataxia with near paralysis (T_4), which progressed to paralysis in one hen. The clinical condition of this hen, however, reverted to grade T_4 after cessation of administration.

Spinal cords from hens given daily i.p. 100 mg/kg injections of 2-hexanone did not exhibit any histopathologic changes. One of these hens, however, showed unequivocal histopathologic changes in the peripheral nerves. The sites of axonal degeneration were accompanied by myelin degeneration, and macrophages were observed containing debris with the staining properties of myelin. Although none of the hens given 200 mg/kg i.p. injections of 2-hexanone showed histopathologic alterations in peripheral nerves, two of these hens developed unequivocal histopathologic lesions in the spinal cord. A longitudinal section from the ventral column of the thoracic spinal cord from one of the hens showed axons with prominent swellings. These swellings have the morphologic configuration of the paranodal swelling that suddenly ends at the nodes of Ranvier. A longitudinal section of the thoracic spinal cord from the other affected hen demonstrated extensive degeneration in the ventral column and a markedly swollen axon and nests of macrophages.

4.4.2. Immunotoxicity Studies

No studies were located regarding immunological effects in humans by any route of exposure to 2-hexanone.

A reduction in total white blood cell counts to 60% of control values ($p < 0.05$), but no changes in differential white cell counts or evidence of bone marrow damage, was found in rats intermittently exposed to 700 ppm 2-hexanone after 8 weeks, during an 11-week study (Katz et

al., 1980). These findings, although inconclusive, suggest that immunological effects may warrant some consideration in future assessments of the potential toxicity of exposure to 2-hexanone.

4.5. OTHER STUDIES

4.5.1. Mechanistic Studies

4.5.1.1. *2-Hexanone and Enzyme Induction*

2-Hexanone and its neurotoxic metabolite 2,5-hexanedione are both effective inducers of microsomal enzyme activities. This can affect the toxicity of other xenobiotics and also can affect the toxicity of 2-hexanone itself (or its precursor, n-hexane) by increasing or decreasing the formation of toxic metabolites.

Nakajima et al. (1991) characterized the CYP450 enzymes in the livers of male Wistar rats that are induced following exposure to 2-hexanone (5 mmol/kg-day), 2,5-hexanedione (5 mmol/kg-day), or phenobarbital (80 mg/kg-day), administered intraperitoneally for 4 days. A control group received an equivalent volume of corn oil vehicle (4 mL/kg). All three treatments caused a statistically significant increase in microsomal protein content and overall CYP450 activity (Table 4-9).

Table 4-9. Effects of 2-hexanone, 2,5-hexanedione, and phenobarbital on microsomal protein and CYP450

Treatment	Body weight (g)	Liver weight (g)	Liver/body weight ratio (%)	Microsomal protein (mg/g liver)	CYP450 (nmol/mg protein)
Control	206 ± 7	6.6 ± 0.2	3.21 ± 0.11	21.5 ± 0.8	0.92 ± 0.002
2-Hexanone	192 ± 6	7.3 ± 0.3[a]	3.80 ± 0.05[a]	25.1 ± 1.5[a]	1.49 ± 0.10[a]
2,5-Hexanedione	184 ± 7[a]	6.4 ± 0.3	3.49 ± 0.07[a]	26.2 ± 1.7[a]	1.62 ± 0.10[a]
Phenobarbital	197 ± 5	7.9 ± 0.4[a]	4.01 ± 0.13[a]	31.5 ± 3.0[a]	2.12 ± 0.19[a]

The enzyme activities (i.e., benzene aromatic hydroxylase [CYP2E1], toluene side chain oxidation [CYP2C6/11], EROD [CYP1A1/2], and PROD [CYP2B1/2]) were measured as indicators of CYP450 activity. All three treatments caused a statistically significant increase in the rate of benzene hydroxylation at low (0.2 mM) and high (6.3 mM) concentrations and toluene side chain oxidation at low (0.2 mM) and high (5.0 mM) concentrations. EROD activity was not affected by pretreatment; however, a statistically significant increase in PROD activity was observed with all three treatments. A summary of the results for the CYP450 activity measured with specific substrates is listed in Table 4-10.

Table 4-10. Effect of enzyme inducers on the activities of CYP450-related enzymes in rats exposed to 2-hexanone or 2,5-hexanedione

Treatment	Enzyme activity					
	BAH[a]		TSO[b]		EROD	PROD
	0.2 mM	6.3 mM	0.2 mM	5.0 mM		
Control	0.68 ± 0.09	0.53 ± 0.11	1.87 ± 0.15	8.34 ± 0.67	0.32 ± 0.06	0.11 ± 0.02
2-Hexanone	1.10 ± 0.19[c]	1.76 ± 0.23[c,d]	5.65 ± 0.62[c]	19.07 ± 1.64[c,e]	0.41 ± 0.30	3.68 ± 0.70[c]
2,5-Hexanedione	0.98 ± 0.16[c]	1.57 ± 0.15[c,d]	5.05 ± 0.46[c]	19.98 ± 0.78[c,e]	0.26 ± 0.44	2.92 ± 0.90[c]
Phenobarbital	0.48 ± 0.11[c]	2.80 ± 0.23[c,d]	5.59 ± 0.87[c]	25.36 ± 6.23[c,e]	0.27 ± 0.04	5.22 ± 0.70[c]

Source: Nakajima et al. (1991).

Using immunoblotting and immunodetection assays, Nakajima et al. (1991) did not detect CYP4501A1/2 in microsomes from treated and control animals. CYP4502B1/2 was induced by treatment with phenobarbital > 2-hexanone = 2,5-hexanedione. Only trace amounts of CYP4502E1 were detected in phenobarbital-treated rats, whereas 2-hexanone and 2,5-hexanedione both induced this isoform efficiently.

In order to explore the effects of 2-hexanone, 2,5-hexanedione, and phenobarbital on CYP4502B1/2, CYP4502E1, and CYP4502C6/11, Nakajima et al. (1991) performed immunoinhibition analyses of toluene side-chain oxidase (TSO) activity by using monoclonal antibodies directed against each of these CYP450 isoforms. Anti-CYP4502E1 inhibited TSO activity in induced microsomes as follows (values are percent of activity in the absence of anti-CYP4502E1): phenobarbital, 97 ± 2%; 2,5-hexanedione, 79 ± 3%; 2-hexanone, 75 ± 11%; and controls, 65 ± 2%. Anti-CYP4502B1/2 inhibited TSO activity in induced microsomes differently: phenobarbital, 31 ± 4%; 2-hexanone, 65 ± 3%; 2,5-hexanedione, 69 ± 5%; and controls, 99 ± 2%. Anti-CYP4502C6/11 inhibited toluene metabolism in induced microsomes as follows: phenobarbital, 75 ± 5%; 2-hexanone, 69 ± 5%; 2,5-hexanedione, 70 ± 3%; and controls, 23 ± 4%.

Similar studies were performed by Imaoka and Funae (1991). The authors treated male Sprague-Dawley rats (number of rats not provided) with 2-hexanone (purity not stated; 5 mmol/kg, i.p.; dissolved in corn oil) daily for 4 days. This dose was considered a maximum tolerated dose. Control rats were given corn oil only. Hepatic microsomes were isolated, and the activities of CYP450 enzymes were determined against specific substrates (Table 4-11).

Table 4-11. Catalytic activities of CYP450 enzyme activities in rat liver following induction by 2-hexanone

Substrate	Enzyme activity (nmol/min-mg protein)[a]	
	Uninduced control	2-Hexanone-treated
Aminopyrine	2.40 ± 0.50	4.37 ± 0.82b
Aniline	0.283 ± 0.044	0.421 ± 0.070[b]
7-Ethoxycoumarin	3.62 ± 0.13	6.01 ± 1.24b
Testosterone-2α	0.684 ± 0.114	0.431 ± 0.158[c]
Testosterone-2β	0.140 ± 0.039	0.240 ± 0.056[c]
Testosterone-6β	0.959 ± 0.176	1.45 ± 0.341[c]
Testosterone-7α	0.056 ± 0.006	0.062 ± 0.013
Testosterone-15α	0.040 ± 0.007	0.056 ± 0.017
Testosterone-16α	1.09 ± 0.203	1.07 ± 0.347
Testosterone-16β	0.058 ± 0.006	0.250 ± 0.106[c]

The content of total CYP450 measured photometrically did not change much with treatment. However, the activities of aminopyrine N-demethylase, aniline hydroxylase, and 7-ethoxycoumarin O-dealkylase were increased by pretreatment with 2-hexanone. Testosterone 2β-, 6β-, and 16β-hydroxylase activities were significantly increased, whereas the 2α-hydroxylase activity was decreased by treatment with 2-hexanone. The authors also measured changes in the levels of 11 forms of CYP450 in hepatic microsomes caused by treatment with 2-hexanone (Table 4-12).

The level of CYP4502C11, a male-specific form, was decreased by treatment with 2-hexanone in parallel with a decrease in testosterone 2α-hydroxylase activity, which is catalyzed by this isozyme (Kamataki et al., 1983) (cf. Table 4-12). CYP4502A2 is a constitutive testosterone 6β-hydroxylase; the increase in the level of this isoform explained the increase in testosterone 6β-hydroxylase activity, shown in Table 4-11. CYP4502B1 and 2B2 are typical phenobarbital-inducible forms. The level of CYP4502B1 in the hepatic microsomes of control rats was very low, and CYP4502B2 was detected at a slightly higher level. Both forms were strongly induced in 2-hexanone-treated rats. These results reflected the increases in testosterone 16β-hydroxylase and aminopyrine N-demethylase activities of hepatic microsomes (cf. Table 4-11) and suggest that 2-hexanone is a phenobarbital-type inducer.

Table 4-12. Changes in CYP450 levels following treatment with 2-hexanone

CYP450 isoform	CYP450 content (pmol/mg protein)[a]	
	Uninduced control	2-Hexanone-treated
2A1	7.0 ± 1.3	7.9 ± 1.5
2A2	10.4 ± 2.3	11.7 ± 2.8
2B1	<0.5	44.3 ± 9.4c
2B2	3.8 ± 1.2	29.3 ± 6.2c
2C6	52.1 ± 17.7	93.4 ± 16.9[b]
2C7	21.9 ± 3.3	24.8 ± 5.8
2C11	457.0 ± 52.6	343.8 ± 46.3[c]
2C13	171.4 ± 35.8	159.7 ± 24.5
2E1	49.8 ± 9.6	102.6 ± 14.8[b]
4A3	17.6 ± 3.2	16.7 ± 2.8

[a]Mean ± SD, number of rats not provided.

[c]Significantly different from control, $p < 0.05$.

Source: Imakoa and Funae (1991).

Imaoka and Funae (1991) determined that the inducibility of CYP4502B1 and 2B2 was strongly correlated with the hydrophobicity (as estimated by the octanol/water partition coefficients, log K_{ow}) of several 2-hexanone homologues: 2-hexanone (1.38) > methyl n-propyl ketone (0.91) > MEK (0.29) > acetone (−0.24). In contrast, the inducibility of P4502E1 was not dependent on hydrophobicity. Each of the aforementioned chemicals, at equimolar concentrations, induced CYP4502E1 to a similar extent, approximately twofold, while acetone, a prototypical inducer of CYP2E1, induced this isoform approximately threefold.

Based on studies of 2-hexanone and the pesticide O-ethyl O-4-nitrophenyl phenylphosphonothioate (EPN) in hens, Abou-Donia et al. (1991, 1985) speculated that the potentiation of the neurotoxic effects of 2-hexanone by EPN may be due to induction of hepatic microsomal CYP450 by EPN with increased production of 2,5-hexanedione (Abou-Donia et al., 1991, 1985a). Similarly, MEK may also potentiate the toxicity of 2-hexanone through induction of CYP450 as MEK but not 2-hexanone and has been shown to decrease hexobarbital sleep time in rats (Couri et al., 1977). While MEK has been shown to potentiate the toxicity of 2-hexanone in rats (Saida et al., 1976), Shibata et al. (2002) have demonstrated that MEK depresses the metabolism of n-hexane in human volunteer subjects. If the metabolic pathways of 2-hexanone, as detailed in Section 3.3 and Figure 3-1, are common in humans and animals and MEK depresses the metabolism of n-hexane but increases the metabolism of 2-hexanone, then the step in 2-hexanone metabolism that MEK likely affects is the ω-1-oxidation to 5-hydroxy-2-hexanone. While no specific CYP450 isoenzymes have been implicated and the mechanisms are not fully elucidated, it appears that 2-hexanone has the ability to influence its own metabolism via effects on CYP450 enzymes that need more research to be fully understood.

It should be noted that, like 2-hexanone, MiBK, a common contaminant in the formulation of the 2-hexanone, has the potential to act as a CYP450 inducer. However, the 3.2% concentration of MiBK in 96% pure formulations of 2-hexanone, as reported by O'Donoghue et al. (1978), may not have a significant impact on the toxicity of 2-hexanone. To determine whether the concentration of MiBK as a contaminant may have altered the observed toxicity of 2-hexanone, other studies were evaluated that used MiBK as a test article. In a 13-week gavage study, 30 male and female Sprague-Dawley rats were treated daily with 0, 50, 250, or 1,000 mg MiBK/kg-bw (MAI, 1986). At the middle and high doses, adverse effects were observed in the liver and kidney, which progressed in severity in the high-dose animals. No treatment-related effects of any kind were observed at 50 mg/kg-day. The Carnegie-Mellon Institute of Research (1977) conducted a 120-day drinking water study with 1.3% MiBK, using female HLA Wistar rats. The authors estimated the dosage to be 1040 mg/kg-day. The only statistically significant finding was increased mean absolute and relative kidney weights in treated rats compared with controls. Histopathological examination revealed renal tubular cell hyperplasia in only one of five of the treated rats. No exposure-related histopathological changes were found in other organs. Based on the foregoing, it can be concluded that the dosage of MiBK received as an impurity in the study by O'Donoghue et al. (1978) did not contribute to the observed 2-hexanone-related effects. O'Donoghue et al. (1978) did not observe adverse effects in the kidney or liver of treated animals, despite these organs being the target organs of toxicity in experimental studies with MiBK from both the oral and inhalation routes (U.S. EPA, 2003a).

4.5.1.2. *2-Hexanone as a Sulfhydryl Reagent*

Both 2-hexanone and its metabolite 2,5-hexanedione can inhibit sulfhydryl-containing enzymes such as fructose-6-phosphate kinase and glyceraldehyde-3-phosphate dehydrogenase (enzymes in the pentose phosphate pathway [oxidative phase] and glycolytic pathway [nonoxidative phase], respectively) (Sabri, 1984; Sabri et al., 1979). Both of these chemicals inhibited fructose-6-phosphate kinase from rabbit muscle or rat brain homogenates; in each case, 2,5-hexanedione was the far more potent inhibitor (Sabri et al., 1979). Preincubation with dithiothreitol protected this enzyme from inhibition, which suggests that these compounds interfere with the sulfhydryl groups required for fructose-6-phosphate kinase activity. However, dithiothreitol could not restore enzyme activity after these compounds had been added. In addition, fructose-6-phosphate kinase activity was also reduced in brain homogenates of rats that had received 2,5-hexanedione at 0.5% in their drinking water for 10–12 weeks (Sabri et al., 1979). Glyceraldehyde-3-phosphate dehydrogenase from rabbit muscle (purified to crystalline state) was also inhibited in vitro by both compounds; in this case, 2-hexanone was the more potent inhibitor (Sabri, 1984). Levels of ATP were reduced in cat sciatic nerves treated with 2,5-hexanedione (Sabri, 1984), possibly an outcome of glyceraldehyde-3-phosphate

dehydrogenase inhibition. 2-Hexanone was found to irreversibly inhibit rat brain and rabbit muscle creatine kinase and mouse brain adenylate kinase (Lapin et al., 1982).

4.5.1.3. *Studies Exploring the Development of Neuropathy*

Groups of 12 Sprague-Dawley rats (sex unspecified) were continuously exposed (24 hours/day) via inhalation to 0, 225, or 400 ppm (0, 922.5, or 1,640 mg/m^3) 2-hexanone (purity not stated) for 16–66 days (Saida et al., 1976). Rats exposed to 400 ppm were sacrificed at 16, 28, and 42 days, and those exposed to 225 ppm were sacrificed at 16, 25, 35, 55, and 66 days to study the sequence of morphological changes. Paralysis was observed after 66 and 42 days at the low and high concentrations, respectively. Neuropathologic changes preceded paralysis and were observed at the initial sacrifice after 16 days of exposure. Two distinct changes occurred quite early and close to the same time: the first to appear was an increase in the number of neurofilaments and the other was an in-pouching of the myelin sheath. In animals exposed to 400 ppm, the first observable change at 16 days was, in larger diameter nerve fibers, a two- to threefold increase in the number of neurofilaments. As the duration of exposure lengthened and the number of neurofilaments increased, several interrelated morphological observations were made. In teased nerve fiber preparations, swelling of the axons could be seen frequently in the paranodal area and less often at focal sites along the internodal segment. High numbers of nerve fibers with in-pouching of the myelin sheath were found per mm^2 of nerve fascicle, increasing with time after administration of the high concentration. A summary of the comparative sequential clinical and pathological observations is presented in Table 4-13.

Table 4-13. Clinical and pathological observations with time of exposure to 2-hexanone in rats

	2-Hexanone exposure						
	400 ppm			225 ppm			
Days exposed	16	28	42	16	25	35	55
Clinical findings	N[a]	N	P[b]	N	N	N	N
In-pouchings (#/mm^2)	6	142	499	23	46	92	86
Denuded fibers (#/mm^2)	0	4	11	0	0	1	2
Swollen axons >11 µm (#/300 fibers)	0	1	3	0	0	0	0

[a]N = normal.
[b]P = paralyzed.

Source: Saida et al. (1976).

The anterior horn cells, nerve roots, nerve trunks, intramuscular nerves, and motor end plates were studied sequentially to determine the site with the earliest pathological involvement. In animals exposed for 16 days to 225 ppm, no abnormalities were found in the motor end plates

or intramuscular nerves of the intrinsic foot muscles. Only after prolonged exposure, 66 days, did the authors find typical signs of denervation in the motor end plates. These end plates showed atrophic axon terminals with Schwann cell processes interposed between the nerve terminal and postsynaptic membrane. There was also a loss of secondary synaptic clefts.

Anterior horn cells and dorsal root ganglion cells were also examined at various intervals of exposure. No changes were observed in these cell bodies, even after typical changes were seen in the main trunk of the sciatic nerve. Specifically, no abnormalities were seen that would suggest an increase in neurofilaments in these cell bodies, and no cells were observed undergoing chromatolysis.

4.5.2. Genotoxicity Studies

Mayer and Goin (1994) tested the ability of 2-hexanone to induce chromosome loss in strain D61.M of *Saccharomyces cerevisiae*. 2-Hexanone, alone or in combination with acetone and MEK, induced only a marginally positive chromosome loss (Mayer and Goin, 1994).

No data were identified for the mutagenicity of 2-hexanone with in vitro cytogenetic tests or in vivo tests.

4.5.3. Structure-Activity Relationships

A large body of toxicological information is available on n-hexane, a compound that is metabolized to 2-hexanone, on MiBK (a branched-chain homologue of 2-hexanone), and on MEK. These compounds have been reviewed in previous IRIS assessments, and a summary of the reference values derived for each is presented in Table 4-14. n-Hexane is the only compound of the above three that is also capable of producing the peripheral neuropathy similar to that observed in humans or animals exposed to 2-hexanone. Neither MiBK nor MEK can give rise to the neurotoxic metabolite 2,5-hexanedione.

Table 4-14. Summary of the toxicities of n-hexane, MiBK, and MEK

Chemical	Experimental dose	Critical effect	Reference value	Reference
n-Hexane (CASRN 110-54-3)	NOAEL[a]: 1762 mg/m^3	Peripheral neuropathy (decreased MCV at 12 weeks)	RfC: 7×10^{-1} mg/m^3	U.S. EPA (2005c)
Methyl isobutyl ketone (CASRN 108-10-1)	NOAEL: 1229 mg/m^3	Reduced fetal body weight, increased fetal death, and skeletal variations in mice and rats	RfC: 3 mg/m^3	U.S. EPA (2003a)
Methyl ethyl ketone (CASRN 78-93-3)	LEC[b]: 5202 mg/m^3	Developmental toxicity (skeletal variations)	RfC: 5 mg/m^3	U.S. EPA (2003b)
	NOAEL: 594 mg/kg-day (0.3% 2-butanol)	Decreased pup body weight	RfD: 0.6 mg/kg-day	

[a]NOAEL = no-observed-adverse-effect level.
[b]LEC = lowest effective concentration.

4.5.4. Potentiation and Other Interaction Studies

4.5.4.1. *Methyl Ethyl Ketone*

In a study of chemical interaction, Saida et al. (1976) exposed rats of unspecified sex (12/group) continuously, 24 hours/day, to 225 ppm (922 mg/m^3) 2-hexanone, 1125 ppm (3318 mg/m^3) MEK, or a combined exposure of 225 ppm (922 mg/m^3) 2-hexanone and 1125 ppm MEK for up to 66 days. No signs of neurotoxicity were observed in the MEK-exposed rats. Paralysis occurred earlier in the rats exposed to the mixture compared with rats exposed to 225 ppm 2-hexanone alone. In addition, an elevated severity of neuropathy, in the form of increased swollen axons, denuded fibers, and in-pouching of myelin sheaths, was observed histologically in the rats coexposed to MEK and 2-hexanone. Thus, MEK appeared to potentiate the toxicity of 2-hexanone. Yu et al. (2002) showed that the potentiating effect of MEK on n-hexane-induced neurotoxicity was due to an inhibitory effect of MEK on phase II biotransformation of 2,5-hexanedione (Yu et al., 2002). Since n-hexane is a precursor to 2-hexanone, and both compounds form the highly toxic 2,5-hexanedione, it is likely that the results of Yu et al. (2002) are applicable to coexposure studies with MEK and 2-hexanone.

As a test of in vivo enzyme induction, groups of five male Wistar rats were continuously exposed via inhalation to 225 ppm 2-hexanone, 750 ppm MEK, or the combination of 225 ppm 2-hexanone and 750 ppm MEK for 7 days (Couri et al., 1977). Subsequently, the animals were given sodium hexobarbital (100 mg/kg, i.p.), a substrate for phenobarbital-inducible CYP450 isoenzymes (Adedoyin et al., 1994; Knodell et al., 1988), and sleep time was measured. The average hexobarbital-induced sleep time of 2-hexanone-treated rats was comparable to that of controls (24.8 vs. 26.0 minutes); however, the sleep times in MEK and 2-hexanone/MEK-exposed rats were significantly ($p < 0.05$) less than in controls, 13.0 and 16.0 minutes, respectively. In a study by O'Donoghue and Krasavage (1979), sodium pentobarbital-induced sleep time was increased in 2-hexanone-treated cats.

4.5.4.2. *Chloroform*

Oral administration of 2-hexanone, followed by i.p. administration of chloroform to rats, resulted in a variety of hepatic and renal effects, including decreased hepatic glutathione levels, increased plasma levels of glutamic pyruvic transaminase and blood urea nitrogen, and degeneration and necrosis of hepatic and renal tissue (Hewitt et al., 1990, 1987; Brown and Hewitt, 1984; Branchflower and Pohl, 1981). Similarly, oral administration of both 2-hexanone and chloroform to rats resulted in altered permeability of the biliary tree (Hewitt et al., 1986). In these studies, some or no effect on the endpoints of interest was observed after administration of 2-hexanone or chloroform alone; administration of both substances resulted in statistically significant and dramatic changes in these effects. The authors speculated that 2-hexanone potentiated the hepatic toxicity of chloroform by decreasing glutathione levels and by increasing the metabolism of chloroform to the potent hepatotoxicant phosgene.

4.5.4.3. *O-Ethyl O-4-Nitrophenyl Phenylphosphonothioate*

2-Hexanone has been shown to potentiate the neurotoxic effects of EPN. In hens, dermal or inhalation exposure to 2-hexanone in combination with dermal application of the organophosphate pesticide EPN has resulted in earlier onset and far more severe clinical and histological manifestations of neurotoxic effects than with either chemical exposure alone (Abou-Donia et al., 1991, 1985a). The authors speculated that this potentiation effect may have been due to induction of hepatic microsomal CYP450 by EPN, leading to increased metabolism of 2-hexanone to its neurotoxic metabolite 2,5-hexanedione. An alternate explanation is that local trauma to the nervous tissue produced by 2-hexanone and EPN might increase vascular permeability and thus increase the entry of these compounds and their metabolites from circulation.

4.6. SYNTHESIS AND EVALUATION OF MAJOR NONCANCER EFFECTS

4.6.1. Oral

There are no studies that have examined the possible association between oral exposure to 2-hexanone and noncancer health effects in humans. There are six subchronic or chronic studies in which 2-hexanone was administered orally to experimental animals. These include a 90-day gavage study in hens, 90-day and 40-week gavage studies in rats, 120-day and 13-month drinking water studies in rats, and a 24-week drinking water study in guinea pigs. These studies demonstrate that the nervous system is the target organ for 2-hexanone toxicity following oral exposure. For example, O'Donoghue et al. (1978), a 13-month drinking water study using COBS CD(SD)BR rats, described the characteristic neuropathologic evidence of giant axonal neuropathy in 80% of animals at the lowest dose tested (143 mg/kg-day).

There are data suggesting that the principal metabolite of 2-hexanone, 2,5-hexanedione, is responsible for the neurotoxicity associated with oral exposure to 2-hexanone. For example, Krasavage et al. (1980) compared the neurotoxicity of 2-hexanone with that of n-hexane, 5-hydroxy-2-hexanone, 2,5-hexanediol, and 2-hexanol by administering equimolar doses of each chemical by gavage to five male COBS CD(SD)BR rats/group, 5 days/week for 90 days. Judged by the time required for the rats to develop hind-limb paralysis, 2,5-hexanedione had a higher neurotoxic potency than 2-hexanone.

In summary, the chronic and subchronic studies conducted with rats, hens, and guinea pigs provide ample evidence that the nervous system is the target of toxicity following oral exposure to 2-hexanone. A summary of the oral studies with 2-hexanone is provided in Table 4-15.

Table 4-15. A synopsis of oral toxicity studies with 2-hexanone

Species, strain	Group size (sex)	Dosage; duration; purity	Effects at LOAEL	NOAEL[a] (mg/kg-day)	LOAEL[a] (mg/kg-day)	Reference
Adult leghorn laying hens (*Gallus gallus domesticus*)	3/group (female)	100 mg/kg, gavage; 7 days/week for 90 days; technical grade containing 70% 2-hexanone and 30% MiBK	Mild ataxia at 12 ± 1 days with progression to severe ataxia by 50 ± 1 days	Not identified	100	Abou-Donia et al., 1982
Rat, COBS/ CD(SD)BR	6/group (male)	660 mg/kg, gavage; 5 days/week for 90 days; 2-hexanone containing 3.2% MiBK and 0.7% unknown contaminants	Clinical and histological findings of neuropathy at 55.8 ± 4.3 days	Not identified	660	Krasavage et al. (1980)
Rat, Wistar	5/group (female)	0, 0.65, or 1.3% (0, 480, or 1010 mg/kg-day) in drinking water; 120 days; purity not stated	Mild atrophy affecting skeletal muscles of the hind limbs in 2 of 5 animals examined	Not identified	480	Homan et al. (1977)
Guinea pig, English short hair	5/group (sex not stated)	0, 0.1, or 0.25% (0, 97, or 243 mg/kg-day) in drinking water; 24 weeks; purity not stated	Decreased pupillary response to light stimulus	Not identified	97	Abdel-Rahman et al. (1978)
Rat, Wistar	6/group (male)	400 mg/kg-day, gavage; 40 weeks; 2-hexanone 98% pure, contaminants not characterized	Hind-limb weakness from the 17th–28th week, with improvement thereafter	Not identified	400	Eben et al. (1979)
Rat, COBS/ CD(SD)BR	10/group (male)	0, 0.25, 0.5, or 1.0% (0, 143, 266, or 560 mg/kg-day) in drinking water; 13 months; 2-hexanone containing 3.2% MiBK and 0.7% unknown contaminants	Clinical neurological deficits	143	266	O'Donoghue et al. (1978)
			Neuropathologic evidence of myofibrillar atrophy of the calf muscle in 1/10 animals	143	266	
			Neuropathologic evidence of myofibrillar atrophy of the quadriceps muscle in 2/10 animals	143	266	
			Neuropathologic evidence of giant axonal neuropathy in 8/10 animals	Not identified	143

4.6.2. Inhalation

Several studies have established associations between inhalation exposure to 2-hexanone and human health effects. Specifically, occupational studies and case reports suggest that inhalation exposure to 2-hexanone in humans may be associated with neurotoxicity. For example, a cross-sectional study of employees at a coated fabrics plant was conducted when it was noted that six workers from the print department had developed severe peripheral neuropathy soon after the plant began phasing in the use of 2-hexanone (Allen et al., 1974; Billmaier et al., 1974). Definite signs, symptoms and electrodiagnostic findings of peripheral neuropathy were confirmed in 68 out of 192 employees. The prevalence of peripheral neuropathy was clearly increased in jobs with evident exposure to 2-hexanone vapors and with time spent at work sites with 2-hexanone exposure.

Mallov (1976) reported one probable and two definite cases of 2-hexanone-induced peripheral neuropathy that were identified during an investigation of 26 painters. Similar to the studies reported above, (Allen et al., 1974; Billmaier et al., 1974), neuropathy was observed in the painters when the formulation of paint solvents was changed from MEK and methyl isoamyl ketone, both not neurotoxic, to 2-hexanone (Mallov, 1976). In another case of occupational exposure to 2-hexanone, symmetrical polyneuropathy was reported in a furniture finisher (Davenport et al., 1976). Six months prior to the onset of the worker's illness, 2-hexanone had been substituted for MiBK. A similar progressive distal extremity weakness developed in a coworker of the patient, which also improved following the coworker's removal from contact with lacquer products.

The toxicity of 2-hexanone via inhalation was studied extensively in experimental animals. As with oral exposures, the target organ for toxicity following inhalation exposure to 2-hexanone was the nervous system, and the most sensitive measures of intoxication were histopathological and clinical findings of peripheral neuropathy. Numerous studies are available, with duration varying from subchronic to chronic, in many different test species, including monkeys, rats, and cats. A summary of the available inhalation studies with 2-hexanone is provided in Table 4-16.

Table 4-16. Synopsis of animal inhalation toxicity studies with 2-hexanone

Species, strain	Number (sex)	Concentration; duration; purity	Effects at LOAEL	NOAEL[a] (mg/m^3)	LOAEL[a] (mg/m^3)	Reference
Developmental study						
Rat, pregnant F-344	25/group (female)	0, 1000, or 2000 ppm (0, 4100, or 8200 mg/m^3); day 0 of gestation through day 21, 6 h/day, 7 d/wk; purity not stated	Hyperactivity in behavioral testing	Not identified	4100	Peters et al. (1981)
Subchronic exposure studies						
Rat, strain not stated	9/group (sex not stated)	0 or 200 ppm (0 or 819 mg/m^3); 6 weeks, 8 h/d, 5 d/wk; purity not stated	Axonal hypertrophy, beading and degeneration of sciatic nerve	Not identified	819	Duckett et al. (1974)
Rat, Wistar	20/group (sex not stated)	40 ppm (164 mg/m^3); 22–88 days, 8h/d, 5d/wk; purity not stated	Peripheral neuropathy (demyelination of sciatic nerve) in 3/20	164	205	Duckett et al. (1979)
Rat, Sprague-Dawley	12/group (sex not stated)	0, 225, or 400 ppm (0, 922.5, or 1640 mg/m^3); 42–66 days, 24 h/d, 7 d/wk; purity not stated	Increased number of fibers with in-pouchings per mm^2 of nerve fascicle	Not identified	922.5	Saida et al. (1976)
Rat, COBS/ CD(SD) BR	5/group (male)	0 or 700 ppm (0 or 2870 mg/m^3); 81 days, 72 h/wk; 96.1% pure with 3.2% MiBK and 0.7% unidentified contaminants	Severe neuropathy consisting of difficulty extending hind limbs and a flat-footed gait with feet splayed in 5/5 at 71 ± 9 days	Not identified	2870	Katz et al. (1980)
Adult leghorn laying hens (*Gallus gallus domesticus*)	5/group	0, 10, 50, 100, 200, or 400 ppm (0, 41, 205, 410, 820, or 1640 mg/m^3); 90 days (continual exposure); technical grade containing 70% 2-hexanone and 30% MiBK	Mild ataxia (27 $\pm$ 2 days) progressing to severe ataxia/near paralysis (89 $\pm$ 1 days)	41	205	Abdo et al. (1982)
Rat, Sprague-Dawley	4/group (sex not stated)	0 or 400 ppm (0 or 1640 g/m^3) (adjusted); 12 weeks, 24 h/d, 7 d/wk; purity not stated	Dragging of hind limbs at 11–12 weeks	Not identified	1640	Mendell et al. (1974)
Domestic Chickens	5/group (not stated)	0 or 200 ppm (0 or 820 mg/m^3), adjusted to 100 ppm (410 mg/m^3)(time not stated); 12 weeks (24 h/d, 7 d/wk); purity not stated	Inability to stand on legs at 4–5 weeks	Not identified	820	Mendell et al. (1974)
Cat, domestic, strain not stated	4/group (sex not stated)	0 or 400 ppm (1640 mg/m^3) (adjusted); 12 weeks, 24 h/d, 7 d/wk; purity not stated	Dragging of hind limbs and forelimb weakness at 5–8 weeks	Not identified	1640	Mendell et al. (1974)

Table 4-16. Synopsis of animal inhalation toxicity studies with 2-hexanone

Species, strain	Number (sex)	Concentration; duration; purity	Effects at LOAEL	NOAEL[a] (mg/m^3)	LOAEL[a] (mg/m^3)	Reference
Rat, Wistar	20/group (sex not stated)	50 ppm (205 mg/m^3); 13 weeks, 8h/d, 5 d/wk; purity not stated	Peripheral neuropathy (demyelination of sciatic nerve) in 3/20	164	205	Duckett et al. (1979)
Chronic exposure studies						
Rat, strain not stated	6/group (sex not stated)	0 or 1300 ppm (5325 mg/m^3); 4 months, 6 h/d, 5d/w; purity not stated	Nerve fiber degeneration in the peripheral nerves, spinal cord, medulla, and cerebellum	Not identified	5325	Spencer et al. (1975)
Rat, Wistar	40/group (sex not stated)	50 ppm (205 mg/m^3); 6 months, 8h/d, 5 d/wk; purity not stated	Widespread demyelination of the sciatic nerve in 32/40	Not identified	205	Duckett et al. (1979)
Rat, Sprague-Dawley	6/group (male)	0 or 100 ppm (0 or 410 mg/m^3); 6 months, 22 h/d, 7 d/wk; 96.66% pure, impurities not characterized	Giant axonal swelling of peripheral nerves after 4 months	Not identified	410	Egan et al. (1980)
Rat, Sprague-Dawley	10/group (male)	0, 100, or 1000 ppm (0, 410, or 4100 mg/m^3); 10 months, 6 h/d, 5d/wk; commercial grade, impurities not stated	Decreased motor conduction velocity between treated and control animals beginning at 29 weeks	Not identified	410	Johnson et al. (1977)
Monkey, *Macaca fascicularis*	8/group (male)	0, 100, or 1000 ppm (0, 410, or 4100 mg/m^3); 10 months, 6 h/d, 5d/wk; commercial grade, impurities not stated	Decreased motor conduction velocity at 9 months (right sciatic-tibial nerve, right ulnar nerve)	Not identified	410	Johnson et al. (1977)
Rat, Sprague-Dawley	18/group (male)	0, 100, or 330 ppm (0, 410, or 1353 mg/m^3); 72 weeks, 6h/d, 5d/wk; purity not stated	Severe polyradiculoneuritis in the lumbar and sacral spinal nerves and roots and the sciatic and tibial nerves in one rat	410	1353	Krasavage and O'Donoghue (1977)
Cat, domestic shorthair	4/group (female)	0, 100, or 330 ppm (0, 410, or 1353 mg/m^3); 2 years (6h/d, 5d/wk); purity not stated	Giant axonal neuropathy of the spinal cord and peripheral nerve in 4/4	410	1353	O'Donoghue and Krasavage (1979)

[a]No-observed-adverse-effect levels (NOAELs) and lowest-observed-adverse-effect levels (LOAELs) determined by 2-hexanone assessment authors.

