REVISED REPORT

Volume 4 – Appendix L (Human Health Risk Assessment)

Willis Avenue Chlorobenzene Site
Remedial Investigation
Geddes, New York

Honeywell

Christopher C. Calkins
Vice President

July 2010

O'BRIEN & GERE

TABLE OF CONTENTS

Acronyms ..... **xxv**

Executive Summary ..... **xxviii**
Site Background xxviii
Site History xxix
Exposure Areas, Receptors, and Exposure Media xxx
Risk Discussion xxxi
Risk Drivers xxxii
Plant Area xxxii
Current/Future Receptors xxxii
Future Receptors xxxii
On-Site Ditches xxxii
Current/Future Receptors xxxii
Future Receptors xxxiii
Former Chlorination Building xxxiii
Current/Future Receptors xxxiii
Future Receptors xxxiii
Southwest Off-Site/Outfall 006 Exposure Area xxxiv
Current/Future Receptors xxxiv
Future Receptors xxxiv
State Fair Blvd/Northwest Off-Site/Outfall 004 Exposure Area xxxiv
Current/Future Receptors xxxiv
Lakeshore Property Area xxxiv
Current/Future Receptors xxxiv
Petroleum Storage Area xxxv
Current/Future Receptors xxxv
Future Receptors xxxv
Chlorobenzene Hot-Spot Area xxxv
Current/Future Receptors xxxv
Future Receptors xxxv
Tributary 5A xxxvi
Current/Future Receptors xxxvi
Hypothetical Drinking Water Source Area xxxvi
Future Receptors xxxvi
Hypothetical Future Indoor Air xxxvi

1. Introduction **1**
1.1. Risk Assessment Guidance 1
1.2. Approach 2

2. Description of Site Areas **3**
2.1. Willis Avenue Plant Study Area 3
2.2. Other Areas of Study 5

3. Conceptual Site Model **6**
3.1. General CSM 6

3.2. Plant Area, On-Site Ditches, and Former Chlorination Building 8
3.3. Southwest Off-Site/Outfall 006 Exposure Area 8
3.4. State Fair Blvd./Northwest Off-Site/Outfall 004/ Exposure Area 9
3.5. Lakeshore Area 9
3.6. Tributary 5A 9
3.7. Petroleum Storage Area 10
3.8. Chlorobenzene Hot-Spot Area 10
3.9. Hypothetical Drinking Water Source Area 10
3.10. Evaluation of Soil Vapor Intrusion Pathway 11
3.10.1. General Considerations 11
3.10.2. Site-Specific Considerations 11

4. Data Evaluation 13
4.1. Data Compilation and General Review 13
4.1.1. Data Sources 13
4.1.2. Chemical Analyses 13
4.1.3. Plant Area 14
4.1.4. Former Chlorination Building 14
4.1.5. On-Site Ditches 14
4.1.6. Southwest Off-Site/Outfall 006 Exposure Area 14
4.1.7. State Fair Blvd./Northwest Off-Site/Outfall 004 Exposure Area 15
4.1.8. Tributary 5A 15
4.1.9. Lakeshore Area 15
4.1.10. Petroleum Storage Area 15
4.1.11. Chlorobenzene Hot-Spots Area 16
4.1.12. Hypothetical Drinking Water Source Area 16
4.2. Data Usability Assessment 16
4.2.1. Data Quality Objectives 16
4.2.2. Data Validation 17
4.3. Identification of Constituents of Potential Concern 17
4.3.1. Media Definitions 17
4.3.2. Comparison with Risk-Based Screening Values 18
4.3.3. Notes on Specific Constituent Groups 20

5. Exposure Assessment 21
5.1. Land Use Assumptions 21
5.2. Exposure Pathway Analysis 21
5.3. Quantification of Exposure 22
5.4. Derivation of Exposure Point Concentrations 23
5.4.1. Calculating Exposure Point Concentrations for Soil, Sediment, Surface Water, and Groundwater 23
5.4.2. EPCs for Air Exposures 23
5.4.3. Derivation of EPCs for Volatile Compounds 24
5.4.4. Derivation of EPCs for Fugitive Dust 24
5.4.5 Derivation of EPCs for Lead in Site-Wide Groundwater 24
5.5. Intake Equations 25
5.6. RME and CT Parameter Estimates 26
5.6.1. Mutagenic Mode of Action Constituents 28

5.6.2. Exposure Frequency for Industrial Worker 28
5.6.3. Exposure Frequency for Adolescent Trespasser 29
5.6.4. Exposure Frequency for Surveillance Worker 29
5.6.5. Incidental Ingestion of Water for the Construction Worker, Utility Worker, and Adolescent Trespasser 29
5.7. Site Exposure Pathway Analyses 29

6. Toxicity Assessment 31
6.1. Non-Carcinogenic Effects 31
6.1.1. Reference Doses 31
6.1.2. RfD Uncertainty Factors 32
6.2. Carcinogenic Effects 32
6.2.1. Weight of Evidence 32
6.2.2. Slope Factors 33
6.3. Toxicity Summaries 33
6.3.1. Constituents with a Mutagenic Mode of Action 34
6.3.2. Adjustment for Dermal Toxicity 34
6.4. Evaluation of Toxicity for Special Constituent Classes 35
6.4.1. Toxicity Equivalents for Chlorinated Dioxins and Furans 35
6.4.2. Polychlorinated Biphenyls 35
6.4.3. Polycyclic Aromatic Hydrocarbons 35
6.4.4. Chromium 36
6.4.5. Surrogates 36

7. Risk Characterization 37
7.1. Plant Area 38
7.1.1. Current/Future Receptors 38
7.1.2. Future Receptors 38
7.2. On-Site Ditches 39
7.2.1. Current/Future Receptors 39
7.2.2. Future Receptors 39
7.3. Former Chlorination Building 40
7.3.1. Current/Future Receptors 40
7.3.2. Future Receptors 41
7.4. Southwest Off-Site/Outfall 006 Exposure Area 41
7.4.1. Current Receptors 41
7.4.2. Future Receptors 42
7.5. State Fair Blvd./Northwest Off-Site/Outfall 004 Exposure Area 42
7.5.1 Current/Future Receptors 42
7.6. Lakeshore Area 43
7.6.1. Current/Future Receptors 43
7.7. Petroleum Storage Area 43
7.7.1. Current Receptors 43
7.7.2. Future Receptors 44
7.8. Chlorobenzene Hot-Spot Area 44
7.8.1. Current Receptors 44
7.8.2. Future Receptors 45
7.9. Tributary 5A 45

7.9.1 Current and Future Receptors....45
7.10. Hypothetical Drinking Water Source Area....46
7.11. Risk Characterization – Summary....46
7.11.1. Current Conditions....46
7.11.2. Future Conditions....48

8. Uncertainty Assessment....52
8.1. Estimation of Chemical Concentrations....52
8.1.1. Mercury Speciation....52
8.2. Calculation of Exposure Point Concentrations....56
8.2.1. General....56
8.2.2. Indoor Air Exposures for Future Industrial Workers....57
8.2.3. Inhalation Exposures for Future Construction Workers....58
8.3. Toxicity Values....59
8.3.1. General....59
8.3.2. Uncertainty of TCDD Equivalents....60
8.3.3. Lead in Drinking Water....64
8.3.4. Carcinogenicity of Trichloroethene....65
8.3.5. Carcinogenicity of Naphthalene through Inhalation....66
8.3.6. Carcinogenicity of Hexavalent Chromium....66
8.3.7. Dichlorobenzene Toxicity....66
8.4. Calculation of Quantitative Risk Estimates....66
8.4.1. Non-Carcinogenic Effects....66
8.4.2. Carcinogenic Effects....66
8.5. Central Tendency Estimates....66
8.6. Multiple Exposure Scenarios....67

9. Conclusions....72
9.1. Plant Area....72
9.1.1. Current/Future Receptors....72
9.1.2. Future Receptors....72
9.2. On-Site Ditches....72
9.2.1. Current/Future Receptors....72
9.2.2. Future Receptors....73
9.3. Former Chlorination Building....73
9.3.1. Current/Future Receptors....73
9.3.2. Future Receptors....73
9.4. Southwest Off-Site/Outfall 006 Exposure Area....73
9.4.1. Current/Future Receptors....73
9.4.2. Future Receptors....74
9.5. State Fair Blvd/Northwest Off-Site/Outfall 004 Exposure Area....74
9.5.1. Current/Future Receptors....74
9.6. Lakeshore Property Area....74
9.6.1. Current/Future Receptors....74
9.7. Petroleum Storage Area....74
9.7.1. Current/Future Receptors....74
9.7.2. Future Receptors....74
9.8. Chlorobenzene Hot-Spot Area....75

9.8.1. Current/Future Receptors 75
9.8.2. Future Receptors 75
9.9. Tributary 5A 75
9.9.1. Current/Future Receptors 75
9.10. Hypothetical Drinking Water Source Area 75
9.10.1. Future Receptors 75
9.11. Hypothetical Future Indoor Air 76

Attachment A

Table 1 Series: Selection of exposure pathways

1.1 Selection of exposure pathways – Plant Area
1.2 Selection of exposure pathways – On-Site Ditches
1.3 Selection of exposure pathways – Former Chlorination Building
1.4 Selection of exposure pathways – Southwest Off-Site/Outfall 006 Exposure Area
1.5 Selection of exposure pathways – State Fair Blvd./Northwest Off-Site/Outfall 004 Exposure Area
1.6 Selection of exposure pathways – Lakeshore Area
1.7 Selection of exposure pathways – Tributary 5A Exposure Area
1.8 Selection of exposure pathways – Petroleum Storage Area
1.9 Selection of exposure pathways – Chlorobenzene Hot-Spot Area
1.10 Selection of exposure pathways – Site Wide Groundwater

Table 2 Series: Occurrence, distribution, and selection of COPC

2.1a Occurrence, distribution, and selection of COPC – Plant Area, Surface Soil (Current/Future Receptors)
2.1b Derivation of toxicity equivalents for dioxins – Plant Area, Surface Soil (Current/Future Receptors)
2.1c Derivation of PCB equivalents for chlorinated chemicals – Plant Area, Surface Soil (Current/Future Receptors)
2.1d Derivation of total chlordanes - Plant Area, Surface Soil (Current/Future Receptors)
2.2a Occurrence, distribution, and selection of COPC – Plant Area, Upper Soil (Current/Future)
2.2b Derivation of toxicity equivalents for dioxins – Plant Area, Upper Soil (Current/Future)
2.2c Derivation of PCB equivalents for chlorinated chemicals – Plant Area, Upper Soil (Current/Future)
2.2d Derivation of total chlordanes – Plant Area, Upper Soil (Current/Future)
2.3a Occurrence, distribution, and selection of COPC – Plant Area, Intermediate Soil (Current/Future)
2.3b Derivation of toxicity equivalents for dioxins – Plant Area, Intermediate Soil (Current/Future)
2.3c Derivation of PCB equivalents for chlorinated chemicals – Plant Area, Intermediate Soil (Current/Future)
2.3d Derivation of total chlordanes – Plant Area, Intermediate Soil (Current/Future)
2.4a Occurrence, distribution, and selection of COPC – Plant Area, Intermediate Groundwater (Current/Future)
2.5 Occurrence, distribution, and selection of COPC – Plant Area, Intermediate Groundwater: Vapor Intrusion
2.6a Occurrence, distribution, and selection of COPC – Former Chlorination Building, Surface Soil (Current/Future)

2.6b Derivation of toxicity equivalents for dioxins – Former Chlorination Building, Surface Soil (Current/Future)
2.6c Derivation of PCB equivalents for chlorinated chemicals – Former Chlorination Building, Surface Soil (Current/Future)
2.7a Occurrence, distribution, and selection of COPC – Former Chlorination Building, Upper Soil (Current/Future)
2.7b Derivation of toxicity equivalents for dioxins – Former Chlorination Building, Upper Soil (Current/Future)
2.7c Derivation of PCB equivalents for chlorinated chemicals – Former Chlorination Building, Upper Soil (Current/Future)
2.8a Occurrence, distribution, and selection of COPC – Former Chlorination Building, Intermediate Soil (Current/Future)
2.8b Derivation of toxicity equivalents for dioxins – Former Chlorination Building, Intermediate Soil (Current/Future)
2.8c Derivation of PCB equivalents for chlorinated chemicals – Former Chlorination Building, Intermediate Soil (Current/Future)
2.9a Occurrence, distribution, and selection of COPC – On-Site Ditches, Surface Soil (Current/Future)
2.9b Derivation of toxicity equivalents for dioxins – On-Site Ditches, Surface Soil (Current/Future)
2.9c Derivation of PCB equivalents for chlorinated chemicals – On-Site Ditches, Surface Soil (Current/Future)
2.10a Occurrence, distribution, and selection of COPC – On-Site Ditches, Upper Soil (Current/Future)
2.10b Derivation of toxicity equivalents for dioxins – On-Site Ditches, Upper Soil (Current/Future)
2.10c Derivation of PCB equivalents for chlorinated chemicals – On-Site Ditches, Upper Soil (Current/Future)
2.11a Occurrence, distribution, and selection of COPC – On-Site Ditches, Intermediate Soil (Current/Future)
2.11b Derivation of toxicity equivalents for dioxins – On-Site Ditches, Intermediate Soil (Current/Future)
2.11c Derivation of PCB equivalents for chlorinated chemicals – On-Site Ditches, Intermediate Soil (Current/Future)
2.12a Occurrence, distribution, and selection of COPC – Southwest Off-Site/Outfall 006 Exposure Area, Surface Soil (Current/Future)
2.12b Derivation of toxicity equivalents for dioxins – Southwest Off-Site/Outfall 006 Exposure Area, Surface Soil (Current/Future)
2.12c Derivation of PCB equivalents for chlorinated chemicals – Southwest Off-Site/Outfall 006 Exposure Area, Surface Soil (Current/Future)
2.12d Derivation of total chlordanes – Southwest Off-Site/Outfall 006 Exposure Area, Surface Soil (Current/Future)
2.13a Occurrence, distribution, and selection of COPC – Southwest Off-Site/Outfall 006 Exposure Area, Upper Soil (Current/Future)
2.13b Derivation of toxicity equivalents for dioxins – Southwest Off-Site/Outfall 006 Exposure Area, Upper Soil (Current/Future)
2.13c Derivation of PCB equivalents for chlorinated chemicals – Southwest Off-Site/Outfall 006 Exposure Area, Upper Soil (Current/Future)

2.13d Derivation of total chlordanes – Southwest Off-Site/Outfall 006 Exposure Area, Upper Soil (Current/Future)
2.14a Occurrence, distribution, and selection of COPC – State Fair Blvd/Northwest Off-Site/Outfall 004 Exposure Area, Surface Soil (Current/Future)
2.14b Derivation of toxicity equivalents for dioxins – State Fair Blvd/Northwest Off-Site/Outfall 004 Exposure Area, Surface Soil (Current/Future)
2.14c Derivation of PCB equivalents for chlorinated chemicals – State Fair Blvd/Northwest Off-Site/Outfall 004 Exposure Area, Surface Soil (Current/Future)
2.15a Occurrence, distribution, and selection of COPC – State Fair Blvd/Northwest Off-Site/Outfall 004 Exposure Area, Upper Soil (Current/Future)
2.15b Derivation of toxicity equivalents for dioxins – State Fair Blvd/Northwest Off-Site/Outfall 004 Exposure Area, Upper Soil (Current/Future)
2.15c Derivation of PCB equivalents for chlorinated chemicals – State Fair Blvd/Northwest Off-Site/Outfall 004 Exposure Area, Upper Soil (Current/Future)
2.16a Occurrence, distribution, and selection of COPC – Lakeshore Area, Surface Soil (Current/Future)
2.16b Derivation of toxicity equivalents for dioxins – Lakeshore Area, Surface Soil (Current/Future)
2.16c Derivation of PCB equivalents for chlorinated chemicals – Lakeshore Area, Surface Soil (Current/Future)
2.16d Derivation of total chlordanes – Lakeshore Area, Surface Soil (Current/Future)
2.17a Occurrence, distribution, and selection of COPC – Lakeshore Area, Upper Soil (Current/Future)
2.17b Derivation of toxicity equivalents for dioxins – Lakeshore Area, Upper Soil (Current/Future)
2.17c Derivation of PCB equivalents for chlorinated chemicals – Lakeshore Area, Upper Soil (Current/Future)
2.17d Derivation of total chlordanes – Lakeshore Area, Upper Soil (Current/Future)
2.18 Occurrence, distribution, and selection of COPC – Lakeshore Area, Shallow Groundwater (Current/Future)
2.19a Occurrence, distribution, and selection of COPC – Tributary 5A, Sediment (Current/Future)
2.19b Derivation of toxicity equivalents for dioxins – Tributary 5A, Sediment (Current/Future)
2.19c Derivation of PCB equivalents for chlorinated chemicals – Tributary 5A, Sediment (Current/Future)
2.19d Derivation of total chlordanes – Tributary 5A, Sediment (Current/Future)
2.20 Occurrence, distribution, and selection of COPC – Tributary 5A, Surface Water (Current/Future)
2.21a Occurrence, distribution, and selection of COPC – Petroleum Storage Area, Surface Soil (Current/Future)
2.21b Derivation of PCB equivalents for chlorinated chemicals – Petroleum Storage Area, Surface Soil (Current/Future)
2.22a Occurrence, distribution, and selection of COPC – Petroleum Storage Area, Upper Soil (Current/Future)
2.22b Derivation of PCB equivalents for chlorinated chemicals – Petroleum Storage Area, Upper Soil (Current/Future)
2.22c Derivation of total chlordanes – Petroleum Storage Area, Upper Soil (Current/Future)
2.23 Occurrence, distribution, and selection of COPC – Petroleum Storage Area, Shallow Groundwater (Current/Future)

2.24 Occurrence, distribution, and selection of COPC – Petroleum Storage Area, Shallow Groundwater: Vapor Intrusion (Current/Future)
2.25a Occurrence, distribution, and selection of COPC – Chlorobenzene Hot-Spot Area, Surface Soil (Current/Future)
2.25b Derivation of PCB equivalents for chlorinated chemicals – Chlorobenzene Hot-Spot Area, Surface Soil (Current/Future)
2.26a Occurrence, distribution, and selection of COPC – Chlorobenzene Hot-Spot Area, Upper Soil (Current/Future)
2.26b Derivation of PCB equivalents for chlorinated chemicals – Chlorobenzene Hot-Spot Area, Upper Soil (Current/Future)
2.27 Occurrence, distribution, and selection of COPC – Chlorobenzene Hot-Spot Area, Shallow Groundwater (Current/Future)
2.28 Occurrence, distribution, and selection of COPC – Chlorobenzene Hot-Spot Area, Shallow Groundwater: Vapor Intrusion (Current/Future)
2.29 Occurrence, distribution, and selection of COPC – Site Wide, Groundwater (Current/Future)

Table 3 Series: Occurrence, distribution, and selection of COPC
3.1 Exposure Point Concentration Summary – Plant Area, Surface Soil (Current/Future)
3.2 Exposure Point Concentration Summary – Plant Area, Upper Soil (Current/Future)
3.3 Exposure Point Concentration Summary – Plant Area, Intermediate Soil (Current/Future)
3.4 Exposure Point Concentration Summary – Plant Area, Intermediate Groundwater (Current/Future)
3.5 Exposure Point Concentration Summary – Former Chlorination Building, Surface Soil (Current/Future)
3.6 Exposure Point Concentration Summary – Former Chlorination Building, Upper Soil (Current/Future)
3.7 Exposure Point Concentration Summary – Former Chlorination Building, Intermediate Soil (Current/Future)
3.8 Exposure Point Concentration Summary – On-Site Ditches, Surface Soil (Current/Future)
3.9 Exposure Point Concentration Summary – On-Site Ditches, Upper Soil (Current/Future)
3.10 Exposure Point Concentration Summary – On-Site Ditches, Intermediate Soil (Current/Future)
3.11 Exposure Point Concentration Summary – Southwest Off-Site Area/Outfall 006 Exposure Area, Surface Soil (Current/Future)
3.11 Exposure Point Concentration Summary – Southwest Off-Site Area/Outfall 006 Exposure Area, Upper Soil (Current/Future)
3.13 Exposure Point Concentration Summary – State Fair Blvd/Northwest Off-Site/Outfall 004 Exposure Area, Surface Soil (Current/Future)
3.14 Exposure Point Concentration Summary – State Fair Blvd/Northwest Off-Site/Outfall 004 Exposure Area, Upper Soil (Current/Future)
3.15 Exposure Point Concentration Summary – Lakeshore Area, Surface Soil (Current/Future)
3.16 Exposure Point Concentration Summary – Lakeshore Area, Upper Soil (Current/Future)
3.17 Exposure Point Concentration Summary – Lakeshore Area, Shallow Groundwater (Current/Future)
3.18 Exposure Point Concentration Summary – Tributary 5A, Sediment (Current/Future)
3.19 Exposure Point Concentration Summary – Tributary 5A, Surface Water (Current/Future)
3.20 Exposure Point Concentration Summary – Petroleum Storage Area, Surface Soil (Current/Future)

3.21 Exposure Point Concentration Summary – Petroleum Storage Area, Upper Soil (Current/Future)
3.22 Exposure Point Concentration Summary – Petroleum Storage Area, Shallow Groundwater (Current/Future)
3.23 Exposure Point Concentration Summary – Chlorobenzene Hot-Spot Area, Surface Soil (Current/Future)
3.24 Exposure Point Concentration Summary – Chlorobenzene Hot-Spot Area, Upper Soil (Current/Future)
3.25 Exposure Point Concentration Summary – Chlorobenzene Hot-Spot Area, Shallow Groundwater (Current/Future)
3.26 Exposure Point Concentration Summary – Site Wide, Groundwater (Current/Future)

Table 4 Series: Values used for daily intake calculations
4.1 RME Values used for daily intake calculations – Plant Area, Surface Soils (Current/Future Receptors)
4.2a RME Values used for daily intake calculations – Plant Area, Surface Soils (Future Receptors)
4.2b RME Values used for daily intake calculations – Plant Area, Upper Soils (Future Receptors)
4.2c RME Values used for daily intake calculations – Plant Area, Intermediate Soils (Future Receptors)
4.2d RME Values used for daily intake calculations – Plant Area, Groundwater (Future Receptors)
4.3 RME Values used for daily intake calculations – On-Site Ditches, Surface Soils (Current/Future Receptors)
4.4a RME Values used for daily intake calculations – On-Site Ditches, Surface Soils (Future Receptors)
4.4b RME Values used for daily intake calculations – On-Site Ditches, Upper Soils (Future Receptors)
4.4c RME Values used for daily intake calculations – On-Site Ditches, Intermediate Soils (Future Receptors)
4.4d RME Values used for daily intake calculations – On-Site Ditches, Groundwater (Future Receptors)
4.5 RME Values used for daily intake calculations – Former Chlorination Building, Surface Soils (Current/Future Receptors)
4.6a RME Values used for daily intake calculations – Former Chlorination Building, Surface Soils (Future Receptors)
4.6b RME Values used for daily intake calculations – Former Chlorination Building, Upper Soils (Future Receptors)
4.6c RME Values used for daily intake calculations – Former Chlorination Building, Intermediate Soils (Future Receptors)
4.6d RME Values used for daily intake calculations – Former Chlorination Building, Groundwater (Future Receptors)
4.7 RME Values used for daily intake calculations – Southwest Off-Site/Outfall 006 Exposure Area, Surface Soils (Current/Future Receptors)
4.8a RME Values used for daily intake calculations – Southwest Off-Site/Outfall 006 Exposure Area, Surface Soils (Future Receptors)
4.8b RME Values used for daily intake calculations – Southwest Off-Site/Outfall 006 Exposure Area, Upper Soils (Future Receptors)
4.9a RME Values used for daily intake calculations – State Fair Blvd./Northwest Off-Site/Outfall 004 Exposure Area, Surface Soils (Current/Future Receptors)

4.9b RME Values used for daily intake calculations – State Fair Blvd./Northwest Off-Site/Outfall 004 Exposure Area, Upper Soils (Future Receptors)
4.10a RME Values used for daily intake calculations – Lakeshore Area, Surface Soils (Current/Future Receptors)
4.10b RME Values used for daily intake calculations – Lakeshore Area, Upper Soils (Future Receptors)
4.10c RME Values used for daily intake calculations – Lakeshore Area, Shallow Groundwater, (Current/Future Receptors)
4.11a RME Values used for daily intake calculations – Tributary 5A, Surface Water, (Current/Future Receptors)
4.11b RME Values used for daily intake calculations – Tributary 5A, Surface Sediment, (Current/Future Receptors)
4.11c RME Values used for daily intake calculations – Tributary 5A, Upper Sediment, (Current/Future Receptors)
4.12 RME Values used for daily intake calculations – Petroleum Storage Area, Surface Soils (Current/Future Receptors)
4.13a RME Values used for daily intake calculations – Petroleum Storage Area, Surface Soils (Future Receptors)
4.13b RME Values used for daily intake calculations – Petroleum Storage Area, Upper Soils (Future Receptors)
4.13c RME Values used for daily intake calculations – Petroleum Storage Area, Shallow Groundwater, (Current/Future Receptors)
4.14 RME Values used for daily intake calculations – Chlorobenzene Hot-Spot Area, Surface Soils (Current/Future Receptors)
4.15a RME Values used for daily intake calculations – Chlorobenzene Hot-Spot Area, Surface Soils (Future Receptors)
4.15b RME Values used for daily intake calculations – Chlorobenzene Hot-Spot Area, Upper Soils (Future Receptors)
4.15c RME Values used for daily intake calculations – Chlorobenzene Hot-Spot Area, Shallow Groundwater, (Current/Future Receptors)
4.16 RME Values used for daily intake calculations – Hypothetical Drinking Water Source Area, Groundwater (Future Receptors)
4.16 RME Supplement A – Values used for daily intake calculations – Hypothetical Drinking Water Source Area, Groundwater (Future Receptors)
4.16 RME Supplement B – Age-Dependent Adjustment Factor – Exposure Parameters

4.1 CT Values used for daily intake calculations – Plant Area, Surface Soils (Current/Future Receptors)
4.2a CT Values used for daily intake calculations – Plant Area, Surface Soils (Future Receptors)
4.2b CT Values used for daily intake calculations – Plant Area, Upper Soils (Future Receptors)
4.2c CT Values used for daily intake calculations – Plant Area, Intermediate Soils (Future Receptors)
4.2d CT Values used for daily intake calculations – Plant Area, Groundwater (Future Receptors)
4.3 CT Values used for daily intake calculations – On-Site Ditches, Surface Soils (Current/Future Receptors)
4.4a CT Values used for daily intake calculations – On-Site Ditches, Surface Soils (Future Receptors)

4.4b CT Values used for daily intake calculations – On-Site Ditches, Upper Soils (Future Receptors)
4.4c CT Values used for daily intake calculations – On-Site Ditches, Intermediate Soils (Future Receptors)
4.4d CT Values used for daily intake calculations – On-Site Ditches, Groundwater (Future Receptors)
4.5 CT Values used for daily intake calculations – Former Chlorination Building, Surface Soils (Current/Future Receptors)
4.6a CT Values used for daily intake calculations – Former Chlorination Building, Surface Soils (Future Receptors)
4.6b CT Values used for daily intake calculations – Former Chlorination Building, Upper Soils (Future Receptors)
4.6c CT Values used for daily intake calculations – Former Chlorination Building, Intermediate Soils (Future Receptors)
4.6d CT Values used for daily intake calculations – Former Chlorination Building, Groundwater (Future Receptors)
4.7 CT Values used for daily intake calculations – Southwest Off-Site/Outfall 006 Exposure Area, Surface Soils (Current/Future Receptors)
4.8a CT Values used for daily intake calculations – Southwest Off-Site/Outfall 006 Exposure Area, Surface Soils (Future Receptors)
4.8b CT Values used for daily intake calculations – Southwest Off-Site/Outfall 006 Exposure Area, Upper Soils (Future Receptors)
4.9a CT Values used for daily intake calculations – State Fair Blvd./Northwest Off-Site/Outfall 004 Exposure Area, Surface Soils (Current/Future Receptors)
4.9b CT Values used for daily intake calculations – State Fair Blvd./Northwest Off-Site/Outfall 004 Exposure Area, Upper Soils (Future Receptors)
4.10a CT Values used for daily intake calculations – Lakeshore Area, Surface Soils (Current/Future Receptors)
4.10b CT Values used for daily intake calculations – Lakeshore Area, Upper Soils (Future Receptors)
4.10c CT Values used for daily intake calculations – Lakeshore Area, Shallow Groundwater, (Current/Future Receptors)
4.11a CT Values used for daily intake calculations – Tributary 5A, Surface Water, (Current/Future Receptors)
4.11b CT Values used for daily intake calculations – Tributary 5A, Surface Sediment, (Current/Future Receptors)
4.11c CT Values used for daily intake calculations – Tributary 5A, Upper Sediment, (Current/Future Receptors)
4.12 CT Values used for daily intake calculations – Petroleum Storage Area, Surface Soils (Current/Future Receptors)
4.13a CT Values used for daily intake calculations – Petroleum Storage Area, Surface Soils (Future Receptors)
4.13b CT Values used for daily intake calculations – Petroleum Storage Area, Upper Soils (Future Receptors)
4.13c CT Values used for daily intake calculations – Petroleum Storage Area, Shallow Groundwater, (Current/Future Receptors)
4.14 CT Values used for daily intake calculations – Chlorobenzene Hot-Spot Area, Surface Soils (Current/Future Receptors)

4.15a CT Values used for daily intake calculations – Chlorobenzene Hot-Spot Area, Surface Soils (Future Receptors)
4.15b CT Values used for daily intake calculations – Chlorobenzene Hot-Spot Area, Upper Soils (Future Receptors)
4.15c CT Values used for daily intake calculations – Chlorobenzene Hot-Spot Area, Shallow Groundwater, (Current/Future Receptors)
4.16 CT Values used for daily intake calculations – Hypothetical Drinking Water Source Area, Groundwater (Future Receptors)
4.16 CT Supplement A – Values used for daily intake calculations – Hypothetical Drinking Water Source Area, Groundwater (Future Receptors)
4.16 CT Supplement B – Age-Dependent Adjustment Factor – Exposure Parameters

Table 5 Series: Non-cancer toxicity data
5.1 Non-cancer toxicity data – oral/dermal
5.2 Non-cancer toxicity data – inhalation

Table 6 Series: Cancer toxicity data
6.1 Cancer toxicity data – oral/dermal
6.2 Cancer toxicity data – inhalation

Table 7 Series: Calculation of cancer risks and non-cancer hazards
7.1a RME: Calculation of chemical cancer risks and non-cancer hazards – Adolescent Trespasser, Plant Area (Current/Future)
7.1b RME: Calculation of chemical cancer risks and non-cancer hazards – Adolescent Trespasser, On-Site Ditches (Current/Future)
7.1c RME: Calculation of chemical cancer risks and non-cancer hazards – Adolescent Trespasser, Former Chlorination Building (Current/Future)
7.1d RME: Calculation of chemical cancer risks and non-cancer hazards – Adolescent Trespasser, Southwest Off-Site/Outfall 006 Exposure Area (Current/Future)
7.1e RME: Calculation of chemical cancer risks and non-cancer hazards – Adolescent Trespasser, State Fair Blvd/Northwest Off-Site/Outfall 004 Exposure Area (Current/Future)
7.1f RME: Calculation of chemical cancer risks and non-cancer hazards – Adolescent Trespasser, Lakeshore Area (Current/Future)
7.1g RME: Calculation of chemical cancer risks and non-cancer hazards – Adolescent Trespasser, Petroleum Storage Area (Current/Future)
7.1h RME: Calculation of chemical cancer risks and non-cancer hazards – Adolescent Trespasser, Chlorobenzene Hot-Spot Area (Current/Future)
7.1i RME: Calculation of chemical cancer risks and non-cancer hazards – Adolescent Trespasser, Tributary 5A (Current/Future)
7.1 RME Supplement A: Calculation of Chemical Cancer Risks for COPC with a Mutagenic Mode of Action
7.2a RME: Calculation of chemical cancer risks and non-cancer hazards – Adult Trespasser, Plant Area (Current/Future)
7.2b RME: Calculation of chemical cancer risks and non-cancer hazards – Adult Trespasser, On-Site Ditches (Current/Future)
7.2c RME: Calculation of chemical cancer risks and non-cancer hazards – Adult Trespasser, Former Chlorination Building (Current/Future)

7.2d RME: Calculation of chemical cancer risks and non-cancer hazards – Adult Trespasser, Southwest Off-Site/Outfall 006 Exposure Area (Current/Future)
7.2e RME: Calculation of chemical cancer risks and non-cancer hazards – Adult Trespasser, State Fair Blvd/Northwest Off-Site/Outfall 004 Exposure Area (Current/Future)
7.2f RME: Calculation of chemical cancer risks and non-cancer hazards – Adult Trespasser, Lakeshore Area (Current/Future)
7.2g RME: Calculation of chemical cancer risks and non-cancer hazards – Adult Trespasser, Petroleum Storage Area (Current/Future)
7.2h RME: Calculation of chemical cancer risks and non-cancer hazards – Adult Trespasser, Chlorobenzene Hot-Spot Area (Current/Future)
7.2i RME: Calculation of chemical cancer risks and non-cancer hazards – Adult Trespasser, Tributary 5A (Current/Future)
7.3a RME: Calculation of chemical cancer risks and non-cancer hazards – Surveillance Worker, Plant Area (Current/Future)
7.3b RME: Calculation of chemical cancer risks and non-cancer hazards – Surveillance Worker, On-Site Ditches (Current/Future)
7.3c RME: Calculation of chemical cancer risks and non-cancer hazards – Surveillance Worker, Former Chlorination Building (Current/Future)
7.4a RME: Calculation of chemical cancer risks and non-cancer hazards – Industrial Worker, Plant Area (Future)
7.4b RME: Calculation of chemical cancer risks and non-cancer hazards – Industrial Worker, On-Site Ditches (Future)
7.4c RME: Calculation of chemical cancer risks and non-cancer hazards – Industrial Worker, Former Chlorination Building (Future)
7.4d RME: Calculation of chemical cancer risks and non-cancer hazards – Industrial Worker, Southwest Off-Site/Outfall 006 Exposure Area (Future)
7.4e RME: Calculation of chemical cancer risks and non-cancer hazards – Industrial Worker, Petroleum Storage Area (Future)
7.4f RME: Calculation of chemical cancer risks and non-cancer hazards – Industrial Worker, Chlorobenzene Hot-Spot Area (Future)
7.5a RME: Calculation of chemical cancer risks and non-cancer hazards – Construction Worker, Plant Area (Future)
7.5b RME: Calculation of chemical cancer risks and non-cancer hazards – Construction Worker, On-Site Ditches (Future)
7.5c RME: Calculation of chemical cancer risks and non-cancer hazards – Construction Worker, Former Chlorination Building (Future)
7.5d RME: Calculation of chemical cancer risks and non-cancer hazards – Construction Worker, Southwest Off-Site/Outfall 006 Exposure Area (Future)
7.5e RME: Calculation of chemical cancer risks and non-cancer hazards – Construction Worker, Petroleum Storage Area (Future)
7.5f RME: Calculation of chemical cancer risks and non-cancer hazards – Construction Worker, Chlorobenzene Hot-Spot Area (Future)
7.6 RME: Calculation of chemical cancer risks and non-cancer hazards – Transient Trespasser, State Fair Blvd/Northwest Off-Site/Off-Site Outfall 004 Exposure Area (Current/Future)
7.7a RME: Calculation of chemical cancer risks and non-cancer hazards – Utility Worker, Plant Area (Future)
7.7b RME: Calculation of chemical cancer risks and non-cancer hazards – Utility Worker, On-Site Ditches (Future)

7.7c RME: Calculation of chemical cancer risks and non-cancer hazards – Utility Worker, Former Chlorination Building (Future)
7.7d RME: Calculation of chemical cancer risks and non-cancer hazards – Utility Worker, State Fair Blvd/Northwest Off-Site/Off-Site Outfall 004 Exposure Area (Current/Future)
7.7e RME: Calculation of chemical cancer risks and non-cancer hazards – Utility Worker, Lakeshore Area (Current/Future)
7.7f RME: Calculation of chemical cancer risks and non-cancer hazards – Utility Worker, Petroleum Storage Area (Future)
7.7g RME: Calculation of chemical cancer risks and non-cancer hazards – Utility Worker, Chlorobenzene Hot-Spot Area (Future)
7.7h RME: Calculation of chemical cancer risks and non-cancer hazards – Utility Worker, Tributary 5A (Current/Future)
7.8 RME: Calculation of chemical cancer risks and non-cancer hazards – Adult Resident, Hypothetical Potable Water (Future)
7.9 RME: Calculation of chemical cancer risks and non-cancer hazards – Child Resident, Hypothetical Potable Water (Future)
7.9 RME Supplement A: Calculation of Chemical Cancer Risks for COPC with a Mutagenic Mode of Action

7.1a CT: Calculation of chemical cancer risks and non-cancer hazards – Adolescent Trespasser, Plant Area (Current/Future)
7.1b CT: Calculation of chemical cancer risks and non-cancer hazards – Adolescent Trespasser, On-Site Ditches (Current/Future)
7.1c CT: Calculation of chemical cancer risks and non-cancer hazards – Adolescent Trespasser, Former Chlorination Building (Current/Future)
7.1d CT: Calculation of chemical cancer risks and non-cancer hazards – Adolescent Trespasser, Southwest Off-Site/Outfall 006 Exposure Area (Current/Future)
7.1e CT: Calculation of chemical cancer risks and non-cancer hazards – Adolescent Trespasser, State Fair Blvd/Northwest Off-Site/Outfall 004 Exposure Area (Current/Future)
7.1f CT: Calculation of chemical cancer risks and non-cancer hazards – Adolescent Trespasser, Lakeshore Area (Current/Future)
7.1g CT: Calculation of chemical cancer risks and non-cancer hazards – Adolescent Trespasser, Petroleum Storage Area (Current/Future)
7.1h CT: Calculation of chemical cancer risks and non-cancer hazards – Adolescent Trespasser, Chlorobenzene Hot-Spot Area (Current/Future)
7.1i CT: Calculation of chemical cancer risks and non-cancer hazards – Adolescent Trespasser, Tributary 5A (Current/Future)
7.1 CT Supplement A: Calculation of Chemical Cancer Risks for COPC with a Mutagenic Mode of Action
7.2a CT: Calculation of chemical cancer risks and non-cancer hazards – Adult Trespasser, Plant Area (Current/Future)
7.2b CT: Calculation of chemical cancer risks and non-cancer hazards – Adult Trespasser, On-Site Ditches (Current/Future)
7.2c CT: Calculation of chemical cancer risks and non-cancer hazards – Adult Trespasser, Former Chlorination Building (Current/Future)
7.2d CT: Calculation of chemical cancer risks and non-cancer hazards – Adult Trespasser, Southwest Off-Site/Outfall 006 Exposure Area (Current/Future)

7.2e CT: Calculation of chemical cancer risks and non-cancer hazards – Adult Trespasser, State Fair Blvd/Northwest Off-Site/Outfall 004 Exposure Area (Current/Future)
7.2f CT: Calculation of chemical cancer risks and non-cancer hazards – Adult Trespasser, Lakeshore Area (Current/Future)
7.2g CT: Calculation of chemical cancer risks and non-cancer hazards – Adult Trespasser, Petroleum Storage Area (Current/Future)
7.2h CT: Calculation of chemical cancer risks and non-cancer hazards – Adult Trespasser, Chlorobenzene Hot-Spot Area (Current/Future)
7.2i CT: Calculation of chemical cancer risks and non-cancer hazards – Adult Trespasser, Tributary 5A (Current/Future)
7.3a CT: Calculation of chemical cancer risks and non-cancer hazards – Surveillance Worker, Plant Area (Current/Future)
7.3b CT: Calculation of chemical cancer risks and non-cancer hazards – Surveillance Worker, On-Site Ditches (Current/Future)
7.3c CT: Calculation of chemical cancer risks and non-cancer hazards – Surveillance Worker, Former Chlorination Building (Current/Future)
7.4a CT: Calculation of chemical cancer risks and non-cancer hazards – Industrial Worker, Plant Area (Future)
7.4b CT: Calculation of chemical cancer risks and non-cancer hazards – Industrial Worker, On-Site Ditches (Future)
7.4c CT: Calculation of chemical cancer risks and non-cancer hazards – Industrial Worker, Former Chlorination Building (Future)
7.4d CT: Calculation of chemical cancer risks and non-cancer hazards – Industrial Worker, Southwest Off-Site/Outfall 006 Exposure Area (Future)
7.4e CT: Calculation of chemical cancer risks and non-cancer hazards – Industrial Worker, Petroleum Storage Area (Future)
7.4f CT: Calculation of chemical cancer risks and non-cancer hazards – Industrial Worker, Chlorobenzene Hot-Spot Area (Future)
7.5a CT: Calculation of chemical cancer risks and non-cancer hazards – Construction Worker, Plant Area (Future)
7.5b CT: Calculation of chemical cancer risks and non-cancer hazards – Construction Worker, On-Site Ditches (Future)
7.5c CT: Calculation of chemical cancer risks and non-cancer hazards – Construction Worker, Former Chlorination Building (Future)
7.5d CT: Calculation of chemical cancer risks and non-cancer hazards – Construction Worker, Southwest Off-Site/Outfall 006 Exposure Area (Future)
7.5e CT: Calculation of chemical cancer risks and non-cancer hazards – Construction Worker, Petroleum Storage Area (Future)
7.5f CT: Calculation of chemical cancer risks and non-cancer hazards – Construction Worker, Chlorobenzene Hot-Spot Area (Future)
7.6 CT: Calculation of chemical cancer risks and non-cancer hazards – Transient Trespasser, State Fair Blvd/Northwest Off-Site/Off-Site Outfall 004 Exposure Area (Current/Future)
7.7a CT: Calculation of chemical cancer risks and non-cancer hazards – Utility Worker, Plant Area (Future)
7.7b CT: Calculation of chemical cancer risks and non-cancer hazards – Utility Worker, On-Site Ditches (Future)
7.7c CT: Calculation of chemical cancer risks and non-cancer hazards – Utility Worker, Former Chlorination Building (Future)

7.7d CT: Calculation of chemical cancer risks and non-cancer hazards – Utility Worker, State Fair Blvd/Off-Site Outfall 004 Exposure Area (Current/Future)
7.7e CT: Calculation of chemical cancer risks and non-cancer hazards – Utility Worker, Lakeshore Area (Current/Future)
7.7f CT: Calculation of chemical cancer risks and non-cancer hazards – Utility Worker, Petroleum Storage Area (Future)
7.7g CT: Calculation of chemical cancer risks and non-cancer hazards – Utility Worker, Chlorobenzene Hot-Spot Area (Future)
7.7h CT: Calculation of chemical cancer risks and non-cancer hazards – Utility Worker, Tributary 5A (Current/Future)
7.8 CT: Calculation of chemical cancer risks and non-cancer hazards – Adult Resident, Potable Hypotethical Water (Future)
7.9 CT: Calculation of chemical cancer risks and non-cancer hazards – Child Resident, Potable Hypothetical Water (Future)
7.9 CT Supplement A: Calculation of Chemical Cancer Risks for COPC with a Mutagenic Mode of Action

Table 9 series: Summary of receptor risks and hazards for COPCs
9.1a RME: Summary of receptor risks and hazards for COPCs – Adolescent Trespasser, Plant Area (Current/Future)
9.1b RME: Summary of receptor risks and hazards for COPCs – Adolescent Trespasser, On-Site Ditches (Current/Future)
9.1c RME: Summary of receptor risks and hazards for COPCs – Adolescent Trespasser, Former Chlorination Building (Current/Future)
9.1d RME: Summary of receptor risks and hazards for COPCs – Adolescent Trespasser, Southwest Off-Site/Outfall 006 Exposure Area (Current/Future)

Acronyms

ABS – Dermal absorption factor
ADAF – Age-dependent adjustment factors
AF – Soil to skin adherence factor
AOS – Area of study
AT – Averaging time
ATSDR – Agency for Toxic Substances and Disease Register
AVG – Average
BGS – Below ground surface
Blvd – Boulevard
BTEX – benzene, ethylbenzene, toluene, xylene
BTX – benzene, toluene, and xylene
BW – Body weight
C_{air} – COPC concentration in air
CalEPA – California Environmental Protection Agency
CDI – Chronic daily intake
CF - Conversion factor
CFR – Code of Federal Regulations
CHSA – Chlorobenzene Hot-Spot Area
COPC – Compound of potential concern
$C_{sediment}$ – Sediment exposure point concentration
CSF – Cancer slope factor
CSM – Conceptual Site Model
C_{sw} – Concentration of each constituent in surface water
CSX – CSX Corporation
CT – Central tendency
C_{water} - Concentration of each constituent in drinking water
DAD - Dermal absorbed dose
DNAPL – Dense non-aqueous phase liquid
DQO – Data quality objectives
ED - Exposure duration
EF - Exposure frequency
EMPC – Estimated Maximum Possible Concentration
EPC – Exposure point concentration
ET – Exposure time
FCB – Former chlorination building
FI – Fraction ingested from contaminated source
Ft – Feet
GA – Groundwater suitable for drinking
GC – Gas chromatograph
HASP – Health and Safety Plan
HEAST – Health Effects Summary Tables
HHRA – Human Health Risk Assessment
HI – Hazard index/indicies
HQ – Hazard quotient
InR – Inhalation rate

IR – Ingestion rate for soil or water
IRIS – Integrated Risk Information System
IRM – Interim Remedial Measure
IEUBK – Integrated Exposure Uptake Biokinetic Model for Lead in Children
Kg – kilograms
L – Liters
L/hr – Liters/hour
LOAEL – Lowest-observed-adverse-effects-level
µg/l – Micrograms per liter
MM – millimeters
MMOA – Mutagenic mode of action
MRL – Minimal Response Level
MW – Monitoring well
NA – Not applicable
NAPL – Non-aqueous phase liquid
NATO/CSS – North Atlantic Treaty Organization/Committee on Challenges of Modern Society
NCEA – National Center for Environmental Assessment
NCP – National Contingency Plan
NIMO – Niagara Mohawk Company
NOAEL – No-observed-adverse-effects-level
NYSDEC – New York State Department of Environmental Conservation
OCWA – Onondaga County Water Authority
ORNL – Oak Ridge National Laboratory
OSWER – Office of Solid Waste and emergency response
PA – Plant area
PAH – Polycyclic aromatic hydrocarbons
PbS – Lead exposure point concentration term
PC - Permeability Coefficient (cm/hour)
PCB – Polychlorinated biphenyls
PCDD/Fs - polychlorinated dibenzo-p-dioxins and dibenzofurans
PEF – Particle emission factor
PPRTV – Provisional Peer-reviewed Toxicity Values
PRGs – Preliminary remediation goals
PSA – Petroleum storage area
QAPP – Quality Assurance Project Plan
RAGS – Risk Assessment Guidance for Superfund
RAIS – Risk Assessment Information System
RBCs – Risk-based concentrations
RfC – Reference concentration
RfD – Reference dose
RI – Remedial Investigation
RI/FS – Remedial Investigation/Feasibility Study
RME – Reasonable maximum exposure
ROS – Regression on Order Statistics
SA - Skin surface area for dermal absorption
SCS – Soil classification and standards
SPDES – State Pollutant Discharge Elimination System
STSC – Superfund Technical Support Center

SVOC – Semi-volatile organic compound
TCDD - Tetrachlorodibenzo-p-dioxin
TEFs- Toxic Equivalency Factors
TEQ – Toxicity equivalent concentration
TPH – Total petroleum hydrocarbons
UCL – Upper confidence limit
USDA – United States Department of Agriculture
USEPA – United States Environmental Protection Agency
VF – Volatilization factor
VOCs – Volatile organic compounds
WHO – World Health Organization

Executive Summary

A human health risk assessment (HHRA) is performed to provide the necessary risk information needed to assist in the decision making process at remedial sites. The risk assessment is used to provide the following items (USEPA 1989):

- An analysis of baseline risks
- Evaluation of the need for remedial action at sites
- A basis for evaluating levels of constituents that can remain onsite and be adequately protective of public health, and
- A basis for comparing potential impacts of various remedial alternatives.

The Willis Avenue Chlorobenzene Site HHRA was performed to assess potential impacts to public health related to the presence of chemical substances at the Site in Geddes, New York. Health risks were evaluated for potential trespassers, workers, and residents under current and future exposure scenarios. Estimated current and future cancer risks are largely within the acceptable regulatory range (1×10^{-4} to 1×10^{-6}), except in the Former Chlorination Building exposure area, which was historically involved in the production of chlorinated benzene products. Estimated current and future non-cancer hazards are also highest in the Former Chlorination Building exposure area, with lesser regulatory exceedances found in other Site exposure areas. Across exposure areas, the construction worker, and to a lesser extent the industrial and utility workers, had higher hazard indices relative to other receptors, as a result of greater time spent in the area and greater potential exposure to contaminated media. Although Site ground water is not used for potable water and municipal water is supplied from the Onondaga County Water Authority (OCWA), potential future residential exposure to ground water as potable water was evaluated and found to pose unacceptable cancer risks and non-cancer hazards. Overall primary Site risk drivers include potential exposure to dioxins, mercury, PCBs, and benzene.

Risk drivers were evaluated on the basis of reasonable maximum exposure (RME) scenarios and are subject to uncertainty including but not limited to:

- Exposure point concentrations are based on the upper confidence limit of mean chemical concentrations.
- Exposure factors include conservative estimates of frequency and duration of exposure.
- Toxicity factors typically account for sensitive sub-populations.

In addition, risks are estimated separately for each exposure area. However, it is unlikely that a given receptor would spend all of their time in one exposure area. Thus the risks and hazards shown for a given exposure area are likely an overestimate, and the true risk to a receptor would likely be a weighted average of the risks from several exposure areas.

Site Background

This human health risk assessment (HHRA) was performed to assess potential impacts to public health related to the presence of chemical substances at the Willis Avenue Chlorobenzene Site (the

Site) in Geddes, New York, and related areas of study (AOS)[1]. The objective of the HHRA was to assess potential risks to human health associated with Site-related chemical substances under current and reasonably foreseeable future land uses and to facilitate the consideration and evaluation of possible future remedial actions. The HHRA was performed as part of the Remedial Investigation (RI) performed by O'Brien & Gere Engineers, Inc. (O'Brien & Gere) on behalf of Honeywell International Inc. (Honeywell) pursuant to Consent Order R7-0201-87-08 (Order) between AlliedSignal and the New York State Department of Environmental Conservation (NYSDEC) dated August 12, 1990.

An HHRA Report was originally submitted to the NYSDEC in June 1999 (Appendix L of the RI report; O'Brien & Gere 1999). The NYSDEC issued comments on that report on January 25, 2002 and the HHRA report was resubmitted in June 2002 (O'Brien & Gere 2002). Comments on the 2002 report were issued by the NYSDEC on July 19, 2004. The HHRA report was resubmitted in October 2004 (O'Brien & Gere 2004) and a summary of the revisions was provided to the NYSDEC in a letter from Honeywell dated December 2, 2004. The NYSDEC provided comments on the October 2004 HHRA in a letter to Honeywell dated March 13, 2007. This document presents the revised HHRA report that addresses the March 13, 2007 comments of the NYSDEC.

Site History

The principal activity of the plant was the production of chlorinated benzene products (monochlorobenzene and dichlorobenzene) from 1918 until production operations were discontinued in 1977; the Site has been inactive since 1977 except as a warehouse for various products produced at the Main Plant Site (1977-1986). Additional operations that reportedly took place at the plant included the production of caustic potash (potassium hydroxide), caustic soda (sodium hydroxide), and chlorine gas. Caustic potash and chlorine were produced by the electrolysis of potassium chloride brine solution. Initially, this was done in diaphragm cells, but in 1947, mercury cells were installed to manufacture these products. The process operations that took place at this facility have been described in detail in the History of the Willis Avenue Plant, Petroleum Storage Facility, and Associated "Hot-Spots" Report (O'Brien & Gere 1990).

Constituents related to former processes, primarily chlorinated benzene products and mercury, have been detected in surface soils (0-2 ft below ground surface (bgs)), subsurface soils (upper soils at 0-10 ft bgs and deep soils at > 10 ft bgs), and groundwater at the Site and related AOS. In addition, elevated mercury and chlorinated benzene concentrations have been detected in drainage ditches, outfalls, utility conduits, dredge spoils areas, and other migration pathways at and in the immediate vicinity of the General Plant Area. The objective of this HHRA was to evaluate current and reasonably foreseeable potential human exposures associated with these media and exposure pathways.

[1]Potential exposures in Onondaga Lake were not evaluated as part of the HHRA. These exposures will be assessed as part of the Onondaga Lake Study. The related areas of study included the Petroleum Storage Area (PSA), Chlorobenzene Hot-Spot Area (CHSA), and Tributary 5A.

Exposure Areas, Receptors, and Exposure Media

Currently, the Site is not in active use and there are no routine activities conducted On-Site. The General Plant Area, which consists of the Plant Area, the Former Chlorination Building, and On-Site Ditches, is surrounded by an eight-foot high fence and is monitored by Honeywell surveillance personnel during working hours. The Willis Avenue Plant Study Area also includes the State Fair Blvd./Northwest Off-Site/Outfall 004 and Southwest Off-Site/Outfall 006 Exposure Areas, as well as the Lakeshore Area. Three additional AOS (Tributary 5A, the Petroleum Storage Area, and the Chlorobenzene Hot-Spot Area) are included in the HHRA as well. Off-Site areas accessible by the public include Southwest Off-Site/Outfall 006 Exposure Area, State Fair Blvd./ Off-Site/Outfall 004 Exposure Area, the Lakeshore Area, Tributary 5A, PSA, and portions of the CHSA. The State Fair Blvd./ Off-Site/Outfall 004 is the most easily accessible, as many of the other areas have fences or railroad tracks on several sides. Based on historical observations, exposures at these areas are expected to be infrequent and of short duration. Based on current conditions at the Site and surrounding areas, the following current receptor populations were identified:

- Adolescent trespasser (Plant Area, On-Site Ditches, Former Chlorination Building, Tributary 5A, Southwest Off-Site/Outfall 006 Exposure Area, State Fair Blvd./ Off-Site/Outfall 004 Exposure Area, Lakeshore Area, Petroleum Storage Area, Chlorobenzene Hot-Spot Area)

- Adult trespasser (Plant Area, Former Chlorination Building, On-Site Ditches, Tributary 5A, Southwest Off-Site/Outfall 006 Exposure Area, State Fair Blvd./ Off-Site/Outfall 004 Exposure Area, Lakeshore Area, Petroleum Storage Area, Chlorobenzene Hot-Spot Area)

- Utility worker (State Fair Blvd./ Off-Site/Outfall 004 Exposure Area, Lakeshore Area, Tributary 5A)

- State Fair Boulevard transient (State Fair Blvd./ Off-Site/Outfall 004 Exposure Area)

- Surveillance worker (Plant Area, Former Chlorination Building, On-Site Ditches)

The Site and AOS are not expected to be developed as residential areas since the exposure areas are located in a heavily industrialized setting and are zoned industrial. Based on this consideration, the following receptors were identified under reasonably foreseeable future conditions.

- Adolescent trespasser (Plant Area, On-Site Ditches, Former Chlorination Building, Tributary 5A, Southwest Off-Site/Outfall 006 Exposure Area, State Fair Blvd./ Off-Site/Outfall 004 Exposure Area, Lakeshore Area, Petroleum Storage Area, Chlorobenzene Hot-Spot Area)
- Adult trespasser (Plant Area, On-Site Ditches, Former Chlorination Building, Tributary 5A, Southwest Off-Site/Outfall 006 Exposure Area, State Fair Blvd./ Off-Site/Outfall 004 Exposure Area, Lakeshore Area, Petroleum Storage Area, Chlorobenzene Hot-Spot Area)
- Adult transient (State Fair Blvd./ Off-Site/Outfall 004 Exposure Area)
- Surveillance worker (Plant Area, On-Site Ditches, Former Chlorination Building)
- Industrial worker (Plant Area, On-Site Ditches, Former Chlorination Building, Southwest Off-Site/Outfall 006 Exposure Area, Petroleum Storage Area)
- Construction worker (Plant Area, On-Site Ditches, Former Chlorination Building, Southwest Off-Site/Outfall 006 Exposure Area, Petroleum Storage Area, Chlorobenzene Hot-Spot Area)

- Utility worker (Plant Area, On-Site Ditches, Former Chlorination Building, Tributary 5A, State Fair Blvd./ Off-Site/Outfall 004 Exposure Area, Lakeshore Area, Petroleum Storage Area, Chlorobenzene Hot-Spot Area)
- Child (< 6 years) resident (Potable water)
- Adult resident (Potable water)

Exposure media considered in both current and future scenarios include soil, sediment, surface water, groundwater, and indoor air. Receptors that may be exposed to surface soils (0-2 ft) include trespassers, surveillance workers, industrial workers, and State Fair Boulevard transients. Construction workers and utility workers may contact upper soils (0-10 ft) and intermediate soils (0-20 ft), respectively. Trespassers and utility workers in the Tributary 5A area may be exposed to sediment and surface water. On-Site groundwater occurs at a depth of approximately 15-20 ft bgs while Off-Site it occurs at approximately 4-5 ft at the Chlorobenzene Hot-Spot Area, Petroleum Storage Area, and Lakeshore Area.

Groundwater at the Plant Study Area and at other AOS is not used as a drinking or industrial water supply and is highly unlikely to be used as a drinking or industrial supply in the future, since the area is supplied by municipal water from OCWA. However, the New York State groundwater classification for the Site and surrounding area is GA (*i.e.*, suitable for drinking use). In accordance with the NYSDEC's request, the hypothetical residential drinking water scenario was evaluated for future receptors in the risk assessment.

Hazard indices (HI) and cancer risks were derived based on the reasonable maximum exposure (RME) and central tendency (CT) concentrations for the identified receptor scenarios. Summaries of current and future receptors HI's and CT's are presented in Tables 7.1 and 7.2, respectively.