4.6.3. Mode-of-Action Information

Exposure to 2-hexanone in humans and experimental animals demonstrates that the nervous system is the target organ of toxicity, regardless of the route of exposure. The toxicity is attributed to the neurotoxic metabolite 2,5-hexanedione. A strong relationship has been noted between the concentration of 2,5-hexanedione in the urine and the onset of neuropathic symptoms (Eben et al., 1979). Similarly, 2,5-hexanedione has been described as eliciting severe neurotoxic symptoms following oral, dermal, or i.p. administration to hens and oral administration to rats (Abou-Donia et al., 1985a; Abdo et al., 1982; Krasavage et al., 1980).

Current research supports a mode of action for γ-diketones, such as the 2-hexanone metabolite 2,5-hexanedione, which involves the covalent cross-linking of neuronal macromolecules with proteins as the primary target. The result is axonal swelling, specifically of giant axons, that ultimately ends in retrograde degeneration of the axon. 2,5-Hexanedione is an electrophilic species that reacts with nucleophilic sites of proteins via a substitution or addition reaction, with the subsequent formation of a covalent bond (Lopachin and Decaprio, 2005). Although 2,5-hexanedione has been shown to react with sulfhydryl groups of enzymes (Section 4.5.1.2), the compound causes distal axonopathy by covalent reaction with nucleophilic lysine ε-amine groups to form 2,5-dimethylpyrrole adducts with neurofilaments and other proteins (LoPachin et al., 2005, 2004). Oxidation of the pyrrole moiety with molecular oxygen can generate a cation intermediate that can undergo further reactions with amino- or sulfhydryl groups. This results in the development of neurofilament aggregates in the distal, subterminal axon that, as they grow larger, form massive swellings, often just proximal to the nodes of Ranvier (Graham, 1999).

One of the major hypotheses related to the mechanism of neurotoxicity of 2,5-hexanedione is covalent binding with axonal components of nerve tissue. In vitro studies in which 2,5-hexanedione was incubated with proteins demonstrated that this compound binds to the lysine ε-amino group, resulting in the formation of the substituted pyrrole adduct ε-N-(2,5-dimethylpyrrole)norleucine (DeCaprio et al., 1982). Covalent binding of 2,5-hexanedione with axonal components leading to pyrrole formation and protein cross-linking was hypothesized as a possible initiation step leading to axonal degeneration and thus may account for the neurotoxic effects observed with exposure to γ-diketones in general (DeCaprio et al., 1988; DeCaprio et al., 1982). In vivo pyrrole formation was confirmed by the demonstration of ε-N-(2,5-dimethylpyrrole)norleucine in the hydrolyzed serum of a hen that had received 2,5-hexanedione at 200 mg/kg-day for two weeks (DeCaprio et al., 1982). The proposed mechanism for 2,5-hexanedione in the development of progressive sensorimotor distal axonopathy is presented in Figure 4-1.

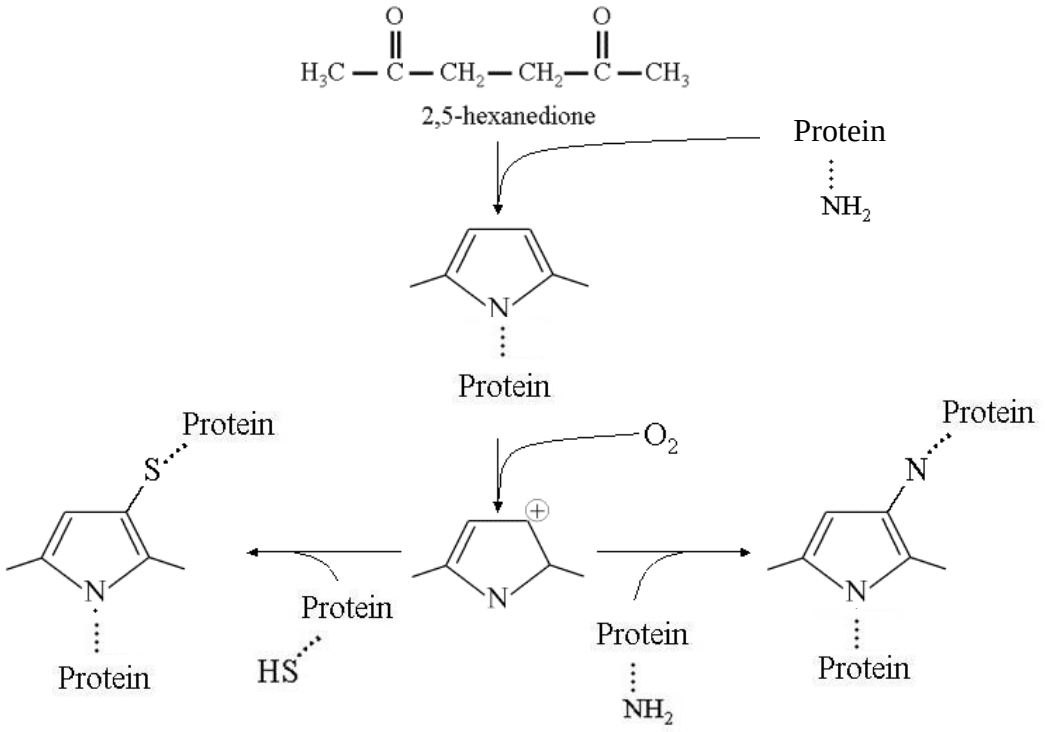

Figure 4-1. Proposed mechanism for 2,5-hexanedione-induced axonopathy.

Note: γ-Diketones, such as 2,5-hexanedione, react with amino groups in all tissues to form pyrroles. The pyrrole moiety can undergo further oxidation reactions with amino- or sulfhydryl groups. This results in the development of neurofilament aggregates (in the distal, subterminal axon), which, as they grow larger, form massive swellings of the axon.

4.7. WEIGHT-OF-EVIDENCE EVALUATION AND CANCER CHARACTERIZATION

4.7.1. Summary of Overall Weight of Evidence

Under EPA's *Guidelines for Carcinogen Risk Assessment* (U.S. EPA, 2005a), there is "inadequate information to assess the carcinogenic potential" of 2-hexanone. Specifically, there are no animal carcinogenicity studies available that examine exposure to 2-hexanone, and there are no studies available that assert a genotoxic potential of 2-hexanone. The available occupational studies do not present evidence for any carcinogenic action of 2-hexanone and are limited by frequent coexposure to other chemicals (e.g., MEK).

4.8. SUSCEPTIBLE POPULATIONS AND LIFE STAGES

4.8.1. Possible Childhood Susceptibility

The susceptibility of the developing brain is based on the timing of neuronal development, the rapid growth that occurs in the third trimester and early infancy, and the lack of a protective barrier early in life (Costa et al., 2004). In the cerebellum, Purkinje cells develop early, weeks 5–7 in humans, whereas granule cells are generated much later, gestational weeks

24–40 in humans. The developing brain is distinguished by the absence of a blood-brain barrier. The development of this barrier is a gradual process, beginning in utero and complete at approximately 6 months of age. Because the blood-brain barrier limits the passage of substances from blood to brain, in its absence, toxic agents can freely enter the developing brain. Since Purkinje-cell degeneration has been observed with adult rats exposed to high levels of 2,5-hexanedione, infants may be at an increased risk for this type of damage at lower levels of exposures, due to the incomplete maturation of the blood-brain barrier (Hernandez-Viadel et al., 2002). However, this would depend on the capacity of infants and small children to bioactivate 2-hexanone to 2,5-hexanedione.

Metabolism of 2-hexanone may vary between children and adults due to differences in the development and maturity of phase I and phase II enzymes (Johnsrud et al., 2003). Studies indicate that the mode of action of 2-hexanone toxicity involves the metabolism to a more toxic metabolites, namely 2,5-hexanedione. Several enzymes, such as CYP2E1, CYP2B1/2, and CYP2C6/11, are inducible following administration of 2-hexanone in animal models (Imaoka and Funae 1991; Nakajima et al., 1991); however, the individual isoforms involved in its metabolism have not been fully elucidated. Toftgard et al. (1986) found that the formation of 2,5-hexanediol from 2-hexanol was catalyzed by a CYP isozyme different from CYP2B and present in liver but not in lung microsomes. The authors concluded that 2-hexanol must be transported to the liver before the neurotoxic metabolite 2,5-hexanedione can be formed (Toftgard et al., 1986). Because of this, changes in CYP protein levels and phase II enzymes during development may likely have an impact on susceptibility to 2-hexanone. As mentioned above, the possible susceptibility of 2-hexanone may be influenced by life stage, but there are few studies to confirm the impact and severity of such exposure. Thus, the evidence of possible childhood susceptibility is inconclusive.

4.8.2. Possible Gender Differences

Evaluations of human occupational exposures have not provided evidence that 2-hexanone acts in a gender-specific way. Most animal studies also have not brought forth strong evidence of a sex-specific action of 2-hexanone. However, it should be mentioned that in a few rat studies 2-hexanone appeared to affect the male reproductive system (Katz et al., 1980; Krasavage et al., 1980; O'Donoghue et al., 1978).

5. DOSE-RESPONSE ASSESSMENTS

5.1. ORAL REFERENCE DOSE (RfD)

The RfD is an estimate (with uncertainty spanning perhaps an order of magnitude) of a daily oral exposure to the human population (including sensitive subgroups) that is likely to be without an appreciable risk of deleterious effects during a lifetime. It can be derived from a no-observed-adverse-effect level (NOAEL), lowest-observed-adverse-effect level (LOAEL), or benchmark dose (BMD), with uncertainty factors generally applied to reflect limitations of the data used.

5.1.1. Choice of Principal Study and Critical Effect—with Rationale and Justification

The 13-month drinking water study (10 animals/dose/sex) conducted by O'Donoghue et al. (1978) is the most suitable study for deriving a 2-hexanone RfD assessment Five other subchronic studies are available and are considered as supporting studies. Of these five studies, Krasavage et al. (1980) and Eben et al. (1979) both observed neurotoxicity after administration of single doses of 2-hexanone via gavage. These two studies were not considered as principal studies because only single relatively high doses were administered and gavage administration is less relevant to human exposure than administration in drinking water. Abdo et al. (1982) observed mild ataxia, which progressed to severe ataxia, in hens gavaged daily with 100 mg/kg 2-hexanone. This study was not chosen as the principal study because the hen's digestive system is anatomically distinct from humans and thus a poor model for assessing the effects of human oral exposure.[3] Finally, two subchronic drinking water studies that utilized multiple doses of 2-hexanone and identified neurotoxicological outcomes were considered. The first study, conducted by Homan et al. (1977), utilized doses that were higher than those used by O'Donoghue et al. (1978), and the purity of 2-hexanone was not stated. The second study, by Abdel-Rahman et al. (1978), utilized lower doses than the chronic study by O'Donoghue et al. (1978); however, the authors did not include complete data sets; that is, only data from the first 4 weeks of the study were presented. Further, the purity of the compound used was not stated.

O'Donoghue et al. (1978) conducted a 13-month study in male COBS/CD(SD) rats. The animals' drinking water contained 0, 0.25, 0.5, or 1.0% (0, 143, 266, or 560 mg/kg-day) 2-hexanone (96% pure, containing 3.2% MiBK and 0.7% unknown contaminants). In this study, 2-hexanone produced a dose-dependent reduction in body weight at all doses tested. The critical endpoints evaluated from this study were the incidences of myofibrillar atrophy of the quadriceps muscle and the calf muscle in male rats. These endpoints were chosen over the other neuropathologic endpoints in Table 5-1 because they occur due to axonal atrophy, an endpoint

[3] The lower portion of a hen's esophagus forms a pouch called the crop, which serves as a temporary storage site for food prior to passage to the stomach. The two-part structure of the hen's stomach, which consists of the proventriculus and the gizzard, further alters the absorption and distribution of chemicals.

identified as the best correlate of nerve dysfunction, regardless of route of exposure (Lehning et al., 2000). Though axonal swelling was observed with high incidence in the peripheral nerve and spinal cord at the lowest dose tested, axonal swelling poorly correlates with nerve dysfunction and can occur without progression to nerve dysfunction (LoPachin et al., 2004, 2003; Lehning et al., 2000, 1995). Because myofibrillar atrophy of the quadriceps and calf muscles displayed a clear dose-dependent response, these data were evaluated further by BMD modeling.

5.1.2. Method of Analysis: Benchmark Dose Modeling

The animal data evaluated for derivation of an RfD for 2-hexanone are displayed in Table 5-1. These data are from a chronic toxicity study in rats in which 10 animals per dose group were administered 2-hexanone in drinking water at four different concentrations (i.e., 0, 0.25, 0.5, and 1.0%) for 13 months (O'Donoghue et al., 1978). The critical endpoints evaluated from this study were the incidences of myofibrillar atrophy of the quadriceps muscle and the calf muscle in male rats, which displayed a clear dose-dependent response.

Table 5-1. Summary of neuropathologic findings in male rats administered 2-hexanone in drinking water for 13 months

Treatment (dose)	Incidence of axonal swelling				Incidence of myofibrillar atrophy	
	Brain	Spinal cord	Dorsal root ganglia	Peripheral nerve	Quadriceps muscle[a]	Calf muscle[a]
Control	0/10	0/5	0/5	0/10	**0/10**	**0/10**
0.25% 2-hexanone (143 mg/kg-day)	2/10	7/10	0/7	8/10	**1/10**	**2/10**
0.5% 2-hexanone (266 mg/kg-day)	4/10	5/5	0/5	10/10	**5/10**	**6/10**
1.0% 2-hexanone (560 mg/kg-day)	8/10	5/5	3/5	10/10	**10/10**	**10/10**

[a]The data in bold were further evaluated for RfD derivation.

Source: O'Donoghue et al. (1978).

The BMD software (BMDS, version 1.3.2) (U.S. EPA, 1999) was used to estimate a point of departure (POD) for deriving an RfD for 2-hexanone from data on myofibrillar atrophy of the quadriceps and calf muscles. This POD, called the BMDL, is defined as the 95 percent lower bound on the benchmark dose (BMD) associated with the benchmark response (BMR). For this study, a BMR of 10% extra risk (ER) was selected because it represents a response at the lower end of the observable range of the data, and provides a consistent basis of comparison across assessments. Table 5-2 presents the "best–fit" model results based on data on the incidence of myofibrillar atrophy of the quadriceps and calf muscles in rats exposed to 2-hexanone in drinking water. A more detailed presentation of the BMD modeling results is

contained in Appendix B-1. In the absence of any compelling biological reason to choose one of these endpoints over the other for RfD derivation, myofibrillar atrophy of the quadriceps muscle was used because this endpoint yielded a slightly lower BMDL than myofibrillar atrophy of the calf muscle.

Table 5.2. Best fit BMD modeling results for data on myofibrillar atrophy of the quadriceps muscle and calf muscle

Endpoint (myofibrillar atrophy)	Model	AIC[a]	*p* Value	BMD (mg/kg-day)	BMDL (mg/kg-day)	BMD/BMDL
Quadriceps muscle	Multistage	22.3952	0.9995	141.4	49.9	2.8
Calf muscle	Quantal quadratic	25.8664	0.9701	88.7	69.2	1.3

[a]AIC = Akaike Information Criterion.

5.1.3. Derivation of Human Equivalent Doses

For 2-hexanone, no PBTK model is currently available. Therefore, the first step required for the final chronic RfD derivation is to determine whether intermittent doses were employed in the animal study and, if so, to adjust these doses to reflect continuous exposures, based on the assumption that the product of dose and time is constant (U.S. EPA, 2002). In the principal study (O'Donoghue et al., 1978), animals were administered 2-hexanone in drinking water 24 hours/day, 7 days/week for 13 months. Therefore, in this case, a duration adjustment is not required (i.e., the POD [adjusted BMDL or $BMDL_{ADJ}$] for 2-hexanone equals the study BMDL) as follows:

$$BMDL_{ADJ} = BMDL \times (\text{\# of hours per day exposed}/24 \text{ hours}) \times (\text{\# of days per week exposed}/7 \text{ days})$$

$$BMDL_{ADJ} = 50 \text{ mg/kg-day} \times (24 \text{ hours}/24 \text{ hours}) \times (7 \text{ days}/7 \text{ days}) = 50 \text{ mg/kg-day}$$

EPA currently does not provide a specific procedure for calculating a human equivalent dose for oral (or dermal) exposure scenarios that parallel calculation of the inhalation human equivalent concentration (HEC). Hence, the $BMDL_{ADJ}$ is used as the point of departure from which to apply uncertainty factors.

5.1.4. Calculation of the RfD—Application of Uncertainty Factors

The RfD for myofibrillar atrophy of the quadriceps muscle as the critical effect is calculated from the $BMDL_{ADJ}$ by application of uncertainty factors (UFs) as follows:

$$RfD = BMDL_{ADJ} \div UF$$

$$RfD = 50 \text{ mg/kg-day} \div 300 = 0.166 \text{ mg/kg-day} = 2 \times 10^{-1} \text{ mg/kg-day}$$

The composite UF of 300 was derived as follows:

- An intraspecies uncertainty factor (UF_H) of 10 was applied to adjust for potentially sensitive human subpopulations. A default value is warranted because insufficient information is currently available to assess human-to-human variability in 2-hexanone toxicokinetics or toxicodynamics.
- A default interspecies uncertainty factor (UF_A) of 10 was applied for extrapolation from animals to humans. No suitable data on the toxicity of 2-hexanone to humans exposed by the oral route only were identified. Insufficient information is currently available to assess rat-to-human differences in 2-hexanone toxicokinetics or toxicodynamics.
- A UF of 3 was applied to account for database deficiencies (UF_D). The database includes subchronic animal studies in rats and hens and a chronic study in rats but does not include multigenerational reproductive and developmental studies. Though no 2-hexanone-specific developmental studies are available, supporting developmental studies with n-hexane, a precursor of 2-hexanone, and 2,5-hexanedione, the ultimate toxic metabolite of n-hexane and 2-hexanone, have been primarily negative. Mouse reproductive/developmental and teratological studies with n-hexane have been negative with doses administered on GDs 6–15 by gavage of up to 2200 mg/kg-day or by daily injection up to 9900 mg/kg-day (Marks et al., 1980), and rat developmental neurotoxicity studies with 2,5-hexanedione have found minimal effects (e.g., aggregated and fused axons, identified with electron microscopy) from daily s.c. injections on GDs 12–20 with 340 mg/kg 2,5-hexanedione (Ogawa et al., 1993). It should be noted that the available studies with 2-hexanone following inhalation exposure suggest the possibility of immunotoxicity and reproductive toxicity as areas of potential concern with human exposure. For example, a reduction in total white blood cell count to ~60% of control values was reported in rats intermittently exposed to 700 ppm 2-hexanone via inhalation for 8 weeks (Katz et al., 1980). In addition, behavioral alterations observed in offspring of pregnant rats exposed to 1000 ppm 2-hexanone (Peters et al., 1981) and atrophy of testicular germinal epithelium observed in male rats exposed to 700 ppm 2-hexanone (Katz et al., 1980) suggest there may be cause for concern. However, there are no studies that evaluate immunotoxicity following oral exposure to 2-hexanone. Because of the absence of studies evaluating the possible immunotoxicity or reproductive toxicity of 2-hexanone following exposure via the oral route, a UF_D of 3 is warranted.
- An uncertainty factor for LOAEL-to-NOAEL extrapolation was not used because the current approach is to address this factor as one of the considerations in selecting a BMR for benchmark dose modeling. In this case, a BMR of a 10% extra risk of myofibrillar atrophy of the quadriceps muscle was selected under an assumption that it represents a minimal biologically significant change.

- A subchronic-to-chronic UF (UF_S) was not applied because the principal study involved a chronic exposure.

5.1.5. RfD Comparison Information

Figure 5-1 presents PODs, applied UFs, and derived RfD for the endpoints considered for 2-hexanone. As stated previously, of the available chronic and subchronic studies, the 13-month drinking water study conducted by O'Donoghue et al. (1978) was considered the most suitable study to derive an RfD. Within this study, two potential endpoints, myofibrillar atrophy of either the quadriceps muscle or the calf muscle were considered. The points of departure based on the best fit models from BMD models from Table 5.2 are presented in Figure 5-1. Axonal swelling in the brain, spinal cord and dorsal root ganglia were endpoints noted in O'Donoghue et al. (1978). These endpoints are also illustrated in Figure 5-1, but as previously mentioned, axonal swelling poorly correlates with nerve dysfunction and can occur without progression to nerve dysfunction and thus is deemed less relevant endpoints. The supporting studies outlined in Table 4-15 were deemed less relevant to human exposure as they either involved single relatively high doses via gavage in rodents (Krasavage et al., 1980; Eben et al., 1979), used a test species such as hens (which might be a poor model for assessing human exposure) (Abdo et al., 1982), were subchronic in design with higher doses administered than the chronic study by O'Donoghue et al. (1978) (Homan et al, 1977), or did not include complete data (Abdel-Rahman et al., 1978).

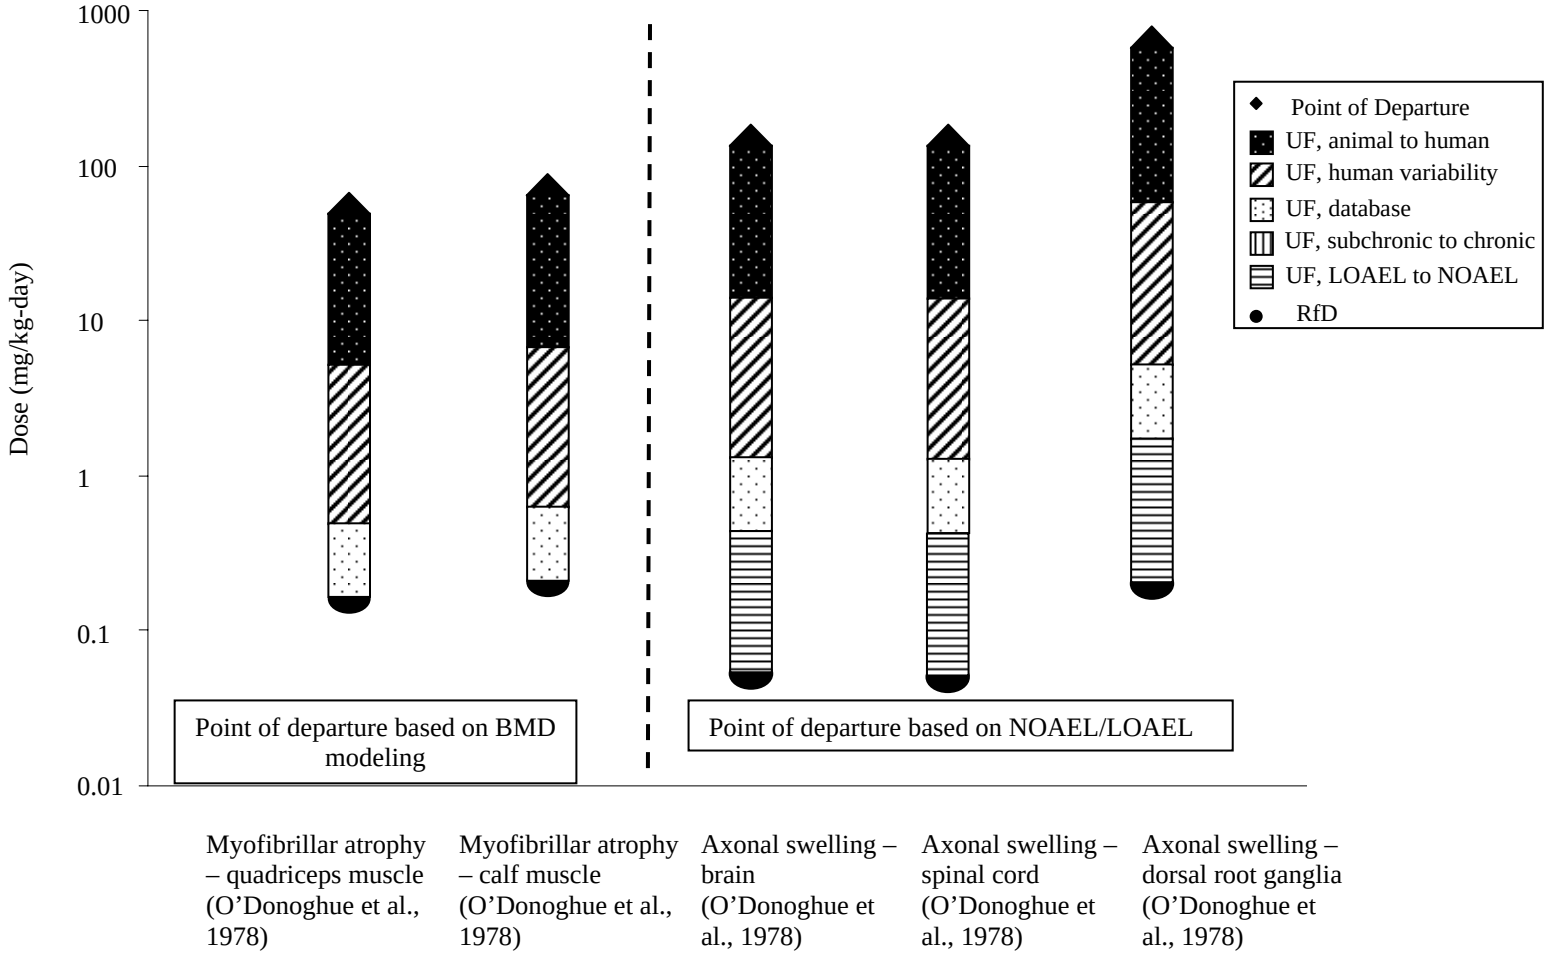

Figure 5-1. Points of departure for endpoints from O'Donoghue et al. (1978) with corresponding applied uncertainty factors and derived RfD.

5.1.6. Previous Oral Assessment

There was no previous RfD assessment for 2-hexanone with which to compare and contrast the RfD developed in this assessment.

5.2. INHALATION REFERENCE CONCENTRATION

The inhalation RfC is an estimate (with uncertainty spanning perhaps an order of magnitude) of a continuous inhalation exposure to the human general population (including sensitive subgroups) that is likely to be without an appreciable risk of deleterious effects over a lifetime. It can be derived from a NOAEL, a LOAEL, or a benchmark concentration (BMC), with UFs generally applied to reflect uncertainties and/or limitations in the data used.

5.2.1. Choice of Principal Study and Critical Effect, with Rationale and Justification

An inhalation study that exposed monkeys and rats to 0, 100, or 1000 ppm (0, 410, or 4100 mg/m^3) commercial grade 2-hexanone for 6 hours per day, 5 days per week for up to 10 months was used as the principal study in the derivation of the RfC (Johnson et al., 1977).

As discussed in Chapter 4, human and animal data indicate that neurological effects are a characteristic and sensitive endpoint of inhalation exposure to 2-hexanone. Neuropathy has been observed in humans following inadvertent occupational exposure (Allen et al., 1975; Billmaier et al, 1974; Gilchrist et al., 1974) and has been demonstrated repeatedly in laboratory animals (Katz et al., 1980; Egan et al., 1980; O'Donoghue and Krasavage, 1979; Johnson et al., 1979, 1977; Duckett et al., 1979, 1974; O'Donoghue et al., 1978; Krasavage and O'Donoghue, 1977; Spencer et al., 1975; Mendell et al., 1974).

Several studies of workers in a coated fabrics plant (Allen et al., 1975; Billmaier et al., 1974; Gilchrist et al., 1974) provide evidence in humans of a concentration-dependent neurotoxic response to 2-hexanone exposure. Although personal air samples were not collected in these studies, the available measures of exposure were sufficient to produce quantitative estimates of 2-hexanone inhalation exposure for two groups of workers (i.e., print operators and print helpers), both of whom exhibited peripheral neuropathy. In these workers, exposure to 2-hexanone also occurred via oral and dermal routes, as the study authors noted that individuals frequently ate at the work site and were accustomed to washing their hands with 2-hexanone. Because the magnitude of exposure to 2-hexanone from these two other exposure routes (i.e., oral and dermal), which could have been considerable, was not quantified by the study authors and the workers were coexposed with MEK, which can potentiate the toxicity of 2-hexanone, this study was deemed unsuitable for use in RfC derivation.

Of the available animal studies on 2-hexanone, the subchronic studies by Abdo et al. (1982), Duckett et al. (1979, 1974), Krasavage and O'Donoghue (1977), Saida et al. (1976), Mendell et al. (1974) and the chronic study by O'Donoghue and Krasavage (1979) were not selected for use in deriving the RfC. Duckett et al. (1979, 1974) did not report the sex of the

animals or the purity of 2-hexanone used. Further, the authors used only one exposure concentration per series of experiments. Krasavage and O'Donoghue (1977) utilized two exposure concentrations (e.g., 100 and 330 ppm); however, the purity of 2-hexanone was not stated and limited data were provided. As mentioned previously, MiBK, a potential inducer of CYP450, is a common contaminant in the formulations of 2-hexanone. Without the more information on the purity of the 2-hexanone administered, it is difficult to ascertain if MiBK impacted the toxicity of 2-hexanone in Krasavage and O'Donoghue (1977). Saida et al. (1976) used two exposure concentrations (e.g., 225 ppm and 400 ppm) but did not state the sex of the animals or the purity of 2-hexanone used. Finally, Mendell et al. (1974) and Abdo et al. (1982) reported findings using hens. Although the exposure-concentration regimen used by Abdo et al. (1982) included five exposure concentrations (i.e., 10, 50, 100, 200, and 400 ppm), hens are not a suitable model for extrapolating experimental results to humans.[4] The remaining studies by Johnson et al. (1977), Katz et al. (1980), and Egan et al. (1980) were all considered further as possible principal studies.

The study by Johnson et al. (1977) was performed in two different animal species, monkeys and rats, with 8 and 10 animals per dose group, respectively. Two concentrations of commercial grade 2-hexanone were employed (100 and 1000 ppm in air) with exposures occurring 6 hours per day, 5 days per week for a duration of 10 months. Concurrent control groups were used in both species. As part of this study, Johnson et al. (1977) conducted four neurological tests in each species (usually once per month) to identify adverse effects in treated versus control animals. These four tests were MCV of the right sciatic-tibial nerve, MCV of the right ulnar nerve, absolute refractory period of these two nerves, and muscle action potentials in response to both sciatic and ulnar nerve stimulation.

The animal studies by Katz et al. (1980) and Egan et al. (1980) consisted of exposure to 2-hexanone (purity > 96%) at a single concentration for a period of 6 months or less, using only one strain and sex of rats. Both Katz et al. (1980) and Egan et al. (1980) utilized clinical chemistry and histopathologic changes to identify treatment-related effects of 2-hexanone. Despite the use of commercial grade 2-hexanone, the study by Johnson et al. (1977) was chosen as the most suitable study on which to base the RfC because Johnson et al. (1977) used two different animal species, including nonhuman primates, and two 2-hexanone exposure concentrations, while also employing larger treatment groups and longer exposure durations than either Katz et al. (1980) or Egan et al. (1980). Although duration of the study by Krasavage and O'Donoghue (1979) was longer than the study by Johnson et al. (1977), the latter utilized monkeys, a more biologically relevant species than rats, when assessing inhalation exposure. Also, Krasavage and O'Donoghue (1979) provide limited information to serve as the basis for a reference concentration.