Risk Discussion

In general, under current conditions, cancer risks for receptors in all exposure areas are within the acceptable regulatory range of 10^{-4} to 10^{-6}, except for the Former Chlorination Building, and hazard indices for receptors in the Plant Area, State Fair Blvd/ Northwest Off-Site/ Outfall 004 Exposure Area, and the Petroleum Storage Area are within the threshold of 1.

Under future conditions, cancer risks for receptors in all exposure areas are within the acceptable regulatory range of 10^{-4} to 10^{-6}, except for the Southwest Off-Site/Outfall 006 Exposure Area and the Former Chlorination Building. Under future conditions, hazard indices for receptors in the State Fair Blvd/ Northwest Off-Site/ Outfall 004 Exposure Area are within the threshold of 1.

It should be noted that it is unlikely that a given receptor would spend all of their time in one exposure area. Thus the risks and hazards shown for a given exposure area are likely an overestimate, and the true risk to a receptor would likely be a weighted average of the risks from several exposure areas.

All receptors at the Former Chlorination Building (FCB) Exposure Area had estimated cancer risk values in excess of 1×10^{-4}, driven primarily by high concentrations of 2,3,7,8-TCDD equivalent in soils; this was responsible for the high HI values as well. In contrast, receptors associated with the

State Fair Blvd./Northwest Off-Site/Outfall 006 Exposure Area, as well as trespassers associated with the Lakeshore Area, had HI and cancer risks below the acceptable regulatory thresholds.

Across all applicable Exposure Areas, the construction worker, and to a lesser extent the industrial and utility workers, had higher HI values relative to the other receptors. This is a function of the assumptions of greater time spent in the area and greater exposure to contaminated media for these receptors relative to others.

The calculated RME HI for the future adult resident and child resident at the hypothetical drinking water source area were 2×10^{2} and 4×10^{2}, while the RME cancer risks were 1×10^{-2} and 7×10^{-3}, respectively. These values were attributable primarily to exposure to the maximum detected concentration of benzene in groundwater. Groundwater at the Site is not suitable for use as a drinking water supply irrespective of any contributions related to waste at the Site. The drinking water pathway was included in this section at the request of NYSDEC; however, this is considered to be an incomplete pathway under reasonably foreseeable land use scenarios.

Risk Drivers

A summary of risk drivers is presented in the RAGS Table 10 series and below.

Plant Area

Current/Future Receptors

There are no unacceptable cancer risks or non-cancer hazards for current/future Site-receptors (adolescent trespasser, adult trespasser, and surveillance worker).

Future Receptors

Under the future exposure scenarios, there are no unacceptable cancer risks associated with any receptor in this exposure area. Non-cancer hazard exceeding the threshold for the future construction worker is driven primarily by exposure to:

- Nickel (HQ = 20)

Non-cancer hazards for the future utility worker is driven primarily by exposure to:

- Mercury (HQ = 3).

On-Site Ditches

Current/Future Receptors

There are no unacceptable cancer risks for current/future Site-receptors. Likewise, there are no unacceptable chemical-specific hazards for the current/future adult trespasser or surveillance worker. The non-cancer hazards for the adolescent trespasser are driven primarily by exposure to:

- 2,3,7,8-TCDD Equivalents (HQ = 3)
- Mercury (HQ = 3).

Future Receptors

There are no unacceptable cancer risks for future Site-receptors. Non-cancer hazards for the future construction worker are driven by exposure to:

- 2,3,7,8-TCDD Equivalents (HQ = 10)
- Mercury (HQ = 30).

Non-cancer hazards for future utility workers is also driven primarily by exposure to:

- 2,3,7,8-TCDD Equivalents (HQ = 9)
- Mercury (HQ = 5).

To a lesser extent, non-cancer hazards for future industrial workers is also driven primarily by these constituents.

Former Chlorination Building

Current/Future Receptors

Cancer risk to the adolescent trespasser, adult trespasser, and surveillance worker was estimated at the higher end of the regulatory threshold range of 10^{-4} to 10^{-6}. This risk was driven primarily by potential exposure to:

- 2,3,7,8-TCDD Equivalents (CR = 4×10^{-4})

Non-cancer hazards for these receptors also exceeded the regulatory threshold and are also driven by potential exposure to:

- 2,3,7,8-TCDD Equivalents (HQ = 20).

Future Receptors

Cancer risks to the future industrial worker, construction worker, and utility worker exceeded the regulatory threshold range of 10^{-4} to 10^{-6}. These risks are driven primarily by potential exposure to:

- 2,3,7,8-TCDD Equivalents (CR range = 1.7×10^{-3} to7.6×10^{-4})

Non-cancer hazards for these receptors also exceeded the regulatory threshold and are also driven by potential exposure to:

- 2,3,7,8-TCDD Equivalents (HQ ranges from 30 to 400).

Southwest Off-Site/Outfall 006 Exposure Area

Current/Future Receptors

There are no unacceptable cancer risks or non-cancer hazards for current/future Site-receptors in the Southwest Off-Site/Outfall 006 Exposure Area.

Future Receptors

There are no unacceptable cancer risks or non-cancer hazards for future industrial worker. Cancer risk to the future construction worker exceeded the regulatory threshold range of 10^{-4} to 10^{-6}. Cancer risk was driven primarily by exposure to:

- Benzene (CR = 1.5×10^{-4})

Non-cancer hazards for the future construction worker exceeded the regulatory threshold of 1 and was driven primarily by exposure to:

- Benzene (HQ = 40)
- Mercury (HQ = 10)
- Xylenes (HQ = 9)

State Fair Blvd/Northwest Off-Site/Outfall 004 Exposure Area

Current/Future Receptors

There are no unacceptable cancer risks or non-cancer hazards for the current/future receptor in this exposure area.

Future Receptors

There are no unacceptable cancer risks or non-cancer hazards for anticipated future receptors in this exposure area.

Lakeshore Property Area

Current/Future Receptors

There are no unacceptable cancer risks or non-cancer hazards for the adolescent trespasser or adult trespasser. There are also no unacceptable cancer risks for the utility worker in this exposure area;

however non-cancer hazards for this receptor exceeded the regulatory threshold. The non-cancer hazard was driven primarily by potential exposure to:

- Benzene (HQ = 9)
- Chlorobenzene (HQ = 3)

Petroleum Storage Area

Current/Future Receptors

There are no unacceptable cancer risks or non-cancer hazards for the adolescent trespasser or adult trespasser in this exposure area.

Future Receptors

There are no unacceptable cancer risks or non-cancer hazards for future industrial or utility worker. There are also no unacceptable cancer risks to the future construction worker; however, non-cancer hazards for the future construction worker exceeded the regulatory threshold of 1 and was driven primarily by exposure to:

- Manganese (HQ = 5)

Chlorobenzene Hot-Spot Area

Current/Future Receptors

There are no unacceptable cancer risks for the adolescent trespasser or the adult trespasser in the CHSA. Non-cancer hazard, however, did exceed the regulatory threshold and was driven by exposure to:

- PCBs (HQ = 4 and 3, respectively)

Future Receptors

There are no unacceptable cancer risks for future industrial worker in the CHSA. Non-cancer hazard, however, did exceed the regulatory threshold and was driven by exposure to:

- PCBs (HQ = 6)

There are no unacceptable cancer risks for future construction worker in the CHSA. Non-cancer hazards, however, did exceed the regulatory threshold and were driven primarily by exposure to:

- Manganese (HQ = 4)
- PCBs (HQ = 6)

There are no unacceptable cancer risks for future utility worker in the CHSA. Non-cancer hazard, however, did exceed the regulatory threshold and was driven primarily by exposure to:

- PCBs (HQ = 7)

Tributary 5A

Current/Future Receptors

There are no unacceptable cancer risks or non-cancer hazards for the adolescent trespasser or the adult trespasser in this exposure area.

Hypothetical Drinking Water Source Area

Groundwater at the Site is not suitable for use as a drinking water supply irrespective of any contributions related to waste at the Site. However, the following section describes the risk drivers that would be expected if it groundwater was used as drinking water source.

Future Receptors

Both cancer risk and non-cancer hazards exceeded their respective regulatory thresholds for future child and adult residents. The cancer risks are driven primarily by exposure to:

- Benzene CRs = 5×10^{-3} and 1×10^{-2}, respectively)
- Arsenic (CRs = 1×10^{-3} and 2×10^{-3}, respectively)
- 1,4-Dichlorobenzene (CR = 2×10^{-4} and 4×10^{-4}, respectively)
- Benzo(b)fluoranthene (CR = 2×10^{-4} and 4×10^{-4}, respectively)

Non-cancer hazards for the future child and adult residents are driven primarily by:

- Benzene (HQ = 300 and 100, respectively)
- Chlorobenzene ((HQ = 50 and 20, respectively)
- Arsenic (HQ = 30 and 10, respectively)
- Toluene ((HQ = 10 and 5, respectively)
- Chromium (HQ = 8 and 4, respectively)
- Iron (HQ = 6 and 2, respectively)
- 1,4-Dichlorobenzene (HQ = 5 and 2, respectively)

Hypothetical Future Indoor Air

Based on the high vapor pressure of many of the compounds detected, a vapor intrusion evaluation will need to be conducted prior to the construction of occupied buildings at the site. Based on the vapor intrusion evaluation, preventative measures may be included in the design and construction of buildings at the Site to mitigate the risk of exposure to on-Site soil gas. Such measures may include the use of a vapor barrier or the installation of a venting system, such as at the groundwater treatment plant.

1. Introduction

This report presents the results of a human health risk assessment (HHRA) of potential impacts to public health related to the presence of chemical substances at the Willis Avenue Chlorobenzene Site (the Site) in Geddes, New York. The objective of the HHRA was to assess potential risks to human health associated with Site-related chemical substances under current and reasonably foreseeable future land uses and to facilitate the consideration and evaluation of possible future remedial actions.

The HHRA was performed as part of the Remedial Investigation (RI) performed by O'Brien & Gere Engineers, Inc. (O'Brien & Gere) on behalf of Honeywell International Inc. (Honeywell) pursuant to Consent Order R7-0201-87-08 (Order) between AlliedSignal and the New York State Department of Environmental Conservation (NYSDEC) dated August 12, 1990. An HHRA Report was submitted to NYSDEC in June 1999 (Appendix L of the RI/FS report; O'Brien & Gere 1999). The NYSDEC issued comments on that report on January 25, 2002 and the HHRA report was resubmitted in June 2002 (O'Brien & Gere 2002). Comments on the 2002 report were issued by the NYSDEC on July 19, 2004. The HHRA report was resubmitted in October 2004 (O'Brien & Gere 2004) and a summary of the revisions was provided to NYSDEC in a letter from Honeywell dated December 2, 2004. NYSDEC provided comments on the October 2004 HHRA in a letter to Honeywell dated March 13, 2007. This document presents the revised HHRA report that addresses the March 13, 2007 comments of NYSDEC, as well as subsequent comments on RAGS D Tables submitted as interim deliverables.

The HHRA focuses on chemical substances detected in soil, sediment and groundwater at and down gradient of the Site. The assessment does not address Site-related chemical substances that may have migrated to Onondaga Lake since Onondaga Lake was investigated and evaluated under a separate Consent Order.

1.1. Risk Assessment Guidance

The following United States Environmental Protection Agency (USEPA) documents were used as principal guidance in the preparation of the HHRA:

- *Risk Assessment Guidance for Superfund, Volume 1, Human Health Evaluation Manual (Part A) Interim Final* (USEPA 1989a)

- *Guidance for Risk Characterization* (USEPA 1995)

- *Exposure Factors Handbook* (USEPA 1997a)

A chemical substance may pose a risk to human health only if receptor populations have the potential to be exposed to the chemical substance in sufficient quantities to affect the health of exposed individuals. As such, a Site-specific health risk assessment involves the following:

- identification of Site-related chemical substances;
- identification of potential mechanisms by which human receptors may be exposed;
- estimation of the concentrations of the chemicals that may be present at locations where receptors may contact them (exposure point concentrations); and

- evaluation of potential adverse effects that may result from the estimated dose of the chemicals if absorbed by receptors.

1.2. Approach

Consistent with the cited guidance, the HHRA was conducted in the following phases:

- *Description of Site Areas (Section 2)*. The first step in the assessment was to identify and describe the physical locations and general characteristics of the Site and related AOS.

- *Conceptual Site Model (Section 3)*. The goal of the conceptual Site model was to characterize the Site with respect to its physical characteristics as well as those of the human populations at or near the Site. The output of this step was a qualitative evaluation of the Site and surrounding populations with respect to those characteristics that potentially influence exposure.

- *Data Evaluation (Section 4)*. The objective of the data evaluation step was to organize the data into a form appropriate for use in the assessment, to evaluate the quality of the data for HHRA purposes, and identify chemicals of potential concern (COPCs).

- *Exposure Assessment (Section 5).* In the exposure assessment, the pathways by which receptors may be exposed to On-Site chemical substances were identified and exposure point concentrations of COPCs were estimated for each complete exposure pathway.

- *Toxicity Assessment (Section 6).* In the toxicity assessment, available toxicological data for Site-related compounds were gathered and reviewed. Dose-response relationships between the extent of potential exposure and the occurrence/severity of potential adverse health effects were evaluated.

- *Risk Characterization (Section 7).* In the risk characterization step, the toxicity and exposure assessments were integrated into quantitative estimates of potential human health risk.

- *Uncertainty Analysis (Section 8).* In this section, the major uncertainties in the calculated risk estimates were discussed.

2. Description of Site Areas

The Willis Avenue Chlorobenzene Site is comprised of the Willis Ave Plant Study Area and three additional Areas of Study (AOS), which are presented in Figures L-1 and L-2. The AOS were either associated with the former production processes but were not located on or immediately adjacent to the Site, or have been included in the study at the request of the NYSDEC. The Willis Avenue Plant Study Area consists of:

- Plant Area
- Former Chlorination Building
- On-Site Ditches
- Southwest Off-Site/Outfall 006 Exposure Area
- State Fair Blvd./Northwest Off-Site/Outfall004 Exposure Area
- Lakeshore Area

The additional AOS consist of:

- Petroleum Storage Area,
- Chlorobenzene Hot-Spot Area,
- Tributary 5A.

A brief description of the various areas comprising the Site is presented below. A more detailed discussion is presented in Section 1 of the RI Report (O'Brien & Gere 2002).

2.1. Willis Avenue Plant Study Area

The Willis Ave Plant Study Area consists of the Willis Ave Plant Area (Plant Area); the On-Site Ditches; the Former Chlorination Building (FCB); Outfall 006 and the associated drainage ditch and mounded area; Outfall 004 and the associated drainage ditch; and the Lakeshore Area (Figure L-2).

Plant Area, On-Site Ditches, and FCB. The Plant Area (Figure L-3) is bounded by State Fair Boulevard to the north, Willis Avenue to the east, CSX railroad tracks to the south, and the Honeywell Semet Residue Ponds to the west. The FCB (Figure L-4) two On-Site Ditches (Figure L-5) are located within the Plant Area, but are treated as separate Exposure Areas in this HHRA to account for potential localized areas of contamination in the On-Site Ditches or FCB. Except for the grassy area near the former office/laboratory, the former plant area is sparsely vegetated. Surface materials consist primarily of concrete building foundations, associated debris, asphalt and gravel. Shallow subsurface materials (approximately 0 to 30 ft) consist of fill materials composed of sand and gravel, ash, cinders, brick fragments, and Solvay Waste. The former office/laboratory is the only building remaining in the plant area and is currently vacant. The Plant Area is completely surrounded by an eight-foot high chain link fence and the only point of access is a gate, which can only be opened by Honeywell personnel. Due to these security measures, there has been no evidence of trespassing or dumping On-Site.

The principal activity of the plant was the production of chlorinated benzene products (monochlorobenzene and dichlorobenzenes) from 1918 until production operations were discontinued

in 1977. The Site has been inactive since 1977 except as a warehouse for various products produced at the Main Plant Site (1977-1986). A fire occurred at the chlorination building in 1930 making it a potential site for the formation of dioxins and furans (Syracuse Herald Journal, July 4th, 1930). Additional operations that reportedly took place at the plant included the production of caustic potash (potassium hydroxide), caustic soda (sodium hydroxide), and chlorine gas. Caustic potash and chlorine were produced by the electrolysis of potassium chloride brine solution. Initially, this was done in diaphragm cells, but mercury cells were installed to manufacture these products in 1947. The process operations that took place at this facility have been described in detail in the *History of the Willis Avenue Plant, Petroleum Storage Facility, and Associated "Hot-Spots" Report* (O'Brien & Gere 1990; Appendix A of the RI Report).

Outfall 006, drainage ditch and mounded area (Southwest Off-Site/Outfall 006 Exposure Area). Outfall 006 is situated to the southwest of the fenced Plant Area and approximately 30 ft north of the CSX railroad tracks (Figure L-6). A shallow drainage ditch extends from the outfall north towards the Plant Area. The above ground portion of the drainage ditch is approximately 75 ft in length and the remainder is below ground. Historic information gathered from State Pollutant Discharge Elimination System (SPDES) discharge permit sampling data indicates that the ditch is dry throughout the year, with the exception of heavy rainfall or snowmelt events. The mounded area is the area extending from the southern plant area boundary back to the CSX railroad tracks. The area is approximately 350 ft by 200 ft in area and vegetation is patchy with scattered pioneer grasses, wild flowers, and tree saplings (brushy cleared land). Access to this area is not restricted; however, the area is remote and generally only accessed by railroad workers or utilities workers.

Outfall 004, drainage ditch, and Niagara Mohawk Utility Line Area (State Fair Blvd./Northwest Off-Site/Outfall 004 Exposure Area)[1]. This area contains three key aspects: proximity to State Fair Boulevard, presence of Outfall 004 and a drainage ditch, and a Niagara Mohawk utility line.

- State Fair Boulevard is situated immediately adjacent to this Exposure Area and is a regularly driven road with minimal pedestrian traffic.

- Outfall 004 is situated approximately 25 ft north and 200 ft west of the northwest corner of the Plant Area fence and near State Fair Boulevard (Figure L-7). The outfall is located along a shallow drainage ditch (approximately 1 to 1.5 ft in depth) that runs in the east-west direction parallel to, and approximately 10 ft south of, State Fair Boulevard. The ditch starts at the corner of Willis Avenue and continues west until it terminates at Tributary 5A near Crucible Specialty Metals. The ditch is dry throughout the year, with the exception of heavy rainfall or snowmelt events.

- A Niagara Mohawk (NIMO) utility line extends along the length of the Exposure Area.

- Cover type in this area is classified as mowed roadside/pathway, which consists of grasses and sedges and vines and low shrubs. Access to this area is not restricted.

[1] Site "Northwest Off-Site/Outfall 004 Exposure Area" was called "State Fair Boulevard/Outfall 004 area" in previous revisions. This represents a change in naming conventions, not a change in the description of the site itself.

Lakeshore Area. The Lakeshore Area is situated to the north of the plant area and between the southern shore of Onondaga Lake and the westbound lane of I-690. The Lakeshore Area is bounded by Onondaga Lake to the north and the fence along I-690 to the south. The Lakeshore Area is presented in Figure L-8. The extent of the Lakeshore Area to the west is defined by the 84-inch water intake at the lake, and the eastern extent is defined by the PA sewer and western end of the East Flume. The area consists of a narrow strip of mowed lawn to the north of I-690 and a concrete pier along the lake, which is accessible by boat from Onondaga Lake. The Lakeshore Area widens as it approaches the Upper East Flume. An eight-foot high chain fence with a locking gate surrounds the area, but boaters can access the area. As described in the RI report, a chlorobenzene dense non-aqueous phase liquid (DNAPL) recovery Interim Remedial Measure (IRM) is on-going at the Lakeshore Area.

2.2. Other Areas of Study

Tributary 5A. Tributary 5A is a small stream that courses for about 3000 ft and discharges into Onondaga Lake (Figure L-9). The stream contains a three-foot diameter culvert (approximately 300 ft long) under I- 690 and a two-foot diameter culvert (over 200 ft long) under a set of railroad tracks. The stream is generally six inches deep and contains several small pools with an average depth of one to two feet. Access to the area is limited by thick vegetation and steep-sided banks; there is also limited open water for fishing in Tributary 5A.

The fish sampling survey conducted in November 2001 by O'Brien & Gere indicated that the game fish present in Tributary 5A are insufficient in size or palatable quality for consumption. Specifically, the largest game fish collected was a largemouth bass, which was 160 mm in length and therefore below the current legal size limit. This fish could not be legally retained for personal consumption. The largest sunfish (pumpkinseed) collected was 123 mm and too small for cleaning and personal consumption. The pumpkinseed may be considered a game fish but does not have a regulated size limit. In addition to the game fish, a creek chub collected was 305 mm long and carp were observed to be eight to twelve inches long. Sport fishermen do not generally consider these fish for personal consumption.

Based on the shallow stream depth and lengthy culverts, upstream migration of the relatively larger fish is considered unlikely. The relatively larger fish that were collected or observed (described above) are likely residents of the small pools. These fish have potentially reached an optimal adult size for the habitat provided in Tributary 5A.

Petroleum Storage Area. The Petroleum Storage Area (PSA) is located to the southwest of the Plant Area. It is bounded to the north by the CSX railroad tracks, to the southeast by a railroad siding and to the west by the Salt City soft coal storage area (Figure L-10). The PSA is mostly covered by concrete and asphalt; access to the area is restricted by fencing and Honeywell surveillance.

Chlorobenzene Hot-Spots Area. The Chlorobenzene Hot-Spot Area (CHSA) is situated to the south of the Plant Area and the PSA, and adjacent to the Suez Power Plant, formerly Trigen (Figure L-11). The area is covered with industrial buildings, concrete, and asphalt; access is restricted by fencing to the north. The southern portion of the CHSA, between the fencing and Industrial Drive, is an accessible piece of sparsely vegetated land. This area contained an underground pipeline that leaked historically creating the present contamination issues.

3. Conceptual Site Model

This section presents the conceptual site model (CSM) for the Site. The CSM describes the Site and additional AOS. The CSM presents hypotheses regarding the contaminants present, their routes of migration, and their potential impact on human receptors, forming the basis for the HHRA approach and assumptions. A general CSM for the Site is presented in Section 3.1 below. The CSM is based on information and analytical data presented in Sections 1 through 4 of the RI report (O'Brien & Gere 2002).

To facilitate the HHRA, the Site and additional AOS were organized into Exposure Areas based on the likely current and future land uses and potential current and future receptor populations.

A conceptual model for each of the defined Exposure Areas is presented in Sections 3.2 through 3.9 and summarized on RAGS D Tables 1.1a through 1.1h.

3.1. General CSM

General descriptions of the Site Areas that support the CSM were provided in Section 2. Process-related constituents, primarily chlorinated benzene products and mercury, have been detected in surface soils, subsurface soils, sediment, and groundwater at the Site. In addition, elevated mercury and chlorinated benzene concentrations have been detected in drainage ditches, outfalls, utility conduits, dredge spoils areas, and other migration pathways at and in the immediate vicinity of the Plant Area.

Currently, there are no routine activities conducted on-site. The Plant Area, FCB, and one of the On-Site Ditches are surrounded by an eight-foot high fence and are monitored by Honeywell surveillance personnel during working hours. Off-Site areas accessible by the public include the Southwest Off-Site/Outfall 006 Exposure Area, Sate Fair Blvd./Northwest Off-Site/Outfall 004 Exposure Area, Tributary 5A, the Lakeshore Area, PSA, and portions of the CHSA. However, based on historical observations, exposures at these areas are expected to be infrequent and of short duration. Based on current conditions at the Site, the current receptor populations per Exposure Area were identified:

Table 3.1. *Identified receptors for the Exposure Areas*.

	Current receptors			**Future Receptors**					
Exposure Area	T/Tr	SW	UW	T/Tr	SW	IW	CW	UW	R
Plant Area	A/Ad[1]	Ad		A/Ad[1]	Ad	Ad	Ad	Ad	
FCB	A/Ad[1]	Ad		A/Ad[1]	Ad	Ad	Ad	Ad

Drinking Water Source area									C/Ad

NOTES:

A = adolescent; Ad = adult; C = Child

CW = construction worker; IW = industrial worker

SW = surveillance worker; T/Tr = trespasser/transient;

UW = utility worker, R = resident

[1] = adolescent and adult trespasser; [2] = adolescent and adult trespasser/adult transient

Source: O'Brien & Gere Engineers, Inc.

The adolescent trespasser is assumed to be on foot for all Exposure Areas except the State Fair Blvd./Northwest Off-Site/Outfall 004 Exposure Area, where bicycle traffic is possible. The other Exposure Areas are either surrounded by a security fence, have a remote location, or are highly industrialized. This is discussed in Sections 5.2 through 5.8. It should be noted that no evidence of trespassing has been observed at the Site.

The Site is not expected to be developed into residential areas, since the areas are located in heavily industrialized settings and are zoned industrial (Town of Geddes Zoning Maps). Based on this consideration, additional receptors were identified under reasonably foreseeable future conditions and included in the table above.

Receptors may be exposed to surface soils (0-2 ft; trespassers, transients, industrial workers), upper soils (0-10 ft; construction workers, utility worker), or deep soils (> 10 ft; utility workers). In addition, future industrial workers may also be exposed to volatile organic compounds (VOCs) in upper soils and groundwater that may infiltrate indoor air via soil vapor migration. Recreational fishermen may be exposed to surface water and sediment from Tributary 5A.

Groundwater occurs at a depth of approximately 15 to 20 ft bgs for the Plant Area, On-Site Ditches, and FCB, while it occurs at approximately 4 to 5 ft at the CHSA, PSA, and Lakeshore Area. Groundwater at the Site is not used as a drinking or industrial water supply and is highly unlikely to be used as a drinking or industrial supply in the future, since the area is supplied by municipal water from OCWA. Furthermore, the yield of the overburden groundwater unit is inadequate for water supply wells, and the high salinity of the bedrock aquifer (approximately 3,000 mg/l chlorides)

precludes its use as drinking water. However, as discussed previously in section 2.2 and in accordance with the NYSDEC's request, the hypothetical drinking water scenario for the Site is evaluated in the risk assessment.

3.2. Plant Area, On-Site Ditches, and Former Chlorination Building

Because the On-Site Ditches and FCB are located within the boundary of the Plant Area, all three areas have the same receptors and media (discussed below). Chemical residues detected in these areas are chlorinated benzenes in surface soils, upper soils, deep soils, and groundwater and mercury in surface soils, upper soils, deep soils, groundwater, and drainage ditches (RAGS D Tables 2.1 to 2.3 and 2.8). Chlorinated dioxins and furans (dioxins and furans) were detected in the surface soils in the vicinity of the FCB[2] (RAGS D Tables 2.4 and 2.5; Section 4.3 of the RI report).

The surface of these areas is mostly covered by concrete building foundations, which limited the number of surface soil samples. Non-concrete portions have been covered by approximately three feet of crushed stone and soil cover following discontinuation of production operations. It should be noted that soil samples collected from 0 to 2 ft bgs are considered surface soil, while samples collected from 0 to 2 ft below the concrete building foundations are considered upper soils (0-10 ft).

Groundwater at Plant Area, On-Site Ditches, and FCB occurs at a depth of approximately 25 - 30 ft bgs. Groundwater is not used as a potable or industrial water supply and is highly unlikely to be used as a potable or industrial supply in the future, since the area is supplied by municipal water from OCWA.

The plant area may be developed as an industrial facility in the future. It is highly unlikely that the plant area would be developed as a residential area, since the area is zoned industrial; the surrounding area is highly industrialized and is expected to remain as such in the reasonably foreseeable future (Town of Geddes Zoning Maps).

Potential current receptors at the Plant Area, On-Site Ditches, and FCB are identified as trespassers who may occasionally climb the fence and access the Site and surveillance workers monitoring the area. Potential future receptors are identified as construction workers, On-Site industrial workers, and utility workers.

3.3. Southwest Off-Site/Outfall 006 Exposure Area

As discussed in Section 2.1, the southwest Off-Site area includes the location of Outfall 006 and mounded area. This area is situated to the south of the fenced plant area and approximately 30 ft north of the CSX railroad tracks and the plant area (Figure L-6).

Chemical residues detected in Outfall 006 surface soils include mercury, chlorobenzene, and polychlorinated biphenyls (PCBs) including Aroclor 1260, as well as concentrations of chlorinated VOCs. Constituents detected in the upper soils from the mounded area include mercury, benzene and

2 Soils were sampled and analyzed for dioxins and furans at the direction of the NYSDEC to evaluate the potential formation of dioxins and furans following a fire at the chlorination building in 1930. (Syracuse Herald Journal, July 4th, 1930)

substituted benzenes (petroleum-based constituents), dichlorobenzenes, and chlorinated VOCs (RAGS D Tables 2.12 and 2.13; Section 4.3 of the RI report).

Potential current receptors at the Southwest Off-Site/Outfall 006 Exposure Area are identified as trespassers who may occasionally be present at the area, as well as railroad or utility workers. Potential future receptors are identified as construction workers and industrial workers.

3.4. State Fair Blvd./Northwest Off-Site/Outfall 004/ Exposure Area

As discussed in Section 2.1, Outfall 004 is situated approximately 25 ft north and 200 ft west of the northwest corner of the plant area fence and near State Fair Boulevard (Figure L-3).

Chemical residues detected in the Exposure Area surface soils include mercury, chlorobenzenes, and PCBs consisting of Aroclor 1260, as well as low concentrations of chlorinated VOCs. Chemical residues detected in upper soils around the NIMO utility line include mercury, chlorobenzenes, Aroclor 1260, as well as chlorinated VOCs and petroleum constituents (Tables 2.14 and 2.15; Section 4.3 of the RI report).

Potential current and future receptors for this area are identified as:

- adolescent trespassers
- adult transients (during the State Fair)
- NIMO utility workers

These exposure pathways are discussed in RAGS D Table 1.1c (Attachment L).

3.5. Lakeshore Area

As discussed in Section 2.1, the Lakeshore Area is situated to the north of the plant area, between the south shore of Onondaga Lake and the westbound lane of I-690 (Figure L-2).

Chemical residues, notably chlorobenzenes and naphthalene, have been detected in upper soils and surface soils on the Lakeshore Area. Constituents detected in groundwater on the Lakeshore Area included benzene, toluene, and chlorinated benzenes.

Additional current and future receptors in this area are utility workers and adolescent and adult trespassers. Current and future receptors at this area are identified as Honeywell workers who are operating the product recovery system. However, these workers are working under an approved health and safety plan (HASP) and are required to utilize appropriate personal protective equipment as specified in the HASP. As such, these receptors were not evaluated in the risk assessment.

3.6. Tributary 5A

As discussed in Section 2.2, Tributary 5A is a small stream that courses through the Site for approximately 3000 ft and discharges into Onondaga Lake (Figure L-9).

Chemical residues detected in Tributary 5A sediment include select metals, polycyclic aromatic hydrocarbons (PAHs), and PCBs (Aroclor 1254). Chemical residues from the surface water include chlorinated VOCs and select metals.

The current and future receptors considered for Tributary 5A are the adolescent and adult trespasser and a utility worker. Based on the potential for fish migration, consideration of the habitat, fish sampling data and limited access for fishermen (Section 2.2.4), edible fish are not likely to be caught in Tributary 5A. The fisherman/fish consumer scenario is not considered probable and, this, was not evaluated.

3.7. Petroleum Storage Area

As discussed in Section 2.2, the PSA is located to the southwest of the former Willis Avenue Plant (Figure L-10).

Three monitoring wells were installed by Groundwater Technology in the early 1980s to detect possible petroleum product leakage. No. 2 fuel oil was not detected in the groundwater during the study; however, benzene, toluene, and xylenes (BTX) and naphthalene were detected. In addition, PCBs (Aroclor 1254), PAHs, and mercury were detected in surface and upper soils. In addition, total petroleum hydrocarbons (TPH) concentrations were detected in 0 to 2 ft soil (100 to 600 mg/kg) and in 2 to 10 ft soil (100 to 800 mg/kg).

Potential current receptors at the PSA are identified as adult and adolescent trespassers who may occasionally be present at the area. In addition, potential future receptors are identified as trespassers, construction workers, industrial workers, and utility workers.

3.8. Chlorobenzene Hot-Spot Area

As discussed in Section 2.2, the CHSA is situated to the south of the plant area and the PSA, adjacent to the Suez Power Plant, formerly Trigen (Figure L-11).

Previous reports have identified benzene and chlorobenzene at monitoring well MW-111 (Blasland & Bouck 1987). Depth to groundwater in this area is approximately 4 to 5 ft bgs. Blasland & Bouck (1987) attributed the source of these compounds to leakage from the chlorobenzene pipeline, which is approximately 5 ft bgs. In addition, chlorobenzenes, PAHs, and mercury were detected in surface and upper soils.

Potential current receptors at the CHSA are identified as adult and adolescent trespassers who may occasionally be present at the area. In addition, potential future receptors are identified as trespassers, construction workers, industrial workers, and utility workers.

3.9. Hypothetical Drinking Water Source Area

On-Site groundwater occurs at a depth of approximately 15 to 20 ft bgs, while Off-Site it occurs at approximately 4 to 5 ft at the CHSA, PSA, and Lakeshore Area. The location of the hypothetical Drinking Water Source Area (on-site and off-site groundwater wells) is presented in Figure L-12.

Groundwater is not used as a drinking or industrial water supply and is highly unlikely to be used as a drinking or industrial supply in the future, since the area is supplied by municipal water from OCWA. Furthermore, the yield of the overburden groundwater unit is inadequate for water supply wells, whereas the high salinity of the bedrock aquifer (approximately 3,000 mg/l chlorides) precludes its use as drinking water.

However, the New York State groundwater classification for the Site and surrounding area is GA (*i.e,*. suitable for drinking use). In accordance with NYSDEC's request, the hypothetical drinking water scenario is therefore evaluated in the risk assessment, which assumes residential development of portions of the Site. The HHRA includes a quantitative evaluation for both child and adult residents hypothetically ingesting groundwater as potable water.

3.10. Evaluation of Soil Vapor Intrusion Pathway

3.10.1. General Considerations

As discussed above, VOCs, notably chlorobenzene and benzene, and elemental mercury, have been detected in soil and groundwater at the Site. VOCs may volatilize from soil and groundwater sources into the unsaturated zone above the water table (soil vapor). If current or future buildings are located above or near contaminated soil or groundwater source, volatile constituents in soil vapor may intrude into the indoor air of buildings via cracks or seams in the foundation. Soil vapor intrusion may occur via the two principal mechanisms of advection or diffusion. Advection refers to the bulk movement of soil gas from the unsaturated zone to indoor air due to a pressure differential between the soil gas and the indoor space. Typically, in temperate climates, advective transport may occur during the winter months when a negative pressure environment is created indoors as a result of indoor heating in well insulated and sealed structures. Since advection requires the bulk movement of air through the soils, advective transport is negligible in very low permeability soils but may be the operative transport pathways in high permeability soils (Johnson and Ettinger 1991).

Diffusive transport reflects the movement of VOCs from the source to the indoor air due to the concentration gradient between the source and the indoor space. Since diffusive transport does not require the bulk movement of air, it may be the operative transport mechanism in low permeability soils or if there is no pressure gradient between the indoor space and the soil vapor. Because molecular diffusion of VOCs occurs much more rapidly in air than in water, the extent of diffusive transport in soils is primarily dependant on the moisture content of the soil as well as the total porosity. VOCs volatilizing from groundwater must first diffuse through the capillary fringe, which is the semi-saturated zone above the water table, before migrating to the unsaturated zone. The capillary fringe has a high moisture content and therefore, the height of the capillary fringe is an important factor in determining the rate of migration of VOCs from groundwater to soil gas. Low permeability "tight" soils, such as clays and silts, typically have significantly larger capillary fringes as compared with high permeability soils such as sands. As such, the rate of diffusive transport is lower in low permeability soils as compared with high permeability soils (Little *et al*. 1992).

3.10.2. Site-Specific Considerations

As part of the HHRA, the potential future migration of VOCs in groundwater to the indoor air of future On-Site industrial buildings was screened.

Screening of groundwater concentrations against vapor intrusion screening values: Groundwater screening values protective of potential vapor intrusion to indoor air were taken from *Draft Guidance for Evaluating the Vapor Intrusion to Indoor Air Pathway from Groundwater and Soils (Subsurface Vapor Intrusion Guidance*, USEPA 2002a). For each VOC constituent, SVOC constituent, and mercury the maximum groundwater concentration was compared to screening values in USEPA (2002a) Table 2c. For most chemicals, these are the groundwater concentrations corresponding to target indoor air concentrations where the soil gas to indoor air attenuation factor is 0.001. However, when this attenuation factor results in a groundwater concentration that is below the MCL, the screening value in Table 2c defaults to the MCL. The screening process for this site did not use these MCL-defaulted values; rather the groundwater concentration based on the attenuation factor was used regardless of whether it is less than the MCL. Constituents were also retained in if no screening value was available The results of the groundwater screening protective of indoor air are summarized in RAGS D Tables 2.5, 2.24, and 2.28.

Because of the lack of occupied structures on the property at the time of sampling, there is no complete human exposure through the vapor intrusion pathway at this time. In the future, however, a building may be erected on the property (such as the groundwater treatment plant) that potentially could be impacted by the migration of vapors from the subsurface. Because the impact of the vapor intrusion pathway can be affected by a wide a variety of factors, including building size, ventilation rate, integrity of the foundation, *etc*., it is not possible to estimate the potential risks associated with vapor intrusion. Therefore, at this stage of evaluation, only COPCs can be identified. As noted above COPCs were identified by comparing groundwater concentrations to groundwater screening values protective of potential vapor intrusion to indoor air. Constituents detected in groundwater above screening levels include; naphthalene and mercury in the Petroleum Storage Area; benzene, chlorobenzene, methylene chloride, and mercury in the Plant Area intermediate ground water; and hexachlorobenzene, 1,2-dichlorobenzene, 1,4-dichlorobenzene, benzene, chlorobenzene, and mercury in the Chlorobenzene Hot-spot Area shallow groundwater. These constituents are present in groundwater at levels that have the potential to impact the quality of indoor air in a future building if erected on the Site.

4. Data Evaluation

The results of the risk assessment are used to assess if remedial actions are necessary at a site and to identify remedial action objectives and medium-specific remedial goals, if necessary. Therefore, it is important that the risk assessment is based on high quality, technically defensible analytical data with respect to the identification and quantification of site-related chemicals. The objectives of the data evaluation were to:

- Evaluate the quality of existing analytical data with respect to risk assessment needs;
- Evaluate the quantity, spatial coverage, and appropriateness of sample locations;
- Evaluate the appropriateness of analytical methods and detection limits'
- Identify data gaps; and,
- Identify COPCs for the Site.

The data evaluation process was conducted in three steps:

A. Data compilation and general review
B. Data usability assessment
C. Identification of COPCs.

4.1. Data Compilation and General Review

4.1.1. Data Sources

The data collected during the RI were used as the input data for the risk assessment. As discussed in the RI report, Site samples were collected from groundwater, surface soils, upper soils, deep soils, and sediments at the Exposure Areas (Appendix A). A summary of the remedial investigation sampling activities (including the 1999 Baseline Ecological Risk Assessment sample collection) is presented in Table 1. Table 2 presents a summary of samples collected from each Exposure Area. The entire data set used in this HHRA is provided as Appendix B. It should be noted that the Exposure Areas for each sample are included in the data set provided in Appendix B.

Data from surface soils, sediments, upper soils, and deep soils were used in the HHRA and are discussed below. A detailed discussion of the analytes detected in those media is presented in Section 4.3 of the RI report.

4.1.2. Chemical Analyses

Consistent with the agreed Work Plan, the RI sampling activities focused on VOCs, semi volatile organic compounds (SVOCs), PCBs/pesticides, and mercury analyses. Metals other than mercury were analyzed in select samples specified by the NYSDEC. The Site is covered with fill material mixed with Solvay waste, which contains elevated metals concentrations (Table 16 of the RI report). The metals concentrations detected in soil samples collected from the Site are comparable to the concentrations reported for Solvay waste (Table 16 of the RI report). As such, the available metals data provide representative estimates of metals concentrations across the Site.

A brief discussion of available data from each of the previously identified Exposure Areas is presented below. Summaries of the detected analytes are presented in the RAGS D Table 2 series.

4.1.3. Plant Area

A sampling summary is provided in Appendix A, and a summary of the constituents detected in soils is presented on RAGS D Tables 2.1 through 2.3. Surface, upper, and deep soil samples were collected from the Plant Area and analyzed as follows:

- Surface soil samples were analyzed for VOCs, SVOCs, PCBs/pesticides, and metals and 16 for polychlorinated dibenzo-p-dioxins and furans (PCDD/Fs).
- Additional upper soil samples were analyzed for VOCs and 10 for mercury.
- Deep soil samples were analyzed for VOCs, SVOCs, and metals.

It should be noted that both mercury and methyl mercury were analyzed in subsurface (upper and intermediate) soil samples collected from the vicinity of the former mercury cell building at the Plant Area. The treatment of unspeciated mercury in the HHRA is described in Section 4.3.3.

In addition, 18 groundwater samples were collected from 11 wells at the Plant Area and analyzed for VOCs, SVOCs, and metals (RAGS D Tables 2.4 and 2.5).

4.1.4. Former Chlorination Building

A sampling summary is provided in Appendix A and a summary of the constituents detected in soils is presented in RAGS D Tables 2.6 through 2.8. Surface, upper, and intermediate soil samples were collected from the FCB and analyzed as follows:

- Surface soil samples were analyzed for PCBs/pesticides, metals and PCDD/Fs.
- Additional upper soil samples were analyzed for PCDD/Fs.
- No intermediate soil samples were collected.

4.1.5. On-Site Ditches

A sampling summary is provided in Appendix A and a summary of the constituents detected in soils is presented on RAGS D Tables 2.9 through 2.11. Surface, upper, and intermediate soil samples were collected from the FCB and analyzed as follows:

- Surface soil samples were analyzed for PCDD/Fs and one sample was analyzed for VOCs, SVOCs, PCBs/pesticides, and metals; these samples provide a representative estimate of conditions at this area based on the dimensions of the On-Site Ditches and will also be used as representative of the upper soils (0-10 ft bgs).

- No additional upper soil samples or intermediate soil samples were collected.

4.1.6. Southwest Off-Site/Outfall 006 Exposure Area

A sampling summary and summary of the constituents detected in surface and upper soils at Southwest Off-Site/Outfall 006 Exposure Area are presented in Appendix A and RAGS D Tables 2.12 and 2.13, respectively. Based on the dimensions of the subsite, the samples provide a representative characterization of surface soil conditions at this location and are as follows:

- Surface soil samples were analyzed for VOCs, PCBs/pesticides, and mercury and two for PCDD/Fs.

- Additional upper soil samples were analyzed for VOCs and PCBs/pesticides and mercury.
- No intermediate soil samples were collected.

4.1.7. State Fair Blvd./Northwest Off-Site/Outfall 004 Exposure Area

A sampling summary and summary of the constituents detected in surface and upper soils at Northwest Off-Site/Outfall 004 Exposure Area are presented in Appendix A and RAGS D Tables 2.14 and 2.15, respectively. Based on the dimensions of the subsite, the samples provide a representative characterization of constituent concentrations at the outfall location and are as follows:

- Four surface soil samples were analyzed for VOCs, PCBs/pesticides, and mercury and two for PCDD/Fs.
- Additional samples from the upper soils were analyzed for VOCs, SVOCs, PCBs/pesticides, and metals.
- No intermediate soil samples were collected.

The samples from the upper soils were collected based on field observations of materials in the test pits. As such, the samples provide a conservative representation of potential conditions around the NIMO utility line. It should be noted that a non-aqueous phase liquid (NAPL) was observed along State Fair Boulevard during the excavations around the NIMO gas pipeline.

4.1.8. Tributary 5A

Surface water and sediment samples were analyzed for VOCs, SVOCs, PCB/pesticides, metals, PCDD/Fs, and methyl mercury from four locations (5A-SED/SW-1 through 4). A sampling summary and summary of the detected constituents in Tributary 5A sediment and surface water are presented in Appendix A and RAGS D Tables 2.19 and 2.20, respectively.

4.1.9. Lakeshore Area

A sampling summary and summary of the detected constituents in the Lakeshore Area surface and upper soils are presented in Appendix A and RAGS D Tables 2.16 and 2.17. A summary of constituents detected in groundwater is presented in RAGS D Table 2.18. These samples are briefly summarized below.

- Surface soil samples were analyzed for VOCs, SVOCs, PCBs/ pesticides, metals, PCDD/Fs.
- No additional upper soil samples or intermediate soil samples were collected, but the surface soils were considered representative of the upper soils (0-10 ft bgs).
- Groundwater samples were analyzed for VOCs, SVOCs, and metals.

4.1.10. Petroleum Storage Area

A sampling summary and summary of the constituents detected at the PSA surface and upper soils are presented in Appendix A and RAGS D Tables 2.21 and 2.22, respectively. A summary of constituents detected in groundwater is presented in RAGS D Tables 2.23 and 2.24. Based on the dimensions of the subsite, the samples provide a representative characterization of constituent concentrations at the PSA and are as follows:

- Four surface soil samples were analyzed for VOCs, PCBs/pesticides, and metals and one sample for PCDD/Fs.

- Additional soil samples were analyzed for VOCs, SVOCs, PCBs/pesticides, and metals.
- No intermediate soil samples were collected.
- Groundwater samples were analyzed for VOCs, SVOCs, and metals.

4.1.11. Chlorobenzene Hot-Spots Area

A sampling summary and summary of the constituents detected in surface and upper soils at the CHSA are presented in Appendix A and RAGS D Tables 2.25 and 2.26, respectively. A summary of the detected constituents in groundwater is presented in RAGS D Tables 2.27 and 2.28. Based on the dimensions of the subsite, the samples provide a representative characterization of constituent concentrations at the CHSA and are as follows:

- Surface soil samples were analyzed for VOCs, SVOCs, PCBs/pesticides, and metals and one sample for VOCs, PCBs/pesticides, metals, mercury, and PCDD/Fs.
- Additional upper soil samples were analyzed for VOCs, SVOCs, PCBs/pesticides, and metals.
- No intermediate soil samples were collected.
- Groundwater samples were analyzed for VOCs, PCBs/pesticides, and metals.

4.1.12. Hypothetical Drinking Water Source Area

In order to assess the hypothetical drinking water scenario, analytical data from groundwater samples at or down gradient of the General Plant Area, CHSA, PSA, and Lakeshore Area were compiled and reviewed. A total of 30 wells, shown on Figure L-12 were identified as being appropriate for the hypothetical drinking water assessment. The selected wells have been sampled and analyzed over multiple rounds for various analytical parameters consisting of VOCs, SVOCs, and metals. The total number of samples for different analytes across the monitoring events conducted between 1991 and 2002 are summarized on RAGS D Table 2.29. Based on an initial review of the available data, no systematic increasing time-related trends are evident in the constituent concentrations. Therefore, for the purposes of the risk assessment, the data were analyzed as a single dataset (*i.e.*, the data were not segregated by monitoring event). The total number of samples by constituent from the 30 wells sampled is presented on RAGS D Table 2.29. This dataset consists of all groundwater samples collected from the Plant Area, Lakeshore Area, PSA, and CHSA, as these are the most recent samples collected.

4.2. Data Usability Assessment

The data usability assessment was conducted in general conformance with *Guidance for Assessing Data Usability for Risk Assessment* (USEPA 1992a).

4.2.1. Data Quality Objectives

Data quality objectives (DQOs) for the Site investigation were developed as part of the approved Work Plan for the RI (O'Brien and Gere 1990). Data quality objectives are qualitative or quantitative measures of the minimum required *sensitivity, accuracy, precision,* and *representativeness* of the collected data for risk assessment purposes. Sensitivity reflects the ability of the chemical analysis to detect chemical residues at concentrations, which allow the quantitative assessment of human health risk. Precision is a measure of the uncertainty in the reported concentration due to variability in the sample collection and analysis process and spatial variability in the chemical concentrations. Accuracy is a measure of the extent to which the reported chemical concentrations in a sample are

consistent with the actual concentrations. Representativeness is a more subjective measure and refers to the extent to which the collected data represent actual conditions at the Site. Representativeness is a function of the sampling locations, number of samples collected, the types of chemical analyses performed, and the accuracy and precision of the collected data.

The objective of the Data Usability Assessment was to evaluate the quality of the analytical data generated as part of the RI relative to the DQOs.

4.2.2. Data Validation

Data validation is an evaluation of the accuracy and precision of the reported analytical measurements. Data validation involves the reconstruction of the analytical process and an evaluation of whether the analysis has been performed correctly. Data validation qualifiers, which reflect the accuracy, precision, and usability of the data, are then applied to individual data points based on USEPA specified guidelines.

The data were validated as described in Appendix I of the RI report. As described in the data validation report, 100% of the pesticide/PCB data, 100% of the dioxin data, 97.3% of the VOC data, 98.4% of the SVOC data, 98.2% of the metals data, and 100% of the PCDD/F data were determined to be usable for qualitative and quantitative purposes.

The following actions were taken with respect to assigned data validation qualifiers:

- R - The data were qualified as unusable for qualitative and quantitative purposes according to data validation guidance. “R”-qualified data were not utilized in the risk assessment.

- J - The analyte was positively identified; the associated numerical value was the approximate concentration of the analyte in the sample. The analytical data were not adjusted to compensate for potential high or low bias in the analytical result, due to uncertainty regarding the magnitude of the bias.

4.3. Identification of Constituents of Potential Concern

The goal of the COPC selection process was to streamline the assessment by focusing on Site-related analytes that may contribute to potential human health risks. Consistent with USEPA procedures (USEPA 1997a) chemical constituents detected at concentrations which are highly unlikely to result in adverse human health effects were not selected as COPCs (*i.e.*, they were not carried through the quantitative risk assessment process).

A list of COPCs for the HHRA was developed based on the data evaluation. Consistent with HHRAs performed previously for Superfund sites in New York State and as approved by USEPA and NYSDEC (O’Brien & Gere 1997), a sequence of comparisons was performed to identify the COPCs for the Site; these are outlined in section 4.3.2.

4.3.1. Media Definitions

This section describes the media that are relevant to this assessment. Appendix A provides a comprehensive list of samples used in this deliverable. Appendix B provides the Site database

organized by Exposure Area and medium. Only data with acceptable qualifiers ("U", "J", "UJ", or no qualifier) were utilized in the RAGS D Table 2 series.

Surface Soil – Surface soil is defined as soil collected from 0 to 2 ft bgs. The soil database contains a start depth and an end depth for a given sample. Surface soil was sorted from the entire soil database by selecting samples with an end depth that was less than or equal to 2 ft. Thus, a sample collected from 1 ft (start depth) to 3 ft (end depth) would not have been included in the RAGS 2 Tables that evaluated surface soils, but rather in tables that evaluated Upper and Intermediate Soils (see below).

Upper and Intermediate Soil – Three exposure scenarios (construction worker, and utility worker,) required the evaluation of surface and subsurface soil combined. This exposure medium was defined as soil collected from 0 to 10 ft bgs (upper soil) with the exception of the Former Chlorination Building, Plant Area, and On-Site Ditches, where the utility worker reaches a depth of up to 20 ft bgs. In these latter Exposure Areas for the utility worker receptor, the exposure medium is considered 0 to 20 ft bgs (intermediate soil). Upper and intermediate soil was sorted from the entire soil database by selecting samples with an end depth that was less than or equal to 10 or 20 ft bgs, respectively

Shallow and Intermediate Groundwater – Two exposure scenarios (construction worker and utility worker scenarios) required the evaluation of direct exposure to shallow or intermediate groundwater. This exposure medium was defined as groundwater samples collected from monitoring wells that contained a depth to water from 0 to 10 ft bgs (shallow groundwater), with the exception of the Former Chlorination Building, Plant Area, and On-Site Ditches, where the PA sewer occurs at a depth of up to 20 ft bgs. For these latter Exposure Areas for the utility worker receptor, the exposure medium was 0 to 20 ft bgs (intermediate groundwater). Shallow and intermediate groundwater was sorted from the Site database by selecting data with a start depth less than or equal to 10 ft bgs or 20 ft bgs, respectively. The start depth was used to sort for shallow and intermediate groundwater samples because of the abundance of samples with start depth less than or equal to 10 ft bgs and 20 ft bgs, respectively.

Sediment - Sediment collected from the 0 to 1 ft bgs interval was sorted from the entire sediment database by selecting samples with an end depth that was less than or equal to 1 ft. Thus, a sample collected from 0 ft (start depth) to 2 ft (end depth) would not have been included in the RAGS Part D Table 2 series that evaluate surface sediment.

Surface Water - Surface water present in water bodies (Tributary 5A) of the Site were evaluated in this assessment.

Site-Wide Groundwater – One exposure scenario (hypothetical drinking water scenario) required the evaluation of all Site groundwater collected from monitoring wells, regardless of depth. This scenario was evaluated for the adult and child resident.

4.3.2. Comparison with Risk-Based Screening Values

Consistent with USEPA guidance (USEPA 1989a), a conservative screening process was applied to select COPCs. To develop the COPC list, the maximum detected concentrations of the detected constituents in surface soil, subsurface soil, surface water, surface sediment, shallow groundwater, and Site-wide groundwater were compared to conservative screening values for the protection of human health.

The screening values utilized were the lowest of the USEPA Region 9 Preliminary Remediation Goals (PRGs) or the USEPA Region 3 Risk Based Concentrations (RBCs) (USEPA October 2007a). RBC and PRGs for tap water were applied to screen surface water and groundwater detections. RBCs and PRGs for residential soils were applied to screen the soil and sediment concentrations. RBCs and PRGs utilized in the screening process corresponded to a cancer risk of 10^{-6} or a hazard quotient of 0.1.

If the maximum detected concentration was less than the identified screening values, it was concluded that exposure to the constituent does not represent an unacceptable risk to human health, and no further evaluation of that exposure was necessary. If the maximum detected concentration exceeded the selected screening value, the constituent was selected as a COPC and retained for further evaluation in this assessment. All Class A carcinogens were retained as COPCs regardless of the levels at which they were found.

Naturally occurring compounds were eliminated from the COPC list if they were essential nutrients. Based on this consideration, calcium, magnesium, potassium, and sodium were not carried forward as COPCs for the risk assessment.

Constituents detected in media that do not have established RBCs or PRGs were carried forward for further evaluation in the risk assessment. Constituents that were not detected in a given Exposure Area were not included in the quantitative evaluation for that Exposure Area.

Risk-based screening values were applied in order to select the COPCs for further evaluation in the HHRA process. The risk-based screening was conducted as follows:

Region III Risk Based Concentrations (RBCs) and Region 9 Preliminary Remediation Goals (PRGs): USEPA Region III (USEPA 2007a) and USEPA Region 9 (USEPA 2004a) have published analyte-specific risk-based screening concentrations. If the maximum detected concentration of a chemical in Site media is less than the published screening value it is highly unlikely that the chemical may represent a significant risk to human health and may be deleted as a COPC. The lower of the Region 3 RBCs or Region 9 PRGs were selected as the screening values for COPC selection. Consistent with previously approved risk assessments in New York State (O'Brien and Gere 1997), the screening values correspond to an excess lifetime cancer risk of 10^{-6} for carcinogens and a hazard quotient of 0.1 for non-carcinogens. If the maximum detected concentration in the Exposure Area was less than the screening level, the analyte was not retained as a COPC. For soils and sediments, the residential soil screening values were used. For groundwater and surface water, the published RBCs and PRGs for tap water were used. The chemical-specific health-based screening values applied in selecting the COPCs are presented in the RAGS D Tables 2 series.

Vapor Intrusion Screening Values for groundwater: Groundwater screening values protective of potential vapor intrusion to indoor air were taken from *Draft Guidance for Evaluating the Vapor Intrusion to Indoor Air Pathway from Groundwater and Soils (Subsurface Vapor Intrusion Guidance;* USEPA 2002a).For each VOC and SVOC constituent, the representative groundwater concentration was compared to screening values in USEPA (2002a) Table 2c. USEPA (2002a) Table 2c provides screening concentrations for VOCs that represent a 10^{-6} cancer risk. Constituents are also screened in if no screening value is available.

Background - In accordance with USEPA (2003a) guidance, background concentrations were not used to screen Site-related compounds for the baseline human health risk assessment. However, the USEPA (2003a) guidance allows for the use of background concentrations, based on statistical evaluation, to be considered for the development of remedial options. In the future, background concentrations may be used in the development of remedial options, as appropriate.

Evaluation of Essential Nutrients - Naturally occurring compounds were eliminated from the COPC list if they were essential nutrients, present at concentrations only slightly elevated above naturally occurring levels, and toxic only at very high doses. Based on this consideration, calcium, sodium, potassium, and magnesium were not included as COPCs for the risk assessment and these compounds were eliminated from the screening tables.

The list of selected COPCs for each Exposure Area is presented in the RAGS D Tables 2 series. At most Exposure Areas, mercury, dioxin toxicity equivalents (TEQs), polychlorinated biphenyls (PCBs), and chlorobenzenes were identified as COPCs. In addition, certain petroleum constituents were identified as COPCs in the Southwest Off-Site/Outfall 006 Exposure Area.

4.3.3. Notes on Specific Constituent Groups

Dioxins: Dioxin congeners were detected in some Site media. During the development of the RAGS D Table 2 series, toxic equivalency factors (TEFs) were applied to individual congeners to extrapolate a combined toxicity equivalent to that of 2,3,7,8-tetrachloro-dibenzo-p-dioxin (2,3,7,8-TCDD), with TEFs obtained from Van den berg *et al*. (2006). The concentration of each dioxin/furan congener was multiplied by the TEF to derive the 2,3,7,8-TCDD equivalent concentration. Once this approach was applied to all congeners, the 2,3,7,8-TCDD equivalents were summed for each sample location and the resulting total 2,3,7,8-TCDD equivalent value was treated as a unique constituent for that location. The maximum TEQ from all sample locations within the Exposure Area was compared to USEPA Region 3 RBCs (USEPA 2007a) and Region 9 PRGs (USEPA 2004a) values for 2,3,7,8-TCDD.

Polychlorinated Biphenyls: Calculation of PCB concentrations for use in determining exposure point concentrations combined individual Aroclors into two groups. "Less chlorinated" PCBs (Aroclor 1016, 1221, 1232, and 1242) were combined for analysis and determination of the exposure point concentration, and were screened in the RAGS D Table 2 series against the screening values for Aroclor 1016. "Highly chlorinated" PCBs (Aroclor 1248, 1254, and 1260) were combined for analysis and determination of the exposure point concentration, and were screened in the RAGS D Table 2 series against the screening values for Aroclor 1254.