[4] Birds have an intricate respiratory system that is exclusive to birds and includes a system of air sacs that surround the internal organs and provide reserve air space to increase lung capacity.

As previously discussed, the toxic effects seen in humans and experimental animals following exposure to 2-hexanone via inhalation provide evidence that the nervous system is the primary target of 2-hexanone toxicity. Data from Johnson et al. (1977) on both sciatic-tibial and ulnar nerve MCVs in 2-hexanone-exposed monkeys and rats were considered for use in deriving the RfC, but, ultimately, the monkey sciatic-tibial nerve MCV data were selected for the following reasons. Both monkeys and rats exhibited significant decrements in sciatic-tibial nerve MCVs at the lowest administered concentration of 2-hexanone, beginning at 9 and 7 months on study, respectively. A neuropathy similar to that observed for the sciatic-tibial nerves occurred in the ulnar nerves of both monkeys and rats. Although monkeys in the low exposure group exhibited statistically significant decreases in ulnar nerve MCVs relative to control values at 1 and 3 months, beginning at 6 months on study, this decline was not statistically significant. As monkeys have a similar respiratory tract and breathing patterns to humans, and the 2,5-hexanedione, the metabolite of 2-hexanone, typically affects long axons such as the sciatic-tibial nerve prior to other nerves, the sciatic-tibial nerve motor conduction velocity in monkeys is used to derive the RfC, though both sciatic-tibial MCV and ulnar MCV for both monkeys and rats were modeled.

5.2.2. Methods of Analysis: Benchmark Concentration Modeling

Table 5-3 displays monthly mean MCV values (in m/second) for both the sciatic-tibial and ulnar nerves of monkeys exposed to three different concentrations of 2-hexanone in air (i.e., 0, 100, or 1000 ppm) for durations ranging from 1 to 10 months. These data were extracted (via digitization [5]) from Figure 1 (for the sciatic-tibial nerve) and Figure 3 (for the ulnar nerve) of Johnson et al. (1977). Similarly, Table 5-4 displays monthly mean MCV values (in m/second) for both the sciatic-tibial and ulnar nerves of rats exposed to three different concentrations of 2-hexanone in air (i.e., 0, 100, or 1,000 ppm) for durations ranging from 2 to 29 weeks. These data were extracted (via digitization) from Figure 2 (for the sciatic-tibial nerve) and Figure 4 (for the ulnar nerve) of Johnson et al. (1977).

Because MCV values are continuous (as opposed to dichotomous), the data in Tables 5-3 and 5-4 were subjected to BMD modeling employing the available continuous models in EPA's

[5] Values from Johnson et al. (1977) were digitized using the line tool on Microsoft Office Word 2003, followed by measuring the values with the distance tool function on Adobe® Acrobat® 6.0 Professional (version 6.0.0, 5/19/2003). To accomplish this task, the figures from Johnson et al. (1977) were inserted into a Word document using the snapshot tool from Adobe® Acrobat® 6.0 Professional. Then, horizontal lines were applied over the data points, the measurement markers on the y-axis, and extended through the y-axis. Lines from the data points to the x-coordinates were not traced over, since Johnson et al. (1977) provided the absolute values in the text. Once all of the lines were traced from the data points through the y-coordinates, a vertical line was traced over the y-axis. Then the Word document was saved in portable document format (pdf) and opened using Adobe® Acrobat® 6.0 Professional. The y-axis was viewed at 300% magnification, and the distance tool was used to measure from the origin to each y-coordinate for each horizontal line, including data points and measurement markers. The distance tool allows measurements to be made down to one hundredth of a millimeter, and repeated measures placed the reproducibility of this technique at greater than 99%.

BMDS, version 1.3.2 (i.e., linear, polynomial, power, and Hill models). The BMR was defined as a 10% relative change in nerve conduction velocity from the control mean. Changes in nerve conduction velocity are thought to represent a clinically significant effect.

A difficulty encountered in conducting a BMD analysis on these data was that no information was provided regarding the standard errors or confidence limits for the mean nerve conduction velocities shown in Figures 1 through 4 in Johnson et al. (1977) nor was any of the raw data on which these means were based presented in the paper. Attempts to obtain the raw data from the investigators were unsuccessful. In BMDS, estimates of the standard deviation of the response in each dose group are needed to calculate BMDs and their corresponding BMDLs. Therefore, an indirect method for estimating this missing information on response variability was devised.

Information regarding the variability in MCV measurements in Johnson et al. (1977) can be derived from the results of statistical tests that are reported in the paper. In this study, two different statistical procedures were employed. An ANOVA was used to test for statistically significant differences in mean MCVs at specific test periods (usually monthly) whenever data across the three exposure groups (i.e., 0, 100, or 1000 ppm) were compared. After approximately 6 months on study, however, animals (both monkeys and rats) in the highest exposure group (1000 ppm) were removed from further 2-hexanone exposure. Consequently, with termination of this 1000 ppm exposure group, only two dose groups remained for each species. Thus, subsequently, the Student's *t*-test was used to test for statistically significant changes in mean MCVs across these two groups (i.e., 0 and 100 ppm) for the remaining test periods.

In an ANOVA, an *F* statistic is used to test for a significant difference among the means of *g* groups. An *F* statistic is defined as, $F(g\text{-}1, N\text{-}g)$ = between-group variance/within-group variance, where g-1 represents the numerator degrees of freedom and N-g represents the denominator degrees of freedom (g is the number of groups and N is the sample size within each group). In the specific case where only two group means are being compared, the *F* statistic reduces to a *t* statistic (i.e., $F(1, N\text{-}g) = t(N\text{-}g)^2$), where *t* has a Student's *t*-distribution. In order to fit a continuous dose-response model in BMDS, an estimate of the within-group variance or s^2 is needed from which the estimated standard deviation can be obtained simply by taking the square root of this variance estimate.

The estimated within-group variance can be derived using the following procedure. If the within-group means and the numbers of observations on which each of these means are based are known, the between-group variance can be calculated. Once the between-group variance has been determined and the corresponding value of the *F* or *t* statistic is known, an estimate of the within-group variance or s^2 can be derived from the following equation: s^2 = (between-group variance)/$F(g - 1, N - g)$ or s^2 = (between-group variance)/$t(N\text{-}g)^2$. In Johnson et al. (1977), for monkeys, *F* statistics were reported for mean MCVs at both 4 and 6 months, while *t* statistics

were reported for mean MCVs at both 9 and 10 months. These data yielded four estimates of the within-group variance or standard deviation. The arithmetic average of these four estimates was then used in BMD modeling as the estimated standard deviation for MCVs in each dose group, assuming a constant variance across dose groups. For rats, *F* statistics were reported in Johnson et al. (1977) for mean MCVs at both 13 and 17 weeks, while a *t* statistic was reported for mean MCVs at 29 weeks. These data yielded three estimates of the within-group variance or standard deviation. The arithmetic average of these three estimates was then used in BMD modeling as the estimated standard deviation for MCVs in each dose group, assuming a constant variance across dose groups.

Table 5-3. Effect of 2-hexanone inhalation exposure on the MCV of the sciatic-tibial and ulnar nerves in monkeys

Exposure duration (months)	2-Hexanone concentration (ppm in air)	Mean MCV: sciatic-tibial nerve (m/s)[a]	Mean MCV: ulnar nerve (m/s)[b]

The "best-fit" model from BMDS was selected by examining the results of the chi-squared goodness-of-fit test and comparing the magnitudes of the Akaike's Information Criterion (AIC). All models with chi-squared *p* values ≥0.1 were considered to exhibit an adequate fit to the data. Of the models exhibiting adequate fit, the model with the lowest AIC was selected as the best-fit model. These criteria for model selection are consistent with those described in the *Benchmark Dose Technical Guidance Document* (U.S. EPA, 2000c). For the MCV data in both monkeys and rats, the 1st-degree polynomial model provided the best fit for both sciatic-tibial and ulnar nerve MCVs.

The 95% lower confidence limits on the benchmark concentration estimates (BMCLs) derived from the best-fit models for sciatic-tibial and ulnar nerve MCV values in monkeys and rats are presented in Table 5-4. Detailed BMDS outputs from the BMD of the monkey and rat MCV data are contained in Appendix B-1.

5.2.3. Exposure Duration Adjustments and Conversion to Human Equivalent Concentrations

Because the RfC is a metric that assumes continuous human exposure for a lifetime, adjustments need to be made to animal (or human) data obtained from intermittent and/or less-than-lifetime exposures, as outlined in the *Methods for Derivation of Inhalation Reference Concentrations and Application of Inhalation Dosimetry* (U.S. EPA, 1994). The first step in this process is adjusting intermittent inhalation exposures to continuous inhalation exposures, based on the assumption that the product of exposure concentration and time is constant (U.S. EPA, 2002). In Johnson et al (1977), animals were exposed to 2-hexanone for 6 hours/day, 5 days/week. Therefore, the $BMCL_{ADJ}$, reflecting continuous inhalation exposure to 2-hexanone,

is derived as follows:

$BMCL_{ADJ}$ = BMCL × hours exposed per day/24 hours × Days exposed per week/7 days.

$BMCL_{ADJ}$ = $243 \times 6/24 \times 5/7$ = 43 ppm, based on monkey sciatic-tibial nerve MCV

= $278 \times 6/24 \times 5/7$ = 50 ppm, based on monkey ulnar nerve MCV

= $232 \times 6/24 \times 5/7$ = 41 ppm, based on rat sciatic-tibial nerve MCV

= $352 \times 6/24 \times 5/7$ = 63 ppm, based on rat ulnar MCV

Furthermore, because RfCs are typically expressed in units of mg/m^3, the above ppm values need to be converted to mg/m^3 using the conversion factor specific to 2-hexanone of 1 ppm = 4.1 mg/m^3. Thus, the final $BMCL_{ADJ}$ values are as follows:

$BMCL_{ADJ}$ = 43×4.1 = 176.3 mg/m^3, monkey sciatic-tibial nerve MCV

= 50×4.1 = 205 mg/m^3, based on monkey ulnar nerve MCV

= 41×4.1 = 168.1 mg/m^3, based on rat sciatic-tibial nerve MCV

= 63×4.1 = 258.3 mg/m^3, based on rat ulnar nerve MCV

Finally, this $BMCL_{ADJ}$ value must be converted to an HEC. The HEC that elicits decreased MCV, which is not a respiratory (or portal-of-entry) effect, but a systemic effect, is derived based on the following. For systemic effects, 2-hexanone is classified as a category 3 gas under EPA guidelines (U.S. EPA, 1994). According to this guidance, in order to convert the concentration effective in animals to human equivalents, a multiplicative factor based on the ratio of blood:gas partition coefficients is employed as follows:

$$HEC = BMCL_{ADJ} \times [(H_{b/g})_A/(H_{b/g})_H]$$

Where,

$(H_{b/g})_A$ = blood:gas partition coefficient for 2-hexanone in animals

$(H_{b/g})_H$ = blood:gas partition coefficient for 2-hexanone in humans.

The blood:gas partition coefficient $(H_{b/g})_H$ for 2-hexanone in humans is 127 (Sato and Nakajima, 1979); however, no value has been reported for monkeys or rats. In the absence of a measured blood:gas partition coefficient in the test species, the ratio $[(H_{b/g})_A/(H_{b/g})_H]$ defaults to unity, and the conversion to a HEC becomes the following:

$BMCL_{HEC}$ = $BMCL_{ADJ} \times [(H_{b/g})_A/(H_{b/g})_H] = 176.3 \times 1$ = 176.3 mg/m^3 based on monkey

sciatic-tibial nerve MCV

= 205×1 = 205 mg/m^3 based on monkey ulnar nerve MCV

= 168.1×1 = 168.1 mg/m^3 based on rat sciatic-tibial nerve MCV

= 258.3×1 = 258.3 mg/m^3 based on rat ulnar nerve MCV

These HEC values are presented in the last column of Table 5-5.

Table 5-5. Summary of BMCLs and HECs for 2-hexanone

Study reference	Study duration and type	2-Hexanone exposure (ppm)	Species/sex	Toxicological endpoint	BMDS "best fit" continuous model	BMC (ppm)	BMCL or POD[a] (ppm)	Adjusted BMCL ($BMCL_{ADJ}$)[b]	HEC[c]
Johnson et al. (1977)	10-month inhalation (subchronic)	0, 100, 1000	Male monkeys (n = 8 per dose group)	Sciatic-tibial nerve motor conduction velocity (at 6 months)	1st degree polynomial	293	243	176	176
				Ulnar nerve motor conduction velocity (at 6 months)	1st degree polynomial	335	278	205	205
Johnson et al. (1977)	29-week inhalation (subchronic)	0, 100, 1000	Male rats (n = 10 per dose group)	Sciatic-tibial nerve motor conduction velocity (at 25 weeks)	1st degree polynomial	271	232	168	168
				Ulnar motor nerve conduction velocity (at 25 weeks)	1st degree polynomial	471	352	258	258

[a]BMCLs or PODs were estimated at a BMR of 0.1 or 10% relative change from controls.

[b]Conversion factors and assumptions: molecular weight (2-hexanone) = 100.16 and 1 ppm = 100.16/24.45 = 4.1 mg/m^3 (at 25°C and 760 mm Hg). Duration adjustment of exposure concentrations and conversion to mg/m^3 was accomplished as follows: $BMCL_{ADJ}$ = 243 ppm × 6h/24h × 5 d/7d = 43 ppm × 4.1 = 176 mg/m^3.

[c]The $BMCL_{HEC}$ was calculated for an extrarespiratory effect of a category 3 gas. The blood:gas partition coefficient (Hb/g) value for 2-hexanone in humans is 127 (Sato and Nakajima, 1979); however, no value has been reported for monkeys or rats. According to EPA's RfC methodology (U.S. EPA, 1994), when the ratio of animal to human blood:gas partition coefficients [(Hb/g)A/(Hb/g)H] is greater than one or the values are unknown, a value of one is used for the ratio by default. Thus, $BMCL_{HEC}$ = 176 × [(Hb/g)A/(Hb/g)H] = 176 mg/m^3.

5.2.4. Calculation of the RfC: Application of Uncertainty Factors

As monkeys have a similar respiratory tract and breathing patterns to humans, and the 2,5-hexanedione, the metabolite of 2-hexanone, typically affects long axons such as the sciatic-tibial nerve prior to other nerves, the $BMCL_{HEC}$ based on sciatic-tibial nerve motor conduction velocity in monkeys (Table 5-4) is used to derive the RfC. It should be noted that ulnar nerve motor conduction velocity in monkeys and sciatic-tibial nerve motor conduction velocity in rats were found to have similar $BMCL_{HEC}$ as the endpoint selected above and would not result in significantly different RfCs if those alternatives were utilized.

The RfC for 2-hexanone based on peripheral neuropathy as the critical effect is derived from the $BMCL_{HEC}$ by application of UFs as follows:

$$RfC = BMCL_{HEC} \div UF$$

$$RfC = 176 \div 1000 = 0.168 \text{ mg/m}^3 \approx 2 \times 10^{-1} \text{ mg/m}^3$$

This composite UF of 1000 is composed of the following:

- A default intraspecies uncertainty factor (UF_H) of 10 was applied to adjust for potentially sensitive human subpopulations (intraspecies variability).
- A default subchronic-to-chronic uncertainty factor (UF_S) of 10 was applied to account for the less-than-lifetime exposure (10 months) in the principal study.
- A factor of 3 was selected to account for uncertainties in extrapolating from rats to humans. This value is adopted by convention where an adjustment from an animal-specific $NOAEL_{ADJ}$ to a $NOAEL_{HEC}$ has been incorporated. Application of a full uncertainty factor of 10 would depend on two areas of uncertainty (i.e., toxicokinetic and toxicodynamic uncertainties). In this assessment, the toxicokinetic component is mostly addressed by the determination of a human equivalent concentration as described in the RfC methodology (U.S. EPA, 1994b). The toxicodynamic uncertainty is also accounted for to a certain degree by the use of the applied dosimetry method and an UF of 3 is retained to fully address this component. An uncertainty factor for LOAEL-to-NOAEL extrapolation was not used because the current approach is to address this factor as one of the considerations in selecting a BMR for benchmark dose modeling. In this case, a BMR of a 10% change in nerve conduction velocity from the control mean was selected under an assumption that it represents a minimal biologically significant change. An uncertainty factor of 3 was applied to account for database deficiencies (UF_D). The database includes a human occupational exposure study (with coexposure to MEK), subchronic animal studies in rats and hens, and a chronic study in cats. One postnatal development and behavior study on 2-hexanone (Peters et al., 1981) exists, identifying a LOAEL of 1000 ppm (no NOAEL

reported), but no other developmental or teratology studies on 2-hexanone exist. However, support for applying a UF_D of 3 in the absence of other 2-hexanone-specific studies is based on the availability of developmental and teratology studies with n-hexane, a precursor of 2-hexanone, and 2,5-hexanedione, a metabolite of n-hexane and 2-hexanone. The rationale for the UF_D of 3 is based on the following: (1) developmental studies with n-hexane concentrations of 100 (GDs 6–15), 400 (GDs 6–15), or 1000 ppm (GDs 8–16) have been negative (Bus et al., 1979; Litton Bionetics, 1979); (2) a teratology study conducted on behalf of the National Toxicology Program, in which dams were exposed on GDs 6–19 to 200, 1000, or 5000 ppm n-hexane, identified a NOAEL of 200 ppm (Mast, 1987), a concentration nearly double the highest NOAEL identified from inhalation studies with 2-hexanone (See Table 4-16); and (3) rat developmental neurotoxicity studies with 2,5-hexanedione, the ultimate toxic metabolite of n-hexane and 2-hexanone, have found minimal effects (e.g., aggregated and fused axons, identified with electron microscopy) from daily s.c. injections on GDs 12–20 with 340 mg/kg 2,5-hexanedione (Ogawa et al., 1993).

5.2.5. RfC Comparison Information

Figure 5-2 presents PODs, applied UFs, and derived RfCs for several studies and endpoints considered for 2-hexanone. Of the chronic and subchronic studies available on inhalation exposure to 2-hexanone, Johnson et al. (1977) was deemed the most suitable to derive an RfC. The endpoints considered from Johnson et al. (1977) include MCV for both sciatic-tibial and ulnar nerves of both rats and monkeys. The PODs based on the best fit models from BMD models from Table 5-4 are presented in Figure 5-2. Subchronic rodent studies by Katz et al. (1980) and Egan et al. (1980) were also considered; however, both studies evaluated exposure to a single concentration of 2-hexanone for a period of less than 6 months, using clinical chemistry or histopathologic changes to identify treatment-related effects. The unpublished study by Krasavage and O'Donoghue (1977) was longer in exposure duration than the study by Johnson et al. (1977) and utilized two exposure concentrations, though purity of 2-hexanone was not specified. The Johnson et al. (1977) study is preferred because the study involved nonhuman primates that are more relevant to assessing human exposure than obligatory nose-breathing species such as rats. Figure 5-2 provides LOAEL and NOAEL PODs from Katz et al. (1980), Egan et al. (1980), and Krasavage and O'Donoghue (1977) as a comparison to the four BMCL endpoints from the Johnson et al. (1977) study.

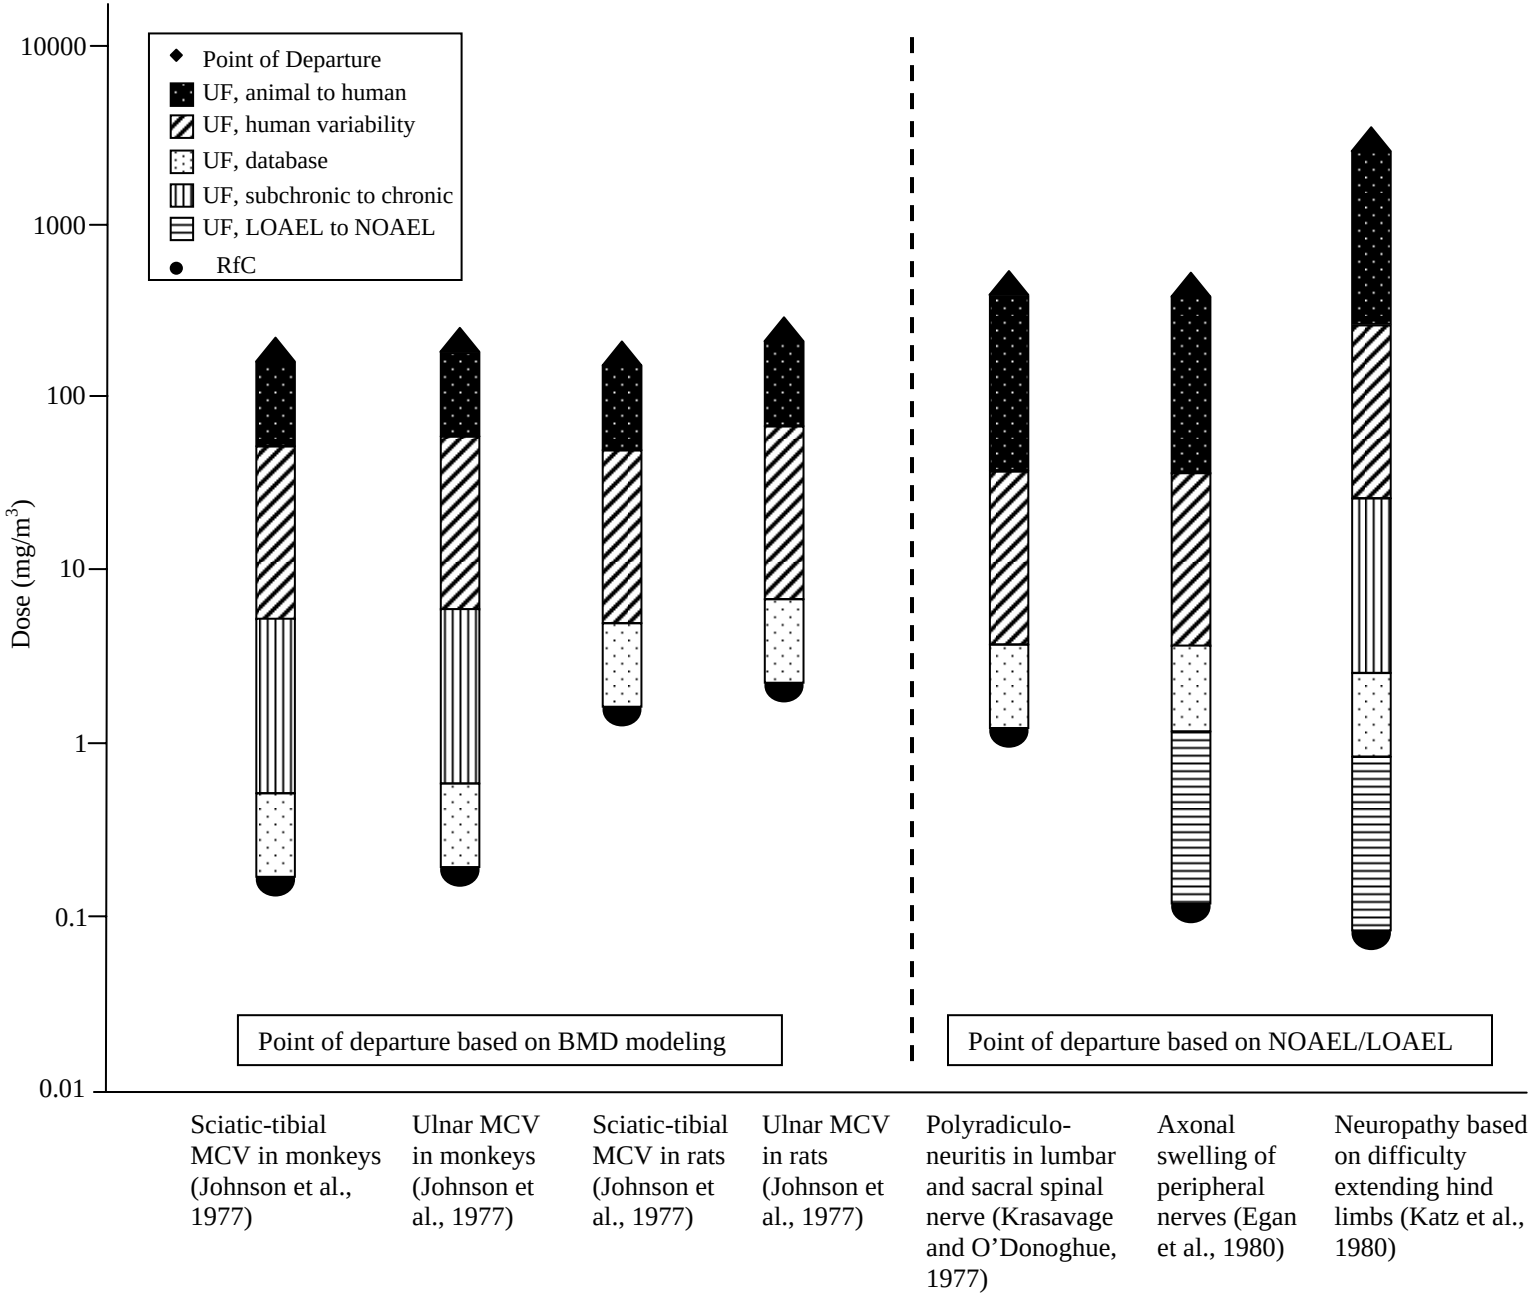

Figure 5-2. PODs for endpoints from select studies from Table 4-16, with corresponding applied UFs and derived RfCs.

5.2.6. Previous Inhalation Assessment

No previous RfC assessment for 2-hexanone exists on IRIS.

5.3. CANCER ASSESSMENT

As discussed in Section 4.6.1, the available database for 2-hexanone contains inadequate information to assess the carcinogenic potential according to *Guidelines for Carcinogen Risk Assessment* (U.S. EPA, 2005a).

6. MAJOR CONCLUSIONS IN THE CHARACTERIZATION OF HAZARD AND DOSE RESPONSE

6.1. HUMAN HAZARD POTENTIAL

2-Hexanone (methyl butyl ketone, CASRN 591-78-6) has the chemical formula $C_6H_{12}O$ and a molecular weight of 100.16. It is a clear, volatile, flammable fluid with a pungent, acetone-like odor. 2-Hexanone is most commonly used as a paint or printing ink thinner, as a solvent for oils, waxes, and resins, or as a cleaning agent. It is currently not produced commercially in the U.S., and no information on importation is available (ATSDR, 1992).

2-Hexanone is well absorbed by the inhalation route and in the gastrointestinal tract. Animal studies suggest that 2-hexanone does not penetrate skin very efficiently, but there is evidence that it penetrates human skin easily (Bos et al., 1991). The distribution of 2-hexanone has not been studied thoroughly. In a rat study, it appeared in the plasma and the lung at higher concentrations than in the liver after both oral and inhalation administration (Duguay and Plaa, 1995) but did not show an affinity for a lipid rich tissue such as the brain (Granvil et al., 1994). In guinea pigs, 2-hexanone was eliminated quite rapidly, with a half-life of a little more than 1 hour for the parent compound and values not exceeding 2½ hours for the major metabolites (DiVincenzo et al., 1976). In rats, on the other hand, 2-hexanone was eliminated more slowly (Bus et al., 1981). The biological half-life of 2-hexanone in humans is not known. A PBTK model has not been proposed.

Metabolites of 2-hexanone include 2-hexanol, 2,5-hexanediol, 5-hydroxy-2-hexanone, 2,5-hexanedione, and some cyclic furan derivatives. The enzymes that metabolize 2-hexanone have not been characterized well. Among the metabolites of 2-hexanone, 2,5-hexanedione is the most important because it is a well-known neurotoxicant. It causes neuropathy specifically of the peripheral giant axons that involves neurofilament cross-linking and axonal swelling and proceeds to retrograde axonal degeneration. 2-Hexanone-induced neuropathy has been observed clinically in occupationally exposed humans (Davenport et al., 1976; Mallov, 1976; Allen et al., 1974; Billmaier et al., 1974), but the findings are frequently obscured by coexposure to other solvents, most frequently MEK, which is known to potentiate the toxicity of 2-hexanone.

A significant number of studies have been conducted in which laboratory animals were exposed orally or via inhalation for up to 2 years. Oral exposure studies used rats (Krasavage et al., 1980) and guinea pigs (Abdel-Rahman et al., 1978), with doses ranging up to 600 mg/kg-day by gavage or up to 1.3% in drinking water (amounting to 1010 mg/kg-day). The 13-month study in rats by O'Donoghue et al. (1978) that gave a detailed report of neuropathy incidences was used in the RfD assessment for 2-hexanone. Inhalation studies employed rats (Egan et al., 1980; Katz et al., 1980; Duckett et al., 1979, 1974; Johnson et al., 1977; Krasavage and O'Donoghue, 1977; Saida et al., 1976; Spencer et al., 1975), cats (O'Donoghue and Krasavage, 1979), and

monkeys (Johnson et al., 1977), with exposures ranging from 10–1300 ppm (41–5325 mg/m^3). The hallmark symptom observed in any of these studies was neuropathy. The 2-hexanone-induced neuropathy also has been characterized mechanistically in animal studies (DeCaprio et al., 1988, 1982). Also a study in beagles that received 2-hexanone via the subcutaneous route reported neuropathy (O'Donoghue and Krasavage, 1981).

It is not clear whether 2-hexanone causes any other significant illness in humans. The available animal studies do not provide sufficient information to assess carcinogenicity of 2-hexanone. Currently, there is no evidence that this chemical causes cancer in humans or animals. According to *Guidelines for Carcinogen Risk Assessment* (U.S. EPA, 2005a), there is "inadequate information to assess the carcinogenic potential" of 2-hexanone.

Estimates of risks from other organizations

Estimates of risk for 2-hexanone derived by other organizations are compiled by the National Library of Medicine and can be found on the TOXNET Web page at http://toxnet.nlm.nih.gov/.

6.2. DOSE RESPONSE

6.2.1. Noncancer/Oral

There are no chronic or subchronic data for oral exposure of humans to 2-hexanone. There is no standard 2-year bioassay for 2-hexanone in any animal species; the only study with a chronic exposure time, the 13-month study in rats by O'Donoghue et al. (1978), was adequately conducted and reported critical, chemical-related effects with sufficient detail to be eligible as the principal study. Myofibrillar atrophy of the quadriceps muscle and the calf muscle in male rats is the critical endpoint evaluated. This endpoint was chosen over other neuropathic endpoints because it occurs due to axonal atrophy, an endpoint that correlates best to nerve dysfunction regardless of route of exposure. Another endpoint described in O'Donoghue et al. (1978) was peripheral nerve axonopathy. This endpoint was not well characterized, with incidences jumping from 0% (0/10 animals) in controls to 80% (8/10 animals) at the lowest dose (143 mg/kg-day) and 100% (10/10 animals) at both higher doses (266 and 560 mg/kg-day). Though peripheral nerve axonopathy may have exhibited the most sensitive response to 2-hexanone exposure, axonal swelling may not be an appropriate proximal marker of neuropathy because this endpoint poorly correlates with nerve dysfunction.

The RfD of 2×10^{-1} mg/kg-day was derived from myofibrillar atrophy of the quadriceps muscle in male COBS/CD(SD)BR rats following 13 months of oral exposure to 2-hexanone (O'Donoghue et al., 1978). There is sufficient evidence from other studies in experimental animals to confirm that the nervous system is the primary target for the toxicological effects of 2-hexanone (Abdo et al., 1982; Krasavage et al., 1980; Eben et al., 1979; Abdel-Rahman et al.,

1978; Homan et al., 1977). Because there are no compelling biological reasons to choose myofibrillar atrophy of the quadriceps muscle over myofibrillar atrophy of the calf muscle, the slightly lower BMDL was chosen. A graphical comparison of the RfDs from these two endpoints is illustrated in Figure 5-1.

A composite UF of 300 was applied; 10 for intraspecies (interindividual) variability, 10 for interspecies variability, and 3 for database uncertainty. Information was unavailable to quantitatively assess toxicokinetic or toxicodynamic differences between animals and humans and the potential variability in human susceptibility; thus, the interspecies and intraspecies UFs of 10 were applied. A threefold database deficiency UF was applied to reflect that, though chronic and subchronic information on 2-hexanone was available, there are no 2-hexanone-specific multigenerational reproductive and developmental studies. Developmental studies on n-hexane, a precursor of 2-hexanone and 2,5-hexanedione, have shown low risk of toxicity, but there is still a level of concern because available studies on 2-hexanone via inhalation exposure have suggested the possibility of immunotoxicity and reproductive toxicity. Rat developmental neurotoxicity studies with 2,5-hexanedione have found minimal effects (e.g., aggregated and fused axons, identified with electron microscopy) from daily s.c. injections on GDs 12–20 with 340 mg/kg 2,5-hexanedione. Thus, due to the absence of studies specifically evaluating immunotoxicity or reproductive toxicity of 2-hexanone via an oral route of exposure, a UF of 3 was applied to account for database deficiency.

The overall confidence in this RfD assessment is medium. Confidence in the principal study (O'Donoghue et al., 1978) is medium. The study involves a comparatively low but acceptable number of animals per group (10) and reports clinical neurological deficits and neuropathologic effects within a dose range in which LOAEL could be identified for the critical effect. Animal studies in two additional species (guinea pigs and hens) corroborate the primacy of the neurological endpoint and confirm the validity of peripheral neuropathy as the critical effect. Confidence in the database is medium. The database lacks chronic exposure information on pure 2-hexanone via any route of exposure, as well as a multigenerational developmental and reproductive toxicity study and a developmental neurotoxicity study. The chronic drinking water study of O'Donoghue et al. (1978) satisfies the minimum oral database requirements for deriving an RfD for 2-hexanone. Reflecting medium confidence in the principal study and medium confidence in the database, confidence in the RfD is medium.