Group A Carcinogens: All detected Group A carcinogens (arsenic, benzene, and hexavalent chromium) were retained as COPCs even if their maximum detected concentration did not exceed their respective screening criterion.

Unspeciated mercury and chromium: In cases where chromium was not speciated, RBCs and PRGs values for hexavalent chromium (Cr^{+6}) were utilized. Unspeciated mercury in soil and sediment was screened against RBC and PRG values for mercury compounds, while unspeciated mercury in groundwater was screened against values for methyl mercury.

Chlordane constituents: All chlordane constituents were summed and screened against the chlordane RBC and technical chlordane PRG criteria.

5. Exposure Assessment

The exposure assessment identifies the mechanisms by which receptors may be exposed to site COPCs. The assessment derives the chemical concentrations to which receptors may be exposed and the chronic daily intake of constituents by receptors.

A summary of the receptor populations and complete exposure pathway for each area is also presented in the RAGS D Table 1 series. For each Exposure Area, the following elements are included:

1. Potentially exposed populations
2. Identification and evaluation of exposure pathways
3. Quantification of exposure
4. Exposure point concentrations (EPCs)
5. Intake equations and parameter estimates
6. Calculation of chemical intakes

5.1. Land Use Assumptions

The risk assessment assumes that future land use at the Plant Area, FCB, On-Site Ditches, and the Southwest Off-Site/Outfall 006 Exposure Area will be industrial (*i.e.*, the areas will not be developed as residential areas). This assumption is based on the consideration that the areas are located in heavily industrialized settings and are zoned industrial.

5.2. Exposure Pathway Analysis

An exposure pathway analysis for the Site is provided in the RAGS D Table 1 series. An exposure pathway describes the course a chemical takes from the source to the exposed individual. An exposure pathway analysis links the sources, locations, and types of environmental releases with population locations and activity patterns to determine the significant pathways of human exposure.

An exposure pathway consists of four elements:

- a source and mechanism of chemical release;
- a retention or transport medium;
- a point of potential human contact with the contaminated medium (referred to as the exposure point); and
- an exposure route (*e.g.*, ingestion) at the contact point.

A pathway is considered to be complete if all of the conditions listed above are satisfied for that pathway. If one or more of these conditions are not met, there is no physical means by which a receptor may be exposed to the compounds of potential concern, and the pathway is classified as incomplete. Incomplete pathways are not considered further in the HHRA.

5.3. Quantification of Exposure

The next step in the exposure assessment is to quantify the magnitude, frequency, and duration of exposure for the complete exposure pathways. General considerations and considerations for Site-specific calculations are presented below.

General Considerations - The exposure quantification was performed in accordance with the following USEPA guidance for exposure assessment activities:

- *Guidelines for Exposure Assessment* (USEPA 1992b)
- *Risk Assessment Guidance for Superfund* (USEPA 1989a)
- *RAGS Volume I: Human Health Evaluation Manual Supplemental Guidance* (USEPA 1991)
- *Supplemental Guidance to RAGS: Calculating the Concentration Term* (USEPA 1992c)
- *Exposure Factors Handbook* (USEPA 1997a)
- *RAGS Volume I: Human Health Evaluation Manual, Part D* (USEPA 2001a)
- *Calculating the Upper Confidence Limits for Exposure Point Concentrations at Hazardous Waste Sites* (USEPA 2002b).

For each complete exposure pathway, the chronic daily intake (CDI) was estimated for the COPCs. There may be considerable uncertainty relating to the estimated CDI for a given receptor group. This uncertainty results from the random variability in exposure parameters, including the estimated exposure point concentrations (EPCs). Uncertainty in the *exposure point concentration* may arise from spatial and temporal variations in the chemical concentration at the exposure point. Variability in the *exposure parameters* occurs because each individual in the population has differences in activity patterns, behavior, and physical and biological characteristics. To account for this inherent variability, USEPA discusses the "average" and "high end" or "upper bound" *exposure estimates* (USEPA 1992b).

Average exposures refer to the estimated CDI for most of the individuals in the exposed population. The average estimate can be derived by using an average value (usually the median value) as the exposure factor. This results in Central Tendency (CT) estimates. Reasonable Maximum Exposure (RME) estimates represent a conservative scenario for the risk estimate. The RME estimate may be used to develop a statement that the risk "is unlikely to exceed" the calculated bounding value. The RME estimate is derived by combining a series of default average and upper bound exposure factor estimates in calculating the CDI. If the calculated RME risks exceed acceptable levels, the CT exposure estimates may be derived and considered in risk management decisions for the Site.

Consideration for Site-Specific Calculations - Consistent with USEPA guidance, RME and CT exposure estimates were derived for the HHRA, as discussed in Section 5.6. The methods, assumptions and results of the exposure assessment are presented below for each of the previously discussed Exposure Areas at the Site. The potential uncertainties inherent in the derived exposure estimates are discussed qualitatively in Section 8 - Uncertainty Assessment

5.4. Derivation of Exposure Point Concentrations

5.4.1. Calculating Exposure Point Concentrations for Soil, Sediment, Surface Water, and Groundwater

Statistical and procedural methods were applied to the data in order to develop an estimate of the EPC for COPCs selected for each Exposure Area, on a medium-specific basis. The general approach is as follows:

- Where a given data set contained less than five sample points or only one unique detected sample, the maximum value for each analyte in that data set was used as the EPC.
- For data sets with five or more data points, and at least two unique detected samples, statistical methods were applied.

In the latter case, the ProUCL statistical software package (Version 4.0; USEPA, 2007b) was used to examine the data distribution and develop an upper confidence level on the arithmetic mean (UCL).

ProUCL was run using Regression on Order Statistics (ROS), which is a method for accounting for non-detect samples in the data set. ROS infers values for non-detect samples based on the distribution of detected data. ProUCL recommends the most appropriate UCL to use given the distribution type. The UCL recommended by ProUCL was subsequently applied as the EPC.

It should be noted that in some cases the 95% UCL is less than the reported average concentration. This is because the arithmetic average reported in the Table 3 series is the mean detected concentration. In instances where the detection frequency is low and non-detect samples largely outnumber detected samples, the 95% UCL recommended by ProUCL V.4 can be smaller than the mean detected concentration, since it reflects the large number of non-detect samples.

5.4.2. EPCs for Air Exposures

The inhalation of air particulates and volatile compounds arising from Site soils will be evaluated in the Site HHRA. The calculation of the particle emission factor (PEF) and the volatilization factors (VFs) are discussed in this section.

Because the methods used to develop the USEPA Region 9 PRG screening values included the inhalation exposure pathway (both particulate and volatile compounds), any soil constituent that screened out during the RAGS D Table 2 series process will not be considered as a COPC for these air pathways. Of those soil constituents that were retained, a VF was calculated for compounds listed in the USEPA Region 3 RBC Table as volatile (Appendix C). The remainder of these constituents will be evaluated as particulate emissions (Appendix C). The derivation of EPCs for evaluating these two pathways is discussed in turn.

5.4.3. Derivation of EPCs for Volatile Compounds

The following equation was used to derive EPCs of volatile compounds in outdoor air for inhalation exposure pathways:

$$C_{air} = \left(\frac{C_{soil}}{VF} \right)$$

where:

C_{air}: Concentration of volatiles in air (mg/m^3)
C_{soil}: Concentration in soil (UCL, mg/kg)
VF: Soil-to-air Volatilization Factor (m^3/kg)

The VF is used for defining the relationship between the concentration of volatile organic constituents in soil and the volatilized constituents in outdoor air. A VF is specific to each volatile compound and each Exposure Area. VFs for this assessment were calculated using Equation 4-8 from the *Supplemental Guidance for Developing Soil Screening Levels for Superfund Sites* (USEPA 2002c) and can be found in Appendix C.

5.4.4. Derivation of EPCs for Fugitive Dust

The PEF is required to calculate the constituent concentration in fugitive dust. The following equation will be used to derive concentrations of inorganics, semi volatiles, PCBs, and pesticides in outdoor air for inhalation exposure pathways (see Appendix C for proposed dust constituent list):

$$C_{air} = \left(\frac{C_{soil}}{PEF} \right)$$

where:

C_{air}: Concentration of inorganic particulates in air (mg/m^3)
C_{soil}: Concentration in soil (mg/kg)
PEF: Particle Emission Factor (m^3/kg)

The PEF is used to convert concentrations of constituents in soil to concentrations in air as a result of fugitive dust emissions from bare surface soils. The USEPA provides the methodology required to calculate the PEF in Appendix C of the *Supplemental Guidance for Developing Soil Screening Levels for Superfund Sites* (USEPA 2002c). Equation 5-5 (USEPA 2002c) was used to derive a PEF for the construction worker scenario. The details of these calculations can be found in Appendix D of this submittal.

5.4.5 Derivation of EPCs for Lead in Site-Wide Groundwater

USEPA (2007d) provides guidance on how to derive a value for the lead exposure point concentration term (PbS) for the child resident exposure scenario. The PbS is the only input parameter of the

Integrated Exposure Uptake Biokinetic Model for Lead in Children (IEUBK) for which a Site-specific value is always required. As stated in the Guidance Manual for the IEUBK Model (USEPA, 2002d), the average, or arithmetic mean lead concentration should be used for the PbS. The water concentrations obtained by these averaging procedures give appropriate central tendency exposure concentration estimates for use in estimating blood lead levels for residential children.

5.5. Intake Equations

The next step in the assessment was to generate estimates of chronic daily intakes (CDIs) based on the magnitude, frequency, and duration of exposure for each identified complete exposure pathway. In accordance with USEPA guidance (USEPA 1989a), RME exposure factors were applied to estimate the CDI from the incidental ingestion, dermal contact, and inhalation pathways. The intake equations applied in the assessment are presented below. The specific variables used in each calculation and their values are defined in the subsections that follow.

Incidental ingestion of COPC from soil or sediment

$$CDI = \frac{C_{soil} \times CF \times IR \times FI \times EF \times ED}{BW \times AT}$$

Dermal uptake of COPC from soil or sediment

$$DAD = \frac{C_{soil} \times CF \times SA \times ABS \times AF \times EF \times ED}{BW \times AT}$$

Incidental ingestion of COPC in surface, ground, or drinking water

$$CDI = \frac{C_{water} \times IR \times EF \times ED}{BW \times AT}$$

Dermal uptake of COPC in surface or groundwater

$$DAD = \frac{C_{water} \times CF \times SA \times PC \times ET \times EF \times ED}{BW \times AT}$$

Inhalation of airborne constituents in the Exposure Area

$$CDI = \frac{C_{air} \times InR \times ET \times EF \times ED}{BW \times AT}$$

where:

ABS = Dermal absorption factor (unitless)

AF = Soil to skin adherence factor (mg/cm^2)
AT = Averaging time (days)
BW = Body weight (kg)
C_{air} = COPC concentration in air (mg/m^3) (Derivation is presented in Section 2.4.7)
$C_{sediment}$ = Sediment exposure point concentration (mg/kg)
C_{sw} = Concentration of each constituent in surface water (mg/L)
C_{water} = Concentration of each constituent in drinking water (mg/L)
CDI = Chronic daily intake (mg/kg-day)
CF = Conversion factor (10^{-6} kg/mg for soil and 10^{-3} L/mL for water)
DAD = Dermal absorbed dose (mg/kg-day)
ED = Exposure duration (years)
EF = Exposure frequency (days/year)
ET = Exposure time (hours/day)
FI = Fraction ingested from contaminated source (unitless)
IR = Ingestion rate for soil (mg/day) or water (L/day)
InR = Inhalation rate (m^3/hour)
PC = Permeability Coefficient (cm/hour)
SA = Skin surface area for dermal absorption (cm^2)

5.6. RME and CT Parameter Estimates

The RAGS D Table 4 series and Appendix E present the parameter values used for each receptor and the rationale for selecting each value. The parameters are also summarized below.

ABS: Dermal absorption factor (unitless). The dermal absorption factor represents the fraction of the constituent in soil that may be absorbed through the skin over each exposure event. These values are chemical-specific and are presented in Appendix F.

AF: Soil to skin adherence factor (mg/cm^2). Soil to skin adherence factors (AF) represent the average mass of soil which adheres to the skin over each exposure event. Based on the July 19, 2004 comments from NYSDEC on the 2002 HHRA report, the adherence factors for particular receptors were updated to reflect conditions under the RME and CT scenarios. These new values were taken from *RAGS E Supplemental Guidance for Dermal Risk Assessment* (USEPA 2004b). These values are presented in RAGS D Tables 4.1 RME through 4.16 CT.

AT: Averaging time (days). The averaging time is the period of time over which exposure is averaged. In accordance with USEPA guidance (USEPA 1989a), the averaging time for exposure to potential carcinogenic compounds is 25,550 days. This accounts for averaging of exposure to a carcinogenic substance over a 70-year lifetime. For exposure to non-carcinogens, the averaging time is calculated as the exposure duration (years) multiplied by 365 days per year. Therefore, the averaging time for exposure to non-carcinogenic substances varies for receptors based on their exposure duration. These values are presented in RAGS D Tables 4.1 RME through 4.16 CT.

BW: Body weight (kg). The body weight estimates are receptor-specific for adults, adolescents, and children. For adults, the body weight of 70 kg (USEPA 1991) was applied as a default, which is slightly less than the mean body weight for men and women aged 18 to 74 years in the United States (71.8 kg). For adolescents, a body weight of 45 kg was used, which is the value recommended by

USEPA based on body weight for males aged 7 to 16 in the United States (USEPA 2000). For children, a body weight of 15 kg was used which corresponds to the average body weight for males and females aged 6 months to 6 years in the United States (USEPA 1997a). These values are presented on RAGS D Table 4 Series.

C_{water} and $C_{soil/sed}$: Concentration of each constituent in ground/surface water (µg/L) and soil/sediment (mg/kg). The lower of the 95 percent upper confidence limit (UCL) and the maximum concentration was selected as the RME exposure point concentration. These values are presented in the RAGS D Tables 3 Series.

C_{air}: Inhalation exposure point concentration (mg/m^3). The concentrations of constituents in ambient air were estimated using the algorithms presented by USEPA for exposure to airborne VOCs and dust (USEPA 1996, 2002a). The PEF and VF values used to calculate the inhalation EPC from the soil EPC are derived in Appendices F and G, respectively. The C_{air} values are presented on RAGS D Table 7.5.

ED: Exposure duration (years). The exposure duration estimates the time period over which a receptor is exposed. This parameter is receptor-specific. These values are presented in the RAGS D Table 4 series and Appendix E.

EF: Exposure frequency (days/year). The exposure frequency is a receptor-specific parameter that estimates the time period over which the receptor exposure occurs. These values are presented in the RAGS D Table 4 series and Appendix E

ET: Exposure time (hours/day). This parameter is receptor-specific for dermal contact with water. These values are presented in the RAGS D Table 4 series and Appendix E

IR_{water}: Ingestion rate for water (L/hour). The ingestion rate applied to the adolescent trespasser at Tributary 5A is for incidental ingestion during temporary contact with water. These values are presented on RAGS D Table 4.11a RME and CT, and Appendix B. Since the Site is also being considered as a hypothetical drinking water source area, an incidental ingestion rate was applied for the hypothetical adult and child resident. These values are presented on RAGS D Table 4.16 RME and CT and Appendix E.

IR_{soil}: Incidental ingestion rate for soil (mg/day). Incidental ingestion rates were applied to the potential receptors for incidental ingestion during activities on the Exposure Areas. These values are presented in the RAGS D Table 4 series and Appendix E.

InR: Inhalation rates (m^3/hour). InR are affected by several individual characteristics, including age, gender, weight, health status, and activity level (sitting, running, walking, etc.). These values are presented in the RAGS D Table 4 series and Appendix E.

PC: Permeability Coefficient (cm/hour). The permeability coefficient represents the rate at which dissolved constituents in water migrate across the skin into the bloodstream. Chemical specific dermal permeability coefficients compiled and published by USEPA (2004a) were applied. The constituent specific values are presented in Appendix F.

SA: Skin surface area for dermal absorption (cm^2). This parameter represents the exposed surface area of the skin, which may contact water or soil. These values are presented in the RAGS D Table 4 series and Appendix E.

The revised RAGS D Table 4 series reflects Honeywell's September 5, 2007 letter detailing responses to NYSDEC comments on the Revised 2004 HHRA (Appendix G1) as well as Honeywell's 2008 responses to NYSDEC comments (Appendix G2). The revised RAGS D Table 4 series also reflects specific comments discussed during a conference call with NYSDEC, USEPA, Honeywell, and O'Brien & Gere on May 30, 2007. The exposure factors utilized for the selected receptors for this assessment are presented in the RAGS D Table 4 series and are summarized in Appendix E. For those exposure factors that could not be easily explained in Appendix E, further justification for selection of these factors is provided below.

5.6.1. Mutagenic Mode of Action Constituents

Chemicals exhibiting a mutagenic mode of action (MMOA) were addressed in the HHRA using Age-Dependent adjustment factors (ADAFs) as described in USEPA's "Supplemental Guidelines for Assessing Susceptibility From Early Life Exposure to Carcinogens" ("Supplemental Guidance") (USEPA 2005). This ADAF evaluation required the modification of the Table 4 Series to include the specific age categories (bins) identified in the Supplemental Guidance (0 to 2 years, 2 to 16 years, >16 years, and all subgroups within these age bins). This ADAF evaluation was derived specifically for this assessment by using the Wastebeds 1-8 Bike Trail HHRA (USEPA 2007c) as an example. The ADAF evaluation is also included in the RAGS D Table 7 series for the child and adolescent receptors.

5.6.2. Exposure Frequency for Industrial Worker

The revised RAGS D Table 4 series includes an exposure frequency for outdoor exposure to surface soil of 188 days per year for a reasonable maximum exposure (RME) scenario and 164 days per year for a central tendency (CT) exposure scenario. These values are departures from the recommended 250 days per year (RME) and 219 days per year (CT) value as noted in USEPA (2004b) RAGS Part E.

The RME EF of 188 days assumes 250 work days per year with exposure reduced by 25% due to snow cover. Similarly for the CT EF, 219 work days per year reduced by 25% due to snow cover yields a CT value of 164 days.

The snow cover percentage of 25% is derived from a thirty year (1972-2000) temperature and snowfall record for Syracuse, NY from the National Weather Service (available at http://www.erh.noaa.gov/bgm/climate/syr/syr_normals.shtml). During the months of December, January, and February, there is on average measurable snowfall (28.6, 33.2, and 24.0 inches, respectively), and average temperatures are below freezing (28.6, 22.7, and 24.5 °F, respectively). Therefore, it can be assumed that snow that falls during these months does not readily melt and provides continuous snow cover. Since the three months include 90 of the 365 days in a year, snow cover percentage of 25% is derived. This percentage is conservative in that the months of March and November are not included. March and November on average have measurable snowfall (18.8 and 11.1 inches, respectively), but also have average temperatures above freezing (33.6 and 39.7 °F, respectively).

The Climate of New York issued by the New York State Climate Office (http://nysc.eas.cornell.edu) also describes a three month period of snow cover for the Syracuse area: "The Southern Plateau, Great Lakes Plain in southern portions of western upstate New York, and the Hudson Valley experience a continuous snow cover from about mid-December to mid-March, with maximum depths usually occurring in February."

5.6.3. Exposure Frequency for Adolescent Trespasser

The RME and CT exposure frequencies for the adult and adolescent trespassers are 42 and 32 days/year, respectively. These values are consistent with the Wastebed B/Harbor Brook HHRA. The 42-day EF is based on the assumption that the trespassing occurs twice per week during the ten summer weeks and once per week during the 22 weeks when the temperature is above 50°F (Appendix G2).

5.6.4. Exposure Frequency for Surveillance Worker

The exposure frequency for the surveillance worker is 31 days/year for the RME scenario and 5 days per year for the CT exposure scenario. These values are adjusted for the amount of time per day spent on the Site outside the vehicle. The RME scenario assumes that the surveillance worker is outside of his or her vehicle for one hour each day. The RME for industrial workers is 250 days/year. This value (250 days/year) is multiplied by 0.125 (1/8 or one hour of exposure divided by an eight hour workday) yielding an exposure frequency of 31 days/year. The exposure frequency for the CT scenario was developed in a similar manner but assumes that the surveillance worker is exposed to Site-related constituents for 10 minutes a day. This approach is consistent with NYSDEC comment 49 in Honeywell's December 2, 2004 response letter to NYSDEC (Honeywell 2004; Appendix H), as well as NYSDEC (2008) comment 11.

5.6.5. Incidental Ingestion of Water for the Construction Worker, Utility Worker, and Adolescent Trespasser

With regard to the incidental ingestion of water for the construction worker, utility worker, adolescent trespasser, and adult trespasser the RME and CT ingestion rates are 0.03 and 0.01 L/day, respectively. Section 6.6.1 of RAGS Part A presents an incidental ingestion rate of 0.05 L/hr for a swimmer (USEPA 1989a). For a non-swimmer, the RME incidental ingestion rate has been estimated to be lower (0.03 L/hr for 1 hr/day), resulting in an ingestion rate of 0.03 L/day. For the CT incidental ingestion rate, a value of 0.01 L/day is used based on best professional judgment.

5.7. Site Exposure Pathway Analyses

The receptor populations, exposure medium, exposure frequencies, and duration are discussed for current and future land uses below.

Current/Future Adolescent and Adult Trespassers: The adolescent and adult trespasser receptors may be exposed to constituents in surface soils via incidental ingestion and dermal contact in all the Exposure Areas except Tributary 5A and groundwater. In the Tributary 5A, they may be exposed to sediment and surface water through ingestion and dermal contact.

Current/Future Surveillance Workers: Surveillance workers in the Plant Area, On-Site Ditches, and FCB may ingest or have dermal contact with surface soils.

Current/Future Utility Workers: Utility workers in the State Fair Blvd./Northwest Off-Site/Outfall 004 Exposure Area may have dermal contact or incidental ingestion of upper soils. Utility workers at the Lakeshore Area may have dermal contact or incidental ingestion of upper soils or shallow groundwater.

Current/Future Transient Adult: The State Fair Blvd./Northwest Off-Site/Outfall 004 area includes a transient adult receptor that may be exposed to surface soil through dermal contact or incidental ingestion.

Future Construction Workers: Construction workers in the Plant Area, On-Site Ditches, FCB, Southwest Off-Site/Outfall 006, PSA, and CHSA may be exposed to constituents in upper soils via dermal contact, incidental ingestion, or inhalation. In addition, construction workers in the PSA and CHSA may be exposed to shallow groundwater through dermal contact or incidental ingestion.

Future Industrial Workers. Future industrial workers in the Plant Area, On-Site Ditches, FCB, SW Off-Site/Outfall 006, PSA, and CHSA may be exposed to constituents in surface soils via incidental ingestion or dermal contact. In addition, a soil vapor survey performed at the Site detected concentrations of chlorobenzenes, benzene, and mercury in soil vapor at certain locations of the Site. Constituents in soil vapor may migrate to indoor air of buildings constructed at the Plant Area, PSA, and CHSA in the future.

Future Utility Workers: Utility workers at the Plant Area, On-Site Ditches, and FCB may be exposed to intermediate soils as well as intermediate groundwater through dermal contact and incidental ingestion. Utility workers in the PSA and CHSA may be exposed to constituents in upper soils and shallow groundwater through dermal contact and incidental ingestion. Utility workers in Tributary 5A may have dermal contact or ingestion of upper sediment or surface water.

Future Adult and Child Residents: Adult and child residents could be exposed to constituents through ingestion of site-wide groundwater as potable water.

6. Toxicity Assessment

In the toxicity assessment, available toxicological data summaries for Site-related compounds are reviewed and the relationships between the extent of exposure to a specific contaminant and the increased likelihood and/or severity of adverse effects are estimated. The potential toxicological effects induced by a given dose of a chemical are classified according to two criteria: 1) carcinogenic effects and 2) non-carcinogenic effects.

6.1. Non-Carcinogenic Effects

Non-carcinogenic health effects occur as a result of damage to cells in one or more human organ, which cause the organ(s) to function less efficiently. Due to the ability of the body to cope with small doses of a chemical, a non-cancer health effect will not occur if intake of a chemical is less than a certain critical dose. This is referred to as a no-observed-adverse-effect-level (NOAEL) for a constituent. If the calculated intake of a chemical is less than the NOAEL for that constituent in a given species, no adverse non-cancer health effects are expected as a result of that exposure.

The specific non-carcinogenic toxic effects that may occur depend on the exposure concentration and the duration of exposure. If an individual is exposed to very high concentrations of a constituent, severe organ dysfunction can occur in a short period of time. This is termed an acute toxic effect. If an individual is exposed to lower levels of a chemical regularly for a long period of time, smaller amounts of repeated damage to the organ can accumulate and ultimately cause the organ to malfunction. These are termed sub-chronic or chronic toxic effects (depending on the exposure duration).

6.1.1. Reference Doses

In order to evaluate potential non-carcinogenic effects following exposure of human populations to chemicals, the USEPA derives chemical-specific “reference doses” (RfDs). If the calculated intake of a chemical is less than the published RfD, no adverse non-carcinogenic effects are expected in the exposed population. A brief discussion of the methods by which RfDs are derived is presented below.

For some constituents, RfDs are derived directly from data on human exposures. Such data includes data relating to occupational exposures that are known to have no adverse effects, normal dietary levels of certain chemicals, therapeutic doses of certain chemicals and epidemiological data relating to populations with background exposures. For most constituents, the USEPA derives RfDs based on laboratory studies, which exposes experimental animals to different concentrations of a constituent and estimates a NOAEL. If data from several animal studies are available, the USEPA seeks to identify the species that is most comparable to humans based on knowledge of specific biologic properties. However, if adequate comparative data is not available, the USEPA selects the study on the most sensitive animal species as the critical study for the basis of the NOAEL. The NOAEL is then used to derive an RfD for potential adverse effects in human populations.

6.1.2. RfD Uncertainty Factors

In most cases, there is considerable uncertainty regarding the extension of toxicological data from animal studies to humans. In other words, the actual RfD for humans or sensitive sub-populations of humans would not be precisely known based on data in animal species. This uncertainty arises because there may be differences between the animal and human species regarding factors such as the metabolism of the chemical, the distribution and clearance rate of the chemical from the body, and the sensitivity of specific organ systems to the chemical. Therefore, the USEPA derives RfDs that are designed to be protective of the public at large, including sensitive sub-populations. The USEPA applies a series of "uncertainty" factors to calculate the final RfD values. Depending on the data, the NOAEL may be divided by an uncertainty factor ranging from 1 to 10,000. Specifically, uncertainty factor values may be used to account for one or more of the following sources of uncertainty:

- to account for variation in the general population and to protect sensitive subpopulations;
- to extrapolate from animal bioassays to human populations (interspecies variability);
- when a NOAEL derived from a subchronic study instead of a chronic study is used as a basis for a chronic RfD; and
- when a LOAEL is used instead of a NOAEL.

6.2. Carcinogenic Effects

The other health effect of concern in the exposure of humans to chemicals in the environment is the induction of cancer. Carcinogenic effects are discussed by weight of evidence (Section 6.2.1) and slope factors (Section 6.2.2).

6.2.1. Weight of Evidence

The USEPA classifies chemicals according to their potential to induce cancer in humans. In general, the USEPA reviews and evaluates available data regarding the potential carcinogenic effects of a constituent, and assigns a "carcinogenicity" classification according to a weight of evidence classification (RAGS D Tables 6.1 and 6.2; Attachment A). A constituent may be classified into one of five groups with respect to the weight of evidence for human carcinogenicity.

- Group A - Known Human Carcinogen. A constituent is classified as Group A if there is sufficient[3] evidence from human observations (epidemiological studies) to support an association between exposure to a chemical agent and cancer in humans.

- Group B - Probable Human Carcinogen. A constituent may be classified as a B1 or a B2 carcinogen. An agent is classified as a B1 carcinogen if there is sufficient evidence for carcinogenicity based on animal studies and limited[3] (suggestive but not conclusive) evidence based on human observations. A B2 carcinogen is an agent for which there is sufficient evidence for carcinogenicity in animals and inadequate evidence for carcinogenicity in humans.

3 The definition of the terms “sufficient”, limited, and adequate are given in USEPA 1986, Guidelines for Carcinogenic Risk Assessment, (51 FR 33992).

- Group C - Possible Human Carcinogen. An agent is classified as a Group C carcinogen if there is limited evidence for carcinogenicity in animals and inadequate evidence for carcinogenicity in humans.

- Group D - An agent is classified as a Group D agent if there is insufficient data available with which to evaluate the carcinogenicity of the chemical.

- Group E - An agent is classified as a Group E agent if there is no evidence for carcinogenic effects based on at least two technically adequate animal studies.

6.2.2. Slope Factors

For group A, B, or C constituents, the USEPA derives chemical-specific cancer slope factors (RAGS D Tables 6.1 and 6.2; Attachment A). A cancer slope factor (CSF) is a number which, when multiplied by the estimated chemical-specific CDI, provides an estimate of the "excess cancer risk" associated with that exposure. Theoretically, the excess cancer risk represents the probability (greater than background) that a carcinogenic event would occur in an individual as a result of a given exposure or pattern of exposures. However, it is important to note that for many constituents the excess cancer risk as calculated by the USEPA procedure may result in a highly conservative estimate of the potential cancer risk. As acknowledged by USEPA (Federal Register 1986), the procedure "does not necessarily give a realistic prediction of the risk. The true value of the risk is unknown, and may be as low as zero."

6.3. Toxicity Summaries

For each constituent that was retained as a COPC, human toxicological effects, including chronic RfDs and CSFs were compiled from the following hierarchy of sources as outlined in the OSWER Directive 9285.7-53, *Human Health Toxicity Values in Superfund Risk Assessments* (USEPA 2003b):

- Tier 1 - EPA's Integrated Risk Assessment System (IRIS).
- Tier 2 - Provisional Peer-Reviewed Toxicity Values (PPRTV) used in USEPA's Superfund Program.
- Tier 3 - Other (peer-reviewed) toxicity values, including:
  - Minimal Risk Level produced by the Agency for Toxic Substances and Disease Registry (ATSDR),
  - California Environmental Protection Agency (CalEPA) values, and
  - EPA Health Effects Assessment Summary Table (HEAST) values.

Third tier toxicological values were not used in this assessment unless these values were supplied by the USEPA Superfund Technical Support Center (STSC).

The non-cancer toxicity values applied in the risk characterizations of oral/dermal exposures evaluated in this report are presented in RAGS D Table 5-1. Non-cancer toxicity values applied for the inhalation of outdoor air is presented in RAGS D Table 5-2. The CSF applied in the risk characterizations of oral/dermal exposures evaluated in this document are presented in RAGS D Table 6-1. Cancer Unit Risk factors used to evaluate the exposure to outdoor air through the inhalation pathway are presented in RAGS D Table 6-2. All values in RAGS D Tables 5 and 6 were

taken either from IRIS or were supplied by the STSC. Toxicity profiles for select COPCs, which significantly contribute to the derived risk estimates, are presented in Attachment L-D.

The values provided by the STSC can be divided into two groups. The first group of toxicity values provided by the STSC is labeled as "PPRTV" in RAGS D Tables 5 and 6. The PPRTV label indicates that the value was presented in a PPRTV Information report supplied to Honeywell by the USEPA. The date associated with the PPRVT value is the date of the specific report for that constituent (*e.g.*, RfC for aluminum, PPRTV report dated October 23, 2006).

The second group of toxicity values provided by the STSC is labeled in RAGS D Tables 5 and 6 according to their original source (ATSDR, HEAST, CalEPA, *etc*.). The use of these toxicity values was approved by the USEPA in electronic mail communications to Honeywell (Appendix I) but there are no PPRTV reports associated with these toxicity values. For example, a March 27, 2008 email (USEPA 2008) from R. Nunes (US EPA Region II) to T. Conklin and P. Sinha (O'Brien & Gere) contained a spreadsheet that endorsed values for several constituents from these sources (ATSDR, HEAST, and CalEPA). This spreadsheet lists a CalEPA value for the arsenic RfC. The source of the RfC is listed as CalEPA (STSC) in the RAGS D Table 5.2 to indicate that this value originated from the CalEPA website and was approved by the STSC as per the March 27, 2008 email. The dates listed on RAGS D Tables 5 and 6 series for the toxicity values selected from these sources follows USEPA protocol (current dates for electronic sources (CalEPA) and date of publication for non-electronic sources).

6.3.1. Constituents with a Mutagenic Mode of Action

Those constituents listed in the USEPA's 2006 Memorandum (USEPA 2006a) as having a MMOA are subject to adjustment by an ADAF, which will be applied to the risk calculations performed for the RAGS D Table 7 series. It should be noted that other PAHs are considered toxicologically related to benzo(a)pyrene, based on the *Provisional Guidance for Quantitative Risk Assessment of Polycyclic Aromatic Hydrocarbons* (USEPA 1993a). Although these are not included on the list of chemicals with a MMOA (USEPA 2006a), they are subject to an ADAF as well.

6.3.2. Adjustment for Dermal Toxicity

Assessing toxicity associated with dermal exposure to constituents in soil and water requires special considerations. Dermal toxicity of a substance depends on factors including the analyte concentration, the potential dose, the area of skin surface exposed, the exposure duration, the absorption of the analyte through the skin, the absorbed dose, and the amount of analyte that can be delivered to a target organ (*i.e.*, biologically effective dose) (USEPA 1997a).

In most instances, it was necessary to use oral toxicity data to estimate dermal toxicity. The dermal chronic daily intake (CDI) represents the absorbed dose of the analyte. However, for many constituents, the oral toxicity data is based on the administered dose rather than the absorbed dose. Therefore, in order to assess dermal exposures, the oral toxicity values were adjusted to reflect the absorbed dose in accordance with USEPA guidance (USEPA 2004b) as follows:

$$RfD_{dermal} = RfD_{oral} \times \text{Gastrointestinal Absorption Efficiency}$$

$$CSF_{dermal} = CSF_{oral} / \text{Gastrointestinal Absorption Efficiency}$$

The absorption efficiency data used for evaluating dermal exposures were obtained from Exhibit 4-1 in RAGS Part E (USEPA 2004b).

6.4. Evaluation of Toxicity for Special Constituent Classes

Special constituent classes that required additional evaluation include chlorinated dioxins and furans (Section 6.4.1), PCBs (Section 6.4.2), PAHs (Section 6.4.3), and chromium (Section 6.4.4), as discussed below. The approach used to apply surrogate compounds for the evaluation of compounds that do not have toxicity data is also discussed (Section 6.4.5). IRIS provides toxicity reference values for mercuric chloride, which is a more toxic form of mercury than elemental mercury. For the assessment of mercury, the toxicity values of mercuric chloride were applied with recognition of the conservative nature of its application.

6.4.1. Toxicity Equivalents for Chlorinated Dioxins and Furans

Toxic Equivalency Factors (TEFs) were applied to assess the human health risks related to exposure to chlorinated dioxins and chlorinated furans. TEFs utilized within this report were provided by Van den Berg *et* al. (2006). The TEFs are located in the *Derivation of toxicity equivalents for dioxins* tables in the RAGS Table 2 Series. A discussion of the TEFs used for quantitative health risk assessment of dioxin and furans is presented below. A more detailed discussion of dioxin toxicity in animals and humans is presented in Section 8.

To facilitate the evaluation of mixtures of PCDD/Fs regulatory authorities have used a TEF approach, a widely accepted approach used by the scientific and regulatory communities in many parts of the world (USEPA 1989b, ATSDR 1997, WHO 1998). 2,3,7,8-tetrachloro-dibenzo-p-dioxin (2,3,7,8-TCDD) is the most widely studied chlorinated dioxin; most of the PCDD/F congeners have not been tested as extensively as 2,3,7,8-TCDD. Available data indicates that some of the congeners may display toxic properties, even though they are less potent than 2,3,7,8-TCDD. The TEF approach assigns a relative potency factor (relative to 2,3,7,8-TCDD) for each PCDD/F congener. The TEFs are based on observed structure activity relationships for PCDD/F compounds, receptor binding affinity or enzyme induction.

6.4.2. Polychlorinated Biphenyls

The IRIS database provides toxicity data for Aroclors 1016, 1248, and 1254. The Aroclors detected at the site consisted of Aroclors 1016, 1242, 1248, 1254, 1260, and 1268. Aroclors with the percent chlorine less than or equal to 42 (*i.e.,* Aroclor 1016 and 1242) will use the RfD for Aroclor 1016. Aroclors with percent chlorine greater than 42 (*i.e.,* Aroclor 1248, 1254, 1260 and 1268) will use the RfD for Aroclor 1254.

6.4.3. Polycyclic Aromatic Hydrocarbons

The USEPA IRIS database has published a CSF for benzo(a)pyrene of $7.3x10^{0}$ $(mg/Kg\text{-}day)^{-1}$. Using this value and TEFs for carcinogenic PAHs, the oral CSF can be calculated for benzo(a)anthracene (TEF = 0.1), benzo(b)fluoranthene (TEF = 0.1), benzo(k)fluoranthene (TEF = 0.01), chrysene (TEF = 0.001), dibenzo(a,h) anthracene (TEF = 1.0), and indeno(ghi)pyrene (TEF = 0.1) (ORNL 2004).

The CSFs for benzo(a)pyrene for oral, dermal and inhalation exposures are $7.3x10^{0}$ $(mg/Kg\text{-}day)^{-1}$, $2.4\ x10^{1}$ $(mg/Kg\text{-}day)^{-1}$, and $3.1\ x10^{0}$ $(mg/Kg\text{-}day)^{-1}$, respectively. Utilizing the above TEFs, the CSFs were calculated for the carcinogenic PAHs for dermal exposure. The inhalation CSF was calculated

from the inhalation unit risk as described in supplemental guidance from the *Provisional Guidance for Quantitative Risk Assessment of Polycyclic Aromatic Hydrocarbons* (USEPA 1993a).

6.4.4. Chromium

In this report, the toxicity value of hexavalent chromium was used as a surrogate for unspeciated chromium; this is a conservative assumption. The USEPA IRIS database provides a discussion on the carcinogenicity of hexavalent chromium and a published CSF for inhalation of 4.2×10^{1} $(mg/Kg\text{-}day)^{-1}$.

6.4.5. Surrogates

Surrogate compounds were utilized in the absence of toxicity data as summarized as summarized below. The selection of the surrogate compounds was based on professional judgment regarding the similarity of the COPC to the surrogate compound.

Table 6.1. *Summary of Surrogates*.

Constituent	Notes
Chromium	Because chromium was not speciated, RfC, RfD, and inhalation unit risk values for chromium VI were utilized.
Less Chlorinated PCBs	Less chlorinated includes Aroclors 1221, 1232, 1016, and 1242. RfD values for Aroclor-1016 (CAS# 126741120) utilized.
Highly Chlorinated PCBs	Highly Chlorinated includes Aroclors 1248, 1254, 1260 [and higher if reported]. RfD values for Aroclor-1254 (CAS# 11097691) utilized.
Mercury	RfC and RfDi for elemental mercury were used because the corresponding values for methyl mercury were unavailable. Mercuric chloride used as a surrogate for oral/dermal RfD value.
PAH's	For carcinogenic PAHs, relative potency approach with respect to benzo(a)pyrene applied to estimate Oral Cancer Slope Factor (see USEPA 1993a *Provisional Guidance for Quantitative Risk Assessment of Polycyclic Aromatic Hydrocarbons*, EPA/600/R-93/089).
Vanadium	Vanadium pentoxide as surrogate for oral/dermal RfD value.
Endosulfan I	Endosulfan used as a surrogate for oral/dermal RfD value.

7. Risk Characterization

In this section of the HHRA, the toxicity and exposure assessments are summarized and integrated into numerical values that may be used to evaluate the likelihood of adverse health effects in populations potentially exposed to Site-related chemicals. RME and CT estimates of potential health risks were developed for each potentially exposed receptor at the Site.

Chronic non-cancer health effects were evaluated by comparing the chemical-specific CDIs with the respective chronic RfD as given below.

1. For each receptor identified during the exposure assessment and each individual exposure pathway, the chemical-specific hazard quotients (HQs) were calculated where HQ is given by:

   Hazard Quotient = CDI/RfD

2. For each exposure pathway, the chemical-specific hazard quotients were summed to calculate the Hazard Index (HI) for that pathway. For each receptor, the pathway specific hazard indexes were summed to obtain the total HI for that receptor. A total HI of less than one indicates that it is highly unlikely that chronic non-cancer toxic effects would occur for the given receptor.

To evaluate carcinogenic effects, the incremental cancer risk associated with exposure to chemicals of concern was calculated using chemical-specific slope factors as described below.

1. For each receptor identified during the exposure assessment and each exposure pathway, the chemical-specific risk is given by:

   Cancer risk = CDI * slope factor.

2. For each receptor, the total incremental excess cancer risk was calculated by summing the pathway specific cancer risk. This calculated risk estimate was then compared with an acceptable range of excess cancer risks of between 10^{-4} and 10^{-6} (40 CFR §300.430[e][2][I][A][2]; CFR 2004).

Details of the chemical-specific, pathway-specific and total HIs or cancer risk for each Exposure Area and receptor are given on RAGS D Tables 7.1 RME through 7.10 CT. Summaries of HIs and cancer risks for each receptor are given by AOS in RAGS D Tables 9.1 RME through 9.25 CT. A brief discussion of the RME risk estimates associated with each receptor is presented below.

7.1. Plant Area

7.1.1. Current/Future Receptors

Adolescent Trespasser

The calculated RME HI for the current and future adolescent trespasser is 1.3 and the calculated cancer risk is 4×10^{-5} (RAGS D Table 7.1a RME; Attachment A). The corresponding CT HI and cancer risk are 0.9 and 2×10^{-5}, respectively (RAGS D Table 7.1a CT). There are no unacceptable cancer risks or non-cancer hazards for this receptor.

Adult Trespasser

The calculated total RME HI for the current and future adult trespasser is 0.5, and the calculated cancer risk is 4×10^{-5} (RAGS D Table 7.2a RME). The corresponding CT HI and cancer risk are 0.3 and 6×10^{-6}, respectively (RAGS D Table 7.2a CT). There are no unacceptable cancer risks or non-cancer hazards for this receptor.

Surveillance Worker

The calculated RME HI for the current and future surveillance worker in the Plant Area is 0.6 and the calculated cancer risk is 3×10^{-5} (RAGS D Table7.3a RME; Attachment A). The corresponding CT HI and cancer risk are 0.05 and 1×10^{-6}, respectively (RAGS D Table7.3a CT). There are no unacceptable cancer risks or non-cancer hazards for this receptor.

7.1.2. Future Receptors

Industrial Worker

The calculated RME HI for the future industrial worker in the Plant Area is 1.9 and the calculated RME cancer risk is 9×10^{-5} (RAGS D Table 7.4a RME; Attachment A). The calculated CT HI and cancer risk are 1.4 and 2×10^{-5}, respectively (RAGS D Table 7.4a CT). The HI for the industrial worker under future Site conditions only marginally exceeds the HI threshold of 1, and is driven by the target HI for autoimmune effects (1.3) arising from the ingestion of mercury in surface soils.

Construction Worker

The calculated RME HI for the future construction worker in the Plant Area is 26 and the calculated RME cancer risk is 3×10^{-5} (RAGS D Table 7.5a RME; Attachment A). The calculated CT HI and cancer risk are 14 and 2×10^{-5}, respectively (RAGS D Table 7.5a CT). The HI for the construction worker under future Site conditions exceeds the HI threshold of 1, and is driven by the target HI for nasal/respiratory effects (18) arising from the inhalation of nickel in upper soils.

Utility Worker

The calculated RME HI for the future utility worker in the Plant Area is 5.3 and the calculated cancer risk is 9×10^{-6} (RAGS D Table 7.7a RME; Attachment A). The calculated CT HI and cancer risk are 5.1 and 7×10^{-6}, respectively (RAGS D Table 7.7a CT). The HI for the utility worker under current and future Site conditions exceeds the HI threshold of 1, and is driven by the target HI for autoimmune effects (4) arising from the ingestion of mercury in intermediate soils.

7.2. On-Site Ditches

7.2.1. Current/Future Receptors

Adolescent Trespasser

The adolescent trespasser RME and CT cancer risks at the On-Site Ditches are 6×10^{-5} and 4×10^{-5}, respectively (RAGS D Tables 7.1b RME and 7.1b CT). The RME and CT HIs for these areas are 6.3 and 4.4, respectively (exceeding the HI threshold of 1). The HI is driven by the target value for autoimmune effects (3.5) arising from ingestion of mercury in surface soils, and developmental effects arising from ingestion of 2,3,7,8-TCDD equivalent in surface soils (2.7). There are no unacceptable cancer risks for this receptor.

Adult Trespasser

The adult trespasser RME and CT cancer risks at the On-Site Ditches are 9×10^{-5} and 2×10^{-5}, respectively (RAGS D Tables 7.2b RME and 7.2b CT). The RME and CT HIs for these areas are 2.6 and 1.6, respectively. The HI marginally exceeds the threshold as a result of contributions from autoimmune effects (1.3) arising from ingestion of mercury and developmental effects arising from the ingestion 2,3,7,8-TCDD equivalent in surface soils (1.3). There are no unacceptable cancer risks for this receptor.

Surveillance Worker

The surveillance worker RME and CT cancer risks at the On-Site Ditches are 7×10^{-5} and 3×10^{-6}, respectively (RAGS D Tables 7.3b RME and 7.3b CT). The RME and CT HIs for these areas are 2.9 and 0.3, respectively. The HI marginally exceeds the threshold as a result of contributions from autoimmune effects (1.6) arising from the ingestion of mercury in surface soils. There are no unacceptable cancer risks for this receptor.

7.2.2. Future Receptors

Industrial Worker

The calculated RME HI for the future industrial worker at the On-Site Ditches is 9.1 and the calculated RME cancer risk is 2×10^{-4} (RAGS D Table 7.4b RME; Attachment A). The calculated CT HI and cancer risk are 6.7 and 5×10^{-5}, respectively (RAGS D Table 7.4b CT). The RME cancer risk exceeds the acceptable regulatory range of 1×10^{-4} – 1×10^{-6} and is driven by the target risk value for ingestion of 2,3,7,8-TCDD equivalent in surface soils. The HI for the industrial worker under future Site conditions exceeds the HI threshold, and is driven by the target HI for autoimmune effects (5.1) arising from the ingestion of mercury in surface soils.

Construction Worker

The calculated RME HI for the future construction worker at the On-Site Ditches is 48 and the calculated RME cancer risk is 5×10^{-5} (RAGS D Table 7.5b RME; Attachment A). The calculated CT HI and cancer risk are 39 and 3×10^{-5}, respectively (RAGS D Table 7.5b CT). The HI for the construction worker under future Site conditions exceeds the HI threshold of 1, and is driven by the target HI for autoimmune (29) and nervous system (33) effects arising from the ingestion & inhalation of mercury in upper soils. There are no unacceptable cancer risks for this receptor.

Utility Worker

The utility worker RME and CT cancer risks at the On-Site Ditches are 2×10^{-5} and 2×10^{-5}, respectively (RAGS D Tables 7.7b RME and 7.7b CT). The RME and CT HIs for these areas are 26 and 24, respectively (exceeding the HI threshold of 1). The HI is driven by the target value for autoimmune effects (17) arising from ingestion of mercury in surface soils, and developmental effects arising from ingestion of 2,3,7,8-TCDD equivalent in intermediate soils (9). There are no unacceptable cancer risks for this receptor.

7.3. Former Chlorination Building

7.3.1. Current/Future Receptors

Adolescent Trespasser

The adolescent trespasser RME and CT cancer risks at the Former Chlorination Building are 4×10^{-4} and 3×10^{-4}, respectively (RAGS D Tables 7.1c RME and 7.1c CT), exceeding the 1×10^{-4} threshold. The RME and CT HIs for these areas are 22 and 15, respectively, exceeding the HI threshold of 1. Cancer risk exceeds the acceptable regulatory range of 1×10^{-4} – 1×10^{-6} and is driven by ingestion of 2,3,7,8-TCDD equivalent in upper soils. The non-cancer hazard is driven by developmental effects arising from the ingestion of 2,3,7,8-TCDD equivalent in surface soils (22).

Adult Trespasser

The adult trespasser RME and CT cancer risks at the Former Chlorination Building are 7×10^{-4} and 1×10^{-4}, respectively (RAGS D Tables 7.2c RME and 7.2c CT), exceeding the 1×10^{-4} threshold. The RME and CT HIs for these areas are 11 and 6, respectively, exceeding the HI threshold of 1. Cancer risk exceeds the acceptable regulatory range of 1×10^{-4} – 1×10^{-6} and is driven by ingestion of 2,3,7,8-TCDD equivalent in upper soils. HI exceeds its threshold of 1 and is driven by developmental effects arising from the ingestion of 2,3,7,8-TCDD equivalent in surface soils (10).

The IEUBK model default exposure parameters and Site-specific parameters were to estimate the geometric mean blood lead level in residential children for the site wide potable water ingestion scenario (Appendix J). The predicted geometric mean blood lead level (58.97 ug/L) was combined with the default model geometric standard deviation for child blood lead (1.6 µg/dL) to generate a distribution of blood lead in resident children. The variability in the distribution is due to differences in lead uptake rates for children exposed to the same environmental lead concentrations (Appendix J). The child blood lead distribution was converted to a probability distribution to determine the

probability of exceeding the target blood lead level. This value was calculated to be 10.6%, exceeding the regulatory target of 5%.

Surveillance Worker

The surveillance worker RME and CT cancer risks at the Former Chlorination Building are 5×10^{-4} and 2×10^{-5}, respectively (RAGS D Tables 7.3c RME and 7.3c CT). The RME and CT HIs for these areas are 9.9 and 1, respectively. Cancer risk exceeds the acceptable regulatory range of 1×10^{-4} – 1×10^{-6} and is driven by ingestion of 2,3,7,8-TCDD equivalent in surface soils. HI exceeds its threshold of one and is driven by developmental effects arising from the ingestion and dermal contact of 2,3,7,8-TCDD equivalent in surface soils (9.9).

7.3.2. Future Receptors

Industrial Worker

The calculated RME HI for the future industrial worker at the Former Chlorination Building is 32 and the calculated RME cancer risk is 2×10^{-3} (RAGS D Table 7.4c RME; Attachment A). The calculated CT HI and cancer risk are 21 and 4×10^{-4}, respectively (RAGS D Table 7.4c CT). Cancer risk exceeds the acceptable regulatory range of 1×10^{-4} – 1×10^{-6} and is driven by ingestion of 2,3,7,8-TCDD equivalent in upper soils. HI exceeds its threshold of 1 and is driven by developmental effects arising from the ingestion and dermal contact of 2,3,7,8-TCDD equivalent in surface soils (32).

Construction Worker

The calculated RME HI for the future construction worker at the Former Chlorination Building is 360 and the calculated RME cancer risk is 8×10^{-4} (RAGS D Table 7.5c RME; Attachment A). The calculated CT HI and cancer risk are 339 and 7×10^{-4}, respectively (RAGS D Table 7.5c CT). Cancer risk exceeds the acceptable regulatory range of 1×10^{-4} – 1×10^{-6} and is driven by ingestion of 2,3,7,8-TCDD equivalent in upper soils. HI exceeds its threshold of 1 and is driven by developmental effects arising from the ingestion and dermal contact of 2,3,7,8-TCDD equivalent in surface soils (355).

Utility Worker

The utility worker RME and CT cancer risks at the Former Chlorination Building are 7×10^{-4} and 6×10^{-4}, respectively (RAGS D Tables 7.7c RME and 7.7c CT), exceeding the 1×10^{-4} threshold. The RME and CT HIs for these areas are 312 and 260, respectively (exceeding the HI threshold of 1). Cancer risk exceeds the acceptable regulatory range of 1×10^{-4} – 1×10^{-6} and is driven by ingestion of 2,3,7,8-TCDD equivalent in upper soils. HI exceeds its threshold of 1 and is driven by developmental effects arising from the ingestion and dermal contact of 2,3,7,8-TCDD equivalent in surface soils (310).

7.4. Southwest Off-Site/Outfall 006 Exposure Area

7.4.1. Current Receptors

Adolescent Trespasser

The adolescent trespasser RME and CT cancer risks at the Southwest Off-Site/Outfall 006 Exposure Area are 4×10^{-5} and 2×10^{-5}, respectively (RAGS D Tables 7.1d RME and 7.1d CT). The RME and

CT HIs for these areas are 2.5 and 1.6, respectively (marginally exceeding the HI threshold of 1). The HI is driven by the target value for autoimmune (0.7) and ocular (0.6) effects arising from ingestion and dermal contact of highly chlorinated PCBs and ingestion of mercury in surface soils. There are no unacceptable cancer risks for this receptor.

Adult Trespasser

The adult trespasser RME and CT cancer risks at the Southwest Off-Site/Outfall 006 Exposure Area are 4×10^{-5} and 6×10^{-6}, respectively (RAGS D Tables 7.2d RME and 7.2d CT). The RME and CT HIs for these areas are 1.3 and 0.7, respectively. There are no unacceptable cancer risks or non-cancer hazards for this receptor.

7.4.2. Future Receptors

Industrial Worker

The calculated RME HI for the future industrial worker at the Southwest Off-Site/Outfall 006 Exposure Area is 3.6 and the calculated RME cancer risk is 9×10^{-5} (RAGS D Table 7.4d RME; Attachment A). The calculated CT HI and cancer risk are 2.2 and 1×10^{-5}, respectively (RAGS D Table 7.4d CT). The HI for the industrial worker under future Site conditions only marginally exceeds the HI threshold of 1, and is driven by the target HI for autoimmune effects (3.2) arising from the ingestion of mercury in surface soils. There are no unacceptable cancer risks for this receptor.

Construction Worker

The calculated RME HI for the future construction worker at the Southwest Off-Site/Outfall 006 Exposure Area is 75 and the calculated RME cancer risk is 2×10^{-4} (RAGS D Table 7.5d RME; Attachment A). The RME cancer risk exceeds acceptable regulatory range of 1×10^{-4} – 1×10^{-6}, and is driven by the cancer risk arising from inhalation of benzene in upper soils (1.4×10^{-4}). The calculated CT HI and cancer risk are 45 and 9×10^{-5}, respectively (RAGS D Table 7.5d CT). The HI for the construction worker under future Site conditions exceeds the H1 threshold of 1, and is driven by the target HI for autoimmune (58) effects arising from the inhalation and ingestion of benzene in upper soils.

7.5. State Fair Blvd./Northwest Off-Site/Outfall 004 Exposure Area

7.5.1 Current/Future Receptors

Adolescent Trespasser

The adolescent trespasser RME and CT cancer risks at the State Fair Blvd./Northwest Off-Site/Outfall 004 Exposure Area are 4×10^{-6} and 3×10^{-6}, respectively (RAGS D Tables 7.1e RME and 7.1e CT). The RME and CT HIs for these areas are 0.4 and 0.3, respectively. There are no unacceptable cancer risks or non-cancer hazards for this receptor.

Adult Trespasser

The adult trespasser RME and CT cancer risks at the State Fair Blvd./Northwest Off-Site/Outfall 004 Exposure Area are 6×10^{-6} and 1×10^{-6}, respectively (RAGS D Tables 7.2e RME and 7.2e CT). The

RME and CT HIs for these areas are 0.2 and 0.1, respectively. There are no unacceptable cancer risks or non-cancer hazards for this receptor.

State Fair Boulevard transient

The RME and CT cancer risks at the State Fair Blvd./Northwest Off-Site/Outfall 004 Exposure Area for the State Fair Boulevard transient are 6×10^{-7} and 8×10^{-8}, respectively (RAGS D Tables 7.6 RME and 7.6 CT). The RME and CT HIs for these areas are 0.07 and 0.009, respectively. There are no unacceptable cancer risks or non-cancer hazards for this receptor.

Utility Worker

The utility worker RME and CT cancer risks at the State Fair Blvd./Northwest Off-Site/Outfall 004 Exposure Area are 2×10^{-6} and 1×10^{-6}, respectively (RAGS D Tables 7.7d RME and 7.7d CT). The RME and CT HIs for these areas are 1.2 and 1.1, respectively, only marginally exceeding the HI threshold of 1. Contributors to the HI include developmental effects arising from the ingestion of 2,3,7,8-TCDD equivalent (0.6) and autoimmune effects (0.5), arising from the ingestion of mercury, both in upper soils. There are no unacceptable cancer risks or non-cancer hazards for this receptor.

7.6. Lakeshore Area

7.6.1. Current/Future Receptors

Adolescent trespasser

The adolescent trespasser RME and CT cancer risks at the Lakeshore Area are 3×10^{-5} and 1×10^{-5}, respectively (RAGS D Tables 7.1f RME and 7.1f CT). The RME and CT HIs for these areas are 0.2 and 0.1, respectively. There are no unacceptable cancer risks or non-cancer hazards for this receptor.

Adult Trespasser

The adult trespasser RME and CT cancer risks at the Lakeshore Area are 2×10^{-5} and 3×10^{-6}, respectively (RAGS D Tables 7.2f RME and 7.2f CT). The RME and CT HIs for these areas are 0.1 and 0.05, respectively. There are no unacceptable cancer risks or non-cancer hazards for this receptor.

Utility Worker

The utility worker RME and CT cancer risks at the Lakeshore Area are 4×10^{-5} and 3×10^{-5}, respectively (RAGS D Tables 7.7e RME and 7.7e CT). The RME and CT HIs for these areas are 15 and 14, respectively, exceeding the H1 threshold of 1. The HI is driven by autoimmune effects (10) arising from dermal contact with benzene in shallow groundwater. There are no unacceptable cancer risks for this receptor.

7.7. Petroleum Storage Area

7.7.1. Current Receptors

Adolescent Trespasser

The adolescent trespasser RME and CT cancer risks at the Petroleum Storage Area are 3×10^{-5} and 1×10^{-5}, respectively (RAGS D Tables 7.1g RME and 7.1g CT). The RME and CT HIs for these areas are 0.1 and 0.09, respectively. There are no unacceptable cancer risks or non-cancer hazards for this receptor.