6.2.2. Noncancer/Inhalation

Dose-dependent development of 2-hexanone-induced neuropathy was confirmed in numerous subchronic studies in rats (Egan et al., 1980; Katz et al., 1980; Duckett et al., 1979, 1974; Johnson et al., 1977; Krasavage and O'Donoghue, 1977; Saida et al., 1976; Spencer et al., 1975) and one chronic study in cats (O'Donoghue and Krasavage, 1979). One 10-month study was Johnson et al. (1977), using two different species (monkeys and rats; n = 8 and n = 10 per

group, respectively) with two concentrations of 2-hexanone (commercial grade). Johnson et al. (1977) utilized four sensitive neurological tests to identify subtle changes in treated versus control animals. The study by Johnson et al. (1977) was chosen as the most suitable study for RfC development. Both sciatic-tibial MCV and ulnar MCV in 2-hexanone-exposed monkeys and rats were considered in deriving the RfC. A graphical comparison of the potential RfCs from these endpoints, as well as other endpoints and studies considered, are illustrated in Figure 5-2. Because monkeys have a similar respiratory tract and breathing patterns to humans and 2,5-hexanedione, the metabolite of 2-hexanone, typically affects long axons such as the sciatic-tibial nerve prior to other nerves, sciatic-tibial nerve MCV in monkeys was used to derive the RfC. It should be noted that ulnar nerve MCV in monkeys and sciatic-tibial nerve MCV in rats were found to have similar $BMCL_{HEC}$ as the endpoint selected above and would not result in significantly different RfCs if those alternatives were utilized.

The RfC of 2×10^{-1} mg/m^3 was derived from the decrease in sciatic-tibial MCV in monkeys exposed to 2-hexanone for 10 months (Johnson et al., 1977). A composite UF of 1000 was applied in the derivation of the RfC: a default of 10 for intraspecies (interindividual) variability, a default of 10 for subchronic-to-chronic uncertainty, 3 for interspecies variability, and 3 for database uncertainty. Information was unavailable to predict potential variability in susceptibility among the population; thus, the intraspecies variability UF of 10 was applied. A subchronic-to-chronic UF of 10 was applied to account for the less-than-lifetime exposure in the principal study, because the data utilized for calculating the RfC were based on values obtained at 25 weeks. An interspecies UF of 3 (rather than 10) was applied because a dosimetric adjustment was made. A UF of 3 was applied to account for database deficiencies. Although a developmental study exists that did not identify a NOAEL (a LOAEL of 1000 ppm was identified), the available developmental studies with n-hexane, a precursor of 2-hexanone, provide support for applying a UF_D of 3. Namely, developmental studies with n-hexane concentrations of 100 (GDs 6–15), 400 (GDs 6–15), or 1000 ppm (GDs 8–16) have been negative; a teratology study in which dams were exposed to n-hexane identified nearly double the highest NOAEL identified from inhalation studies with 2-hexanone. Also, rat developmental neurotoxicity studies with 2,5-hexanedione, the ultimate toxic metabolite of n-hexane and 2-hexanone, have found minimal effects from daily s.c. injections on GDs 12–20 with 340 mg/kg 2,5-hexanedione.

The overall confidence in this RfC assessment is medium. Confidence in the principal study is medium; it involves exposures in two species via the inhalation route and sensitive diagnostic tests for determining treatment-related neurotoxicity. In addition, animal studies in four different species (monkeys, rats, cats, and hens) and occupational exposures corroborate the primacy of the neurological endpoint and confirm the relevance of the critical effect for decreased MCV values.

6.2.3. Cancer

Under the *Guidelines for Carcinogen Risk Assessment* (U.S. EPA, 2005a), there is inadequate information to assess the carcinogenic potential of 2-hexanone. As such, data are unavailable to calculate quantitative cancer risk estimates.

APPENDIX B-1. DOSE-RESPONSE MODELING FOR DERIVATION OF AN RfD FOR 2-HEXANONE

B-1.1. METHODS

The models in U.S. EPA's benchmark dose (BMD) software (BMDS) (version 1.3.2) were fit to data sets for myofibrillar atrophy of the quadriceps and calf muscle in a 13-month drinking water study with exposure to 2-hexanone (O'Donoghue, 1978). The dose levels used were those reported in the study. A BMR of a 10% extra risk of myofibrillar atrophy of the quadriceps muscle or calf muscle was selected under an assumption that it represents a minimal biologically significant change. Models were run using the default restrictions on parameters built into the BMDS.

B-1.2. RESULTS

The BMD modeling results for myofibrillar atrophy of the quadriceps and calf muscles are summarized in Table B-1.1 and Table B-1.2, respectively. The tables show the BMDs and the 95% lower bounds on the doses (BMDLs) derived from each endpoint modeled. The remainder of this section shows detailed summaries of the best-fit models for myofibrillar atrophy of the quadriceps and calf muscles, presented sequentially.

Table B-1.1. BMD modeling results for animals with myofibrillar atrophy of the quadriceps muscle

Model	AIC[a]	*p* Value	BMD	BMDL	BMD/BMDL
Gamma multi-hit	24.6565	0.9034	150.665	86.2822	1.746189

APPENDIX B-2. EXPOSURE-RESPONSE MODELING FOR DERIVATION OF AN RfC FOR 2-HEXANONE

B-2. 1. METHODS

The models in U.S. EPA's benchmark dose (BMD) software (BMDS) (version 1.3.2) were fit to multiple data sets presented in an inhalation study with exposure to monkeys and rats (Johnson et al., 1977). Motor conduction velocity (MCV) was determined to be the most relevant endpoint in both species and was modeled for the sciatic and tibial nerves. The exposure concentrations used were those reported in the study. The U.S. EPA (2000c) BMD methodology suggests that in the absence of any other idea of what level of response to consider adverse, a change in the mean equal to one control standard deviation from the control should be used as the benchmark response (BMR). A BMR of a 10% change in nerve conduction velocity from the control mean was selected under an assumption that it represents a minimal biologically significant change. Thus, a 10% BMR was utilized in the derivation of the reference concentration (RfC).

B-2.2. RESULTS

The BMD modeling results are summarized in Table B-2.1. This table shows the BMDs and 95% lower bounds on doses (BMDLs) derived from each endpoint modeled in monkeys and rats. The remainder of this section shows detailed summaries of the modeling results for monkey sciatic and ulnar nerves for both monkeys and rats (all 1st degree polynomial), presented sequentially.

Table B-2.1. Summary of BMDS modeling results for 2-hexanone

Animal/endpoint	Model[a]	*p* Value	AIC[b]	BMD	BMDL
Monkey sciatic-tibial nerve (MCV at 6 months)	**1st degree polynomial**	**0.59**	**105.59**	**293.184**	**243.262**
	2nd degree polynomial	--	107.29	169.254	68.8063
	Power	--	105.58	293.184	243.262
	Hill	--	--	--	--
Monkey ulnar nerve (MCV at 6 months)	**1st degree polynomial**	**0.90**	**105.31**	**334.691**	**278.471**
	2nd degree polynomial	--	107.29	293.8	94.1174
	Power	--	109.31	334.691	278.471
	Hill	--	--	--	--
Rat sciatic-tibial nerve (MCV at 25 weeks)	**1st degree polynomial**	**0.79**	**121.55**	**270.959**	**232.105**
	2nd degree polynomial	--	123.48	355.94	100.045
	Power	--	125.48	329.704	232.56
	Hill	--	--	--	--
Rat ulnar nerve (MCV at 25 weeks)	**1st degree polynomial**	**0..26**	**122.77**	**470.964**	**352.274**
	2nd degree polynomial	--	606.18	133.181	87.3758
	Power	--	125.48	177.555	14.1388
	Hill	--	--	--	--

[a]Bolded values were the models used for further evaluation and RfC derivation.
[b]AIC = Akaike Information Criterion.

PROVISIONAL PEER REVIEWED TOXICITY VALUES FOR 1,1,2-TRICHLOROETHANE (CASRN 79-00-5) Derivation of Subchronic and Chronic Inhalation RfCs

Background

On December 5, 2003, the U.S. Environmental Protection Agency's (EPA's) Office of Superfund Remediation and Technology Innovation (OSRTI) revised its hierarchy of human health toxicity values for Superfund risk assessments, establishing the following three tiers as the new hierarchy:

1. EPA's Integrated Risk Information System (IRIS).

2. Provisional Peer-Reviewed Toxicity Values (PPRTV) used in EPA's Superfund Program.

3. Other (peer-reviewed) toxicity values, including:

   - Minimal Risk Levels produced by the Agency for Toxic Substances and Disease Registry (ATSDR),
   - California Environmental Protection Agency (CalEPA) values, and
   - EPA Health Effects Assessment Summary Table (HEAST) values.

A PPRTV is defined as a toxicity value derived for use in the Superfund Program when such a value is not available in EPA's Integrated Risk Information System (IRIS). PPRTVs are developed according to a Standard Operating Procedure (SOP) and are derived after a review of the relevant scientific literature using the same methods, sources of data, and Agency guidance for value derivation generally used by the EPA IRIS Program. All provisional toxicity values receive internal review by two EPA scientists and external peer review by three independently selected scientific experts. PPRTVs differ from IRIS values in that PPRTVs do not receive the multi-program consensus review provided for IRIS values. This is because IRIS values are generally intended to be used in all EPA programs, while PPRTVs are developed specifically for the Superfund Program.

Because new information becomes available and scientific methods improve over time, PPRTVs are reviewed on a five-year basis and updated into the active database. Once an IRIS value for a specific chemical becomes available for Agency review, the analogous PPRTV for that same chemical is retired. It should also be noted that some PPRTV manuscripts conclude that a PPRTV cannot be derived based on inadequate data.

Disclaimers

Users of this document should first check to see if any IRIS values exist for the chemical of concern before proceeding to use a PPRTV. If no IRIS value is available, staff in the regional Superfund and RCRA program offices are advised to carefully review the information provided in this document to ensure that the PPRTVs used are appropriate for the types of exposures and circumstances at the Superfund site or RCRA facility in question. PPRTVs are periodically updated; therefore, users should ensure that the values contained in the PPRTV are current at the time of use.

It is important to remember that a provisional value alone tells very little about the adverse effects of a chemical or the quality of evidence on which the value is based. Therefore, users are strongly encouraged to read the entire PPRTV manuscript and understand the strengths and limitations of the derived provisional values. PPRTVs are developed by the EPA Office of Research and Development's National Center for Environmental Assessment, Superfund Health Risk Technical Support Center for OSRTI. Other EPA programs or external parties who may choose of their own initiative to use these PPRTVs are advised that Superfund resources will not generally be used to respond to challenges of PPRTVs used in a context outside of the Superfund Program.

Questions Regarding PPRTVs

Questions regarding the contents of the PPRTVs and their appropriate use (e.g., on chemicals not covered, or whether chemicals have pending IRIS toxicity values) may be directed to the EPA Office of Research and Development's National Center for Environmental Assessment, Superfund Health Risk Technical Support Center (513-569-7300), or OSRTI.

INTRODUCTION

An RfC for 1,1,2-trichloroethane is not listed on IRIS (U.S. EPA, 2006) or in the HEAST (U.S. EPA, 1997). EPA review documents for 1,1,2-trichloroethane that were identified in the CARA list (U.S. EPA, 1991, 1994) and examined for relevant information were a Health Effects Assessment (U.S. EPA, 1984) and a Drinking Water Health Advisory (U.S. EPA, 1987), neither of which attempted an inhalation toxicity assessment. ATSDR (1989) declined to derive minimal risk levels for inhalation exposure to 1,1,2-trichloroethane. ACGIH (2001, 2003), NIOSH (2003), and OSHA (2003) all list TWA occupational exposure levels of 10 ppm (55 mg/m^3) for 1,1,2-trichloroethane to protect against central nervous system depression, eye and upper respiratory tract irritation, and liver damage. The toxicity of 1,1,2-trichloroethane has been studied by NTP (2003) by oral exposure, and has been reviewed by IARC (1991, 1999). WHO (2003) does not have a toxicological review for this chemical. Literature searches were

conducted for the period from 1988 to July 2003 in the following databases: TOXLINE (including NTIS and BIOSIS updates), CANCERLIT, MEDLINE, CCRIS, GENETOX, HSDB, EMIC/EMICBACK, DART/ETICBACK, RTECS and TSCATS. Additional literature searches from July 2003 through October 2004 were conducted by NCEA-Cincinnati using MEDLINE, TOXLINE, Chemical and Biological Abstracts databases.

REVIEW OF PERTINENT LITERATURE

Human Studies

No relevant data were located regarding the toxicity of 1,1,2-trichloroethane to humans following inhalation exposure.

Animal Studies

On June 7, 2002 HAP Task Force of Millwood, VA presented to the EPA's Office of Pollution Prevention and Toxics a non-peer reviewed subchronic inhalation study on 1,1,2-Trichloroethane (1,1,2-TCE) conducted by WIL Laboratories, Ashland, OH. In this study 8 week old 10 male and 10 female Fischer 344 CDF (F-344) Crl:BR rats in each group were exposed to filtered air, 15, 40 and 100 ppm of 1,1,2-Trichloroethane through inhalation route for 13 weeks. Minimal hepatocellular vacuolation was observed in 15 and 40 ppm dosed groups. According to the author of the study the presence of minimal hepatocellular vacuolation, which might represent lipid accumulation, without centrilobular necrosis or an increase in serum levels of enzymes indicative of hepatocellular injury suggest that this degree of vacuolation lacks toxicological significance. Olfactory epithelium, including atrophy and respiratory epithelial metaplasia of the nasal turbinate were found in the 40 and 100 ppm dosed groups of animals. The authors of this study concluded that based on the results of the study for whole-body inhalation for 1,1,2-Trichloroethane to rats for 13 weeks, the NOEL was less than 15 ppm and NOAEL was less than 40 ppm. According to this study the hepatic and nasal effects observed in this study were not considered to be toxicologically significant. Olfactory epithelial atrophy and respiratory epithelial metaplasia are considered to be precancerous lesions. Such precancerous lesions are not adequate for developing an RfC.

In an unpublished study by Dow Chemical Company (briefly summarized by ACGIH, 2001; ATSDR, 1989; and U.S. EPA, 1984), unspecified numbers of male and female rats, guinea pigs, and rabbits were exposed to 1,1,2-trichloroethane vapors at a concentration of 15 ppm, 7 hours per day, 5 days per week for 6 months. No treatment-related adverse effects were noted regarding growth, mortality, organ weight, hematology, or clinical chemistry. Nor were there indications of treatment-related histopathologic changes. Sixteen 7-hour exposures of rats to a 1,1,2-trichloroethane vapor concentration of 30 ppm resulted in minor fatty changes and cloudy

swelling in the liver of female rats, but male rats appeared unaffected. The secondary accounts of these unpublished studies do not provide sufficient detail to provide a basis for an RfC for 1,1,2-trichloroethane.

A single male dog and 24 Sprague-Dawley rats (12/sex) were exposed to 1,1,2-trichloroethane at a target vapor concentration of 100 ppm (mean measured concentration of 84 ppm) 7 hours per day (on alternate days) for up to 6 months (Mellon Institute, 1947). Air-exposed animals (1 dog and 12 male and 12 female rats) served as controls. Endemic lung infection in the entire rat colony resulted in high mortality among treated and control rats (57 and 62%, respectively) during the study and rendered it unuseable for determining the toxicity of 1,1,2-trichloroethane. The treated dog exhibited a 13.2% decrease in body weight gain relative to the control dog, but no obvious treatment-related effects on hematology or clinical chemistry, and no pathological signs. Inclusion of only a single treated dog is an obvious limitation of this study.

DERIVATION OF A PROVISIONAL SUBCHRONIC AND CHRONIC RfC FOR 1,1,2-TRICHLOROETHANE

Due to the lack of adequate health effects data for either subchronic or chronic duration inhalation exposure, it is not feasible to derive a subchronic or chronic p-RfC for 1,1,2-trichloroethane.

PROVISIONAL PEER REVIEWED TOXICITY VALUES FOR 1,2,4-TRIMETHYLBENZENE (CASRN 95-63-6)

Background

On December 5, 2003, the U.S. Environmental Protection Agency's (EPA's) Office of Superfund Remediation and Technology Innovation (OSRTI) revised its hierarchy of human health toxicity values for Superfund risk assessments, establishing the following three tiers as the new hierarchy:

1. EPA's Integrated Risk Information System (IRIS).

2. Provisional Peer-Reviewed Toxicity Values (PPRTV) used in EPA's Superfund Program.

3. Other (peer-reviewed) toxicity values, including:

   - Minimal Risk Levels produced by the Agency for Toxic Substances and Disease Registry (ATSDR),
   - California Environmental Protection Agency (CalEPA) values, and
   - EPA Health Effects Assessment Summary Table (HEAST) values.

A PPRTV is defined as a toxicity value derived for use in the Superfund Program when such a value is not available in EPA's Integrated Risk Information System (IRIS). PPRTVs are developed according to a Standard Operating Procedure (SOP) and are derived after a review of the relevant scientific literature using the same methods, sources of data, and Agency guidance for value derivation generally used by the EPA IRIS Program. All provisional toxicity values receive internal review by two EPA scientists and external peer review by three independently selected scientific experts. PPRTVs differ from IRIS values in that PPRTVs do not receive the multi-program consensus review provided for IRIS values. This is because IRIS values are generally intended to be used in all EPA programs, while PPRTVs are developed specifically for the Superfund Program.

Because new information becomes available and scientific methods improve over time, PPRTVs are reviewed on a five-year basis and updated into the active database. Once an IRIS value for a specific chemical becomes available for Agency review, the analogous PPRTV for that same chemical is retired. It should also be noted that some PPRTV manuscripts conclude that a PPRTV cannot be derived based on inadequate data.

Disclaimers

Users of this document should first check to see if any IRIS values exist for the chemical of concern before proceeding to use a PPRTV. If no IRIS value is available, staff in the regional Superfund and RCRA program offices are advised to carefully review the information provided in this document to ensure that the PPRTVs used are appropriate for the types of exposures and

circumstances at the Superfund site or RCRA facility in question. PPRTVs are periodically updated; therefore, users should ensure that the values contained in the PPRTV are current at the time of use.

It is important to remember that a provisional value alone tells very little about the adverse effects of a chemical or the quality of evidence on which the value is based. Therefore, users are strongly encouraged to read the entire PPRTV manuscript and understand the strengths and limitations of the derived provisional values. PPRTVs are developed by the EPA Office of Research and Development's National Center for Environmental Assessment, Superfund Health Risk Technical Support Center for OSRTI. Other EPA programs or external parties who may choose of their own initiative to use these PPRTVs are advised that Superfund resources will not generally be used to respond to challenges of PPRTVs used in a context outside of the Superfund Program.

Questions Regarding PPRTVs

Questions regarding the contents of the PPRTVs and their appropriate use (e.g., on chemicals not covered, or whether chemicals have pending IRIS toxicity values) may be directed to the EPA Office of Research and Development's National Center for Environmental Assessment, Superfund Health Risk Technical Support Center (513-569-7300), or OSRTI.

INTRODUCTION

Neither a reference dose (RfD) nor a reference concentration (RfC) are available for 1,2,4-trimethylbenzene in the Integrated Risk Information System (IRIS) database (U.S. EPA, 2007) or the Health Effects Assessment Summary Tables (HEAST) (U.S. EPA, 1997). There is no Agency for Toxic Substances and Disease Registry (ATSDR) Toxicological Profile on 1,2,4-trimethylbenzene, other trimethylbenzene isomers, or mixtures of trimethylbenzene isomers (ATSDR, 2006). The Chemical Assessments and Related Activities (CARA) list (U.S. EPA, 1991, 1994a) and the HEAST (U.S. EPA, 1997) list a Health and Environmental Assessment (HEA) for trimethylbenzenes (U.S. EPA, 1987a); however, the available toxicity data were considered inadequate for quantitative risk assessment (U.S. EPA, 1997). The CARA (U.S. EPA, 1991, 1994a) lists a Drinking Water Health Advisory for 1,2,4-trimethylbenzene (U.S. EPA, 1987b). Because available human and animal toxicity data were considered inadequate for longer-term and lifetime quantitative risk assessment, the U.S. EPA (1987b) derived an RfD of 0.64 mg/kg-day for 1,2,4-trimethylbenzene based on assumptions that the Threshold Limit Value (TLV) of 25 ppm (125 mg/cu.m) for mixed trimethylbenzenes recommended by the American Conference of Governmental Industrial Hygienists (ACGIH, 2001, 2005) represents a NOAEL for 1,2,4-trimethylbenzene and that exposure results in 50% absorption. The National Institute of Occupational Safety and Health (NIOSH) adopted a recommended exposure limit (REL) time-weighted average (TWA) of 25 ppm (123 mg/m^3) for 1,2,4-trimethylbenzene (NIOSH, 2006). The Occupational Safety and Health Administration (OSHA) has not adopted a permissible exposure limit (PEL) for 1,2,4-trimethylbenzene (OSHA, 2006). Health assessments for 1,2,4-trimethylbenzene are not available from other major sources, including CalEPA (2006), the

National Toxicology Program (NTP, 2006), the World Health Organization (WHO, 2006), and the International Agency for Research on Cancer (IARC, 2006).

A Group D (not classifiable as to human carcinogenicity) cancer classification is included in the Drinking Water Standards and Health Advisories list (U.S. EPA, 2004). A cancer assessment for 1,2,4-trimethylbenzene is not available on IRIS (U.S. EPA, 2007) or the HEAST (U.S. EPA, 1997). A cancer assessment for 1,2,4-trimethylbenzene is not available from CalEPA (2006), the National Toxicology Program (NTP, 2006), the World Health Organization (WHO, 2006), or the International Agency for Research on Cancer (IARC, 2006). Occupational exposure limits for 1,2,4-trimethylbenzene listed by NIOSH (2006) include no cancer notation.

Literature searches were performed to identify relevant information for 1,2,4-trimethylbenzene for the years 1986-1998 in the databases HSDB, RTECS, TSCATS, MEDLINE, and TOXLINE. Update literature searches were conducted in TOXLINE, MEDLINE (plus PubMed cancer subset), and DART/ETICBACK for the time period including January, 1998 to December, 2005. Update search of the TOXCENTER database was performed for the time period of August, 2000 to December, 2005. Databases searched without date limitations in December, 2005, included TSCATS, RTECS, GENETOX, HSDB and CCRIS. Search of Current Contents encompassed July to December, 2005.

REVIEW OF PERTINENT DATA

Human Studies

Oral Exposure

No data were located regarding the oral toxicity or carcinogenicity of 1,2,4-trimethylbenzene in humans.

Inhalation Exposure

Data regarding the inhalation toxicity of 1,2,4-trimethylbenzene in humans come from an occupational exposure study in which workers were exposed to a mixture of trimethylbenzene isomers. Bättig et al. (1958) examined 27 workers exposed to Fleet-X DV 99 solvent in the painting shop of a Swiss transportation plant. The solvent was analyzed spectrographically and was found to consist primarily of aromatic hydrocarbons (97.5%) and paraffinic and naphthenic hydrocarbons (2.5%). The aromatic hydrocarbon portion was composed of 1,2,4-trimethylbenzene (>50%), 1,3,5-trimethylbenzene (>30%), and possibly included 1,2,3-trimethylbenzene, 1-methyl-2-ethyl benzene, 1-methyl-3-ethyl benzene, and 1-methyl-4-ethyl benzene. Based on analysis of air samples collected from the plant, the concentration of the solvent was roughly estimated at 10-60 ppm (49-295 mg/m^3). The control group consisted of 10 unskilled workers employed in a different section of the plant. Although the authors stated that the Fleet-X DV 99 solvent was used for "a period of some ten years," the average exposure duration of the workers was not reported. The workers reported CNS symptoms (vertigo, headaches and drowsiness) more often than the control group (70% versus 30% in the controls).

Chronic asthma-like bronchitis (30% of workers versus 10% of controls), anemia [defined as < 4.5 million erythrocytes/mm^3 and usually combined with normal hemoglobin] (52% versus 20%) and alterations in blood clotting (30% versus 10%) were also observed in the exposed workers. The incidence of CNS symptoms was statistically significantly higher in the exposed workers than in the control group (Fisher's exact test conducted for this assessment; $p<0.05$). For the other effects, the incidences did not significantly differ between the groups. A higher incidence of vitamin C deficiency was observed in the control group, suggesting that the two groups may not have been matched for socioeconomic status. If the assumption is made that the solvent exclusively contained trimethylbenzene isomers, then this study identifies a LOAEL in the range of 10-60 ppm (49-295 mg/m^3) for signs of neurotoxicity.

Animal Studies

Oral Exposure

The database of repeated oral exposure studies in animals for 1,2,4-trimethylbenzene is limited to a 4-week study (Borriston Laboratories, 1984) and a chronic exposure carcinogenicity study (Maltoni et al., 1997). No oral developmental or reproductive toxicity studies were located for 1,2,4-trimethylbenzene.

The primary focus of the Borriston Laboratories (1984) study was the ability of 1,2,4-trimethylbenzene to induce nephrotoxicity. In this study, groups of 10 male Fischer-344 rats were administered doses of 0.5 or 2.0 g/kg neat 1,2,4-trimethylbenzene by gavage 5 days/week for 4 weeks; the duration-adjusted doses were 357 and 1429 mg/kg-day, respectively. A group of rats serving as controls were gavaged with saline. Gross necropsy was conducted in all rats, but only the kidneys underwent histopathologic examination. Mortality rates during treatment in the control, low-, and high-dose groups were 0/10, 1/10, and 10/10, respectively. Deaths in the high-dose group occurred as early as the third day of treatment. Final body weight and absolute kidney weight of low-dose rats were not significantly different than controls. Gross necropsy findings in low-dose animals included speckled cortical surfaces in the kidneys and white gelatinous material inside the urinary bladders. High-dose rats exhibited mottled and red thymus, spotty kidney and liver surfaces, enlarged adrenals, gas filled and yellow intestines and lung congestion. The presence or absence of hydrocarbon nephropathy was determined by examining the incidence of hyaline droplet changes, regenerative epithelium and tubular dilation with granular material. Treatment with 1,2,4-trimethylbenzene did not significantly increase the incidence or severity of nephropathy relative to controls; however, according to the authors, it is possible that high-dose rats died before nephropathy could develop. A NOAEL or LOAEL could not be determined due to the limited scope of the study, although the high dose of 1429 mg/kg-day was clearly a frank effects level (FEL) for mortality.

Maltoni et al. (1997) investigated the carcinogenicity of 1,2,4-trimethylbenzene (99% pure) in a long-term oral exposure experiment. Male and female Sprague-Dawley rats (50/sex/group) received doses of either 0 or 800 mg/kg (4 days/week) of 1,2,4-trimethylbenzene by gavage in 1 ml olive oil for 104 weeks. Food and water consumption and body weights were recorded throughout the experiment. Upon death or terminal sacrifice at 123 weeks, the animals were subjected to systemic necropsy. Histopathology was performed on brain, pituitary gland,

Zymbal glands, salivary glands, Harderian glands, head, tongue, thymus, mediastinal lymph nodes, lung, heart, diaphragm, liver, spleen, pancreas, kidneys, adrenal glands, esophagus, stomach, intestine (four levels), bladder, prostrate, uterus, vagina, gonads, interscapular fat pad, subcutaneous and mesenteric lymph nodes, sternum, femur, spinal cord and any other organs and tissues with pathological lesions. No statistical analysis of the data was presented.

"Slight" reduction in the survival of the female Sprague-Dawley rats and an "intermediate" reduction in the survival of male rats were reported (Maltoni et al., 1997). However, quantitative survival data were not presented in the report and no statistical analysis of the decreases in survival were presented. Although the study report indicated that food and water consumption and body weight data were recorded, these data were not included in the report. There was no significant increase in the incidence of animals bearing either malignant or benign + malignant tumors (Table 1). Fisher's exact tests conducted for EPA indicated that the differences in total tumors between the exposed and treated animals were not statistically significant ($p<0.05$). Neuroesthesioepitheliomas were observed in the nasal cavity of 3/100 exposed animals (M + F). This tumor was not seen in concurrent controls, and a Fisher's exact test of the data showed that the increase in incidence of neuroesthesioepitheliomas was not statistically significant ($p<0.05$). The authors, however, indicated that these tumors are quite rare in the colony of Sprague-Dawley rats used for these experiments and suggested that this finding presents some evidence for carcinogenicity of 1,2,4-trimethylbenzene.

Table 1. Incidences of Benign and Malignant Tumors in Male and Female Sprague-Dawley Rats after a Long-term (104 week) Oral Exposure to 1,2,4-Trimethylbenzene.[a]

Dose (mg/kg bw)[b]	Animals		Percent of animals with tumors	
	Sex	Number	Benign + Malignant	Malignant
800	M	50	62	26
	F	50	66	24
	M + F	100	64	25
0	M	50	54	24
	F	50	70	22
	M + F	100	62	23

[b]Gavage dose administered 4 days/week for 104 weeks and animals were terminated after 123 weeks.

Inhalation Exposure

Korsak and Rydzyński (1996) examined the neurotoxic effects of acute exposure of male Wistar rats (10/group) to 1,2,4-trimethylbenzene (>97% pure) and other trimethylbenzene isomers, and also examined the neurotoxic effects of subchronic exposure to 1,2,4-trimethylbenzene and 1,2,3-trimethylbenzene. In the acute experiment, rats were exposed to concentrations of 250-2000 ppm (1227-9816 mg/m^3) for 4 hours. Acute exposure to 1,2,4-trimethylbenzene caused concentration-related impairment in a rotarod performance test (EC_{50} = 4693 mg/m^3) and concentration-related decreased pain sensitivity (as measured by increased paw-lick response latency; EC_{50} = 5682 mg/m^3).

In the subchronic experiment, rats were exposed to 1,2,4-trimethylbenzene at concentrations of 0, 25, 100 or 250 ppm (0, 123, 491 or 1227 mg/m^3), 6 hours/day, 5 days/week for 3 months and observed for exposure-related clinical signs and body weight effects (Korsak and Rydzyński, 1996). Rotarod performance and hot-plate behavior were measured as indices of the neurotoxicity of trimethylbenzene isomers. Rotarod performance was tested prior to start of the study, weekly during exposure, and 2 weeks after the termination of the exposure. Hot-plate behavior was tested immediately after termination of the exposure. Fisher's exact test was used for analysis of rotarod performance and the Kruskall-Wallis test used for changes in pain sensitivity (hot plate behavior). Exposures to 1,2,4-trimethylbenzene did not result in any apparent body weight effects or clinical signs of toxicity. However, exposure-related indicators of neurotoxicity were noted. Rotarod performance failure increased in a concentration-related manner in the groups exposed to 1,2,4-trimethylbenzene, but reached the level of statistical significance (40% failure; $p<0.05$) only in the highest (1227 mg/m^3) exposure group following 8 or 13 weeks of exposure. The incidence of rotarod performance failure in control rats was 0% throughout the study period. Although the mean rotarod performance failure rate in the highest exposure group remained at 30% after a 2-week recovery period, the rate was not significantly different from controls. Pain-sensitivity was also decreased in a concentration dependent manner (evidenced by increased latency of the paw-lick response). As shown in Table 2, the increased latency reached the level of statistical significance in the 491- and 1227-mg/m^3 groups. After a 2-week recovery period, the highest (1227 mg/m^3) exposure group no longer exhibited a significant difference in pain sensitivity, relative to controls. This study identified a NOAEL of 123 mg/m^3 and a LOAEL of 491 mg/m^3 (6 hours/day, 5 days/week) for significantly decreased pain sensitivity.

Table 2. Exposure-Related Effect on Latency of the Paw-Lick Response in Rats Exposed to 1,2,4-Trimethylbenzene Vapors 6 Hours/Day, 5 Days/Week for 3 Months.[a]

Number of rats	Exposure level (mg/m^3)	Mean latency of paw-lick response (seconds)
9	0	15.4 ± 5.8[b]
10	123	18.2 ± 5.7
9	491	27.6 ± 3.2[c]
10	1227	30.1 ± 7.9[c]

[a] Source: Korsak and Rydzyński, 1996
[b] The authors did not specify whether standard deviation or standard error of the mean is presented
[c] Statistically significantly different from controls ($p \leq 0.01$)

Gralewicz et al. (1997a) investigated 1,2,4-trimethylbenzene-induced behavioral effects on groups of male Wistar rats (15/group) exposed to vapor concentrations of 0, 50, 100 or 250 ppm (0, 123, 491 or 1227 mg/m^3) for 6 hours/day, 5 days/week for 4 weeks. To assess the effect of exposure on short-term working memory, choice accuracy in a radial arm maze was tested. Effects on spontaneous activity were evaluated with an open field test. Effects on long-term memory and learning ability were assessed on the basis of conditioned passive and active avoidance tests. The hot-plate test was performed to compare the groups with respect to the decrease in responsiveness to a thermal stimulus following a brief intermittent foot shock. Animals were subjected to the following sequence of behavioral testing:

1. radial maze: 2 weeks before exposure and on days 14-18 after exposure,
2. open field activity: day 25 after exposure,
3. passive avoidance: days 35-45 after exposure,
4. hot-plate test: days 50 and 51 after exposure,
5. active avoidance: day 54 after exposure.

The data were analyzed by ANOVA and comparisons among treatments were made using Sheffe's test, or Tukey's test for 2-way ANOVA.