Adult Trespasser

The adult trespasser RME and CT cancer risks at the Petroleum Storage Area are 2×10^{-5} and 3×10^{-6}, respectively (RAGS D Tables 7.2g RME and 7.2g CT). The RME and CT HIs for these areas are 0.06 and 0.04, respectively. There are no unacceptable cancer risks or non-cancer hazards for this receptor.

7.7.2. Future Receptors

Industrial Worker

The calculated RME HI for the future industrial worker at the Petroleum Storage Area is 0.2 and the calculated RME cancer risk is 5×10^{-5} (RAGS D Table 7.4e RME; Attachment A). The calculated CT HI and cancer risk are 0.1 and 8×10^{-6}, respectively (RAGS D Table 7.4e CT). There are no unacceptable cancer risks or non-cancer hazards for this receptor.

Construction Worker

The calculated RME HI for the future construction worker at the Petroleum Storage Area is 7.7 and the calculated RME cancer risk is 9×10^{-6} (RAGS D Table 7.5e RME; Attachment A). The calculated CT HI and cancer risk are 4.7 and 7×10^{-6}, respectively (RAGS D Table 7.5e CT). The HI values exceed the H1 threshold of 1, and are driven by nervous system effects (6), arising from the inhalation of manganese from upper soils. There are no unacceptable cancer risks for this receptor.

Utility Worker

The utility worker RME and CT cancer risks at the Petroleum Storage Area are 5×10^{-6} and 4×10^{-6}, respectively (RAGS D Tables 7.7f RME and 7.7f CT). The RME and CT HIs for these areas are 1.5 and 1.3, respectively, only marginally exceeding the H1 threshold of 1. Contributors to the HI include autoimmune effects (1) arising from dermal contact with benzene in shallow groundwater. There are no unacceptable cancer risks or non-cancer hazards for this receptor.

7.8. Chlorobenzene Hot-Spot Area

7.8.1. Current Receptors

Adolescent Trespasser

The adolescent trespasser RME and CT cancer risks at the Chlorobenzene Hot-Spot Area are 5×10^{-5} and 2×10^{-5}, respectively (RAGS D Tables 7.1h RME and 7.1h CT). The RME and CT HIs for these areas are 4.1 and 2.1, respectively (exceeding the H1 threshold of 1). The HI is driven by ocular (4) and autoimmune (4) effects arising from the ingestion of, and dermal contact with, highly chlorinated PCBs in surface soils. There are no unacceptable cancer risks for this receptor.

Adult Trespasser

The adult trespasser RME and CT cancer risks at the Chlorobenzene Hot-Spot Area are 7×10^{-5} and 9×10^{-6}, respectively (RAGS D Tables 7.2h RME and 7.2h CT). The RME and CT HIs for these areas are 2.7 and 1.2, respectively, only marginally exceeding the H1 threshold of 1. The HI is driven by ocular (3) and autoimmune (3) effects arising from the ingestion of, and dermal contact with, highly chlorinated PCBs in surface soils. There are no unacceptable cancer risks for this receptor.

7.8.2. Future Receptors

Industrial Worker

The calculated RME HI for the future industrial worker at the Chlorobenzene Hot-Spot Area is 6 and the calculated RME cancer risk is 1×10^{-4} (RAGS D Table 7.4f RME; Attachment A). The calculated CT HI and cancer risk are 2.2 and 2×10^{-5}, respectively (RAGS D Table 7.4f CT). The RME cancer risk exceeds the acceptable regulatory range of 1×10^{-4} – 1×10^{-6} and is driven by ingestion and dermal contact with highly chlorinated PCBs in surface soils. The same drivers are responsible for HI, exceeding the threshold of 1; ocular (6) and autoimmune (6) effects are dominant in this respect.

Construction Worker

The calculated RME HI for the future construction worker at the Chlorobenzene Hot-Spot Area is 14 and the calculated RME cancer risk is 3×10^{-5} (RAGS D Table 7.5f RME; Attachment A). The calculated CT HI and cancer risk are 11 and 2×10^{-5}, respectively (RAGS D Table 7.5f CT). The HI values exceed the HI threshold of 1 and are driven by ocular (6) and autoimmune (7) effects arising from the ingestion of highly chlorinated PCBs in upper soils. There are no unacceptable cancer risks for this receptor.

Utility Worker

The utility worker RME and CT cancer risks at the Chlorobenzene Hot-Spot Area are 1×10^{-5} and 9×10^{-6}, respectively (RAGS D Tables 7.7g RME and 7.7g CT). The RME and CT HIs for these areas are 10 and 7, respectively. The HI for this area exceeds the HI threshold of 1 and is driven by ocular (7) and autoimmune effects (8), arising from the ingestion of highly chlorinated PCBs in upper soils. There are no unacceptable cancer risks for this receptor.

7.9. Tributary 5A

7.9.1 Current and Future Receptors

Adolescent Trespasser

The adolescent trespasser RME and CT cancer risks at the Tributary 5A are 3×10^{-5} and 2×10^{-5}, respectively (RAGS D Tables 7.1i RME and 7.1i CT). The RME and CT HIs for these areas are 1.9 and 1.4, respectively (marginally exceeding the HI threshold of 1). The HI is driven by the ingestion of chromium in sediment (1.1). There are no unacceptable cancer risks or non-cancer hazards for this receptor.

Adult Trespasser

The adult trespasser RME and CT cancer risks at the Tributary 5A are 5×10^{-5} and 8×10^{-6}, respectively (RAGS D Tables 7.2i RME and 7.2i CT). The RME and CT HIs for these areas are 0.9 and 0.6, respectively. There are no unacceptable cancer risks or non-cancer hazards for this receptor.

Utility Worker

The utility worker RME and CT cancer risks at the Tributary 5A are 4×10^{-6} and 4×10^{-6}, respectively (RAGS D Tables 7.7h RME and 7.7h CT). The RME and CT HIs for these areas are 6.7 and 6.4, respectively. The HI for this area exceeds the HI threshold of 1 and is driven by the ingestion of chromium in sediment (4). There are no unacceptable cancer risks for this receptor.

7.10. Hypothetical Drinking Water Source Area

As discussed in previous sections of this report, groundwater at the Site is not suitable for use as a drinking water supply irrespective of any contributions related to waste at the Site. The drinking water pathway was included in this section at the request of the NYSDEC.

Adult Resident

The RME and CT cancer risks for the future adult resident are 1×10^{-2} and 4×10^{-3}, respectively (RAGS D Tables 7.8 RME and 7.8 CT). This exceeds the acceptable regulatory range of 1×10^{-4} – 1×10^{-6} and is driven by ingestion of benzene. The RME and CT HIs for these areas are each 175, and are driven by autoimmune effects (122), arising from the ingestion of benzene.

Child Resident

The RME and CT cancer risks for the future child resident are each 7×10^{-3} (RAGS D Tables 7.9 RME and 7.9 CT). This exceeds the acceptable regulatory range of 1×10^{-4} – 1×10^{-6} and is driven by ingestion of benzene. The RME and CT HIs for these areas are each 408, and are driven by autoimmune effects (284), arising from the ingestion of benzene.

7.11. Risk Characterization – Summary

7.11.1. Current Conditions

Under current conditions, cancer risks for receptors in all exposure areas are within the acceptable regulatory range of 10^{-4} to 10^{-6}, except for the Former Chlorination Building, in which RME total cancer risks exceed the regulatory range for the adolescent and adult trespasser, and the surveillance worker.

Under current conditions, hazard indices for receptors in the Plant Area, State Fair Blvd/ Northwest Off-Site/ Outfall 004 Exposure Area, and the Petroleum Storage Area are within the threshold of 1. RME hazard indices that exceed 1 include:

- Adolescent trespasser in the On-Site Ditches, Former Chlorination Building, Southwest Off-Site/Outfall 006 Exposure Area, Chlorobenzene Hot-Spot Area, and Tributary 5A.

- Adult trespasser in the On-Site Ditches, Former Chlorination Building, Southwest Off-Site/Outfall 006 Exposure Area, and Chlorobenzene Hot-Spot Area.
- Surveillance worker in the On-Site Ditches and Former Chlorination Building
- Utility worker in the Lakeshore Area and Tributary 5A.

A summary of estimated cancer risks and non-cancer hazards is presented below in Table 7.1.

Table 7.1. *Summary of current RME and CT estimated cancer risks and hazard indexes*.

Exposure Area	Receptor	RME or CT	Cancer Risk	HI
Plant Area	Adolescent Trespasser	RME	$4x10^{-5}$	$1x10^{0}$
		CT	$2x10^{-5}$	$9x10^{-1}$
	Adult Trespasser	RME	$4x10^{-5}$	$5x10^{-1}$
		CT	$6x10^{-6}$	$3x10^{-1}$

7.11.2. Future Conditions

Under future conditions, cancer risks for receptors in all exposure areas are within the acceptable regulatory range of 10^{-4} to 10^{-6}, except for the construction worker in the Southwest Off-Site/Outfall 006 Exposure Area and the Former Chlorination Building, in which RME total cancer risks exceed the regulatory range for the adolescent trespasser, adult trespasser, surveillance worker, industrial worker, construction worker, and utility worker.

Under future conditions, hazard indices for receptors in the State Fair Blvd/ Northwest Off-Site/ Outfall 004 Exposure Area are within the threshold of 1. RME hazard indices that exceed 1 include:

- Adolescent trespasser in the On-Site Ditches, Former Chlorination Building, Southwest Off-Site/Outfall 006 Exposure Area, Chlorobenzene Hot-Spot Area, and Tributary 5A.

- Adult trespasser in the On-Site Ditches, Former Chlorination Building, Southwest Off-Site/Outfall 006 Exposure Area, and Chlorobenzene Hot-Spot Area.
- Surveillance worker in the On-Site Ditches and Former Chlorination Building
- Industrial worker in the Plant Area, On-Site Ditches, Former Chlorination Building, Southwest Off-Site/Outfall 006 Exposure Area, and Chlorobenzene Hot-Spot Area
- Construction worker in the Plant Area, On-Site Ditches, Former Chlorination Building, Southwest Off-Site/Outfall 006 Exposure Area, Petroleum Storage Area, and Chlorobenzene Hot-Spot Area
- Utility worker in the Plant Area, On-Site Ditches, Former Chlorination Building, Lakeshore Area, Chlorobenzene Hot-Spot Area, and Tributary 5A
- Child and adult resident in the potable water use scenario

Table 7.2 below summarizes cancer risk and non-cancer hazards for potential future conditions at the Site.

8. Uncertainty Assessment

The risk measures used in this HHRA are not precise, deterministic estimates of risk, but conditional estimates controlled by a considerable number of consecutive upper-bound assumptions regarding exposure and toxicity. They are designed to estimate an upper bound of the potential health risk value, as opposed to present a precise and realistic estimate of actual health risks. This is done by convention, consistent with USEPA protocols. The main sources of uncertainty relative to the assumptions, results, and conclusions of the HHRA are:

- estimation of chemical concentrations,
- estimation of exposure point concentrations,
- evaluation of exposure scenarios,
- estimation of toxicity values, and
- calculation of quantitative risk estimates.

Uncertainties related to these sources are discussed below.

8.1. Estimation of Chemical Concentrations

The data were validated as described in Appendix A of the RI report. Some data were qualified as "J" values, indicating that the reported concentrations were "estimated" values. However, the uncertainty in the reported concentrations was within acceptable levels as specified in the Site-specific Quality Assurance Project Plan (QAPP). As such, the analytical data is representative of the chemical concentrations in Site media. Analytical data that were qualified as rejected, “R,” were not utilized in the HHRA.

8.1.1. Mercury Speciation

Mercury can be present in the environment in organic and inorganic forms, with the organic forms exhibiting greater toxicity to nearly all receptors (ATSDR 1999). The toxic effects of the organic form of mercury, methyl mercury, are most pronounced following exposure because of its high bioavailability and minimal attenuation in tissue. Neither form of mercury is classified as carcinogenic; however, non-cancer hazards can be estimated for each of these compounds via application of the appropriate toxicity data (oral Rfd, dermal Rfd, inhalation Rfc), which vary depending on the type of mercury.

To perform a hazard assessment of mercury, the concentrations of each form of mercury in environmental media must be known. However, laboratory sample analysis did not include mercury speciation for all Exposure Areas or media. In cases where mercury was speciated, conservative health hazard estimates were made for each of these compounds (mercury and methyl mercury). Where data was only available for total mercury, health hazard estimates were completed exclusively for elemental mercury.

Evaluation of mercury health hazards posed to an individual by assessing only the less toxic form of mercury may decrease the conservativeness of the hazard estimate. Consequently, there is a certain amount of uncertainty inherent in the evaluation since it is possible that some fraction of the total mercury is the more bioavailable and toxic form, methyl mercury. To account for potential underestimation of health hazards associated with exposure to unspeciated mercury, a sensitivity analysis was completed.

This sensitivity analysis was completed by developing a ratio of methyl mercury to mercury for all locations where speciated data was available. Table 8.1 presents the Exposure Areas and media where speciated data was both available and unavailable.

Table 8.1. *Prevalence of mercury speciation at the Willis Avenue Site*.

Speciated Mercury		**Unspeciated Mercury**	
Exposure Area	**Media**	**Exposure Area**	**Media**
Plant Area	Surface Soil, Upper Soil, Intermediate Soil	Plant Area	Intermediate Groundwater
Former Chlorination Building	Surface Soil, Upper Soil, Intermediate Soil		
On-Site Ditches	Surface Soil, Intermediate Soil, Upper Soil	Northwest Off-Site/Outfall 004	Surface Soil, Upper Soil
Southwest Off-Site/Outfall 006	Surface Soil, Upper Soil	Lakeshore Area	Surface Soil, Upper Soil, Shallow Groundwater
Tributary 5A	Sediment, Surface Water	Petroleum Storage Area	Shallow Groundwater
Petroleum Storage Area	Surface Soil, Upper Soil	Chlorobenzene Hot-Spot Area	Shallow Groundwater
Chlorobenzene Hot-Spot Area	Surface Soil, Upper Soil	Site Wide Groundwater Exposure Area	Groundwater – All Depths

Methyl mercury to total mercury ratios were developed based on the average ratio of detected concentrations of these compounds at each sample location within an exposure area. Table 8.2 presents the ratios developed for each Exposure Area and the Exposure Areas to which the ratios will be applied.

Table 8.2. *Methyl mercury to total mercury ratios developed for Exposure Areas and media.*

Exposure Area	Media	Ratio	Applied to Exposure Area:	Rationale
Plant Area	Surface Soil	0.0026	Lakeshore Area – Surface Soil	Close proximity, identical depth
	Upper Soil	0.0026	Lakeshore Area – Upper Soil	Close proximity, identical depth
	Intermediate Soil	0.0026	None	Application to Plant Area groundwater not appropriate
Former Chlorination Building (FCB)	Surface Soil	0.0028	None	Application to FCB groundwater not appropriate
	Upper Soil	0.0028		
	Intermediate Soil	0.0028		
On-Site Ditches	Surface Soil	0.00014	NW Off-Site/ Outfall 004 Exposure Area- Surface Soil and Upper Soil	Same Exposure Area **/** Close proximity and identical depth
	Intermediate Soil	0.00014		
	Upper Soil	0.00014		
Southwest Off-Site/Outfall 006 Exposure Area	Surface Soil	0.00020	None	None required
	Upper Soil	0.00020	None	None required
Tributary 5A	Sediment	0.023	None	No other location with sediment
Petroleum Storage Area	Surface Soil	0.00024	None	Application to CHSA groundwater not appropriate
	Upper Soil	0.00024	None	
Chlorobenzene Hot-Spot Area (CHSA)	Surface Soil	0.0033	None	Application to CHSA groundwater not appropriate
	Upper Soil	0.0033		

New hazard quotients were found by applying the methyl mercury ratio to the total mercury exposure point concentration for each receptor, media, and Exposure Area (exposure scenario). Similarly, the inverse of the methyl mercury ratio was applied to the total mercury exposure point concentration to calculate the remaining portion that is elemental mercury. New exposure point concentrations were used to calculate chronic daily intakes for each exposure scenario. The hazard quotients for each form of mercury were then determined by dividing the newly calculated chronic daily intake by the appropriate RfD. The hazard quotients for mercury and methyl mercury were then added together for each exposure scenario to obtain a hazard index.

Table 8.3. *Original total mercury and new ratio based methyl mercury hazard estimates*.

Exposure Area	Media	Receptor	Pathway	Original Mercury Hazard Quotient (RME)	Ratio Applied	Calculated Mercury Hazard Quotient (RME)	Calculated Methyl Mercury Hazard Quotient (RME)	Calculated Mercury and Methyl Mercury Hazard (RME)	New HI greater than 1.0 (Y/N)
Northwest Off-Site/Outfall 004 Exposure Area	Surface Soil	Adolescent Trespasser	Ingestion	1.36E-01	0.00014	1.36E-01	5.73E-05	1.36E-01	N
			Dermal	NA	NA	NA	NA	NA	NA
		Adult Trespasser	Ingestion	4.38E-02	0.00014	4.38E-02	1.84E-05	4.38E-02	N

			Dermal	NA	NA	NA	NA	NA	NA
	Upper Soil	Utility Worker	Ingestion	3.71E-01	0.00014	3.71E-01	1.56E-04	3.71E-01	N
			Dermal	NA	NA	NA	NA	NA	NA
Lakeshore Area	Surface Soil	Adolescent Trespasser	Ingestion	2.60E-03	0.0026	2.60E-03	2.03E-05	2.62E-03	N
			Dermal	NA	NA	NA	NA	NA	NA
		Adult Trespasser	Ingestion	8.37E-04	0.0026	8.35E-04	6.53E-06	8.41E-04	N
			Dermal	NA	NA	NA	NA	NA	NA
	Upper Soil	Utility Worker	Ingestion	9.86E-03	0.0026	9.84E-03	7.69E-05	9.91E-03	N
			Dermal	NA	NA	NA	NA	NA	NA

As shown in Table 7, there is a nominal difference between the hazard quotient for total mercury and the combined hazard index for mercury and methyl mercury. Additionally, no total mercury, elemental mercury, or methyl mercury hazard quotient exceeds 1.0. The reason for such a nominal difference after applying the methyl mercury ratio is twofold. First, the ratios of methyl mercury to mercury were found to be extremely small, meaning only a small fraction of each sample is the more toxic methyl mercury. Second, the oral RfD for methyl mercury was not markedly lower than that of mercury (0.0001 mg/kg-day for methyl mercury and 0.0003 mg/kg-day for mercury). The dermal RfD shows a greater difference for mercury (0.000021 mg/kg-day) and methyl mercury (0.0001 mg/kg-day); however, since no dermal absorption factor exists for mercury or methyl mercury dermal exposure was not applicable. The end result of these contributing factors was a minor difference in unspeciated mercury and speciated mercury hazard indices.

Considering that the methyl mercury concentrations were estimated based on ratios of methyl mercury to mercury in other samples, there is a degree of uncertainty associated with this assessment. However, the uncertainty does not affect the outcome of this risk assessment as none of the newly calculated hazard quotients for mercury or methyl mercury approach an unacceptable level. By comparison, even in the most conservative and unreasonable scenario, assuming that all of the mercury at the areas where mercury was not speciated is assumed to be methyl mercury, then only

one exposure scenario would result in an unacceptable hazard quotient. The Northwest Off-Site/Outfall 004 Utility Worker exposed to upper soil through ingestion would have a hazard quotient of 1.11 if all of the mercury in that Exposure Area were methyl mercury, which is nominally above what is considered acceptable (1.0). This assumption is both highly conservative and highly unlikely and it is therefore concluded that a lack of speciated mercury samples at some Exposure Areas did not alter the conclusions of this risk assessment.

8.2. Calculation of Exposure Point Concentrations

8.2.1. General

Conservative judgments were applied in calculating RME exposure point concentrations. Depending on the Exposure Area and COPC, maximum detected concentrations or UCLs were used as exposure point concentrations (EPC). As such, it is highly unlikely that the estimated EPCs underestimate representative concentrations in the Site media.

In addition, as noted in the text, the maximum detected concentration was applied as a default value if there were less than five detects. This was done as a conservative measure, since there was insufficient number of samples to assess the shape of the underlying distribution.

ProUCL statistical software package (Version 4.0; USEPA 2007b) was used to examine the data distribution and develop an upper confidence level (UCL) on the arithmetic mean. ProUCL was run using Regression on Order Statistics (ROS), which is a method for accounting for non-detect samples in the data set. ROS infers values for non-detect samples based on the distribution of detected data. ProUCL recommends the most appropriate UCL to use given the distribution type. The UCL recommended by ProUCL was subsequently applied as the EPC. The ProUCL output is presented in Appendix K.

Data Temporal Distribution

Analytical data has been collected from various media since January of 1991 in order to support various phases of investigation at the Site. The majority of data collection efforts occurred in two distinct time periods (1991/1992 and 1997/1998). The histogram presented below depicts the number of sample locations sampled for each year of data utilized in this assessment. Data collected during this time period reflected initial investigatory efforts (early 1990s) and significant additional sampling to support remedial investigation efforts (late 1990s).

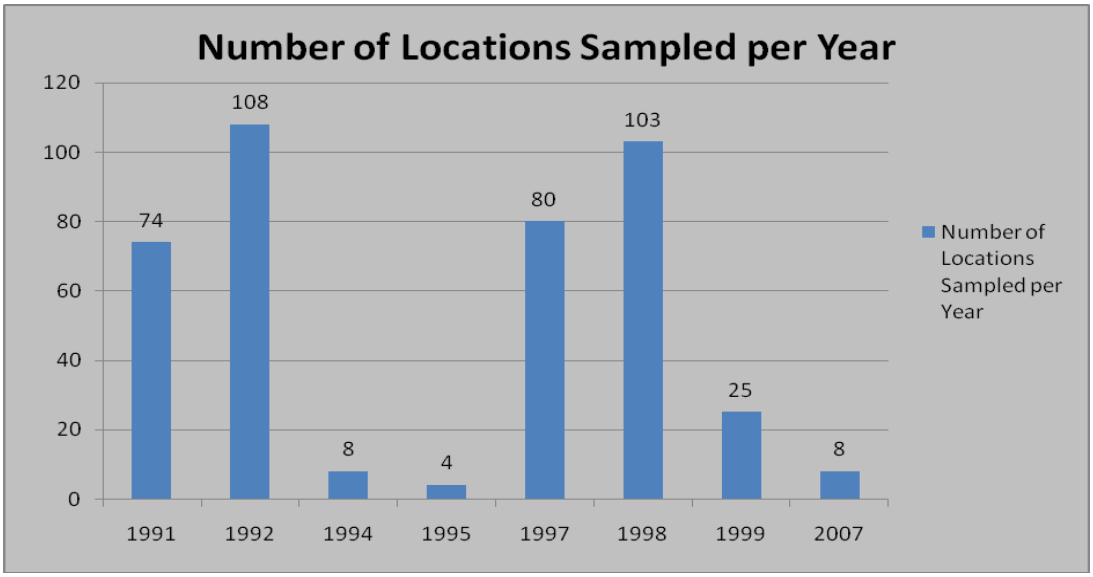

Figure 8.1. *Historical sampling frequency*.

All of the data utilized in this and other assessments were validated in accordance with USEPA specified guidelines. Data validation involves the reconstruction of the analytical process and an evaluation of whether the analysis has been performed correctly. The data validation process was used to determine which data was considered usable in quantitative and qualitative evaluations. For the purposes of this report, data that was qualified as rejected "R" or that was a quality control sample were not utilized in this assessment.

A Data Usability Assessment was also completed in accordance with the Data Quality Objectives specified for the Site. Among other parameters, the Data Usability Assessment evaluated the representativeness of the data which is a measure of whether the collective data represent actual conditions at the Site. The data was confirmed to be representative of Site conditions.

The historical nature of the dataset is still considered to reflect actual Site conditions because constituent concentrations are not expected to increase over time and are actually likely to attenuate. Therefore, the dataset, in its entirety, is legitimately utilized in this HHRA. It is important to note that this HHRA has been an iterative process as the initial version of the report was developed in 2002 as an Appendix (L) to the Remedial Investigation Report. Subsequent revisions to this document include one in 2004 and this revision. The temporal distribution of the data is not expected to affect the overall interpretation of potential human health risk posed by the Site to selected receptors.

8.2.2. Indoor Air Exposures for Future Industrial Workers

As part of the HHRA, the future migration of volatile constituents in groundwater to the indoor air of future On-Site industrial buildings was evaluated. Groundwater concentrations were compared to screening levels, but a quantitative risk was not calculated.

8.2.3. Inhalation Exposures for Future Construction Workers

As discussed in Sec 5.4.4, PEF is used to calculate the constituent concentration in fugitive dust. For this Report, a single PEF value for the construction worker was calculated on the basis of total Site area ("Site-wide PEF"). This section presents a sensitivity analysis to determine the influence of using this single Site-wide PEF versus using a separate PEF for each Exposure Area with a construction worker receptor. The figure below presents the Site-wide PEF and the PEF for individual Exposure Areas as a function of area. For the PEF calculation, each Exposure Area is assumed to be in the shape of a square of the area shown on the X-axis in the figure below. It is further assumed that a road of 6.1m width bisects the exposure point area and thereby entrains particulate matter in the air immediately above it, which is subject to inhalation by a receptor at the exposure point.

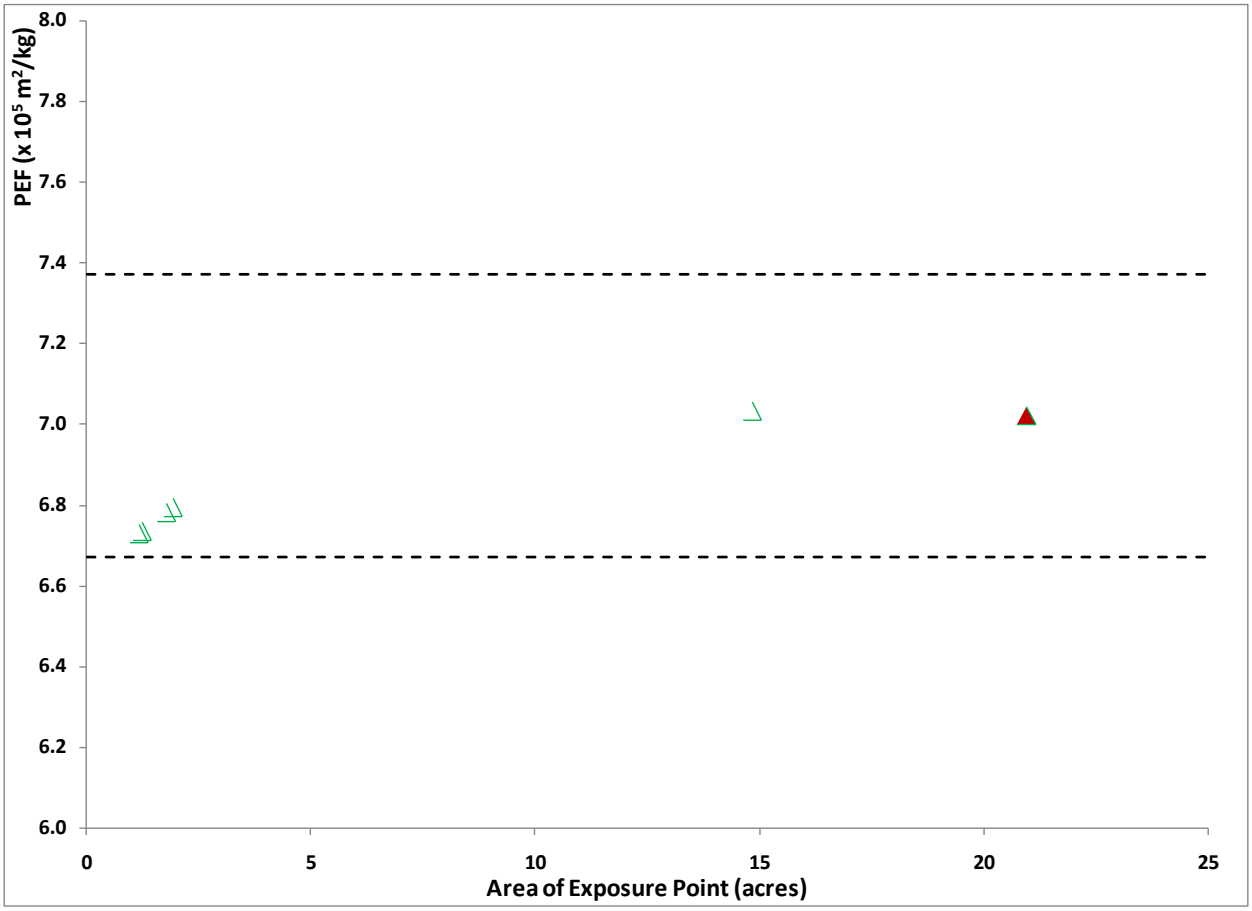

Figure 8.2. *Exposure area and Site-wide PEF values as a function of area.*

The unfilled triangles represent the calculated PEFs for the various exposure points within the Site (with the exception of the On-Site Ditches), while the red filled triangle represents the calculated PEF using total Site area, ("Site-wide PEF"). The dotted lines represent the ±5% range around the red filled triangle. The PEFs are of the order of 7×10^5 for the exposure points shown in the figure, and are within 5% of the Site-Wide PEF. The one exception to this trend is the calculated PEF for the On-Site Ditches (not shown), which has a value of ~2×10^8. The figure below presents the area (orange squares) and PEF value (blue bars) for each Exposure Area and the Site-Wide PEF.