There was no significant effect of 1,2,4-trimethylbenzene exposure on body weight gain during the 4-week exposure. Passive-avoidance learning was significantly ($p<0.001$) retarded in groups exposed to 491 or 1227 mg/m^3 of 1,2,4-trimethylbenzene and tested 35-45 days after the end of the exposure period. Retardation of passive-avoidance learning was more pronounced in the 491 mg/m^3 exposure group than in the 1227 mg/m^3 group. In the hot-plate test following foot shock, evaluation of rats 50 days following termination of exposures to 491 or 1227 mg/m^3 of 1,2,4-trimethylbenzene revealed significantly ($p<0.01$) increased paw-lick latency times, in comparison to unexposed controls. There was no significant change in the active avoidance test, although there was a trend toward decreased avoidance responses with increasing 1,2,4-trimethylbenzene exposure concentration. Short-term working memory did not appear to be adversely affected by 1,2,4-trimethylbenzene exposure. In the open field test there was no significant effect on spontaneous movement or on rearing behavior; however, there was a significant ($p<0.05$) increase in grooming behavior of animals exposed to 1,2,4-trimethylbenzene at 491 mg/m^3. Although grooming behavior also was increased above controls in the 123 and 1227 mg/m^3 groups, the difference was not statistically significant. The results of these experiments suggest that 4-week exposures at concentrations that produced no overt clinical signs of toxicity can produce long-term effects on the functional state of the rat central nervous system. Based on findings of significantly retarded passive avoidance learning and increased paw-lick latency in rats of the 491 and 1227 mg/m^3 exposure groups, the 123 mg/m^3 group represented a NOAEL and the 491 mg/m^3 group represented a LOAEL (6 hours/day, 5 days/week) for persistent neurotoxic effects.

Gralewicz and Wiaderna (2001) employed the same general protocol used by Gralewicz et al. (1997a) in a comparative study of the behavioral effects of repeated inhalation exposure to individual trimethylbenzene isomers or *m*-xylene. The study included a group of 11 adult male Wistar rats exposed to 100 ppm (491 mg/m^3) of 1,2,4-trimethylbenzene (purity not stated) and a control (air only) group of 10 male rats. Exposures were for 6 hours/day, 5 days/week for 4

weeks. The sequence of behavioral testing varied slightly from that employed by Gralewicz et al. (1997a) and included:

1. radial maze: 1 week before exposure and on days 14-18 after exposure,
2. open field activity: day 8 before exposure and day 25 after exposure,
3. passive avoidance: days 39-48 after exposure,
4. hot-plate test: days 50 and 51 after exposure,
5. active avoidance: days 54 and 60 after exposure.

No significant exposure-related effects were seen regarding body weights or short-term working memory (as determined in the radial arm maze test) for any of the trimethylbenzene isomers or *m*-xylene. Acquisition, but not retention, of the two-way active avoidance response was significantly impaired in all solvent-exposed groups. Results of other behavioral tests demonstrated exposure-related effects for each of the solvents. In the case of 1,2,4-trimethylbenzene, significantly increased spontaneous locomotor activity in the open field, impaired passive avoidance learning and significantly longer paw-lick latencies in the hot-plate test 24 hours after foot shock were observed. These results support the findings of the earlier study (Gralewicz et al., 1997a) in which the 491 mg/m^3 (6 hours/day, 5 days/week) exposure level represented a LOAEL for neurotoxic effects in 1,2,4-trimethylbenzene-exposed rats.

Gralewicz et al. (1997b) investigated the effect of a 4-week (6 hours/day, 5 days /week) inhalation exposure to 1,2,4-trimethylbenzene (purity not stated) at concentrations of 0, 25, 100 or 250 ppm (0, 123, 491 or 1227 mg/m^3) on the occurrence of spike-wave discharges (SWD) in the neurocortex of male Wistar rats (9-10/group). Bursts of SWD increase in number and/or duration with advancing age and it was hypothesized that exposure to neurotoxic solvents may accelerate the aging process in the brain. Electrodes were implanted into the fronto-parietal cortex and into the dorsal hippocampus. One-hour EEG recordings were performed immediately before initiation of exposure, at the end of the exposure period, 1 month later and 3 months later. The occurrence of SWD bursts is limited to the state of awake immobility. The number and total duration of SWD bursts were determined from each EEG. The data were analyzed by ANOVA and multiple comparisons among treatments was performed with Tukey's test. The study results included information regarding mean body weights, but the study report did not provide details of body weight data collection.

The study authors (Gralewicz et al., 1997b) indicated that 1,2,4-trimethylbenzene exposure resulted in no statistically significant body weight effects. In the control and lowest (123 mg/m^3) exposure groups, the total duration of SWD showed an increasing trend with time, in comparison to pre-exposure SWD and reached statistical significance ($p<0.05$) at 3 months after exposure. In contrast, the total duration of SWD tended to decline with time in the mid- and high-exposure groups after exposure. The decrease in SWD occurrence, however, was statistically significant only for the measurements performed 1 month after the end of exposure in the mid-exposure (491 mg/m^3) group. A similar trend was seen when the number of SWD bursts per hour was determined. The frequency of SWD bursts increased with age in the control and lowest exposure groups and tended to decline with time in the mid- and high-exposure groups. The data, however, were highly variable and were statistically significantly different from pre-exposure SWD only for the highest exposure level at 3 months after exposure. Thus,

there were no clear 1,2,4-trimethylbenzene induced concentration-related effects on SWD, although the results are suggestive that long-term effects on brain activity may have occurred.

Korsak et al. (2000) exposed groups of male and female rats (10/sex/group; 20/sex/group at the highest exposure concentration) of outbred Imp:WIST to 1,2,4-trimethylbenzene (97% pure) vapors at target concentrations of 0, 123, 492 or 1230 mg/m^3 for 6 hours/day, 5 days/week for 3 months. Animals were observed twice daily for clinical signs of toxicity. Body weights were recorded prior to initiation of exposures and weekly thereafter and food consumption was measured weekly. Blood was drawn for hematological examination prior to initiation of exposures and 1 week prior to exposure termination. Clinical chemistry testing was performed at the end of the 3-month exposure period. Organ weights were determined for lungs, liver, spleen, kidneys, adrenals, heart and gonads. Histopathological examinations were performed on tissues from brain, nose, larynx, trachea, thymus, lungs, heart, liver, spleen, kidney, adrenals, thyroid, pancreas, gonads, urinary bladder, stomach, duodenum, small and large intestines and salivary glands.

Clinical findings were unremarkable (Korsak et al., 2000). No significant exposure-related effects were seen regarding food consumption or body weights. The few differences in some relative or absolute organ weights did not appear to be of toxicological relevance. Significant concentration-related trends ($p<0.01$) for decreased numbers of red blood cells and increased numbers of white blood cells were noted for male (but not female) rats. In the male rats of the highest 1,2,4-trimethylbenzene exposure group (1230 mg/m^3), both red and white blood cell counts were significantly different ($p<0.01$) from those of control males. A significant trend ($p<0.01$) for concentration-related decreased reticulocyte counts was observed in female rats and the difference was significant ($p<0.05$) in the 1230 mg/m^3 group. Hematological testing also revealed a significant trend ($p<0.01$) for decreased clotting time in female (but not male) rats; the decrease reached the level of statistical significance ($p<0.05$) in the 492 and 1230 mg/m^3 groups. Clinical chemistry results were unremarkable, with the exception of significantly increased serum sorbitol dehydrogenase in all 1,2,4-trimethylbenzene-exposed groups of male rats (not concentration related). Histopathological examinations revealed exposure-related significantly increased severity of pulmonary lesions, which included increased proliferation of peribronchial lymphatic tissue in males of the mid- (but not highest) exposure level, increased alveolar macrophages in males of the highest exposure level and increases in interstitial lymphocytic infiltrations in males of the mid- (but not highest) exposure level and females of the highest exposure level. No significant exposure-related changes were seen in the other examined organs and tissues. The mid exposure level of 492 mg/m^3 can be considered a LOAEL for hematological and respiratory effects in this study. The low exposure level of 123 mg/m^3 is a NOAEL.

Korsak et al. (1997) exposed male Wistar rats of IMP:DAK outbreed stock (10/group) to 1,2,4-trimethylbenzene (≥97% pure) at concentrations of 0, 25, 100 or 250 ppm (0, 123, 491 or 1227 mg/m^3) for 90 days (6 hours/day, 5 days/week). Lung lavage fluid was collected 24 hours after termination of the subchronic exposure and centrifuged at 400 g for 10 minutes. Differential counts of bronchoalveolar lavage (BAL) cell smears were determined by light microscopy after staining and the trypan blue test was used to determine cell viability. Total

protein concentration, mucoprotein concentration, lactate dehydrogenase and acid phosphatase activity were determined in the BAL supernatant.

All rats exposed to 1,2,4-trimethylbenzene for 90 days survived the experiment and there were no significant differences in final body weight. Statistically significant increases were observed in total cell and macrophage numbers in BAL of all treated groups after 90 days in comparison to controls. Significant increases were also observed in total protein, lactate dehydrogenase (LDH) and acid phosphatase (AP) in BAL fluid of all treated groups. However, the observed increases in these parameters were either at or near their highest observed response at the lowest exposure concentration, and there was no indication of further concentration-related increases. For the observed effects, the lowest exposure level used (123 mg/m^3) would be a LOAEL; however, the toxicological significance of these effects is not clear.

In a study by IBT (1981), groups of 5 male and 5 female COBS rats were exposed to 49 or 480 mg/m^3 MCS-1809 6 hours/day, 5 days/week for 4 weeks (IBT, 1981). MCS-1809 was identified as a compound containing 75% 1,2,4-trimethylbenzene and 25% C9 aromatics (Monsanto, 1992). The test atmosphere was generated by passing the MCS-1809 through a nebulizer; no information on the particle size distribution was reported. Based on the vapor pressure of 1,2,4-trimethylbenzene, it is likely that the animals were predominantly exposed to 1,2,4-trimethylbenzene vapors rather than a mist. The following parameters were used to assess toxicity: daily observations, weekly body-weight measurements, organ weights (adrenal glands, brain, gonads, heart, kidneys, liver, lungs, spleen and thyroid gland), gross necropsy and histopathological examination of adrenal glands, brain, bronchi, gonads, heart, kidneys, liver, lungs, pancreas, pituitary glands, lymph nodes, spleen, trachea and thyroid gland of the control and 480 mg/m^3 groups (tissues from the 49 mg/m^3 group were examined if significant findings were found in the 480 mg/m^3 group).

Exposure to MCS-1809 did not result in deaths. Clinical signs of toxicity in the 480 mg/m^3 group included ataxia and hypoactivity that persisted between exposures, ptosis, red ocular discharge, and ruffed fur. Less pronounced hypoactivity and ruffed fur were observed in the 49 mg/m^3 group. In the 480 mg/m^3 group, significant decreases in body weight gain (35% lower in the males; no significant alteration in females), increases in absolute (females only) and relative liver weights and decreases in absolute and relative spleen weights (females only) were observed. A significant increase in absolute liver weight was also observed in the 49 mg/m^3 female rats. Histological alterations were limited to focal or diffuse testicular atrophy in 3/5 male rats exposed to 480 mg/m^3 in the absence of statistically significant changes in testis weight; no testicular effects were observed in the 49 mg/m^3 (testes examined in four rats from this group) or control groups. This study identified a NOAEL of 49 mg/m^3 and LOAEL of 480 mg/m^3 (6 hours/day, 5 days/week) for clinical signs of toxicity (persistent ataxia and hypoactivity, ptosis, ocular discharge), decreased body weight gain, and histopathological evidence of testicular atrophy. The increased absolute liver weight observed in the 49 mg/m^3 female rats was not considered adverse because no histological alterations were observed at the 49 or 480 mg/m^3 concentrations.

Bättig et al. (1958) exposed 8 male rats (strain not reported) to air concentrations of 1700 ppm of Fleet-X DV 99 solvent for 4 months (8 hours/day, 5 days/week). Other rats (sex, strain,

and number not specified) were exposed to 500 ppm for 70 days (8 hours/day, 5 days/week). As described earlier, Fleet-X DV 99 is a solvent containing 97.5% aromatic hydrocarbons (>50% 1,2,4-trimethylbenzene and >30% 1,3,5-trimethylbenzene) and 2.5% of paraffinic and naphthenic hydrocarbons. The 500- and 1700-ppm concentrations would be approximately 2523 and 8155 mg/m^3, respectively, if the aromatic hydrocarbon fraction of the vapors were comprised exclusively of trimethylbenzenes. Within 2 weeks of exposure, 4 of the 8 rats exposed to 1700 ppm died and were replaced, while none of the animals in the 500-ppm group died. Histopathologic examinations, performed only on 1700-ppm animals that died, revealed cloudy swelling and fatty infiltration in the kidneys, peripheral fatty infiltration in the liver, an increase in secondary nodules in the spleen and marked congestion of the pulmonary capillaries with alveolar wall thickening. Alterations in differential white blood cell counts (increase in the percentage of segmented neutrophilic granulocytes and a decrease in the percentage of lymphocytes) were reported at 500 ppm. Increases in drinking water consumption (43-45% higher than in the control group) were observed in the 1700-ppm group. The authors reported that during the exposure period, the 1700-ppm animals were initially "highly excited and aggressive" followed by a period of narcosis and ataxia. Because histopathology was only performed on the animals that died, no histopathology data are available on the 500-ppm rats. Due to the limited scope of the study, a NOAEL or LOAEL cannot be identified. The high concentration of 1700 ppm (8155 mg/m^3) is a FEL for mortality.

Bernshtein (1972) exposed rats (number, sex and strain not specified) to 1000 mg/m^3 (200 ppm) of a mixture of trimethylbenzenes for 6 months (4 hours/day, 6 days/week). An inhibition of phagocytic activity of the leukocytes was reported. This study was summarized by Sandmeyer (1981) and further experimental details were not provided.

Korsak et al. (1997) examined the effect of acute exposures (6 min) to the trimethylbenzene isomers, 1,2,3-trimethylbenzene (90-95% pure), 1,3,5-trimethylbenzene (99% pure) and 1,2,4-trimethylbenzene (97% pure) on the respiratory rate of Balb/C male mice (8-10/group) at concentrations ranging from 253 to 1591 ppm (1926-9453 mg/m^3). The concentration depressing mouse respiratory rate by 50% (RD_{50}) was calculated by least squares regression and the Kruskall-Wallis test was applied for evaluation of protein and enzyme levels in the BAL fluid. All three trimethylbenzene isomers showed irritating effects on the respiratory tract and caused concentration-dependent decreases in respiratory rate. The concentration depressing the respiratory rate in mice to 50% was 519 ppm (2547 mg/m^3) for 1,2,4-trimethylbenzene.

The developmental toxicity of 1,2,4-trimethylbenzene was assessed by Saillenfait et al. (2005). Groups of mated (sperm-positive) Sprague-Dawley rats (24/group) were exposed (whole body) to 1,2,4-trimethylbenzene (97% pure) at vapor concentrations of 0, 100, 300, 600 or 900 ppm (0, 491, 1475, 2950 or 4425 mg/m^3) for 6 hours/day on gestation days 6 through 20. Maternal food consumption was recorded for the intervals of gestation days 6-13 and 13-21. Maternal body weights were recorded weekly during gestation. At necropsy on gestation day 21, the uterus was weighed and numbers of corpora lutea, implantation sites, resorptions and dead and live fetuses were recorded. Live fetuses were weighed, sexed and examined for external anomalies. Half of the live fetuses from each litter were prepared for visceral examination, the others were subjected to skeletal examination.

All dams survived to scheduled necropsy (Saillenfait et al., 2005). No clinical signs of 1,2,4-trimethylbenzene-induced toxicity were observed. Maternal food consumption was significantly ($p<0.01$) depressed in the 600- and 900-ppm groups (approximately 12-14% and 15-19%, respectively, relative to controls). The 900-ppm dams exhibited significantly reduced mean body weight gain (22-52% lower than controls) throughout the exposure period. Significantly ($p<0.01$) reduced body weight gain (30% lower than controls) was observed in the 600-ppm group, but only during the first week of 1,2,4-trimethylbenzene exposure. At necropsy on gestation day 21, mean body weight gain (corrected for gravid uterine weight) was significantly depressed in both 600- and 900-ppm dams (approximately 50% lower than controls). Mean fetal body weight was significantly lower in both 600- and 900-ppm exposure groups (approximately 5 and 11% lower, respectively, than controls). There were no other significant indications of maternal or fetal toxicity. This study identified a NOAEL of 300 ppm (1475 mg/m^3) and a LOAEL of 600 ppm (2950 mg/m^3, 6 hours/day on gestation days 6 through 20) for maternal and fetal body weight effects. However, the observed fetal toxicity was likely secondary to maternal toxicity because the decreased fetal body weight was noted only at exposure levels resulting in significantly depressed maternal body weight gain.

Other Studies

Limited genotoxicity data suggest that 1,2,4-trimethylbenzene is not mutagenic. 1,2,4-trimethylbenzene produced negative results in the Ames test with *Salmonella typhimurium* strains TA97a, TA98, TA100 and TA102 both in the presence and absence of rat liver S9 metabolic activation (Janik-Spiechowicz et al., 1998). 1,2,4-Trimethylbenzene was not cytogenic in the mouse micronucleus test, but elicited a positive response in sister chromatid exchange (SCE) tests with bone marrow cells of Imp:Balb/c mice treated *in vivo* (Janik-Spiechowicz et al., 1998).

DERIVATION OF PROVISIONAL SUBCHRONIC AND CHRONIC RfDs FOR 1,2,4-TRIMETHYLBENZENE

Limited information is available regarding the oral toxicity of 1,2,4-trimethylbenzene in humans and animals. The nephrotoxicity study by Borriston Laboratories (1984) is too limited in scope to be used to identify a NOAEL or LOAEL for 1,2,4-trimethylbenzene, although the 2000 mg/kg dose (1429 mg/kg-day) is clearly a FEL for increased mortality. The study of Maltoni et al. (1997) is also unsuitable for derivation of an RfD, as only one dose level was employed, decreased survival occurred at this dose level and reporting of the results was inadequate. Thus, the database for 1,2,4-trimethylbenzene is inadequate to derive a provisional RfD.

DERIVATION OF PROVISIONAL SUBCHRONIC AND CHRONIC RfCs FOR 1,2,4-TRIMETHYLBENZENE

Several studies have examined the inhalation toxicity of mixtures predominantly containing one or more trimethylbenzene isomers, or pure 1,2,4-trimethylbenzene. Significant

increases in the incidence of CNS toxicity (vertigo, dizziness, headaches) and non-significant increases in the incidences of respiratory effects (bronchitis) and hematological effects (hyperchromic anemia and blood clotting alterations) have been observed in workers exposed to 10-60 ppm (49-295 mg/m^3) of a solvent containing >80% trimethylbenzene isomers (Bättig et al., 1958). Many of these effects reported in humans have been observed in experimental animals repeatedly exposed to 1,2,4-trimethylbenzene or other trimethylbenzene isomers or trimethylbenzene mixtures. For example, hematological effects have been reported in experimental animals exposed to a trimethylbenzene mixture (Bernshtein, 1972) or 1,2,4-trimethylbenzene (Korsak et al., 2000). Signs of adverse CNS effects have been observed in animals exposed to mixtures containing 1,2,4-trimethylbenzene (Bättig et al., 1958; IBT, 1981) or 1,2,4-trimethylbenzene alone (Gralewicz and Wiaderna, 2001; Gralewicz et al., 1997a, 1997b; Korsak and Rydzyński, 1996). Results of other animal studies provide evidence of 1,2,4-trimethylbenzene-induced respiratory effects (Korsak et al., 1997, 2000). Other effects observed in animal studies include testicular atrophy in rats exposed to 480 mg/m^3 (98 ppm) of a mixture containing 75% 1,2,4-trimethylbenzene for 4 weeks (6 hours/day, 5 days/week) (IBT, 1981) and lung, liver, kidney and spleen effects in rats exposed to 1700 ppm (8155 mg/m^3) of a solvent containing >80% trimethylbenzene isomers for 4 months (8 hours/day, 5 days/week) (Bättig et al.,1958).

The lowest estimated level of occupational exposure to the solvent Fleet-X DV 99 (>80% 1,2,4- and 1,3,5-trimethylbenzene) in the study of Bättig et al. (1958) was 10 ppm (49 mg/m^3). Assuming that the solvent exclusively contained trimethylbenzene isomers, the 49 mg/m^3 exposure concentration can be considered to represent a LOAEL. Although the Bättig et al. (1958) report provides the lowest inhalation LOAEL (49 mg/m^3) of any study, it may be an inappropriate study for consideration as the principal study for a number of reasons. Importantly, Bättig et al. (1958) identified spectrophotographically the presence of various aromatic hydrocarbons, to include naphthenic and paraffenic compounds, in addition to 1,2,4-trimethylbenzene in the solvent mixture. While 1,2,4-trimethylbenzene comprised up to 50% of the Fleet-X DV 99 mixture, it is virtually impossible to confidently attribute human toxicities solely to 1,2,4-trimethylbenzene (i.e. the study LOAEL is for the mixture not the individual compound). Additional concerns that warrant exclusion of the Bättig et al. (1958) human study from consideration include inappropriate selection of a human control population [e.g. nutritional status (Vit. C deficient)], and the fact that average Fleet-X DV 99 solvent exposure duration, for the 27 exposed workers examined, was not reported.

An advantage of some of the animal models of 1,2,4-trimethylbenzene inhalation exposure over the Bättig et al. (1958) human study is that controlled atmospheres involved the compound of interest at relatively high purities (e.g. 97% 1,2,4-trimetylbenzene in the Korsak et al., 2000 study). However, available repeated exposure inhalation studies in animals are limited to subchronic exposure duration (4 weeks to 3 months) in which the lowest identified LOAEL for 1,2,4-trimethylbenzene was 491 mg/m^3 (Gralewicz and Wiaderna, 2001; Gralewicz et al., 1997a; Korsak and Rydzyński, 1996); furthermore, many of the effects observed in these rodent studies are of unclear toxicological significance and/or have concentration-responses that are difficult to interpret.

Provisional RfCs may be derived based on adverse pulmonary or hematological effects reported in male or female rats, respectively, exposed to 1,2,4-trimethylbenzene (97% pure) for 3 months (Korsak et al., 2000). The selection of the Korsak et al. (2000) study as the basis for deriving RfCs is supported by previous observations in rats (Korsak et al., 1997) and humans (Bättig et al., 1958) exposed to pure 1,2,4-trimethylbenzene or a mixture of trimethylbenzenes, respectively, for ≥ 90 days. Indeed, pulmonary lesions and hematological abnormalities in rats exposed to pure 1,2,4-trimethylbenzene for 3 months (Korsak et al., 2000) are consistent with observations in humans following presumably longer duration exposure to a mixture containing 1,2,4-trimethylbenzene (Bättig et al., 1958).

Subchronic p-RfC

The subchronic p-RfC for 1,2,4-trimethylbenzene is derived from the NOAEL of 25 ppm (123 mg/m^3) identified in the Korsak et al. (2000) rat subchronic inhalation study. Two different toxic effects (pulmonary or hematological) were identified in male or female rats, respectively, in this study at the same LOAEL/NOAEL. As such, two separate subchronic p-RfC derivations are presented below to identify the most sensitive endpoint. Under an assumption of category 3 for decreased clotting time in female Imp:WIST rats, an adjusted experimental NOAEL can be derived using the NOAEL of 123 mg/m^3 and the exposure duration data from Korsak et al. (2000) as follows:

$$NOAEL_{[ADJ]}\ (mg/m^3) = \text{rat NOAEL}\ (mg/m^3) \times 6hr/24hr \times 5\ days/7\ days$$
$$= 123\ mg/m^3 \times 0.25 \times 0.71$$
$$= 21.8\ mg/m^3$$

According to equation (4-48) for extrarespiratory effects [Methods for Derivation of Inhalation Reference Concentrations and Application of Inhalation Dosimetry (EPA/600/8-90/066F October 1994)], a human equivalent concentration ($NOAEL_{[HEC]}$) can be calculated as follows:

$$NOAEL_{[HEC]}\ (mg/m^3) = NOAEL_{[ADJ]}\ (mg/m^3) \times (H_{b/g})_A/(H_{b/g})_H$$

*blood:gas (b/g) partition coefficients for 1,2,4-trimethylbenzene could not be located, therefore a default value of 1 is used for the term $(H_{b/g})_A/(H_{b/g})_H$. The human $NOAEL_{[HEC]}$ is equivalent to the duration adjusted rat NOAEL of 21.8 mg/m^3. A **subchronic p-RfC of 7E-2 mg/m^3** based on a hematological effect is derived by dividing the $NOAEL_{[HEC]}$ of 21.8 mg/m^3 by a composite UF of 300, as follows:

UF (animal to human) = 3
UF (interindividual variability) = 10
UF (database deficiencies) = 10

$$\text{Subchronic p-RfC} = NOAEL_{[HEC]} / UF$$
$$= 21.8\ mg/m^3 / 300$$
$$= 0.07\ mg/m^3 \text{ or } 7E\text{-}2\ mg/m^3$$

Under an assumption of category 1 for pulmonary toxicity in male rats, the same duration adjusted rat NOAEL of 21.8 mg/m^3 is obtained as shown above. Histopathological observations in lung tissue of male Imp:WIST rats exposed to 1,2,4-trimethylbenzene for 3 months indicated inflammatory lesions primarily in the bronchiolar region. Therefore, according to equation 4-22 for Category 1 tracheobronchial effects [Methods for Derivation of Inhalation Reference Concentrations and Application of Inhalation Dosimetry (EPA/600/8-90/066F October 1994)], a $NOAEL_{[HEC]}$ can be calculated as follows:

$$\begin{aligned} NOAEL_{[HEC]}\ (mg/m^{3)} &= NOAEL_{[ADJ]}\ (mg/m^3) \times RGDR_{TB}{}^{\dagger} \\ &= 21.8\ mg/m^3 \times 1.6 \\ &= 34.9\ mg/m^3 \end{aligned}$$

† Derivation of the $RGDR_{TB}$ can be found in Appendix 1

A **subchronic p-RfC of 1E-1 mg/m^3** based on pulmonary effects is derived by dividing the $NOAEL_{[HEC]}$ of 34.9 mg/m^3 by the same composite UF of 300 identified above:

$$\begin{aligned} \text{Subchronic p-RfC} &= NOAEL_{[HEC]} / UF \\ &= 34.9\ mg/m^3 / 300 \\ &= 0.1\ mg/m^3 \text{ or } 1E\text{-}1\ mg/m^3 \end{aligned}$$

The composite UF includes a factor of 3 for extrapolation from animal to human, 10 for interindividual variability, and 10 for database deficiencies. The reduced uncertainty of 3 for animal to human extrapolation is due in part to both the conversion of the rat NOAEL to a human equivalent concentration as well as the consistency of hematological and pulmonary toxicity between rats and humans exposed to 1,2,4-trimethylbenzene. The database deficiencies include lack of developmental toxicity studies in a second species, multigeneration reproductive toxicity studies, and a lack of confidence in the large majority of available animal studies reporting effects of undetermined toxicological significance with concentration-responses that are difficult to interpret. The derivations shown above clearly indicate that decreased clotting time in female rats due to subchronic inhalation exposure to 1,2,4-trimethlybenzene is the more sensitive or health protective endpoint under consideration.

Chronic p-RfC

The **chronic p-RfC of 7E-3 mg/m^3** based on decreased clotting time in female rats (Korsak et al., 2000) is derived by dividing the $NOAEL_{[HEC]}$ of 21.8 mg/m^3 by a composite UF of 3000, as follows:

$$\begin{aligned} \text{Chronic p-RfC} &= NOAEL_{[HEC]} / UF \\ &= 21.8\ mg/m^3 / 3000 \\ &= 0.007 \text{ or } 7E\text{-}3\ mg/m^3 \end{aligned}$$

As for the chronic RfC, the composite UF includes a factor of 10 for extrapolation from subchronic to chronic exposure, 3 for extrapolation from animal to human, 10 for interindividual variability, and 10 for database deficiencies.

Confidence in the principal study (Korsak et al., 2000) is low. While it is remarkable that hematological and pulmonary effects are apparently conserved from rats (Korsak et al., 2000) to humans (Bättig et al., 1958), the concentration-response for either compartment in rats (particularly male rats) is difficult to interpret. Specifically, the low inhalation concentration (123 mg/m^3) in female rats from the Korsak et al. (2000) study was clearly a NOAEL for decreased clotting time (hematological compartment); this NOAEL was also identified for pulmonary effects (e.g. proliferation of peribronchial lymphatic tissue, interstitial lymphocytic infiltration of parenchyma, bronchitis and bronchopneumonia) in male rats. Interestingly, female rats seemed slightly more resistant to these pulmonary effects. However, the overall commutative score, following statistical trend analysis, of all pulmonary lesions suggested that the lungs of male and female Imp:WIST rats are significantly affected by inhalation exposure to 1,2,4-trimethylbenzene at the mid dose of 492 mg/m^3 (Korsak et al., 2000). However, paradoxically, in male rats of the high dose group the pulmonary effects decreased compared to animals in the mid dose group. This counter-intuitive concentration-response relationship might suggest a concentration-dependent transition in mode of action for pulmonary toxicity (note the increase in absolute lung weight of male Imp:WIST rats at the mid concentration of 492 mg/m^3, which is the concentration at which inflammatory foci were identified in lung tissue, and yet in the high concentration group lung weight decreased back to control levels (Korsak et al., 2000); more work would be required to verify.).

According to the derivations provided above it appears that the hematological endpoint (i.e. decreased clotting time in female rats) may be a more appropriate endpoint to consider for inhalation exposure to 1,2,4-trimethylbenzene. Further work in this area is certainly warranted. The human occupational report from Bättig et al. (1958) identified a lower inhalation effect level (e.g. LOAEL = 49 mg/m^3) compared to any of the available animal data. However, the utility of this study in derivation of RfCs is limited by poor reporting of results, undetermined exposure levels, the lack of statistical analysis of results, the lack of information on the exposed and control groups (e.g., age, education level, length of employment), small group sizes and possibly a poorly matched control group (as evidenced by increased incidence of vitamin C deficiency in controls). Also, the controls worked in adjacent rooms and the possibility that they also may have been exposed to trimethylbenzene cannot be excluded. Confidence in the database is low because the database is lacking developmental toxicity data in a second species and reproductive toxicity studies. Reflecting low confidence in the principal study and database, confidence in the provisional subchronic and chronic RfC values is low.

PROVISIONAL CARCINOGENICITY ASSESSMENT FOR 1,2,4-TRIMETHYLBENZENE

Weight-of-evidence Classification

No information was located regarding the carcinogenicity of 1,2,4-trimethylbenzene or mixtures of trimethylbenzene isomers in humans. The database of information regarding the carcinogenicity of trimethylbenzene in animals is limited to a single carcinogenicity study in which male and female Sprague-Dawley rats (50/sex/group) were administered 1,2,4-trimethylbenzene via oral gavage at doses of 0 or 800 mg/kg for 104 weeks (Maltoni et al.,

1997). Although quantitative survival data were not included in the study report, the authors noted "intermediate" and "slight" reduction in the survival of 1,2,4-trimethylbenzene treated male and female rats, respectively. Under the conditions of the study, oral exposure to 1,2,4-trimethylbenzene did not cause a statistically significant increase in the incidence of animals bearing either malignant tumors or benign and malignant tumors (combined) or in the incidence of neuroesthesioepitheliomas. The study of Maltoni et al. (1997) included a single animal species (rat) and a single 1,2,4-trimethylbenzene dose level (800 mg/kg). Based on limitations in study design and reporting of results and the lack of additional carcinogenicity data in animals, the database of information for 1,2,4-trimethylbenzene is inadequate to establish the potential carcinogenicity of 1,2,4-trimethylbenzene. Limited genotoxicity data demonstrated that 1,2,4-trimethylbenzene was not mutagenic in several strains of *Salmonella typhimurium*, and did not elicit cytogenicity in the mouse micronucleus test, but did elicit a positive response in sister chromatid exchange (SCE) tests with bone marrow cells of Imp:Balb/c mice treated *in vivo* (Janik-Spiechowicz et al., 1998). These data provide inadequate evidence for genotoxic activity.

Collectively, the available carcinogenicity and genotoxicity data do not adequately assess the carcinogenic potential of 1,2,4-trimethylbenzene in humans or animals. Under the current U.S. EPA (2005) cancer guidelines, the human and animal data are inadequate for a determination of the human carcinogenic potential of 1,2,4-trimethylbenzene.

Quantitative Estimates of Carcinogenic Risk

There are no appropriate human or animal data from which to derive an oral slope factor or inhalation unit risk for 1,2,4-trimethylbenzene.

APPENDIX 1

According to equation 4-22 for Category 1 tracheobronchial effects [Methods for Derivation of Inhalation Reference Concentrations and Application of Inhalation Dosimetry (EPA/600/8-90/066F October 1994)], a $NOAEL_{[HEC]}$ is calculated using the duration adjusted animal NOAEL and a dosimetric adjustment factor (DAF). In this case the DAF is the RGDR for the tracheobronchial region of the lung ($RGDR_{TB}$). The $RGDR_{TB}$ is calculated as follows:

$$RGDR_{TB} = (RGD_{TB})_A/(RGD_{TB})_H = \frac{(V_E/SA_{TB})_A}{(V_E/SA_{TB})_H} \quad \frac{(e^{-SA_{ET}/V_E})_A}{(e^{-SA_{ET}/V_E})_H}$$

where,

Rat

V_E = 160.07 ml/min or 0.16 L/min (derived using equation 4-4, default body wt. for Wistar rats, and the default intercept and coefficient values provided in Table 4-6)

SA_{TB} = 22.5 cm^2 (Table 4-4)

SA_{ET} = 15.0 cm^2 (Table 4-4)

Human

V_E = 13.8 L/min (default value based on human body weight of 70 kg)

SA_{TB} = 3,200 cm^2 (Table 4-4)

SA_{ET} = 200.0 cm^2 (Table 4-4)

$$= \frac{(0.16 \text{ L/min} / 22.5 \text{ cm}^2)_A}{(13.8 \text{ L/min} / 3{,}200 \text{ cm}^2)_H} \quad \frac{(e^{-15.0 \text{ cm2}/ 0.16 \text{ L/min}})_A}{(e^{-200.0 \text{ cm2}/ 13.8 \text{ L/min}})_H} \ ^*$$

* the exponential portion of the equation is much smaller than 1; thus this half of the equation is negligible.

$$= 0.007 / 0.0043$$

$$RGDR_{TB} = 1.6$$

PROVISIONAL PEER REVIEWED TOXICITY VALUES FOR 1,2-DICHLOROETHANE (ETHYLENE DICHLORIDE) (CASRN 107-06-2) Derivation of a Chronic Oral RfD

Background

On December 5, 2003, the U.S. Environmental Protection Agency's (EPA's) Office of Superfund Remediation and Technology Innovation (OSRTI) revised its hierarchy of human health toxicity values for Superfund risk assessments, establishing the following three tiers as the new hierarchy:

1. EPA's Integrated Risk Information System (IRIS).

2. Provisional Peer-Reviewed Toxicity Values (PPRTV) used in EPA's Superfund Program.

3. Other (peer-reviewed) toxicity values, including:

   - Minimal Risk Levels produced by the Agency for Toxic Substances and Disease Registry (ATSDR),
   - California Environmental Protection Agency (CalEPA) values, and
   - EPA Health Effects Assessment Summary Table (HEAST) values.

A PPRTV is defined as a toxicity value derived for use in the Superfund Program when such a value is not available in EPA's Integrated Risk Information System (IRIS). PPRTVs are developed according to a Standard Operating Procedure (SOP) and are derived after a review of the relevant scientific literature using the same methods, sources of data, and Agency guidance for value derivation generally used by the EPA IRIS Program. All provisional toxicity values receive internal review by two EPA scientists and external peer review by three independently selected scientific experts. PPRTVs differ from IRIS values in that PPRTVs do not receive the multi-program consensus review provided for IRIS values. This is because IRIS values are generally intended to be used in all EPA programs, while PPRTVs are developed specifically for the Superfund Program.

Because new information becomes available and scientific methods improve over time, PPRTVs are reviewed on a five-year basis and updated into the active database. Once an IRIS value for a specific chemical becomes available for Agency review, the analogous PPRTV for that same chemical is retired. It should also be noted that some PPRTV manuscripts conclude that a PPRTV cannot be derived based on inadequate data.

Disclaimers

Users of this document should first check to see if any IRIS values exist for the chemical of concern before proceeding to use a PPRTV. If no IRIS value is available, staff in the regional Superfund and RCRA program offices are advised to carefully review the information provided in this document to ensure that the PPRTVs used are appropriate for the types of exposures and circumstances at the Superfund site or RCRA facility in question. PPRTVs are periodically updated; therefore, users should ensure that the values contained in the PPRTV are current at the time of use.

It is important to remember that a provisional value alone tells very little about the adverse effects of a chemical or the quality of evidence on which the value is based. Therefore, users are strongly encouraged to read the entire PPRTV manuscript and understand the strengths and limitations of the derived provisional values. PPRTVs are developed by the EPA Office of Research and Development's National Center for Environmental Assessment, Superfund Health Risk Technical Support Center for OSRTI. Other EPA programs or external parties who may choose of their own initiative to use these PPRTVs are advised that Superfund resources will not generally be used to respond to challenges of PPRTVs used in a context outside of the Superfund Program.

Questions Regarding PPRTVs

Questions regarding the contents of the PPRTVs and their appropriate use (e.g., on chemicals not covered, or whether chemicals have pending IRIS toxicity values) may be directed to the EPA Office of Research and Development's National Center for Environmental Assessment, Superfund Health Risk Technical Support Center (513-569-7300), or OSRTI.

INTRODUCTION

IRIS (U.S. EPA, 2002) reports that an RfD for 1,2-dichloroethane (1,2-DCA) is not available at this time. In addition, no RfD for 1,2-DCA was listed in the HEAST (U.S. EPA, 1997). U.S. EPA (1984, 1985a) reviewed chronic and subchronic oral studies (Alumot et al., 1976; Lane et al., 1982; Munson et al., 1982; NCI, 1978) but did not attempt to derive an oral RfD because 1,2-DCA is carcinogenic. U.S. EPA (1985b) presented interim RfD derivations based on the oral multigeneration study by Lane et al. (1982) and on inhalation data, but U.S. EPA (1987) concluded that no appropriate data were available for determining an RfD, and therefore, did not estimate a lifetime health advisory for this chemical. However, the NCI (1978) study was considered only for carcinogenic effects in the analysis by U.S. EPA (1987). Therefore, lacking any further update, no RfD for 1,2-DCA appears in the Drinking Water and Health Advisories List (U.S. EPA, 2000). No other EPA documents pertinent to derivation of an RfD for 1,2-DCA were located in the CARA lists (U.S. EPA, 1991, 1994).

ATSDR (1994, 2001) derived an intermediate-duration oral MRL of 0.2 mg/kg-day from a 13-week dosed-water study in rats (NTP, 1991) in which a LOAEL of 58 mg/kg-day for increased kidney weight was identified. Uncertainty factors used in the MRL derivation included 3 for use of a minimal LOAEL, 10 for interspecies extrapolation, and 10 for human variability.

Other resources consulted included the NTP (2001) Management Status Report, the IARC monograph series (IARC, 1979, 1999), WHO (1995), and Patty's Toxicology (Reid, 2001). Literature searches of the following databases were conducted from 1993 to April 2001 for relevant studies: TOXLINE, MEDLINE, TSCATS, GENETOX, HSDB, CANCERLIT, CCRIS, EMIC/EMICBACK, DART/ETICBACK, and RTECS.

REVIEW OF THE PERTINENT LITERATURE

Human Studies

The most recent reviews (ATSDR, 1994, 2001; U.S. EPA, 1984, 1985a,b; IARC, 1999; WHO, 1995) reported that information concerning the toxic effects of ingested 1,2-DCA in humans comes primarily from case reports of individuals who accidentally or intentionally ingested 1,2-DCA. Only crude estimates of ingested dose are available, limiting the value of the data. Symptoms of 1,2-DCA intoxication include cardiac arrhythmia, bronchitis, hemorrhagic gastritis and colitis, hepatocellular damage, renal tubular necrosis and calcification, and central nervous system depression. Although an association between 1,2-DCA in drinking water and major birth defects was found in epidemiological studies, concurrent mixed chemical exposures indicate that the results are only suggestive, do not establish a cause-and-effect relationship, and should be interpreted with caution. Primary routes of exposure in these epidemiological studies may have been both oral and inhalation (volatilized from household water). No studies were located regarding immunological, reproductive, or developmental effects in humans exposed solely to 1,2-DCA by ingestion. The literature search identified no new studies examining the toxicity of 1,2-DCA in humans following oral exposure.

Animal Studies

In an NCI (1978) carcinogenicity study, Osborne-Mendel rats (50/sex/group) were treated with 1,2-DCA in corn oil by gavage at TWA doses of 47 or 95 mg/kg-day, 5 days/week for 78 weeks. B6C3F1 mice (50/sex/group) were also treated for 78 weeks with 97 or 195 mg/kg-day (male mice) and 149 or 299 mg/kg-day (female mice), 5 days/week. Untreated and vehicle controls (20/sex/group) were maintained concurrently. Signs of toxicity, body weight, and food consumption were evaluated throughout the study. Observation continued for 13 weeks after the dosing period. Comprehensive gross and histological examinations were performed upon moribund condition, death, or sacrifice at the end of the bioassay. Hematological and clinical chemistry determinations were not conducted.

In rats, there was no effect on body weight gain, but mortality was significantly ($p<0.001$) increased in 95 mg/kg-day treated male and female rats compared with controls. Survival of male and female rats treated with 95 mg/kg-day was 50% at weeks 55 and 57, respectively. For rats treated with 47 mg/kg-day, survival was reported as 52% at 82 weeks for male rats and 50% at 85 weeks in female rats. Of the vehicle controls, 50% of male and female rats survived at least 72 and 88 weeks, respectively, while 50 and 60% of untreated male and female control rats survived until the end of the study. The study authors attributed the high mortality in the rats to toxic effects and bronchopneumonia, rather than to cancer. Several rats (number not reported) in both the 47 and 95 mg/kg-day dose groups had a hunched appearance and transient labored breathing beginning during the 6th week of treatment. Although one or two control rats (untreated or vehicle not specified) started to show these signs, the incidence was substantially higher in the treated groups than in the control groups. The only treatment-related nonneoplastic lesion found upon microscopic examination was spleen hematopoiesis in female rats which occurred in 1/20 (5%) vehicle controls, 0/50 low dose, and 16/50 (32%) of 95 mg/kg-day dosed animals. A LOAEL of 47 mg/kg-day (TWA = 34 mg/kg-day), the lowest dose tested, for serious clinical signs of labored breathing and hunched appearance is identified in both sexes of rats. However, this study was limited by dosage adjustments and poor survival.

Female mice treated with 195 mg/kg-day also had significantly increased mortality, possibly related to cancer, but mortality was not affected in the other groups of mice. For female mice, mortality (36/50, 72%) was significant in the 195 mg/kg-day group; these deaths may have been tumor-related as 25/36 (69%) had one or more tumors. For male mice, there was no statistically significant association between 1,2-DCA dosage and mortality. Clinical signs in treated groups were unremarkable compared with controls. Body weight was not affected by treatment in male mice or low-dose female mice. Body weight in high-dose female mice became significantly depressed around 30 weeks and was reduced by >45% of control weight at 90 weeks. The incidence of chronic murine pneumonia was dose-related in mice; present in 0/17 untreated control, 0/19 vehicle control, 5/46 (11%) low dose, and 11/47 (23%) high dose males, and in 0/19 untreated control, 0/20 vehicle control, 1/50 (2%) low dose and 6/48 (13%) high dose females. However, only the incidence in high dose males is statistically significant (Fisher's Exact test by SRC $p<0.05$). No other treatment-related nonneoplastic lesions were found in mice. A NOAEL and LOAEL of 149 (TWA = 106 mg/kg-day) and 299 mg/kg-day (TWA = 214 mg/kg-day), respectively, the only two doses tested in female mice, are identified for reduced body weight in female mice. A NOAEL and LOAEL of 97 (TWA = 69 mg/kg-day) and 195 mg/kg-day (TWA = 139 mg/kg-day), respectively, the only two doses tested in male mice, are identified for significant dose-related incidence of chronic murine pneumonia in male mice.

Groups of F344/N rats, Sprague-Dawley rats, Osborne-Mendel rats, and B6C3F1 mice (10 animals/sex) were exposed to drinking water containing 0, 500, 1000, 2000, 4000, or 8000 ppm of 1,2-DCA for 13 weeks (NTP, 1991). The high concentration was close to the solubility limit for 1,2-DCA in water. The authors estimated daily doses based on drinking water consumption and average body weights as follows:

Concentration in Water (ppm)	Doses in mg/kg-day in Rats					
	F344/N		Sprague-Dawley		Osborne-Mendel	
	Male	Female	Male	Female	Male	Female
500	49	58	60	76	54	82
1000	86	102	99	106	88	126
2000	147	182	165	172	146	213
4000	259	320	276	311	266	428
8000	515	601	518	531	492	727

Concentration in Water (ppm)	Doses in mg/kg-day Mice	
	Male	Female
500	249	244
1000	448	647
2000	781	1182
4000	2710	2478
8000	4207	4926

Additional groups of F344/N rats (10/sex) were administered 1,2-DCA by gavage on 5 days/week for 13 weeks to compare toxicity resulting from bolus administration with that of the continuous exposure in drinking water. Gavage doses were 0, 30, 60, 120, 240, or 480 mg/kg-day in the male rats and 0, 18, 37, 75, 150, or 300 mg/kg-day in the female rats. Signs of toxicity, body weight, food and water consumption, hematology and serum chemistry (in control and $\geq$2000 ppm male rat groups only) were evaluated throughout the study, and comprehensive gross and histological examinations were performed at the end of the exposure period.

Rat drinking water studies: None of the rats given 1,2-DCA in drinking water died. No treatment-related clinical signs were observed. Significantly (Dunn's test or Shirley's test) decreased mean body weights were seen in male F344/N rats at 4000 ($p<0.01$) and 8000 ppm ($p<0.01$) (259 and 515 mg/kg-day), in male Sprague-Dawley rats at 8000 ppm (518 mg/kg-day) ($p<0.05$), and in male Osborne-Mendel rats at 8000 ppm (492 mg/kg-day) ($p<0.05$). There were no significant reductions in body weight gain in female rats of any strain. Dose-related decreased water consumption occurred in all treated groups; 4-44% in F334/N males, 5-42% in F334/N females, 14-56% in male Sprague-Dawley males, 25-70% in Sprague-Dawley females, 17-60% in Osborne-Mendel male rats, and 21-58% in Osborne-Mendel female rats. Increases in erythrocyte counts and mild decreases in mean cell volume, measured in males, were attributed by the authors to dehydration. Alkaline phosphatase activity was significantly decreased on

selected test days at ≥2000 ppm in F344/N (≥147 mg/kg-day) and Sprague-Dawley (≥165 mg/kg-day) males, but was unaffected in Osborne-Mendel males. Alanine aminotransferase activity was significantly decreased on selected test days at ≥4000 ppm in F344/N (≥259 mg/kg-day) and Osborne-Mendel (≥266 mg/kg-day) males, at 8000 ppm (492 mg/kg-day) in Sprague-Dawley males. Blood urea nitrogen (BUN) levels were significantly increased in F344/N males at ≥2000 ppm (≥147 mg/kg-day) on days 7 and 14, and on day 3 at 4000 ppm. In Sprague-Dawley males, BUN levels were significantly increased at 2000 ppm (165 mg/kg-day) on days 7 and 45, at 4000 ppm (276 mg/kg-day) on days 7 and 45, and at 8000 ppm (518 mg/kg-day) on days 3, 7, and 45. BUN levels were significantly increased in male Osborne-Mendel rats at ≥4000 ppm (≥266 mg/kg-day) on day 3. Creatine kinase activity was unaffected in male rats of all three strains. Sorbitol dehydrogenase activity was significantly increased at 8000 ppm (515 mg/kg-day) on days 14 and 45 in F344/N males and at 8000 ppm (518 mg/kg-day) on day 14 in Sprague-Dawley males. Sorbitol dehydrogenase activity were unaffected in Osborne-Mendel males. Absolute kidney weights were significantly (Dunn's test or Shirley's test $p<0.05$ or <0.01) increased at >500 ppm in female F344/N (≥58 mg/kg-day), Sprague-Dawley (≥76 mg/kg-day) and Osborne-Mendel rats (≥82 mg/kg-day), at ≥1000 ppm (≥86 mg/kg-day) in male F344/N rats, and at 1000 ppm (≥88 mg/kg-day) in male Osborne-Mendel rats. Absolute kidney weight changes were not significant in male Sprague-Dawley rats. Relative kidney weights were significantly increased at ≥500 ppm in Sprague-Dawley (≥76 mg/kg-day) and Osborne-Mendel (≥82 mg/kg-day) females, and at ≥1000 ppm (≥102 mg/kg-day) F344/N females. Relative kidney weights were significantly increased at ≥1000 ppm (≥86 mg/kg-day) in F344/N males, at ≥4000 ppm (≥266 mg/kg-day) in Osborne-Mendel males, and at 1000, 4000, and 8000 ppm (99, 276, and 518 mg/kg-day) in Sprague-Dawley males. Absolute liver weights were significantly increased at 2000 ppm (147 mg/kg-day) in male F344/N rats, at 1000 (102 mg/kg-day) and 4000 ppm (320 mg/kg-day) in female F344/N rats and at 1000 ppm (88 mg/kg-day) in male Osborne-Mendel rats. Absolute liver weight changes were not significant in male and female Sprague-Dawley rats and in female Osborne-Mendel rats. Relative liver weights were significantly increased at ≥2000 ppm (≥147 mg/kg-day) in F344/N males, at ≥4000 ppm (≥320 mg/kg-day) in F344/N female rats, at ≥500 ppm (≥60 mg/kg-day) in Sprague-Dawley male rats, at 8000 ppm (531 mg/kg-day) in Sprague-Dawley female rats, at 1000 and 2000 ppm (88 and 146 mg/kg-day) in Osborne-Mendel male rats. Relative liver weight changes were not significant in Osborne-Mendel females. No lesions attributable to 1,2-DCA were observed in the liver. The only histopathological finding was minimal to mild renal tubular regeneration, which was found in all groups of treated and control F344/N male rats, Sprague-Dawley male and female rats, and Osborne-Mendel male and female rats at similar incidence and severity. Minimal to mild renal tubular regeneration at similar incidence and severity was found in all groups of treated and control F344/N male and female rats, Osborne-Mendel male and female rats, and Sprague Dawley male and female rats. Kidney and liver weights were increased in dosed rats of all three strains. No compound-related lesions were observed except for a dose-related incidence of renal tubular regeneration in female F344/N rats: 0/10 in controls, 0/10 at 58 mg/kg-day, 1/10 at 102 mg/kg-day, 2/10 at 182 mg/kg-day, 3/10 at 320 mg/kg-day and 9/10 at 601 mg/kg-day. Statistical analyses of the lesion incidence were not reported, but only the incidence at the high dose (601 mg/kg-day) is statistically significant according to Fisher's Exact Test performed for this assessment. However,

support for potentially associated renal functional deficits from serum chemistry measurements was lacking, as serum chemistry analyses were only performed in males. This lesion was of minimal severity in all affected rats. A minimal LOAEL of 58 mg/kg-day, the lowest dose tested, is identified for increased kidney weight in female F344/N rats. The increased kidney weight, without changes in body weight at this dose, is considered to be an early stage adverse effect because dose-related incidence of renal histopathology (tubular regeneration, indicative of previous tubular injury with subsequent repair) also developed at higher doses in the same strain of rats.

Mouse drinking water study: Before the end of the study deaths occurred only in 8000 ppm treated females (90%). No treatment-related clinical signs were observed. Body weight gain was significantly reduced (Dunn's test or Shirley's test $p<0.01$) in high-dose males. Hematological and serum chemical analyses were not performed. Increased liver weight and/or liver:body weight ratio was significant at $\geq$500 ppm ($\geq$249 mg/kg-day) in males and $\geq$1000 ppm ($\geq$647 mg/kg-day) in females. Increased kidney weight and/or kidney:body weight ratio was significant at $\geq$1000 ppm ($\geq$448 mg/kg-day) in males and $\geq$500 ppm ($\geq$244 mg/kg-day) in females. A dose-related increased incidence of tubular regeneration (minimal to moderate) occurred in males; 0/10 in controls, 1/10 at 500 ppm (249 mg/kg-day), 2/10 at 1000 ppm (448 mg/kg-day), 2/10 at 2000 ppm (781 mg/kg-day), 8/10 ($p<0.01$) at 4000 ppm (2710 mg/kg-day) and 9/10 ($p<0.01$) at 8000 ppm (4207 mg/kg-day). Other renal lesions, including karyomegaly (10/10), dilatation (5/10), protein casts (8/10), and mineralization (5/10), occurred significantly in males at the highest dose. Tubular regeneration was observed in 1/10 females at 4000 ppm (2478 mg/kg-day); no other renal lesions were reported in females. Treatment-related lesions were not reported in other organs. Significantly increased absolute and relative kidney weights occurred in male mice at $\geq$249 mg/kg-day. In addition, a dose-related increased incidence of tubular regeneration, achieving statistical significance at $\geq$2710 mg/kg-day, occurred in males. A NOAEL and minimal LOAEL of 249 and 448 mg/kg-day, respectively, are identified for increased kidney weight in male mice. The increased kidney weight is considered to be an early stage adverse effect because dose-related incidence of renal histopathology developed at higher doses in male mice.

Rat gavage study: Additional groups of F344/N rats (10/sex) were administered 1,2-DCA by gavage on 5 days/week for 13 weeks to compare toxicity resulting from bolus administration with that of the continuous exposure in drinking water. Gavage doses were 0, 30, 60, 120, 240, or 480 mg/kg-day in the male rats and 0, 18, 37, 75, 150, or 300 mg/kg-day in the female rats. Signs of toxicity, body weight, food and water consumption, hematology and serum chemistry (in control, 120 and 240 mg/kg-day male rat groups only) were evaluated throughout the study, and comprehensive gross and histological examinations were performed at the end of the exposure period. Deaths occurred in all males before the end of the study at $\geq$240 mg/kg-day and 90% of females at 300 mg/kg-day; clinical signs preceding death included tremors, salivation, and emaciation. Pathology in moribund/dead animals included necrosis in the thymus and cerebellum. No deaths occurred at other doses. Small but significant changes in various hematological parameters occurred in higher dose groups and were considered to be indicative of

dehydration and attributed to significantly reduced water consumption (60% compared to controls). There were no effects on growth at sublethal doses. Other effects included minimal to mild hyperplasia and inflammation of the forestomach epithelium (sometimes with foci of necrosis and mineralization); 0/10 in controls of each sex, 1/10 males at 120 mg/kg-day, 5/10 males at 240 mg/kg-day, 3/10 males at 480 mg/kg-day, and 3/10 females at 300 mg/kg-day (histological examinations were not performed on low dose animals). Liver weight and liver:body weight ratio significantly increased in males at 120 mg/kg-day (no data from higher doses due to mortality) and females at all doses. Kidney weight and/or kidney:body weight ratio significantly increased in males at $\geq$30 mg/kg-day and $\geq$75 mg/kg-day in females. No liver lesions were reported and incidence of renal tubular regeneration in dosed groups was comparable to vehicle control. Small, but significant, changes in various hematological and serum chemistry parameters, compared with controls, were measured in males dosed at 120 and 240 mg/kg-day; however, these measurements were not conducted in other male treatment groups. These changes were considered to be indicative of dehydration and attributed to significantly reduced water consumption (60% compared with controls). These experiments identify an FEL of 240 mg/kg-day for significant mortality in male F344/N rats. It is difficult to discern a LOAEL in this study, as organ weight changes were not accompanied by histological alterations. The NOAEL is 120 mg/kg-day. Based on significant organ weight changes in rats treated by gavage or drinking water, the liver and kidney appear to be target organs for 1,2-dichloroethane.

WHO (1995) briefly reviewed a study by Van Esch et al. (1977), whereby rats of both sexes (number and strain not specified) were treated by gavage with 1,2-DCA at 0, 10, 30 or 90 mg/kg-day for 5 days/week for 90 days. Six rats were dosed with 300 mg/kg-day for 5 days and all rats died. Decreased weight gain was observed at the two highest doses. Increased relative kidney weight occurred in both sexes at 90 mg/kg-day, but increased relative liver and brain weight was seen only in the females at 90 mg/kg-day. Clinical chemistry parameters were normal, and there were no treatment-related histopathological lesions. Sporadic hematological changes were seen, but not in a dose-related manner. The histology on the six rats that died after receiving 300 mg/kg-day 1,2-DCA for 5 days revealed fatty degeneration of the liver and an increase in liver triglycerides. A NOAEL and LOAEL of 90 and 300 mg/kg-day, respectively, are identified for fatty liver with increased triglycerides.

Sprague-Dawley rats (10/sex/dose) received 0 (vehicle control), 37.5, 75, or 150 mg/kg-day of 1,2-DCA in corn oil by gavage for 90 consecutive days (Daniel et al., 1994). Signs of toxicity, body weight, and food consumption were evaluated throughout the study. Ophthalmoscopic examinations were performed prior to treatment and during the last week of the study. Blood and urine chemistry analyses were performed during the last week of the study. Comprehensive gross examinations were performed at necropsy. There were no treatment-related deaths or clinical signs of toxicity. Body weight gain and food consumption were significantly decreased at 150 mg/kg-day in males, but comparable to control in all other groups. In males, relative brain, kidney, and liver weights were significantly increased at $\geq$75 mg/kg-day. In females, relative kidney weight was increased at $\geq$75 mg/kg-day and relative liver weight at

150 mg/kg-day. No significant ocular changes were observed. In females, red blood cells, lymphocytes, hemoglobin, and hematocrit were significantly decreased while platelets, white blood cells, neutrophils and monocytes were significantly increased at the highest dose. In males, hemoglobin and hematocrit were significantly decreased at the two highest doses while platelets were increased only in the high dose group. In females, potassium levels were increased and albumin levels decreased in the two highest dose groups, while in males, alkaline phosphatase was increased at these same doses (data not presented). Urinalysis data were unremarkable. None of the few gross or microscopic lesions observed were considered to be of toxicological significance (no further details reported). A NOAEL and LOAEL of 37.5 and 75 mg/kg-day, respectively, for hematological changes are identified.

Bred female Sprague Dawley rats (25-26/group) were given 0 (vehicle control), 1.2, 1.6, 2.0 or 2.4 mmol/kg-day 1,2-DCA dissolved in corn oil (0, 119, 158, 198 or 238 mg/kg-day) by oral gavage on gestation days 6-20 (15 days) (Payan et al., 1995). No maternal deaths occurred. A dose-related reduction in maternal weight body gain during pregnancy occurred, with statistical significance achieved at the two highest doses (>30% reduction). Pregnancy rates were similar in all groups. No significant effect of 1,2-DCA was noted on the mean number of implantation sites and live fetuses, fetal sex ratio, and male and female fetal weights. There was a slight but significant trend for increase in the mean percentages of nonsurviving implants and resorptions relative to control animals with statistically significant differences only at 198 mg/kg-day. Incidences of visceral and skeletal variations and malformations of the fetus were similar in all groups. A NOAEL and LOAEL of 158 and 198 mg/kg-day, respectively, are identified for increases in nonsurviving implants and resorptions.

In a study to determine the possible immunotoxicity of 1,2-DCA, male CD-1 mice (32/group) were treated with drinking water containing 0, 20, 200 or 2000 ppm 1,2-DCA (0, 3, 24 or 189 mg/kg-day, as calculated by the authors) for 90 days (Munson et al., 1982). Reduced water consumption was seen at 24 and 189 mg/kg-day, and an appreciable decrease in growth was seen in the high-dose group. No significant effects were seen on organ weights, hematological parameters, or immunological function. Since this study was mainly concerned with immunological end points, histological examination of organs and tissues was not conducted. This study identifies a NOAEL of 189 mg/kg-day, the highest dose tested, for immunological effects in mice.

In a 2-year study, groups of rats (18/sex/dose) of unspecified strain were fed a feed mash fumigated with 1,2-DCA that resulted in concentrations of 0, 250, or 500 ppm (equivalent to ≈0, 12, or 25 mg/kg-day) (Alumot et al., 1976). No effects were found on mortality, growth, food consumption, or liver or kidney function as determined by analysis of serum chemistry indices, but histological examinations were not performed. No differences were found in the percentage of females bearing litters, litter size, mortality, and body weights of pups. In a preliminary study, in which rats were fed a dietary level of 1600 ppm (≈80 mg/kg-day) for 7 weeks, hepatic biochemical changes consisting of a significant 15% increase in fat accumulation and 75% increase in total triglycerides were observed, although liver weight was unchanged. Histological

examinations were not performed. A NOAEL of 25 mg/kg-day for changes in serum chemistry is identified. A NOAEL and LOAEL of 25 and 80 mg/kg-day, respectively, are identified for biochemical changes in the liver indicating an increase in fat and triglyceride storage. However, this study is limited by inadequacies in the conduct and reporting (U.S. EPA, 1985b).

In a multigeneration reproduction study, male and female ICR Swiss mice were given drinking water containing 0, 30, 90, or 290 ppm of 1,2-DCA, giving nominal daily doses of 0, 5, 15, or 50 mg/kg-day (Lane et al., 1982). No parental treatment-related effects were observed in F0 and F1B generations as judged by mortality rates, fluid intake, body weight gain, and gross pathology. No significant increase in gross, visceral or skeletal anomalies or any fetotoxic effects were observed. Furthermore, there were no significant differences between treated and control groups for number of pregnant females, weight gain, implants/litter, resorptions, live fetuses and 4- and 21-day survival. There was also no evidence of dominant lethality in treated males mated to untreated females. This study identifies a NOAEL of 50 mg/kg-day, the highest dose tested, for parental and fetal toxicity.

DERIVATION OF A PROVISIONAL ORAL RfD FOR 1,2-DICHLOROETHANE

Cardiac arrhythmia, bronchitis, central nervous system depression, and injury to the liver, kidneys, and gastrointestinal tract have occurred in humans following ingestion of 1,2-DCA (ATSDR, 1994, 2001; IARC, 1999; U.S. EPA, 1984, 1985a,b; WHO, 1995); however, no human studies are suitable for derivation of an RfD for 1,2-DCA. One- and two-generation reproduction studies found no chemical-related effects on fertility indices in long-term feed or drinking water studies in mice and rats (Alumot et al., 1976; Lane et al., 1982), but exposure to a higher oral gavage dose of 198 mg/kg-day caused increases in nonsurviving implants and resorptions in rats that also experienced maternal toxicity (>30% decreased body weight gain) (Payan et al., 1995). While reproductive performance was not evaluated, histological examinations showed no changes in male or female reproductive tissues in rats administered $\leq$480 mg/kg-day by gavage for $\leq$90 days (Daniel et al., 1994; NTP, 1991; Van Esch et al., 1977), in rats and mice exposed to $\leq$492 and $\leq$4,210 mg/kg-day, respectively, in drinking water for $\leq$13 weeks (NTP, 1991), or in rats and mice exposed to $\leq$95 and $\leq$299 mg/kg-day, respectively, by gavage for $\leq$78 weeks (NCI, 1978).

Clinical signs of toxicity have only been observed in the gavage studies; tremors, salivation, and emaciation at $\geq$240 mg/kg-day (NTP, 1991) and hunched appearance and labored breathing at $\geq$47 mg/kg-day (NCI, 1978) in rats. However, in another gavage study no clinical signs of toxicity were observed at $\leq$150 mg/kg-day (Daniel et al., 1994). In drinking water studies, clinical signs of toxicity were not observed at $\leq$727 mg/kg-day in rats and $\leq$4,926 mg/kg-day in mice (NTP, 1991).

Increased organ weights in animal oral studies (Daniel et al., 1994; NTP, 1991; Van Esch et al., 1977) at ≥18 mg/kg-day, and clinical chemistry results in an oral study (Daniel et al., 1994) at ≥75 mg/kg-day, support the kidney and liver as target organs for 1,2-DCA toxicity. While animals studies point to the kidney and liver as target organs of 1,2-DCA toxicity, the database indicates that the dose-relation for toxic effects, including kidney and liver effects, following gavage or dosed drinking water exposure differ. Dose-related organ histopathology was observed in drinking water studies, but not in gavage studies. While kidney and liver weights increased following dosed water administration of 1,2-DCA, accompanying dose-related histopathology was only observed in the kidney. Therefore, the kidney is selected as the target organ for chronic toxicity effects of 1,2-DCA.

Renal effects reported in animals include increases in kidney weight and minimal-to-moderate histopathological changes after longer-term exposures. Relative kidney weight was increased without altered histology in rats that were treated with 75-90 mg/kg-day by gavage for 90 days (Daniel et al,. 1994; Van Esch et al., 1977). An NTP (1991) 13-week gavage study in rats found significant dose-related increases in kidney weight and kidney-to-body-weight ratio at 30-120 mg/kg-day in males and 75-150 mg/kg-day in females (kidney weight was not measured in higher-dose animals because of mortality). Exposure to 1,2-DCA in the drinking water for 13 weeks caused significant dose-related increases in kidney weight and kidney-to-body-weight ratio in rats at ≥58 mg/kg-day and mice at ≥244 mg/kg-day (NTP, 1991). Histopathological examination of the animals in drinking water studies showed dose-related increased incidences of minimal-to-moderate renal regeneration in female rats at ≥102 mg/kg-day and in male mice at ≥249 mg/kg-day (NTP, 1991). These changes are indicative of previous tubular injury with subsequent repair. More severe renal effects including karyomegaly, dilation, protein casts, and mineralization occurred in male mice exposed to 4,207 mg/kg-day of 1,2-DCA (NTP, 1991). However, there were no changes in kidney weight in mice after exposure to189 mg/kg-day in drinking water for 90 days (Munson et al., 1982), and kidney function, as measured by changes in serum levels of urea and uric acid, was normal in rats exposed to 25 mg/kg-day in food for 2 years (Alumot et al., 1976). Histological examination of the kidney was not performed in either of these studies. No histological changes were observed in the kidneys of rats and mice that were administered ≤95 and ≤299 mg/kg-day, respectively, by gavage for ≤78 weeks (NCI, 1978), or in the kidneys of rats that were administered ≤480 mg/kg-day by gavage for 13 weeks (NTP, 1991).

It is more appropriate to base an RfD on an effect level from a drinking water study rather than from a gavage study due to toxicokinetic considerations. Bolus administration may cause saturation of the detoxification/ excretion mechanism resulting in higher blood levels and apparent adverse effects at lower gavage doses. The lowest dose in female rats, 58 mg/kg-day, a minimal LOAEL for increased kidney weight (NTP, 1991) is selected as the basis of the RfD. The increased kidney weight is considered to be an early-stage adverse effect because a dose-related increase in the incidence of renal tubular regeneration developed at doses greater than the minimal LOAEL in the same strain (F344/N) of rats. Increased kidney weights at

≥448 mg/kg-day, accompanied by renal tubular regeneration at higher doses, were also observed in another drinking water study in male mice (NTP, 1991).

With a modifying factor of unity, dividing the minimal LOAEL of 58 mg/kg-day by an uncertainty factor of 3,000 (3 for use of a LOAEL, 10 for extrapolation to chronic duration, 10 for interspecies extrapolation, and 10 for human variability) results in the provisional RfD of **0.02 mg/kg-day.**

p-RfD = LOAEL ÷ (UF x MF)
= 58 mg/kg-day ÷ (3,000 x 1)
= **0.02 mg/kg-day**

STATEMENT OF CONFIDENCE

Confidence in the principal study (NTP, 1991) is medium. The study used adequate numbers of mice and three strains of rats and administered the test chemical in an extensive range of doses by gavage or dosed-drinking water for comparison of bolus and continuous exposure. Sufficient detail was provided for both methods and results. Confidence in the database is medium. Although it describes a range of dose-related effects in subchronic and developmental toxicity studies, the single chronic study indicates serious effects at the lowest level, which have not been confirmed in other studies, and the test chemical was administered by gavage. Medium confidence in the RfD for 1,2-DCA results.

PROVISIONAL PEER REVIEWED TOXICITY VALUES FOR 1,2-DICHLOROPROPANE (CASRN 78-87-5) Derivation of a Carcinogenicity Assessment

Background

On December 5, 2003, the U.S. Environmental Protection Agency's (EPA's) Office of Superfund Remediation and Technology Innovation (OSRTI) revised its hierarchy of human health toxicity values for Superfund risk assessments, establishing the following three tiers as the new hierarchy:

1. EPA's Integrated Risk Information System (IRIS).

2. Provisional Peer-Reviewed Toxicity Values (PPRTV) used in EPA's Superfund Program.

3. Other (peer-reviewed) toxicity values, including:

   - Minimal Risk Levels produced by the Agency for Toxic Substances and Disease Registry (ATSDR),
   - California Environmental Protection Agency (CalEPA) values, and
   - EPA Health Effects Assessment Summary Table (HEAST) values.

A PPRTV is defined as a toxicity value derived for use in the Superfund Program when such a value is not available in EPA's Integrated Risk Information System (IRIS). PPRTVs are developed according to a Standard Operating Procedure (SOP) and are derived after a review of the relevant scientific literature using the same methods, sources of data, and Agency guidance for value derivation generally used by the EPA IRIS Program. All provisional toxicity values receive internal review by two EPA scientists and external peer review by three independently selected scientific experts. PPRTVs differ from IRIS values in that PPRTVs do not receive the multi-program consensus review provided for IRIS values. This is because IRIS values are generally intended to be used in all EPA programs, while PPRTVs are developed specifically for the Superfund Program.

Because new information becomes available and scientific methods improve over time, PPRTVs are reviewed on a five-year basis and updated into the active database. Once an IRIS value for a specific chemical becomes available for Agency review, the analogous PPRTV for that same chemical is retired. It should also be noted that some PPRTV manuscripts conclude that a PPRTV cannot be derived based on inadequate data.

Disclaimers

Users of this document should first check to see if any IRIS values exist for the chemical of concern before proceeding to use a PPRTV. If no IRIS value is available, staff in the regional Superfund and RCRA program offices are advised to carefully review the information provided in this document to ensure that the PPRTVs used are appropriate for the types of exposures and circumstances at the Superfund site or RCRA facility in question. PPRTVs are periodically updated; therefore, users should ensure that the values contained in the PPRTV are current at the time of use.

It is important to remember that a provisional value alone tells very little about the adverse effects of a chemical or the quality of evidence on which the value is based. Therefore, users are strongly encouraged to read the entire PPRTV manuscript and understand the strengths and limitations of the derived provisional values. PPRTVs are developed by the EPA Office of Research and Development's National Center for Environmental Assessment, Superfund Health Risk Technical Support Center for OSRTI. Other EPA programs or external parties who may choose of their own initiative to use these PPRTVs are advised that Superfund resources will not generally be used to respond to challenges of PPRTVs used in a context outside of the Superfund Program.

Questions Regarding PPRTVs

Questions regarding the contents of the PPRTVs and their appropriate use (e.g., on chemicals not covered, or whether chemicals have pending IRIS toxicity values) may be directed to the EPA Office of Research and Development's National Center for Environmental Assessment, Superfund Health Risk Technical Support Center (513-569-7300), or OSRTI.

INTRODUCTION

An inhalation unit risk for 1,2-dichloropropane is not available on IRIS (U.S. EPA, 2003) or in the HEAST (U.S. EPA, 1997). Relevant documents in the CARA list (U.S. EPA, 1991, 1994) include a Health Effects Assessment (U.S. EPA, 1987a), a Drinking Water Criteria Document (U.S. EPA, 1987b), and a Health and Environmental Effects Profile (U.S. EPA, 1985). An inhalation unit risk was not derived in any of these documents due to the absence of adequate inhalation cancer data. CAL/EPA (1997, 2001) derived an inhalation unit risk of 1.8E-05 (ì g/m^3)$^{-1}$ by route-to-route extrapolation from an oral slope factor of 3.6E-02 (mg/kg-day)$^{-1}$. Available reviews by IARC (1986, 1999), ATSDR (1989), IPCS (1993) and Reid (2001), and the NTP (2001) status report, were consulted to identify relevant studies. Literature searches of the following databases were conducted from 1984 to October 2001: TOXLINE, MEDLINE,

TSCATS, GENETOX, HSDB, CANCERLIT, CCRIS, EMIC/EMICBACK, DART/ETICBACK and RTECS.

REVIEW OF THE PERTINENT LITERATURE

Human Studies

An epidemiological study of 71 Italian florists, who were found to have used an average of 162 kg/year of 1,2-dichloropropane (as well as other fumigants, insecticides and fungicides), showed that the mean frequency of peripheral lymphocyte micronuclei for the florists was higher than the mean for 75 controls (Bolognesi et al., 1995). However, due to the confounding exposure to other chemicals, it is not clear that this finding was attributable to 1,2-dichloropropane exposure.

Animal Studies

The available reviews identified a single study regarding the carcinogenicity of 1,2-dichloropropane in animals by inhalation exposure (U.S. EPA, 1987a,b). Heppel et al. (1948) briefly described an experiment in which 80 C3H mice were exposed a total of 37 times to 400 ppm of 1,2-dichloropropane, 4 to 7 hours per exposure, and observed for 7 months. Only 3/80 mice survived; multiple hepatomas were seen in all 3 survivors. The early mortality was associated with severe necrotic liver lesions. No additional inhalation cancer studies were located in the literature search.

An oral cancer bioassay conducted in rats and mice by NTP (1986) concluded that there was *some evidence of carcinogenicity* in both male and female mice based on increased incidences of liver tumors (primarily adenomas), *equivocal evidence of carcinogenicity* in female rats based on mammary gland adenocarcinomas, and *no evidence of carcinogenicity* in male rats.

Other Studies

1,2-Dichloropropane has produced generally positive results in a variety of genotoxicity assays (ATSDR, 1989; IARC, 1999; U.S. EPA, 1987a,b). In bacteria, 1,2-dichloropropane induced reverse mutations in *Salmonella* with and without activation in a number of studies, but was not mutagenic in *Streptomyces*. 1,2-Dichloropropane weakly induced mutations in the fungus *Aspergillus*, but did not produce chromosomal effects in this species. In mammalian cells, results were positive for mutation in mouse lymphoma cells when tested with activation, but not without. With or without activation, results were positive for sister chromatid exchange and chromosomal aberrations in Chinese hamster ovary cells. *In vivo* studies found that 1,2-

dichloropropane did not induce sex-linked recessive lethal mutations in *Drosophila* or dominant lethal mutations in mice, but did produce chromosomal aberrations in rat bone marrow.

FEASIBILITY OF DERIVING A PROVISIONAL INHALATION UNIT RISK FOR 1,2-DICHLOROPROPANE

The only relevant inhalation study (Heppel et al., 1948) was inadequate to evaluate the carcinogenicity of 1,2-dichloropropane. On the basis of the available information, it is not feasible to derive a provisional inhalation unit risk for 1,2-dichloropropane.

PROVISIONAL PEER REVIEWED TOXICITY VALUES FOR 2,4-DICHLOROPHENOL (CASRN 120-83-2)

Background

On December 5, 2003, the U.S. Environmental Protection Agency's (EPA's) Office of Superfund Remediation and Technology Innovation (OSRTI) revised its hierarchy of human health toxicity values for Superfund risk assessments, establishing the following three tiers as the new hierarchy:

1. EPA's Integrated Risk Information System (IRIS).

2. Provisional Peer-Reviewed Toxicity Values (PPRTV) used in EPA's Superfund Program.

3. Other (peer-reviewed) toxicity values, including:

   - Minimal Risk Levels produced by the Agency for Toxic Substances and Disease Registry (ATSDR),
   - California Environmental Protection Agency (CalEPA) values and
   - EPA Health Effects Assessment Summary Table (HEAST) values.

A PPRTV is defined as a toxicity value derived for use in the Superfund Program when such a value is not available in EPA's Integrated Risk Information System (IRIS). PPRTVs are developed according to a Standard Operating Procedure (SOP) and are derived after a review of the relevant scientific literature using the same methods, sources of data, and Agency guidance for value derivation generally used by the EPA IRIS Program. All provisional toxicity values receive internal review by two EPA scientists and external peer review by three independently selected scientific experts. PPRTVs differ from IRIS values in that PPRTVs do not receive the multi-program consensus review provided for IRIS values. This is because IRIS values are generally intended to be used in all EPA programs, while PPRTVs are developed specifically for the Superfund Program.

Because new information becomes available and scientific methods improve over time, PPRTVs are reviewed on a five-year basis and updated into the active database. Once an IRIS value for a specific chemical becomes available for Agency review, the analogous PPRTV for that same chemical is retired. It should also be noted that some PPRTV manuscripts conclude that a PPRTV cannot be derived based on inadequate data.

Disclaimers

Users of this document should first check to see if any IRIS values exist for the chemical of concern before proceeding to use a PPRTV. If no IRIS value is available, staff in the regional Superfund and RCRA program offices are advised to carefully review the information provided in this document to ensure that the PPRTVs used are appropriate for the types of exposures and

circumstances at the Superfund site or RCRA facility in question. PPRTVs are periodically updated; therefore, users should ensure that the values contained in the PPRTV are current at the time of use.

It is important to remember that a provisional value alone tells very little about the adverse effects of a chemical or the quality of evidence on which the value is based. Therefore, users are strongly encouraged to read the entire PPRTV manuscript and understand the strengths and limitations of the derived provisional values. PPRTVs are developed by the EPA Office of Research and Development's National Center for Environmental Assessment, Superfund Health Risk Technical Support Center for OSRTI. Other EPA programs or external parties who may choose of their own initiative to use these PPRTVs are advised that Superfund resources will not generally be used to respond to challenges of PPRTVs used in a context outside of the Superfund Program.

Questions Regarding PPRTVs

Questions regarding the contents of the PPRTVs and their appropriate use (e.g., on chemicals not covered, or whether chemicals have pending IRIS toxicity values) may be directed to the EPA Office of Research and Development's National Center for Environmental Assessment, Superfund Health Risk Technical Support Center (513-569-7300), or OSRTI.

INTRODUCTION

A chronic reference dose (RfD) for 2,4-dichlorophenol (2,4-DCP) is available on IRIS (U.S. EPA, 2007). The RfD of 0.003 mg/kg-day is based on decreased delayed hypersensitivity response in a rat study (Exon and Koller, 1985). Rats were exposed during gestation, through lactation and in drinking water for 15 weeks and a NOEL of 0.3 mg/kg-day was identified (Exon and Koller, 1985). Uncertainty factors of 10 each for interspecies extrapolation and protection of sensitive humans were applied to the NOEL to derive the RfD. The source document was a U.S. EPA (1985) Drinking Water Criteria Document (DWCD). The Drinking Water Standards and Health Advisories list (U.S. EPA, 2006) includes the same chronic RfD of 0.003 mg/kg-day as reported on IRIS. The HEAST (U.S. EPA, 1997) reports a subchronic RfD of 0.003 mg/kg-day for 2,4-DCP, adopting the chronic RfD from IRIS as the subchronic RfD. ATSDR (1999) has prepared a toxicological profile for chlorophenols. An intermediate-duration oral Minimal Risk Level (MRL) of 0.003 mg/kg-day was derived for 2,4-DCP by ATSDR (1999). The MRL is based on the same study, endpoint, and uncertainty factors as the IRIS chronic RfD. The World Health Organization (WHO, 1989, 2003) evaluated the toxicity of 2,4-DCP. WHO (2003) declined to derive health-based guideline values, citing limitations in the toxicity database. Because a chronic RfD is available on IRIS, the present document does not include a chronic provisional-RfD (p-RfD); however, a subchronic p-RfD is included.

An RfC for 2,4-DCP is not available on IRIS (U.S. EPA, 2007) or in the HEAST (U.S. EPA, 1997). ATSDR (1999) did not derive any inhalation MRLs for 2,4-DCP, as there were no inhalation toxicity studies of this compound. The CARA list (U.S. EPA, 1991, 1994) includes a Health and Environmental Assessment (HEA) for 2,4-DCP (U.S. EPA, 1987a) and a Health and

Environmental Effects Document (HEED) for Chlorinated Phenols (U.S. EPA, 1987b), in addition to the DWCD (U.S. EPA, 1985) cited above, but none of these documents reported pertinent data regarding subchronic or chronic inhalation toxicity. The American Conference of Governmental Industrial Hygienist (ACGIH, 2006), Occupational Safety and Health Administration (OSHA, 2006) and National Institute for Occupational Safety and Health (NIOSH, 2006) have not established occupational health standards for 2,4-DCP.

A carcinogenicity assessment for 2,4-DCP is not available on IRIS (U.S. EPA, 2007) or in the HEAST (U.S. EPA, 1997). The Drinking Water Standards and Health Advisories document classifies the carcinogenicity of 2,4-DCP in category E, evidence of noncarcinogenicity for humans (U.S. EPA, 2006). The International Agency for Research on Cancer (IARC, 1999) concluded that there was *evidence suggesting lack of carcinogenicity* for 2,4-DCP in experimental animals based on an oral study in mice and two oral studies in rats (NTP, 1989; Exon and Koller, 1985). 2,4-DCP is not included in the National Toxicology Program's (NTP) 11th Report on Carcinogens (NTP, 2006). Patty's Toxicology (Gingell et al., 2001) was also consulted for relevant information.

To identify toxicological information pertinent to the derivation of provisional toxicity values for 2,4-DCP, searches were conducted in August, 2006 for literature dating from the 1960s to 2006 using the following databases: MEDLINE , TOXLINE, BIOSIS, TSCATS CCRIS, Current Contents, DART/ETIC, GENETOX, HSDB and RTECS.

REVIEW OF PERTINENT DATA

Human Studies

Studies exist regarding the toxicity of chlorophenol mixtures in humans, but neither the literature search nor available reviews (U.S. EPA, 1987a,b; ATSDR, 1999; IARC, 1986, 1999; WHO, 1989) identified any studies regarding the toxicity of 2,4-DCP as a single agent in humans. Among workers in a 2,4-DCP and 2,4,5-trichlorophenol manufacturing plant, chloracne and porphyria were detected (Bleiberg et al., 1964). Elevated serum transaminase levels and evidence of liver damage (regeneration and hemofuscin deposition) were detected by liver biopsy in two cases. Poland et al. (1971) examined employees from the same plant 6 years after the report of Bleiberg et al. (1964). Of the 73 male workers examined, 48 (66%) had some degree of acne, and chloracne was found in 13 workers (18%); no cases of clinical porphyria were documented and only one worker had uroporphyrinuria. The severity of the chloracne was not correlated with job location within the plant or duration of employment. A causal relationship between these effects and exposure to 2,4-DCP in these workers cannot be assumed due to concurrent exposure to a variety of chlorinated compounds.

The literature search did not identify any studies regarding carcinogenicity of 2,4-DCP as a single agent in humans. There are several case-control (Eriksson et al., 1981; Hardell, 1981; Hardell et al., 1981, 1982; Hardell and Sandstrom, 1979) and cohort studies (Axelson et al., 1980, Bueno de Mesquita et al., 1993; Hogsted and Westerlund, 1980; Kogevinas et al., 1992, 1993; Saracci et al., 1991; Lynge, 1987; Riihimaki et al., 1982, 1983; U.S. Air Force, 1983;

Vena et al., 1998) of workers involved in the manufacture of phenoxy herbicides based on 2,4-DCP. In these studies, workers were exposed to a mixture of chemicals including 2,4-DCP and it was not possible to link mortality or tumor incidence to any particular chemical exposure in any of these studies. A follow up of a cohort study to investigate the potential carcinogenic effect of phenoxy herbicides (e.g., 2,4-dichlorophenol) in Danish workers (Lynge, 1985) reported soft tissue sarcomas in male workers. However, the total cancer risk among persons employed in the manufacturing and packaging of phenoxy herbicides was equivalent to the cancer risk in the Danish population. Furthermore, this study had several potential biases, such as exposure to mixtures of other chemicals. Therefore, observed cancer incidences cannot be linked to 2,4-dichlorophenol.

Morbidity and Mortality Weekly Report (MMWR, 2000) reported 5 human fatalities associated with acute exposure to 2,4-DCP in occupational settings. In each of these cases, dermal exposure was significant and chemical burns were common. Inhalation exposure was possible in several of the cases, but the proportion of dose attributable to inhalation exposure could not be determined (MMWR, 2000). Kintz et al. (1992) also reported a fatality associated with dermal exposure to 2,4-DCP. After spilling the pure compound on his right thigh and arm, a 33-year old man experienced seizures and died. His blood level of 2,4-DCP was measured to be 24.3 mg/L.

Animal Studies

Oral Exposure

Subchronic Exposure — In a subchronic study using CD-1 mice, Borzelleca et al. (1985a) administered 2,4-DCP (99% pure) in drinking water to groups of 20 male and 20 female mice for 90 days. Concentrations of 0.2, 0.6 or 2.0 mg/L in 10% Emulphor were added to the drinking water of treated animals; two control groups received either vehicle or deionized water. Water was provided *ad libitum* and intake was measured twice weekly. Clinical observations were made twice daily and body weights were measured weekly. At study termination, surviving mice were sacrificed and necropsied. Blood was collected for hematology (erythrocyte count, leukocyte count [total and differential], platelet count, hematocrit, hemoglobin [Hb], prothrombin and thromboplastin times, plasma fibrinogen) and clinical chemistry (aspartate aminotransferase [AST], alanine aminotransferase [ALT], lactate dehydrogenase [LDH], alkaline phosphatase [ALP], blood urea nitrogen [BUN], glucose, bilirubin, albumin, total protein, cholesterol, creatinine, phosphorus, calcium, globulin, albumin/globulin ratio and electrolytes). Hepatic microsomal enzyme activities (ethoxycoumarin O-deethylase, testosterone hydroxylation, cytochrome p-450 reductase) were also measured. Brain, liver, spleen, lung, thymus and kidney weights were recorded. No tissues were examined histologically.

Based on measured water consumption and body weights, the authors estimated doses of 0, 40, 114 and 383 mg/kg-day for male mice and 0, 50, 143 and 491 mg/kg-day for female mice (Borzelleca et al., 1985a). Treatment with 2,4-DCP did not result in significant differences in body weight, absolute or relative organ weights or microsomal enzyme activity when compared with the vehicle control; however, the vehicle itself (Emulphor) apparently increased body weight and altered some organ weights compared with the naïve controls. Among male rats

treated at the high dose, there was a significant increase in leukocytes (35% higher than vehicle control, $p \leq 0.05$). In females at the high dose, a significant increase in ALP was observed (1.7-fold higher, $p \leq 0.05$). The significance of these changes is uncertain in the absence of toxicological correlates. No other changes in hematology or clinical chemistry were dose-related. Effect levels cannot be identified from these data due to the confounding effect of the vehicle and the absence of histopathological evaluation.

The NTP sponsored a 13-week study to evaluate the toxic effects of subchronic oral exposure to 2,4-DCP and to determine the appropriate doses to be used in a 2-year study (NTP, 1989). F344/N rats and B6C3F1 mice (10/sex) were given 2,4-DCP (>99% pure) in the diet at concentrations of 0, 2500, 5000, 10,000, 20,000 or 40,000 ppm. Clinical observations were performed twice daily; body weight and food consumption were measured twice during the study. After 13 weeks, all animals were subjected to necropsy and histological examination of a comprehensive list of tissues (>40) was conducted on the control and high-dose animals. In the 10,000 ppm and 20,000 ppm rats, the bone marrow, colon, heart, jejunum, stomach and urinary bladder were evaluated histologically; the femoral bone marrow was also examined in 2500 ppm and 5000 ppm female rats. Histologic examination of the liver was performed in 2500, 5000 and 10,000 ppm mice of both sexes.

Using limited data on food consumption and body weight from the report (NTP, 1989), doses in rats can be estimated as 160, 310, 675, 1373 and 2703 mg/kg-day in males and 182, 338, 750, 1376 and 2795 mg/kg-day in females. All rats survived to study termination. Body weights decreased in a dose-related fashion in both sexes. Terminal body weight was significantly lower than controls in males exposed to 10,000 ppm and higher ($p<0.01$ in t-test performed for this review). Terminal body weight was lower than controls by 5%, 20% and 40% at 10,000, 20,000, and 40,000 ppm, respectively. In females, terminal body weight was significantly below control values at concentrations of 20,000 and 40,000 ppm (11% and 21% lower). Average food consumption (measured on weeks 7 and 13) was decreased to 77% and 81% of control values in males and females exposed to 40,000 ppm. Statistical comparison of the food consumption rates was not reported. Rats exposed to 40,000 ppm exhibited hunched posture and rough hair coats. At necropsy, histopathology evaluations revealed bone marrow atrophy in all animals of both sexes exposed to the two highest concentrations and in females (6/10) of the 10,000 ppm group. The incidence of bone marrow atrophy in controls and lower dose groups, if any, was not reported. No other histopathology findings were reported. This study identifies a LOAEL of 10,000 ppm (750 mg/kg-day) for bone marrow atrophy in females. Male rats treated at this concentration also had slight reductions in body weight (5%). The 5000 ppm concentration (338 mg/kg-day) represents a NOAEL.

Based on limited data on food consumption and body weight from the report (NTP, 1989), doses in mice[1] can be estimated as 782, 1533, 1627, 2960 and 6805 mg/kg-day in males and 973, 2438, 3305, 3913 and 8911 mg/kg-day in females. Among high-dose mice, mortality was 100% within the first 3 weeks on study; survival was not different from controls in other

[1] Two measurements of body weight and food consumption were available for all but the high-dose group; due to the mortality in this group, only the initial body weight was available. Food consumption for this group was assumed to be equal to the intake measured in the next lower dose group (20,000 ppm group) for the purpose of these calculations.

dose groups of either sex. There was some evidence for an effect of 2,4-DCP treatment on body weight. In male mice exposed to 20,000 ppm, terminal body weight was 12% below that of controls ($p<0.01$ based on t-test conducted for this review). In females at this concentration, body weights were reduced by about 10-15% from control values during most of the study, but there was no difference from controls in terminal body weight due to a 10% decline in control weights during the final week; the authors did not suggest a cause for this decrease in control weights. Average food consumption (measured at weeks 7 and 13) was 67 to 77% of control values in mice of both sexes exposed to 10,000 ppm, and 44 to 57% of controls at 20,000 ppm; statistical comparison of the consumption rates was not presented. At 10,000 ppm and higher concentrations, mice of both sexes exhibited rough hair coats; the incidences were not reported. Histologic examination of the liver showed hepatocellular necrosis in male mice at all dose levels (0/10, 4/10, 4/10, 6/10, 10/10 at 0, 2500, 5000, 10,000, and 20,000 ppm). The increase was statistically significant ($p<0.05$) at all treatment levels; however, the severity was characterized as minimal at concentrations below 20,000 ppm. Syncytial alterations (multinucleated hepatocytes) were observed in all male mice exposed to 10,000 and 20,000 ppm 2,4-DCP, but not in exposed females, controls of either sex, or males exposed to 2500 or 5000 ppm. NTP (1989) noted renal tubular epithelial necrosis in eight male and three female mice at 40,000 ppm; all of these animals died in the first three weeks on study. The 2500 ppm concentration (782 mg/kg-day) is considered a minimal LOAEL based on mild hepatocellular necrosis in male mice; no NOAEL can be identified.

Exon et al. (1984; Exon and Koller, 1985) evaluated the immunotoxicity of 2,4-DCP in male and female Sprague-Dawley rats exposed prenatally or both pre- and postnatally. All animals were offspring (10/group) of dams exposed via drinking water to concentrations of 0, 3, 30 or 300 ppm 2,4-DCP (99% pure) from 3 weeks of age through breeding (at 90 days) and parturition (these were the same rats used in the reproductive study reported in the same publication; see below). Upon weaning, the prenatal-only groups were maintained untreated until 6 weeks of age, when immunocompetence was assessed. Dams of the pre- and postnatal groups were treated throughout the lactation period and, after weaning, offspring were given the treatment compound in the drinking water at the same concentrations until 13 weeks of age. Based on reported body weight and default water consumption values (U.S. EPA, 1988), the postnatal exposure concentrations correspond to doses of approximately 0.3, 3.0 and 30 mg/kg-day. The animals were weighed biweekly and observed daily for clinical signs. At 6 weeks and 13 weeks of age, respectively, the immunocompetence of groups treated prenatally and both pre- and postnatally was evaluated. Humoral and cell-mediated immune responses and macrophage function were assessed. Humoral immunity was quantified using ELISA assays for IgG antibodies to bovine serum albumin (BSA) or keyhole limpet hemocyanin (KLH). Cell-mediated immunity was measured using delayed-type hypersensitivity response to oxazolone (ear application) or BSA (footpad injection). Finally, macrophage function was assessed *in vitro*. Body and organ weights (liver, spleen and thymus) were recorded at sacrifice; complete necropsies were performed, as well as histopathologic evaluation of the liver, spleen and thymus.

Among the rats treated prenatally (and not postnatally), there was no effect on body weight when measured at 6 weeks of age; however, absolute spleen weights were significantly increased (29%, $p<0.05$) in rats treated at 300 ppm. Prenatal exposure alone did not significantly

alter any of the immune parameters assessed, and there were no significant histopathology findings.

Among rats treated at 300 ppm both pre- and postnatally, there was a significant increase (35%, $p \leq 0.05$) in anti-KLH antibody production compared with controls. Delayed-type hypersensitivity response, measured as the mean footpad swelling, was significantly reduced at both 30 and 300 ppm (40% and 43%, $p \leq 0.05$) (See Table 1). Absolute spleen and liver weights were significantly increased at the highest concentration (almost 2-fold higher spleen weight and 19% higher liver weight; $p \leq 0.05$); body and thymus weights were not affected. There were no histopathological differences among the groups. The LOAEL from this study is 30 ppm (3 mg/kg-day) based on decreased cell-mediated immunity (delayed-type hypersensitivity response); the NOAEL is 3 ppm or 0.3 mg/kg-day.

Table 1. Significant effects of prenatal and postnatal exposure to 2,4-DCP on immune parameters

2,4-DCP (ppm)	Anti-KLH antibody production (mean ± SE absorbance at 405 nm)	Delayed-type hypersensitivity (mean ± SE mm footpad swelling)
0	1.24 ± 0.10	1.10 ± 0.13
3	1.30 ± 0.10	0.85 ± 0.11
30	1.39 ± 0.10	0.67 ± 0.11 [a]
300	1.68 ± 0.08 [a]	0.63 ± 0.11 [a]

[a] Significantly different by analysis of variance and least-square means comparison.

Chronic Exposure — In the chronic NTP studies, F344/N rats and B6C3F1 mice (50 animals/sex/dose) were administered 2,4-DCP (>99% pure) in feed for 103 weeks (NTP, 1989). Dietary concentrations of 0, 5000 or 10,000 ppm were given to male rats and mice of both sexes; female rats were given concentrations of 0, 2500 or 5000 ppm. The authors estimated the doses of 2,4-DCP to be 210 or 440 mg/kg-day for male rats, 120 or 250 mg/kg-day for female rats, 800 or 1300 mg/kg-day for male mice and 430 or 820 mg/kg-day for female mice. Clinical observations were conducted twice daily, while body weight was measured weekly through week 13 and then monthly thereafter. Food consumption was measured monthly. After 103 weeks of dosing, all animals were sacrificed and necropsied. Histopathology of a comprehensive set of tissues (>40) was evaluated in control and high-dose animals; histopathology of low-dose animals was limited to the liver, nose, pituitary and thyroid of male rats; adrenal glands, lymph nodes, pancreas and spleen of female rats; liver, prostate, spleen and tarsal joints for male mice; and uterus for female mice.

Survival was not affected by treatment in rats of either sex, and there were no clinical signs of toxicity (NTP, 1989). Mean body weights in high-dose male and female rats were generally lower than those of controls (5-12%) beginning in week 3 (males) or week 31 (females), but statistical comparisons were not reported, nor were estimates of variability or individual body weight data that would permit statistical comparisons. Food consumption was significantly lower than controls (5-6%, $p<0.05$ based on t-tests conducted for this review) in males of both treatment groups and in high-dose females. Reductions in body weight predated differences in food consumption, indicating a toxic, rather than an organoleptic effect. The only nonneoplastic lesion that was significantly increased over controls was multifocal degeneration

of the nasal epithelium in male rats (25/45, 38/48, 42/46); the increases were significant at both doses ($p<0.05$). This study identifies a LOAEL of 210 mg/kg-day for nasal lesions in male rats; no NOAEL was identified.

There were no compound-related increases in the incidence of any neoplastic lesions in rats (NTP, 1989). The incidence of mononuclear cell leukemia was significantly decreased in dosed male rats relative to that in controls (control, 31/50; low dose, 17/50; high dose, 17/50).

In mice, treatment did not affect survival, nor were there any clinical signs of toxicity (NTP, 1989). Mean body weights of high-dose male mice and both dosed groups of female mice were generally lower than those of controls, although statistical comparisons were not provided. In high-dose males, body weight decrements occurred between weeks 25 and 86 and ranged from 3-9% in magnitude. In low-dose females, body weight decrements began in week 34 and ranged from 5-11%; in high-dose females, the reduction from control values increased over the course of the study and the mean terminal body weight was 17% below controls. Average food consumption was significantly lower than controls in high dose mice of both sexes (22% and 15%, for males and females, respectively; $p<0.05$ based on t-tests conducted for this review). However, body weight decrements preceded reductions in food consumption temporally, indicating that palatability of the diet was not an issue. A dose-related increase in the incidence of syncytial alteration of hepatocytes was observed in dosed male mice (11/50; 33/49; 42/48; $p<0.01$ at both doses based on Fisher's exact tests conducted for this review). This effect was also observed in the subchronic toxicity study with male mice, in which other evidence of liver toxicity (hepatocellular necrosis) was also observed. A LOAEL of 800 mg/kg-day was identified based on liver lesions (syncytial alteration of hepatocytes) in male mice and no NOAEL was identified.

As with rats, treatment did not result in a significantly increased incidence of any neoplastic lesion in mice (NTP, 1989). There was a marginally significant dose-related trend ($p=0.037$) in the incidence of squamous papilloma or carcinoma of the forestomach in male mice (0/50, 0/50, 3/50), but pairwise comparison did not indicate a significant increase at the high dose ($p=0.121$). The authors did not consider this increase to be treatment-related, as there was a negative trend for female mice and 2,4-DCP treatment did not increase the incidence of forestomach hyperplasia in the male mice. The incidence of malignant lymphomas was decreased in high-dose female mice (4/50) relative to controls (12/50). Under the conditions of these 2-year feeding studies, there was no evidence of carcinogenic activity for rats and mice fed 2,4-DCP.

In an oral carcinogenicity study, groups of Sprague-Dawley rats received both pre-and postnatal exposure to 2,4-DCP (99% pure) at concentrations of 0, 3, 30 or 300 ppm in drinking water (0, 0.45, 4.5 or 45 mg/kg-day[2]) for up to 24 months (Exon and Koller, 1985). Groups of 13 female rats were exposed from weaning through breeding at 90 days of age and until parturition. Offspring (groups of about 24/sex) were then given the test compound in drinking water from weaning until death or 24 months of age. Daily clinical observations were conducted, body weights of offspring were measured monthly and blood samples for hematology

[2] Based on default values for body weight and water consumption (U.S. EPA, 1988).

(erythrocyte and leukocyte counts, Hb, mean corpuscular volume [MCV] and packed-cell volume) were collected bimonthly. Necropsies were performed on tumor-bearing or moribund animals (and, presumably, survivors sacrificed at study termination), including histologic examination of the lung, heart, liver, spleen, kidney, adrenal, intestine, stomach, urinary bladder, brain, spinal cord, muscle and any tumors. The authors did not report any information on body weights or clinical signs of toxicity for the carcinogenicity study. When data from males and females exposed to 300 ppm 2,4-DCP for 14 months were combined, both erythrocyte count and Hb content were significantly increased (9% and 16%, respectively; $p \leq 0.05$). No other hematology data were reported or discussed. The toxicological significance of this finding is uncertain in the absence of data from other exposure levels and/or time periods; however, more pronounced hematological effects (bone marrow atrophy) were observed in female rats exposed to higher doses (750 mg/kg-day, NTP, 1989). Because this study was aimed at assessing the carcinogenicity of 2,4-DCP and no data on nonneoplastic findings (other than the single hematology measurements) were reported, effect levels were not derived for this study.

2,4-DCP administration had no effect on the incidence, latency or types of tumors relative to untreated controls (Exon and Koller, 1985). In a cocarcinogenicity study conducted simultaneously, tumor incidences in rats treated prenatally with the carcinogen ethylnitrosourea (ENU) and exposed to 2,4-DCP (either prenatally, postnatally or both) were not different from ENU-only treated rats. However, the authors noted that the group treated only with ENU had an unusually low incidence of tumors, potentially confounding the results of the cocarcinogenicity study with 2,4-DCP.

Kobayashi et al. (1972) evaluated the toxicity of 2,4-DCP in ICR mice fed the compound in the diet for 6 months. The study was published in Japanese and was not translated for this review; the summary contained herein is based on the English abstract and tables. The purity of the compound was not specified in the abstract. Groups of seven mice were fed concentrations of 0, 0.02%, 0.05%, 0.1% or 0.2% 2,4-DCP in the diet. From the available data, it appears that the high concentration group began treatment approximately 3 weeks later than the other groups; this is not discussed in the abstract. While the abstract does not specify the toxicological endpoints examined, the tables indicate that hematology (erythrocyte and leukocyte count), liver function (AST or ALT) and organ weights (liver, kidney, spleen and heart) were assessed in all treatment groups and histopathology evaluations (liver, kidney, spleen, heart and adrenal glands) were performed on controls and animals in the 0.1% and 0.2% groups.

Reuber (1983) reviewed all available studies related to the carcinogenicity of the phenoxy herbicide 2,4-dichlorophenoxy acetic acid (2,4-D) and its primary metabolite, 2,4-dichlorophenol (2,4-DCP). This report indicated that while 2,4-D was carcinogenic to both male and female rats, 2,4-DCP only demonstrated promoter activity in mouse skin cancer studies.

Based on measured body weights and food consumption rates, the authors estimated the doses to be 0, 45, 100 and 230 mg/kg-day. The authors reported that there were no effects on behavior. Both the abstract and the tabulated data on body weight, food consumption, hematology, liver function and organ weights (liver, kidney) indicated no effect of 2,4-DCP treatment. The authors reported that the histologic examinations showed “slight unfavorable” effects on the liver (the table reports these as “small round cell infiltration, swelling of hepatic

cells, unequal size of hepatic cells and dark cells") at the highest dose; however, the numbers of affected animals were small (1 or 2 in a group of 7), so the toxicological significance is difficult to assess. The authors considered the 100 mg/kg-day dose to be a NOEL in mice. However, due to the small numbers of animals used in this study and the lack of a full translation, it was not considered appropriate to assign effect levels based on these data.

Reproductive/Developmental Studies — Aoyama et al. (2005) conducted a two-generation reproductive toxicity study in Wistar-Hannover rats exposed to 2,4-DCP via the diet. Groups of 24 rats/sex/group (aged 5 weeks) were given 2,4-DCP (99.7% pure) at concentrations of 0, 500, 2000 or 8000 ppm for 10 premating weeks and during mating, gestation and lactation. Pregnant dams were allowed to give birth and on postnatal day (PND) 4, the litters were culled to 8 pups (4/sex when possible). On PND 21, groups of 24 male and female weanlings (1 male and 1 female from each litter) were selected to become F1 parents. F0 parents and any weanlings not selected to be F1 parents were necropsied at this time. F1 parents were treated in the same manner as the F0 parents with dietary 2,4-DCP during 10 premating weeks and through lactation of the F2 pups. Upon weaning of the F2 generation, F1 parents and F2 pups were sacrificed and necropsied.

Clinical observations of parental animals were conducted daily and body weights and food consumption measured weekly (Aoyama et al., 2005). Female estrous cyclicity was evaluated by vaginal smear for 2 weeks prior to mating. Upon parturition, fertility and gestation parameters were recorded and the number and sex of live pups noted. Pups were weighed on PND 0, 4, 7, 14 and 21. Developmental milestones (pinna unfolding, tooth eruption, eye opening) were recorded in both generations. In addition, age at preputial or vaginal opening was evaluated in F1 pups selected to be parents, while anogenital distance on PND 4 was recorded in F2 pups. At necropsy (after weaning of pups for parental animals and at weaning for F2 pups), the number of uterine implantation sites was noted in female parents and sperm count and motility were recorded in male parents. The following organs were examined histologically in parental animals: liver, kidneys, pituitary, reproductive organs of both sexes and mammary glands. In F2 pups, the brain, thymus, spleen and uterus were weighed, but not examined histologically. Levels of pituitary and ovarian hormones (FSH, LH, prolactin, 17ß-estradiol and progesterone) were measured in F1 parent females upon necropsy.

Using mean body weight and food consumption values, the authors estimated doses of 33.4, 134 and 543 mg/kg-day for males and 49.1, 194 and 768 mg/kg for females (Aoyama et al., 2005). Clinical signs of toxicity (soiled fur in the abdominal/genital regions) were apparent in the highest dose group. At the highest dose, food consumption and body weight were significantly ($p \leq 0.01$) lower in both males and females of the F0 generation and in parental females of the F1 generation throughout most of premating, gestation and lactation (data presented graphically). Females exposed at 2000 ppm also exhibited occasional statistically significant (p-value and data not reported) reductions in food consumption and/or body weight (during premating in the F0 generation and during gestation in the F1 generation).

The mean number of implantation sites was slightly decreased in a dose-dependent fashion in both F0 and F1 parents, but was statistically significant ($p \leq 0.05$) only at the high dose in the F1 generation (10.2 vs. 12.7 in controls; Aoyama et al., 2005). In addition, the number of

live pups appeared to decrease with dose in both generations, but there were no statistically significant reductions. The age at preputial separation was significantly ($p \leq 0.05$) longer (42.2 days vs. 41.2 days in controls) in high-dose parental males of the F1 generation; however, the authors attributed this effect to reduced body weight. In contrast, despite lower body weight in high-dose females (F1), the age at vaginal opening was accelerated, albeit nonsignificantly (31.5 days vs. 32.2 days in controls). Neither sperm parameters nor female hormone concentrations were affected by treatment. Among high-dose parents, significant increases in relative organ weight (kidneys, testes) occurred in the absence of absolute organ weight changes and were attributable to decreased body weight. No other organ weight changes occurred in a dose-dependent manner and/or across generations.

Birth weight of pups was not affected by treatment (Aoyama et al., 2005). Pups of high-dose parents of both generations had reduced body weights (compared with controls) beginning on PND 7 and continuing through weaning. As dams treated at this dose (both generations) had significantly reduced food consumption and body weight, the reductions in pup weight are not unexpected. At the highest dose, eye opening was significantly ($p \leq 0.01$) delayed in pups of both generations and both sexes (50.5 to 65.3% of pups with eyes open on PND 14 vs. 89.1 to 94.6% of controls). Other developmental parameters were not affected by treatment. Upon necropsy of weanlings, there were significant reductions in absolute weights of brain, thymus and spleen in the high-dose group; however, these were attributable to reduced body weight. In contrast, the uterus weight of both F1 and F2 females was significantly increased at the high dose (42% and 20%, respectively; $p \leq 0.01$) and at the mid-dose in F1 females (25%, $p \leq 0.05$). Histologic examination of selected uteri of high-dose weanlings in the F2 generation indicated increased epithelial cell height (7/10 vs. 1/10 controls).

The authors indicated that the NOAEL for parental toxicity was 500 ppm and called the 2000 ppm concentration the “minimum toxic dose” based on reduced food consumption and body weight in parental females. Palatability of the treatment diet was not likely the cause of reduced weight. There were no reductions in food consumption or body weight in F0 males, indicating that this group consumed the treatment compound readily. Further, body weight reductions in high-dose F1 females preceded reductions in food consumption, indicating a toxic effect rather than an organoleptic effect. Body weight reductions have been reported in other studies (NTP, 1989), including a gavage study (Rodwell et al., 1989). Thus, the 2000 ppm concentration (194 mg/kg-day in females) is considered a minimal LOAEL based on reduced body weight and the 500 ppm concentration (49.1 mg/kg-day in females) is the NOAEL for parental toxicity.

For reproductive endpoints, the authors identified the 8000 ppm concentration (768 mg/kg-day in females) as a toxic dose based on reduced number of implantation sites in F1 parental females, increased uterine weight in F1 and F2 weanlings and accelerated sexual maturation of F1 females. In addition, eye opening was significantly delayed at this dose. The 2000 ppm concentration (194 mg/kg-day in females) is a NOAEL for reproductive effects.

Exon et al. (1984; Exon and Koller, 1985) evaluated a limited number of reproductive parameters in a study using female Sprague-Dawley rats exposed to 2,4-DCP (99% pure) from 3 weeks of age, through breeding with untreated males and until parturition. This information was

collected in conjunction with the immunotoxicity study on the progeny of exposed rats (see above). Groups of 13 rats were exposed via drinking water to concentrations of 3, 30 or 300 ppm 2,4-DCP (estimated to result in doses of 0.45, 4.5 and 45 mg/kg-day[3]). Percent conception, litter size, percent stillborn, birth and weaning weight and survival to weaning were evaluated. The authors reported that there were no treatment-related effects on the dams. Although the text indicated that the percent stillborn tended to be greater in the treatment groups, the increases were not statistically significant (2% in the high- and mid-concentration groups, 1% in the low concentration group and 0 in controls). The average litter size was smaller in the high-concentration group (6.3±1.6) compared with controls (9.8±1.3), but the difference was not statistically significant[4]. Other parameters were not affected by treatment. Due to the limited number of parameters assessed in this study, effect levels were not identified.

A two-generation rat reproductive study was conducted to investigate potential endocrine-mediated effects. One of the herbicides, 2,4-dichlorophenol, was administered at 0, 500, 2000 and 8000 ppm in the diet. Increased uterine weights were observed in both F1 and F2 females. A reduced number of implantation sites and reduced live births in F1 parental animals were observed at 2000 ppm and higher exposure levels (Yamasaki et el., 2005).

To understand the structural basis for estrogenic activity, Tarasaka et al. (2006) performed DNA-micro array assay of several structurally similar chemicals, including 2,4-dichlorophenol. This assay demonstrated the estrogenic activity of 2,4-dichlorophenol by down regulating enzymes and signaling pathway compared to chemicals with high levels of estrogenic activity.

Using prostate cancer cell lines, Kim et al. (2005) evaluated the endocrine disrupting activity of 2,4-dichlorophenoxyacetic acid and 2,4-dichlorophenol. These chemicals did not show any androgenic activity. However, co-exposure with 5alpha-dihydroxytestosterone synergistic androgenic activity was demonstrated in this assay.

Rodwell et al. (1989; Dow Chemical Co., 1983) evaluated the developmental toxicity of 2,4-DCP in F344 rats. Groups of 34 sperm-positive female rats were given 2,4-DCP (99.2% pure, in corn oil) via gavage on gestation days (GD) 6-15. Doses of 0, 200, 375 or 750 mg/kg-day were administered. Maternal body weights were recorded on GD 0, 6, 10, 12, 15 and 20. On GD 20, dams were sacrificed by carbon dioxide and subjected to caesarean section. The uterus was weighed and examined for number and location of viable and nonviable fetuses and early and late resorptions. Number and location of *corpora lutea* were recorded. Fetuses were weighed, measured, sexed and examined externally; half were then prepared for soft tissue examination and the remainder prepared for skeletal examination.

Four dams in the high-dose group died during treatment (Rodwell et al., 1989; Dow Chemical Co., 1983). Clinical observations in the high-dose group included red staining around the eyes, nares and mouth; abdominal alopecia; and respiratory rales. While incidences were not

[3] Based on default values for body weight and water consumption (U.S. EPA, 1988).
[4] Exon and Koller (1985) reported that the decrease in litter size was statistically significant at $p \leq 0.10$; Exon et al. (1984) reported that it was not statistically significant. The latter interpretation was accepted here given the relatively high critical value (0.10) used to assess significance in the 1985 paper.

reported, the authors indicated that these were observed in a majority of animals at this dose and in some animals exposed to 375 mg/kg-day. A few high-dose rats also displayed ataxia, prostration and reduced activity. In addition, yellow staining of fur in the urogenital area occurred in all treated groups (incidence not provided, but reported to increase with dose). Maternal body weight gain during treatment was significantly ($p<0.05$) lower than control weight gain in all dose groups (82%, 77%, and 32% of controls during GD 6-15 at the low, mid-, and high doses); further, the body weight decrements persisted after exposure ceased, although the decrease was statistically significant only at the high dose. There were no significant differences in reproductive or teratogenic parameters. Significantly ($p<0.05$) increased incidences of unossified sternebrae (4/22 litters vs. 0/27 litters in controls) and delayed ossification of vertebral arches (6/22 litters vs. 0/27 litters in controls) were observed in the high-dose group. The high dose in this study was a Frank Effect Level (FEL) due to 4 maternal deaths. The LOAEL for maternal toxicity was 200 mg/kg-day, based on clinical signs and decreased body weight gain during treatment; no NOAEL can be identified for maternal toxicity. Developmental effects (increased skeletal variations) were observed at the maternal FEL of 750 mg/kg-day, but not at lower doses; thus, the NOAEL for developmental toxicity was 375 mg/kg-day.

Inhalation Exposure

The literature search identified no studies regarding toxicity of 2,4-DCP in animals following inhalation exposure. Similarly, the available reviews (U.S. EPA, 1987a,b; ATSDR, 1999; IARC, 1986, 1999; WHO, 1989) did not identify any inhalation toxicity studies of this compound.

Other Studies

Acute Toxicity — Borzelleca et al. (1985a,b) reported oral LD50 values of 1276 mg/kg and 1352 mg/kg for male and female CD1-ICR mice observed for up to 14 days. Kobiyashi et al. (1972) calculated oral LD50 values of 1600 mg/kg in ICR mice (same value for males and females) and 3670 and 4500 mg/kg in male and female Sprague-Dawley rats (respectively) observed for up to 10 days.

Dermal Carcinogenicity Studies — Boutwell and Bosch (1959) examined the ability of 2,4-DCP to act as a complete carcinogen on the skin of mice and to promote skin tumors following a single initiating dose of dimethylbenzanthracene (DMBA). In the study for complete carcinogenesis, a group of 23 female Sutter mice (2-3 months of age) was treated with a topical application of 25 μL of 20% 2,4-DCP in benzene applied twice weekly to the back of each mouse for 24 weeks. Of the 23 mice, 16 (70%) survived to 24 weeks, at which time 75% of the survivors (12 mice) had papillomas and 6% (1 mouse) had a carcinoma. The average number of papillomas per mouse was 1.62. At 39 weeks, 62% of surviving mice (number not reported) had carcinomas. There was no control group maintained concurrently in this experiment. The absence of a similarly-treated concurrent control group, along with the significant mortality (30%) in this short-duration study, limits the usefulness of these data.

In the promotion experiment, a group of 33 female Sutter mice was treated with an initial topical application of 75 µL of 0.3% DMBA in benzene, followed by 25 µL of 20% 2,4-DCP in benzene applied twice weekly to the back of each mouse for 15 weeks (Boutwell and Bosch, 1959). At 15 weeks, 27 of 33 (82%) 2,4-DCP-treated mice survived, compared to 15 of 20 (75%) in the control group. Based on information in the publication, the control group was treated with an initiating dose of DMBA; it is not clear whether the controls received applications of vehicle (benzene) on the promotion schedule[5]. At the end of treatment, the incidence of papillomas was significantly increased ($p<0.01$) in 2,4-DCP-treated surviving mice (13/27), compared with controls (1/15). The average number of papillomas per mouse was 1.07 vs. 0.07 in controls. Three of 27 (11%) 2,4-DCP-treated survivors had carcinomas, compared to no carcinomas in the initiator only group; however this difference was not statistically significant ($p>0.05$).

U.S. EPA (1980) criticized several aspects of this study, including the failure to histologically confirm tumor types and the use of creosote-coated wooden cages to house the animals. The use of creosote-treated cages could not be confirmed; the publication indicates that "screen-bottomed metal cages" were used. In addition, U.S. EPA (1980) noted that the high concentration of 2,4-DCP (20% in benzene) applied to the skin may have caused physical abrasion of the skin. 2,4-DCP is known to be corrosive to the skin (HSDB, 2006) and this irritant property may have enhanced the papillomatous response in both studies. It is also important to note that there was significant mortality in the control group of the promotion study (25%) despite the short duration of the study (15 weeks). The reason for this high rate of mortality or that of the 2,4-DCP treated group in the complete carcinogenicity study (30%), was not discussed by the authors.

Genotoxicity — Genotoxicity testing of 2,4-DCP has generally given negative results. Positive results in clastogenicity testing have often been associated with cell toxicity. 2,4-DCP produced no increases in revertant colonies in *Salmonella typhimurium* strains TA98, TA100 or TA1537 with or without exogenous metabolic activation (Haworth et al., 1983; Rasanen et al., 1977). The mutagenic effect of 2,4-DCP in *Salmonella typhimurium* strain TA1535 was initially considered to be equivocal in the presence of hamster liver S9 metabolic activation (Haworth et al., 1983). However, a reevaluation of the data resulted in a determination that the response was negative (Zeiger, 1990). 2,4-DCP significantly increased trifluorothymidine (Tft) resistance in the mouse L5178Y assay at concentrations of 30-60 µg/mL when tested without metabolic activation (Myhr et al., 1990). 2,4-DCP was cytotoxic to V79 Chinese hamster cells, but did not induce 6-thioguanine-resistant mutants when tested at concentrations up to 50 µg/mL without exogenous metabolic activation (Jansson and Jansson, 1986). In a cell-mediated test (wherein metabolic activation was provided by co-cultured cells), 2,4-DCP was weakly mutagenic at concentrations that were also cytotoxic to V79 cells (cell survival 41-54% of controls; Fiskesjo, 1988).

In cultured CHO cells, 2,4-DCP did not induce chromosomal aberrations at concentrations up to 75 µg/mL (0.51 mM) without S9 (8-hour treatment) and at up to 150 µg/mL

[5] In other experiments using DMBA followed by promotion testing of agents dissolved in benzene, the control is reported as a "benzene control"; in this experiment, it is not.

(1.02 mM) with S9 (2-hour treatment) (Anderson et al., 1990). In another CHO cell assay, chromosomal aberrations developed in a significant percentage of cells both with and without activation (Hilliard et al., 1998). Aberrations were observed in 14% of cells following a 3-hour treatment at 1.4 mM without S9 and in 14.5% cells treated at 0.6 mM with S9, compared with 1.5% of control cells (Hilliard et al., 1998). Cell survival was reduced in both of these cases (27% and 54% of controls, respectively), raising the possibility that the aberrations were related to toxicity (Hilliard et al., 1998). Testing of human TK6 lymphoblasts for chromosomal aberrations resulted in an equivocal (nonsignificant) increase (5% of cells with aberrations, compared with 0% in controls) for 2,4-DCP at 0.8 mM, a concentration that gave 59% survival compared with controls. 2,4-DCP increased the frequency of sister chromatid exchanges (SCEs) both in the presence and absence of S9 (Anderson et al., 1990).

The cytogenic effect of 2,4-dichlorophenol was studied in bone marrow, germ cells and spermhead abnormalities in mice treated intraperitoneally at 1/10, 1/5, ½ dose levels (Amer and Aly, 2001). This report demonstrated weaker genotoxic effects as indicated by lower percentage of induced chromosomal aberrations and spermhead abnormalities.

2,4-DCP induced error-prone DNA repair (*umu*-test) in *S. typhimurium* cells when tested without metabolic activation (Ono et al., 1992). In an *in vitro* alkaline elution/rat hepatocyte genotoxicity assay, 2,4-DCP produced evidence of DNA damage; however, cytotoxicity tests showed significant toxicity at concentrations resulting in DNA damage and the authors suggested that DNA effects likely resulted from activation of degradative endonucleases in dead or dying cells (Storer et al., 1996). 2,4-DCP did not induce unscheduled DNA synthesis in primary cultures of rat hepatocytes at a concentration of 50 nmol/mL (Probst et al., 1981). In a prophage-induction assay, 2,4-DCP did not induce DNA damage in *E. coli* at doses up to 480 μmol (DeMarini et al., 1990). 2,4-DCP produced negative results in an *in vivo-in vitro* mouse hepatocyte replicative DNA synthesis (RDS) test (Miyagawa et al., 1995).

Genotoxicity testing of 2,4-DCP is complicated by the fact that this compound uncouples oxidative phosphorylation, leading to depletion of cellular energy supplies. Mitsuda et al. (1963) reported that a concentration of 42 μM 2,4-DCP caused 50% inhibition of ATP production in rat liver mitochondria *in vitro*; in fact, 2,4-DCP was the most potent of the mono- and dichlorophenols tested in this study. Disturbances in energy production may be responsible for the cellular toxicity observed in genotoxicity assays, many of which were conducted at high concentrations. Cell toxicity can lead to false-positive findings, especially in assays for clastogenicity, because DNA damage commonly occurs in apoptotic and necrotic cells (Storer et al., 1996; Hilliard et al., 1998).

DERIVATION OF A PROVISIONAL SUBCHRONIC ORAL RfD VALUE FOR 2,4-DICHLOROPHENOL

A chronic oral RfD of 0.003 mg/kg-day based on an immunotoxicity study (Exon et al., 1984) is available on IRIS. Several oral toxicity studies, including the immunotoxicity study, are available for use in deriving a provisional subchronic oral RfD for 2,4-DCP. Table 2 summarizes the findings of those studies in which a NOAEL and/or LOAEL was identified. As

Table 2. Summary of Oral Noncancer Dose-Response Information

Species	Sex	Doses (mg/kg-day)	Exposure Duration	NOAEL (mg/kg-day)	LOAEL (mg/kg-day)	Responses	Comments	Reference
Chronic Studies								
Rats	M/F	0, 210, 440 (M) 0, 120, 250 (F)	103 weeks	NA	210	Multifocal degeneration of nasal epithelium		NTP, 1989
Mice	M/F	0, 800, 1300 (M) 0, 430, 820 (F)	103 weeks	NA	800	Syncytial alteration of hepatocytes in males		NTP, 1989
Subchronic Studies								
Rats	M/F	0, 160, 310, 675, 1373 (M) 0, 182, 338, 750, 1376, 2795 (F)	13 weeks	338	750	Bone marrow atrophy in females		NTP, 1989
Mice	M/F	0, 782, 1533, 1627, 2960, 6805 (M) 0, 973, 2438, 3305, 3913, 8911 (F)	13 weeks	NA	782	Mild hepatocellular necrosis		NTP, 1989
Rats	M/F	0, 0.3, 3, 30	Pre- and postnatal	0.3	3	Decreased cell-mediated immunity	Immunotoxicity study. Exposure prenatally, through lactation and via drinking water from weaning until 13 weeks of age	Exon and Koller, 1985
Reproductive/Developmental Studies								
Rats	F	0, 200, 375, 750	GD 6-15	NA (maternal) 375 (develop-mental)	200 (maternal) 750 (develop-mental)	Maternal toxicity: clinical signs, reduced body weight gain Developmental effects: increased incidence of skeletal variations		Rodwell et al., 1989; Dow Chemical Co., 1983

Table 2. Summary of Oral Noncancer Dose-Response Information

Species	Sex	Doses (mg/kg-day)	Exposure Duration	NOAEL (mg/kg-day)	LOAEL (mg/kg-day)	Responses	Comments	Reference
Rats	M/F	0, 33.4, 134, 543 (M) 0, 49.1, 194, 768 (F)	10 weeks premating, through gestation and lactation	49.1 (parental) 194 (reproductive)	194 (parental) 768 (reproductive)	Parental toxicity: transient reductions in body weight of dams Reproductive effects: reduced number implantation sites (F1 dams), delayed eye opening and effects on uterus in offspring	Two-generation reproductive toxicity study	Aoyama et al., 2005

the table indicates, the LOAEL for immunotoxicity (3 mg/kg-day; Exon et al., 1984) is much lower (almost 2 orders of magnitude) than LOAELs for other endpoints. This study was thus selected as the basis for the subchronic p-RfD. The critical effect in this study is a decrease in cell-mediated immunity, as measured by decreased footpad swelling. The data selected for modeling are shown in Table 3. Models for continuous variables in U.S. EPA's Benchmark Dose Software (BMDS) were fit to the cell-mediated immunity data in accordance with U.S. EPA (2000) methodology. A default benchmark response (BMR) of one standard deviation from the control mean was used. Appendix A contains details of the modeling and a plot of the best fitting model.

Table 3. Cell-mediated Immunity Data as Modeled

2,4-DCP (ppm)	2,4-DCP (mg/kg-day)	No. of rats	Delayed-type hypersensitivity (mm footpad swelling)		
			Mean	SE	SD
0	0	10	1.10	0.13	0.41
3	0.3	10	0.85	0.11	0.35
30	3.0	10	0.67	0.11	0.35
300	30	10	0.63	0.11	0.35

Source: Exon et al. (1984; Exon and Koller, 1985)

The test for homogenous variance indicated that the homogenous variance model provided adequate fit to the variance data. Using the homogenous variance model, the linear model did not provide adequate fit to the means, so the remaining models were applied; however, none provided adequate fit. In order to try to achieve model fit, the high dose group was dropped from the analysis. Using the reduced data set, the homogenous variance model again provided adequate fit to the variance data, and the linear model provided adequate fit to the means. BMD and BMDL predictions from the modeling of the reduced data set were 3.21 and 1.84 mg/kg-day, respectively. The BMDL from this study (2 mg/kg-day) was thus selected as the point-of-departure (POD) for derivation of the subchronic p-RfD.

The **subchronic p-RfD of 0.02 mg/kg-day** is calculated as the BMDL of 2 mg/kg-day divided by an uncertainty factor of 100, as shown below:

Subchronic p-RfD = BMDL/UF
= 2 mg/kg-d / 100
= 0.02 mg/kg-day

An interspecies uncertainty factor of 10 was applied and another 10-fold uncertainty factor was used for protection of sensitive individuals. A factor of 1 for duration was applied, as the exposure included prenatal and lactational exposure, followed by exposure via drinking water to 13 weeks of age. Since a BMDL was used as the POD, no adjustment for use of a LOAEL was necessary. No database uncertainty factor was used; the toxicological database for 2,4-DCP contains chronic studies in two species, several subchronic studies in rats and mice, two developmental toxicity studies in rats, and a multigeneration reproductive toxicity study in rats. The database lacks a neurotoxicity study; however, existing studies suggest that neurotoxic effects occur only at high doses.

Confidence in the principal study (Exon et al., 1984) is medium because, despite the investigation of sensitive endpoints, the sample sizes were relatively small (10 per dose). Confidence in the database is high because the database includes well-conducted chronic studies in two species, several subchronic studies in rats and mice, two developmental toxicity studies in rats, and a multigeneration reproductive toxicity study in rats. Medium to high confidence in the subchronic p-RfD follows.

FEASIBILITY OF DERIVING PROVISIONAL SUBCHRONIC AND CHRONIC INHALATION p-RfC VALUES FOR 2,4-DICHLOROPHENOL

There are no inhalation studies available for use in developing subchronic and/or chronic provisional RfCs (p-RfC) for 2,4-DCP.

PROVISIONAL CARCINOGENICITY ASSESSMENT FOR 2,4-DICHLOROPHENOL

Weight-of-Evidence Classification

Under the 2005 Guidelines for Carcinogen Risk Assessment (U.S. EPA, 2005), 2,4-DCP is *not likely to be carcinogenic to humans via oral exposure.* There is *inadequate information to assess the carcinogenic potential* of 2,4-DCP to humans via inhalation exposure. There are no human data addressing the potential carcinogenicity of 2,4-DCP alone, either via oral or inhalation exposure. 2,4-DCP tested negative in adequate 2-year NTP dietary bioassays using both rats and mice. In addition, a second adequate chronic study in rats found no increase in tumor formation with chronic 2,4-DCP exposure (Exon and Koller, 1985). 2,4-DCP has not been tested for carcinogenicity via inhalation exposure. In an old publication where dermally-applied 2,4-DCP was tested both for complete carcinogenicity and as a promoter, an increased incidence of papillomas was observed (Boutwell and Bosch, 1959); however, there are a number of limitations that call into question these results, including: lack of control in the complete carcinogenicity study, high mortality in the control group for the promotion study and use of a potentially corrosive concentration of 2,4-DCP in the skin applications. Genotoxicity testing of 2,4-DCP has largely given negative responses; instances where positive responses were reported have often been associated with cytotoxicity.

Quantitative Estimates of Carcinogenic Risk

There are no appropriate human or animal data from which to derive an oral slope factor or inhalation unit risk for 2,4-DCP.

APPENDIX A. BENCHMARK DOSE MODELING OF CELL-MEDIATED IMMUNITY (MEAN FOOTPAD SWELLING) (EXON ET AL., 1984; EXON AND KOLLER, 1985)

The model fitting procedure for continuous data is as follows. The simplest model (linear) is first applied to the data while assuming constant variance. If the data are consistent with the assumption of constant variance ($p \geq 0.1$), then the fit of the linear model to the means is evaluated. If the linear model adequately fits the means ($p \geq 0.1$), then it is selected as the model for BMD derivation. If the linear model does not adequately fit the means, then the more complex models are fit to the data while assuming constant variance. Among the models providing adequate fit to the means ($p \geq 0.1$), the one with the lowest AIC for the fitted model is selected for BMD derivation. If the test for constant variance is negative, the linear model is run again while applying the power model integrated into the BMDS to account for nonhomogenous variance. If the nonhomogenous variance model provides an adequate fit ($p \geq 0.1$) to the variance data, then the fit of the linear model to the means is evaluated. If the linear model does not provide adequate fit to the means while the nonhomogenous variance model is applied, then the polynomial, power and Hill models are fit to the data and evaluated while the variance model is applied. Among those providing adequate fit to the means ($p \geq 0.1$), the one with the lowest AIC for the fitted model is selected for BMD derivation. If the test for constant variance is negative and the nonhomogenous variance model does not provide an adequate fit to the variance data, then the data set is considered unsuitable for modeling.

Following the above procedure, continuous-variable models in the EPA BMDS (version 1.3.2) were fit to the data shown in Table 3 (page 23) for decreased cell-mediated immunity (as measured by mean footpad swelling) in rats. Using these data, the constant variance model provided adequate fit to the variance data. With the homogeneous variance model applied, the linear model did not provide an adequate fit to the means, as shown in Table A-1. Further, none of the remaining models provided adequate fit to the data (there were not enough dose groups to apply the Hill model). In order to achieve model fit, the high dose group was dropped from the analysis. With the reduced data set, the homogenous variance model again fit the variance data adequately. With the homogenous variance model applied, the linear model provided adequate fit to the means (Figure A-1). The BMDs and the 95% lower confidence limits (BMDLs) associated with a change of 1 standard deviation (SD) from the control were calculated using the linear model with homogenous variance model applied.

Table A-1. Model Predictions for Footpad Swelling in Rats Exposed to 2,4-DCP (Exon et al. 1984; Exon and Koller, 1985)

Model	Variance *p*-value[a]	Means *p*-value[a]	BMD_{1sd} (mg/kg-day)	$BMDL_{1sd}$ (mg/kg-day)
All dose groups				
Linear (constant variance)	0.9413	0.04207	40.30	21.74
Polynomial (constant variance)[b]	0.9413	0.01183	40.30	21.74
Power (constant variance)[c]	0.9413	0.01183	40.30	21.74
Hill (constant variance)[c]	NA[d]			
Without high dose group				
Linear (constant variance)	0.8418	0.1747	3.21	1.84

[a]Values <0.10 fail to meet conventional goodness-of-fit criteria
[b]Coefficients restricted to be negative; no adequate fit with any degree polynomial; 2-degree polynomial shown
[c]Power restricted to ≥ 1
[d]NA = not applicable (insufficient degrees of freedom available to fit this model)

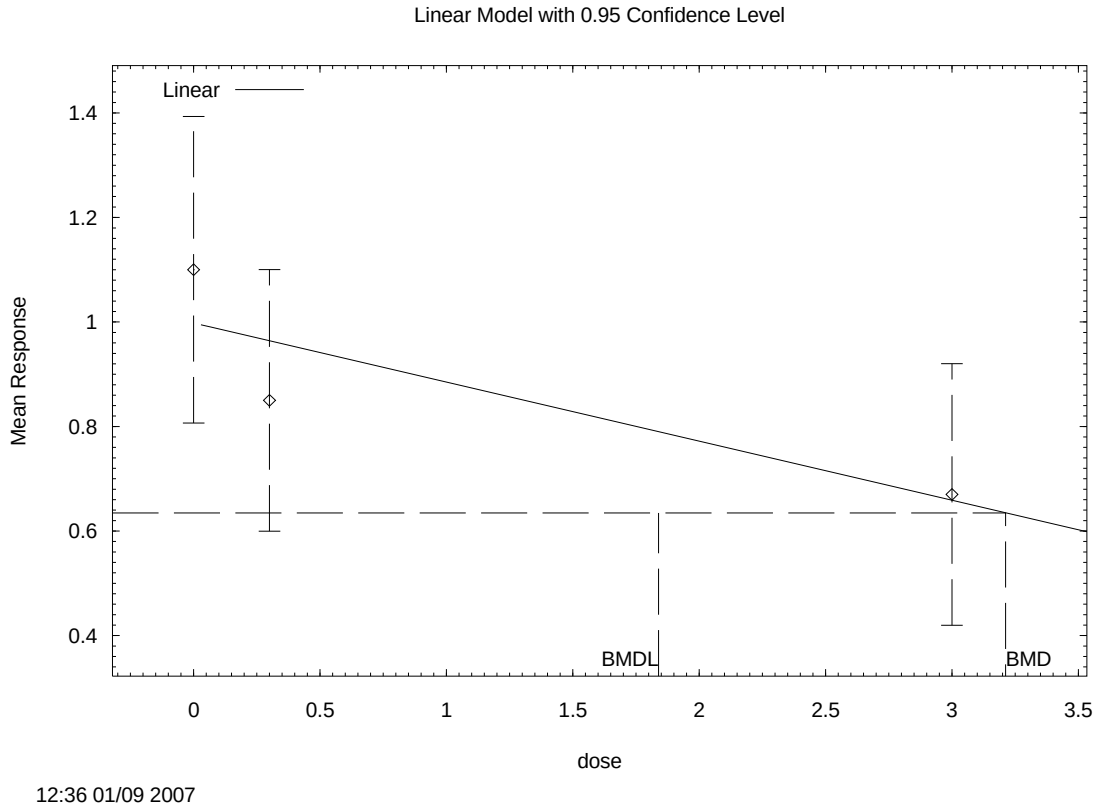

Figure A-1. Mean Footpad Swelling (mm) in Rats Exposed to 2,4-DCP (Reduced dataset) (Exon et al., 1984; Exon and Koller, 1985)

BMDs and BMDLs indicated are associated with a change of 1 SD from the control, and are in units of mg/kg-day.

Bob,

Here's the first installment. I also sent a note to STSC to ask specifically about naphthalene. I will also ask for an estimate of when the PPRTVs that are in development will be completed. I'll let you know what I find out.