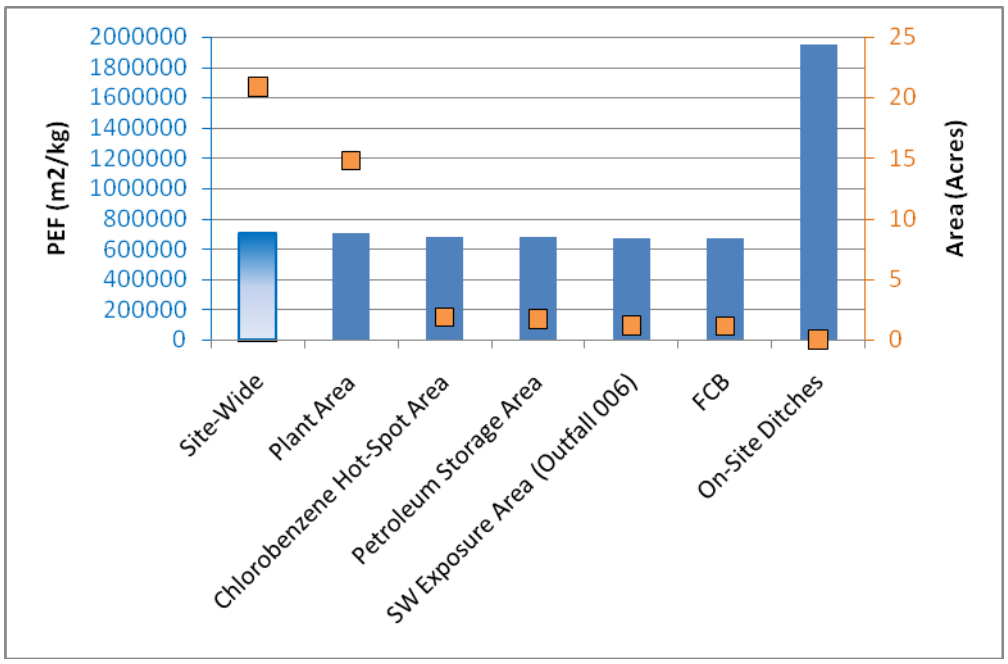

Figure 8.3. *Comparison of Site-wide and individual exposure area PEF values.*

While the PEF for the On-Site Ditches differs from the Site-Wide value, it is important to note that the ditches are long narrow trenches and would ordinarily not have a roadway bisecting them. Furthermore, the total area of the On-Site Ditches is 0.04 acres; a hypothetical road 6.1 m wide running the entire length of the ditch would occupy approximately 0.02 acres, or 50% of the exposure point area itself. These two factors suggest that it is highly unlikely that a road would be constructed through the On-Site Ditches, and any calculated result for the PEF would therefore be implausible and can be removed from the analysis.

Therefore, as seen in the figures above, the remaining PEF values for the individual Exposure Areas all lie within 5% of the Site-wide PEF, and we conclude that the Site-wide PEF reasonably captures the concentration of constituents in fugitive dust for the inhalation pathway for the construction worker.

8.3. Toxicity Values

8.3.1. General

A general discussion of the uncertainties and conservatism inherent in the USEPA approach for deriving RfDs and cancer slope factors has been presented in Section 6 of the HHRA and is briefly summarized below.

Reference Doses (RfDs) - For some chemicals, RfDs are derived directly from data on human exposures. Such data includes occupational exposures that are known to have no adverse effects, normal dietary levels of certain chemicals, therapeutic doses of certain chemicals, and epidemiological data relating to populations with background exposures. For most chemicals, USEPA derives RfDs based on laboratory studies in which experimental animals were exposed to different concentrations of a chemical, and a NOAEL is estimated. If data from several animal studies are available, USEPA seeks to identify the species that is most comparable to humans based on knowledge of specific biologic properties. If adequate comparative data is not available, USEPA selects the study on the most sensitive animal species as the critical study for the basis of the NOAEL. The NOAEL is then used to derive a RfD for potential adverse effects in human populations.

RfD Uncertainty Factors - In most cases, there is considerable uncertainty regarding the extension of toxicological data from animal studies to humans. In other words, the actual RfD for humans or sensitive sub-populations of humans would not be precisely known based on data in animal species. This uncertainty arises because there may be differences between the animal and human species regarding factors such as the metabolism of the chemical, the distribution and clearance rate of the chemical from the body, and the sensitivity of specific organ systems to the chemical. Therefore, the USEPA derives RfDs that are designed to be protective of the public at large, *including sensitive sub-populations*. The USEPA applies a series of "uncertainty" factors to calculate the final RfD values. Depending on the data, the NOAEL may be divided by an uncertainty factor ranging from 1 to 10,000. For human data, in most cases, the uncertainty factor of 10 is applied for the application of data from the public at large to sensitive sub-populations. For animal data a typical uncertainty factor of 100 (10 for sensitive sub-population and 10 for animal-human extrapolation) is applied for deriving the human RfD.

Cancer Slope Factors - Additional uncertainty arises from the USEPA use of the linearized multi-stage model for estimating the cancer slope factor. The linearized multi-stage model is one mathematical model, which may describe the carcinogenic process. The model assumes that at low doses, there is a linear relationship between the dose of a chemical and the excess cancer risk. In addition, the model assumes that there is no threshold dose for the induction of cancer. However, there are many instances in which this assumption may not hold true for the carcinogenic process. Examples of such effects are chemicals that cause an increased high dose cancer incidence due to stimulated cell proliferation rates (Cohen and Ellwein 1990; Ames and Gold 1990), chemicals for which metabolic parameters limit the delivered dose to the target organ (Zeise and Wilson 1986), promoters, or in instances where DNA repair mechanisms may be dose dependent (Zeise and Wilson 1986). In these instances, the linearized multi-stage model may provide a "plausible upper limit" of potential cancer risk (51 FR 33992). However, as acknowledged by USEPA (51 FR 33992), "such an estimate does not necessarily give a realistic prediction of the risk. The true value of the risk is unknown, and may be as low as zero."

8.3.2. Uncertainty of TCDD Equivalents

The toxicity equivalency factor (TEF) scheme compares the relative toxicity of individual dioxin-like compounds to that of TCDD, which is the most toxic congener. The toxicity equivalent (TEQ) is calculated by multiplying the exposure level of a particular dioxin-like compound by its TEF. The sum of each dioxin/furan toxicity equivalent at a given location equals the total sample TEQ.

Dioxin TEQs were a contributor to risk estimates calculated and presented in this HHRA. However, there is considerable uncertainty as to the potential carcinogenic and non-cancer chronic impacts of

TEQs to humans. Given this uncertainty, and the application of the TEF approach, which assumes 2,3,7,8-TCDD-like activity to the range of PCDD/F congeners, there is a high likelihood that the actual human health risks associated with the detection of PCDD/Fs at the site are lower than the estimates presented in this HHRA.

The 2,3,7,8-TCDD is considered to be the most potent of the PCDD/F compounds with respect to potential toxic effects. 2,3,7,8- TCDD may induce a wide range of toxic effects in laboratory animals including effects on the liver, sex hormone balance, immune system, and *in utero* development (ATSDR 1998). In addition, 2,3,7,8-TCDD has been shown to induce cancer in laboratory animals at relatively low administered doses (USEPA 1992d). There may be considerable variability in the toxic potency of 2,3,7,8-TCDD depending on the test animal species and toxic effect being considered (ATSDR 1998). Guinea pigs are generally the most dioxin-sensitive mammalian species. By comparison, the hamster may be 5,000 to 10,000 times more resistant in similar toxicity tests.

Very few of the toxic effects of 2,3,7,8-TCDD observed in animal species have been reported in exposed human populations (USEPA 1992d). The only toxic effect that has been definitively associated with TCDD exposure in human populations is chloracne (an acne-like skin condition) in heavily exposed individuals (USEPA 1992d). Numerous studies and health surveys of human populations exposed to relatively high levels of TCDD have failed to detect a clear association between TCDD exposure and the adverse health effects reported in laboratory animal studies (USEPA 1992d). However, certain studies of occupationally exposed workers in the United States (Fingerhut *et al*. 1991) and Germany (Manz *et al.* 1991) have reported a possible increase in lung cancer and thyroid cancer rates in occupationally exposed workers. A significant reduction in breast cancer rates was observed in women living in Seveso, Italy, which was the Site of a large dioxin release in July 1976 (Bertazzi *et al*. 1993). This observation is consistent with a similar reduction in mammary tumor risk in laboratory animals.

The IRIS database does not contain a weight-of-evidence cancer classification for 2,3,7,8-TCDD. The USEPA is currently re-evaluating the risks and hazards from exposures to PCDD/Fs. In its proposed rule to add a chemical category that includes dioxin and dioxin-like compounds to the list of toxic chemicals subject to release reporting requirements, the USEPA acknowledged that existing data shows "2,3,7,8-TCDD is a potent toxicant in animals and has the potential to produce a wide spectrum of toxic effects in humans" (USEPA 1997b). In the preamble of the rule, the USEPA further states that "available human data cannot clearly demonstrate whether a cause and effect relationship exists between 2,3,7,8-TCDD exposure and increased incidence of cancer.

There is little direct evidence regarding the toxic effects and potency PCDD/F compounds other than 2,3,7,8-TCDD. As a conservative assumption, USEPA and other regulatory agencies assume that other PCDD/F compounds may induce the same toxic effects as TCDD, though they are likely to be less potent than TCDD (USEPA 1989b). It is recognized that chlorination at the 2,3,7,8 positions is required for a PCDD/F compound to potentially exert toxic effects (USEPA 1989b). Therefore, in order to evaluate the toxic potential of PCDD/F mixtures, Van den Berg et al. (2006) publishes a TEF for each PCDD/F compound. The TEFs are based on observed structure activity relationships for PCDD/F compounds, receptor binding affinity or enzyme induction. The TEF approach assumes that receptor binding is necessary (but not exclusive) for biological activity of PCDD/F compounds and the affinity of a given PCDD/F congener to the receptor reflects the relative biologic potency of a given congener. However, it is important to recognize a given toxic response in a biological organism probably involves many physiologic events other than receptor activation. As such, it is

reasonable to assume that the congener-specific relative toxic potency may not be the same as the relative receptor affinity. In fact, given the diverse mechanisms for different toxic responses, it is reasonable to assume that the relative potencies may be different for different toxicological endpoints.

As of the revision of this HHRA, the IRIS database did not contain a CSF or RfD for PCDD/Fs. The NYSDEC requested that a qualitative discussion of non-cancer PCDD/F exposures be presented in the uncertainty section, with references to advisory levels prepared by the ATSDR (or other agencies). The following information appears in the ATSDR toxicological profile on PCDD/Fs (ATSDR 1998) as compiled and referenced in the ATSDR Toxicological Profiles (on CD; ATSDR 2003).

It is the ATSDR's policy to use health guidance values (*i.e.*, Minimal Response Levels and Environmental Media Evaluation Guides) derived for 2,3,7,8-TCDD for other dioxin-like compounds as total TEQs. The ATSDR has derived an acute-duration oral minimal response level (MRL) of 0.0002 µg/day (2×10^{-4} µg/kg/day) for 2,3,7,8-TCDD based on its ability to suppress serum total hemolytic complement activity in $B6C3F_1$ mice (White *et al*. 1986). An intermediate-duration oral MRL of 0.00002 µg/day (2×10^{-5} µg/kg/day) was derived based on observed decreases in thymus weight in guinea pigs (Decaprio *et al*. 1986). A chronic-duration oral MRL of 0.000001 µg/day (1×10^{-6} µg/kg/day) was derived for 2,3,7,8-TCDD based on altered social interaction with peers in monkeys exposed to 2,3,7,8-TCDD prenatally and during lactation (Schantz *et al*. 1992). Neither a reference concentration (RfC) nor a RfD is listed in IRIS (USEPA 2004c) for any of the PCDD/Fs.

To further examine the exposure to dioxins on the Site, dioxin equivalents were compared to the ATSDR Minimal Risk Level (MRL) for 2,3,7,8-TCDD. The MRL is an estimate of the daily human exposure to a hazardous substance that is likely to be without appreciable risk of adverse non-cancer health effects over a specified duration of exposure (ATSDR 1998). These substance specific estimates, which are intended to serve as screening levels, are used by ATSDR health assessors and other responders to identify contaminants and potential health effects that may be of concern at hazardous waste sites (ATSDR 1998).

ATSDR uses the no observed adverse effect level/uncertainty factor (NOAEL/UF) approach to derive MRLs for hazardous substances. MRLs, based on non-cancer health effects only, are presented in units of µg/mg/day. MRLs are derived for the acute (1 to 14 days), intermediate (>14 to 364 days), and chronic (365 days and longer) exposure durations. The table below presents the TEQ values which represent the maximum sample TEQ of the cohort of samples for a particular Exposure Area and media. All Exposure Area TEQs exceeded acute, intermediate, and chronic ATSDR MRL values.

Table 8.4. *Exposure Area TEQ Comparison to ATSDR MRLs. "X" designates an exceedance.*

Exposure Area	Medium	Exposure Area TEQ (mg/kg)	ATSDR Acute MRL (2,3,7,8-TCDD) **2.0E-07** (mg/kg/day)	ATSDR Intermediate MRL (2,3,7,8-TCDD) **2.0E-08** (mg/kg/day)	ATSDR Chronic MRL (2,3,7,8-TCDD) **1.0E-09** (mg/kg/day)
Plant Area	Surface Soil	$2.09x10^{-3}$	X	X	X
Plant Area	Upper Soil	$2.09x10^{-3}$	X	X	X

Northwest Offsite/Outfall 004 Area	Upper Soil	$5.28x10^{-4}$	X	X	X
Lakeshore Area	Surface Soil	$7.62x10^{-5}$	X	X	X
Lakeshore Area	Upper Soil	$7.62x10-^{5}$	X	X	X
Tributary 5A	Sediment	$2.66x10^{-5}$	X	X	X

ATSDR recommends a decision matrix approach to aid in drawing conclusions about the public health implication of certain compounds. This approach is based on the use of a decision framework that compares Site-specific TEQ concentrations to ranges of values to which a particular action is assigned. The ranges are identified as screening level range (< 50 ppt), evaluation level range (> 50 ppt but < 1 ppb), and action level range (>1 ppb). Depending on how a particular TEQ compares to these values, one of three response decisions may be concluded. If the Exposure Area TEQ is below or equal to 50 parts per trillion, no further evaluation is required. Second, should the TEQ fall within the evaluation level range, evaluation of Site-specific factors is recommended. Site specific factors that may be evaluated include bioavailability, ingestion rates, pathway analysis, soil cover, climate, other constituents, community concerns, demographics, and background exposures. Thirdly, an Exposure Area TEQ that is greater than or equal to 1 part per billion is within the action level range, which may trigger the potential consideration of public health actions. Examples of public health actions may include surveillance, research, health studies, community education, and exposure investigations.

Table 8.5. *Dioxin TEQ decisions matrix screening*.

RAGS Table	Exposure Area	Medium	Location TEQ (mg/kg)	Screening Level Range (<0.00005 mg/kg)	Evaluation Level Range (0.00005 mg/kg – 0.001 mg/kg)	Action Level Range (> 0.001 mg/kg)
2.1	Plant Area	Surface Soil	$2.09x10^{-3}$			X
2.2	Plant Area	Upper Soil	$2.09x10^{-3}$			X
2.3	Plant Area	Intermediate Soil	$2.09x10^{-3}$			X
2.6	Former Chlorination Building	Surface Soil	$2.23x10^{-1}$			X
2.7	Former Chlorination Building	Upper Soil	$2.52x10^{-1}$			X
2.8	Former Chlorination Building	Intermediate Soil	$2.52x10^{-1}$			X
2.9	On-site Ditches	Surface Soil	$7.54x10^{-3}$			X
2.10	On-site Ditches	Upper Soil	$7.54x10^{-3}$			X
2.11	On-site Ditches	Intermediate Soil	$7.54x10^{-3}$			X
2.12	Southwest Offsite/ Outfall 006	Surface Soil	$6.96x10^{-4}$		X	
2.13	Southwest Offsite/ Outfall 006	Upper Soil	$6.96x10^{-4}$		X	
2.14	Northwest Offsite/ Outfall 004 Area	Surface Soil	$5.28x10^{-4}$		X	
2.15	Northwest Offsite/ Outfall 004 Area	Upper Soil	$5.28x10^{-4}$		X	
2.16	Lakeshore Area	Surface Soil	$7.62x10^{-5}$		X	
2.17	Lakeshore Area	Upper Soil	$7.62x10^{-5}$		X	
2.19	Tributary 5A	Sediment	$2.66x10^{-5}$	X		

The decision matrix described above was applied to the Exposure Area TEQs developed for this Site and is presented in Table 8. One Exposure Area TEQ (Tributary 5A, sediment), was below the screening action level. Six Exposure Area TEQs were within the evaluation level range indicating that Site-specific conditions should be considered in decision making. The TEQs within this range are for surface soil and upper soil of the Southwest Offsite/Outfall 006, Northwest Offsite/Outfall 004, and the Lakeshore Area. Nine Exposure Area TEQs were within the action level range of the decision matrix which represents the dioxin equivalent concentrations present in surface soil, upper soil, and intermediate soil for the Plant Area, Former Chlorination Building, and On-Site Ditches.

Although some of the Exposure Area TEQ fall within the action level range of the ATSDR decision matrix, current and expected use of the site along with anticipated remedial action renders specific dioxin-related action unwarranted. Further, RME non-cancer hazard results indicate that many 2,3,7,8-TCDD hazard quotients are within below one. Those HQ that are not below one generally exceed one by less than one order of magnitude. Although the ATSDR action level can reflect, in certain instances, a concentration of dioxin TEQ at which consideration of action to interdict/prevent exposure occurs, a site-specific evaluation may indicate that none of these actions may be necessary.

8.3.3. Lead in Drinking Water

Groundwater data from all available depths was used to evaluate a potable use scenario for the adult and child resident at the Site. The maximum concentration of lead in groundwater is high and well above EPA's action level of 15 µg/L. The lack of cancer or non-cancer toxicity data precludes the

development of risk or hazard estimates. However, for the child resident, exposure to lead in drinking water has been evaluated using the IEUBK model.

This pathway has been evaluated because the current use designation for this aquifer is as a potable water supply and the National Contingency Plan states the groundwater must be returned to its most beneficial use. The Site is zoned as industrial and is unlikely to be developed as a residential area. Therefore, residential use of the Site is highly unlikely. Municipal water currently supplies existing buildings and facilities with potable water and therefore Site groundwater is not used as a potable water source. Because the affected nature of the groundwater is known, potable water wells are not likely be drilled or authorized in the future.

A change in zoning from industrial to residential is more likely than the use of groundwater as a potable water supply. Any residential or other structure built on the Site in the future will undoubted be connected to municipal water supply. It may be interesting to note that most lead enters the home after it leaves the municipal water supply or well (USEPA 1993b) by leaching out of the pipes or solder during corrosion reactions. The USEPA and scientific data indicates that the newer the home, the greater the risk of lead contamination (USEPA 1993b). This is because mineral deposits that form a coating over the surface of the solder connections and protect against leaching can take up to five years to form. As such, more likely than not, water in buildings less than five years old has high levels of lead contamination. Should the area be zoned differently and residential homes be built, the piping and solder within the newly constructed homes is more likely to contribute to elevated levels of lead than other sources.

8.3.4. Carcinogenicity of Trichloroethene

Trichloroethene (TCE) is a chemical with known cancer risk and non-cancer hazard effects. A draft assessment of health risks due to TCE by the USEPA (2001b) provided a range of cancer slope factors (2×10^{-2} to 4×10^{-1} mg/kg-d) to evaluate cancer risk. The RAGS Table D series in the present report were developed using the upper bound of this range (*i.e.*, 4×10^{-1} mg/kg-d) for the dermal, ingestion, and inhalation exposure pathways. The estimate of cancer risk due to TCE in this report is therefore a conservative one.

There are currently no recommended values for assessing non-cancer exposure to TCE. However, the New York State Department of Health (NYSDOH) guideline for TCE in air is 5 $\mu g/m^3$ (NYSDOH, 2006). For comparison, in the present risk assessment, TCE was detected under only one receptor/exposure point combination (Southwest Off-Site/Outfall 006; future construction), for which the exposure point air concentration was found to be 1.33×10^{-5} mg/m^3 or 1.33×10^{-2} $\mu g/m^3$, well below the guideline. Similarly, the New York State MCL for TCE in groundwater (as well as the drinking water standard; NYSDOH, 2006) is 5 $\mu g/l$; in comparison, no TCE was detected in either groundwater or surface water samples in this report.

8.3.5. Carcinogenicity of Naphthalene through Inhalation

Naphthalene is carcinogenic through inhalation exposure. CalEPA provides a PPRTV unit risk for naphthalene of $3.4x10^{-5}$ $(ug/m^3)^{-1}$. This corresponds to a screening value for indoor air of 72 ug/L, which is lower than the value used in this HHRA. However, usage of the 72 ug/L value would not affect whether naphthalene is above screening level in the RAGS D Table 2 series.

8.3.6. Carcinogenicity of Hexavalent Chromium

The RAGS D Table 6 series includes an inhalation unit risk value for chromium based on hexavalent chromium, but oral and dermal cancer slope factors were not available. However, the National Toxicology Program has identified chromium as carcinogenic through the oral pathway and EPA is in the process of developing an oral toxicity value for hexavalent chromium.

8.3.7. Dichlorobenzene Toxicity

At the time of this report, 1,2-, 1,3-, and 1,4- dichlorobenzene were in the IRIS review process. This process will lead to an updated non-carcinogenic endpoint for 1,3-dichlorobenzene and updated carcinogenic and non-carcinogenic endpoints for 1,2- and 1,4-dichlorobenzene.

8.4. Calculation of Quantitative Risk Estimates

8.4.1. Non-Carcinogenic Effects

For each exposure pathway, the chemical-specific hazard quotients were summed to calculate the HI for that pathway. For each receptor, the pathway-specific hazard indexes were summed to obtain the total HI for that receptor.

The additivity assumption for calculating hazard indexes is based on the concept that multiple chemicals, acting on the same target organ or by the same mechanism of toxicity, will have an additive effect with respect to the potential damage that is caused to that organ. The additivity assumption does not hold true for chemicals that do not act on the same target organ or by the same mechanism of toxicity. Therefore, USEPA guidance states that if the total HI for the Site exceeds 1, the COPCs may be segregated according to target organ, and the HIs re-derived for each sub group of chemicals. As previously discussed, for receptors and areas for which the HI exceeded 1, the derived risks were dominated by one or two chemicals. As such, segregation of the HI by target organ would have resulted in the same overall conclusions.

8.4.2. Carcinogenic Effects

Uncertainties associated with the Linearized Multistage Model for low dose cancer risk assessments have been discussed in Section 8.4.1. As described in that section, the model and associated assumptions likely result in a conservative estimate of potential lifetime excess cancer risk.

8.5. Central Tendency Estimates

Central tendency (CT) risk calculations were completed for Exposure Areas and receptors for which the HI exceeded 1 or the cancer risk exceeded 1×10^{-6}. The input parameters and calculated CT risk estimates are presented in the RAGS D Table 4, 7, 9, and 10 series. Based on the NYSDEC's direction, the RME exposure point concentrations were applied as exposure point concentrations for the CT calculations. For other input parameters, average values were estimated based on data

published in the *Exposure Factors Handbook* (USEPA 1997a) or professional judgment regarding site specific exposure frequency and duration estimates.

8.6. Multiple Exposure Scenarios

Current and future expected exposures assume that receptors will be exposed to one Exposure Area. The tables below summarize the risks and hazards to each current and future receptor for each Exposure Area. The largest contributor to the risk or hazard is shown in bold. These tables show that the FCB leads to unacceptable risks and hazards for most receptors. However, it is unlikely that a receptor such as the surveillance worker would spend all of their time in the FCB. Thus the risks and hazards shown for the FCB are likely an overestimate, and the true risk to a receptor would likely be a weighted average of the risks from several Exposure Areas.

Table 8.6. *Summary of current RME and CT cancer risks and hazard indexes by receptor*.

Receptor	Exposure Area	RME or CT	Cancer Risk	HI

Adult Resident	**Potable Water**	**CT**	**$4x10^{-3}$**	**$2x10^{2}$**

9. Conclusions

In general, under current conditions, cancer risks for receptors in all exposure areas are within the acceptable regulatory range of 10^{-4} to 10^{-6}, except for the Former Chlorination Building, and hazard indices for receptors in the Plant Area, State Fair Blvd/ Northwest Off-Site/ Outfall 004 Exposure Area, and the Petroleum Storage Area are within the threshold of 1.

Under future conditions, cancer risks for receptors in all exposure areas are within the acceptable regulatory range of 10^{-4} to 10^{-6}, except for the Southwest Off-Site/Outfall 006 Exposure Area and the Former Chlorination Building. Under future conditions, hazard indices for receptors in the State Fair Blvd/ Northwest Off-Site/ Outfall 004 Exposure Area are within the threshold of 1.

It should be noted that it is unlikely that a given receptor would spend all of their time in one exposure area. Thus the risks and hazards shown for a given exposure area are likely an overestimate, and the true risk to a receptor would likely be a weighted average of the risks from several exposure areas. A summary of risk drivers is presented in RAGS Table 10 series (Attachment A) and below.

9.1. Plant Area

9.1.1. Current/Future Receptors

There are no unacceptable cancer risks or non-cancer hazards for current/future Site-receptors (adolescent trespasser, adult trespasser, and surveillance worker).

9.1.2. Future Receptors

Under the future exposure scenarios, there are no unacceptable cancer risks associated with any receptor in this exposure area. Non-cancer hazard exceeding the threshold for the future construction worker is driven primarily by exposure to:

- Nickel (HQ = 20)

Non-cancer hazard for the future utility worker is driven primarily by exposure to:

- Mercury (HQ = 3).

9.2. On-Site Ditches

9.2.1. Current/Future Receptors

There are no unacceptable cancer risks for current/future Site-receptors. Likewise, there are no unacceptable chemical-specific hazards for the current/future adult trespasser or surveillance worker. The non-cancer hazards for the adolescent trespasser are driven primarily by exposure to:

- 2,3,7,8-TCDD Equivalents (HQ = 3)
- Mercury (HQ = 3).

9.2.2. Future Receptors

There are no unacceptable cancer risks for future Site-receptors. Non-cancer hazards for the future construction worker are driven by exposure to:

- 2,3,7,8-TCDD Equivalents (HQ = 10)
- Mercury (HQ = 30).

Non-cancer hazards for future utility workers are also driven primarily by exposure to:

- 2,3,7,8-TCDD Equivalents (HQ = 9)
- Mercury (HQ = 20).

To a lesser extent, non-cancer hazards for future industrial workers are also driven primarily by these constituents.

9.3. Former Chlorination Building

9.3.1. Current/Future Receptors

Cancer risk to the adolescent trespasser, adult trespasser, and surveillance worker was estimated at the higher end of the regulatory threshold range of 10^{-4} to 10^{-6}. This risk was driven primarily by potential exposure to:

- 2,3,7,8-TCDD Equivalents (CR range = 4×10^{-4} to 7×10^{-4})

Non-cancer hazards for these receptors also exceeded the regulatory threshold and are also driven by potential exposure to:

- 2,3,7,8-TCDD Equivalents (HQ range = 10 to 20).

9.3.2. Future Receptors

Cancer risks to the future industrial worker, construction worker, and utility worker exceeded the regulatory threshold range of 10^{-4} to 10^{-6}. These risks are driven primarily by potential exposure to:

- 2,3,7,8-TCDD Equivalents (CR range = 2×10^{-3} to 8×10^{-4})

Non-cancer hazards for these receptors also exceeded the regulatory threshold and are also driven by potential exposure to:

- 2,3,7,8-TCDD Equivalents (HQ ranges from 30 to 400).

9.4. Southwest Off-Site/Outfall 006 Exposure Area

9.4.1. Current/Future Receptors

There are no unacceptable cancer risks or non-cancer hazards for current/future Site-receptors in the Southwest Off-Site/Outfall 006 Exposure Area.

9.4.2. Future Receptors

There are no unacceptable cancer risks or non-cancer hazards for future industrial worker. Cancer risk to the future construction worker exceeded the regulatory threshold range of 10^{-4} to 10^{-6}. Cancer risk was driven primarily by exposure to:

- Benzene (CR = 1.5×10^{-4})

Non-cancer hazards for the future construction worker exceeded the regulatory threshold of 1 and were driven primarily by exposure to:

- Benzene (HQ = 40)
- Mercury (HQ = 10)
- Xylenes (HQ = 9)

9.5. State Fair Blvd/Northwest Off-Site/Outfall 004 Exposure Area

9.5.1. Current/Future Receptors

There are no unacceptable cancer risks or non-cancer hazards for the current/future receptor in this exposure area.

9.5.2. Future Receptors

There are no unacceptable cancer risks or non-cancer hazards for anticipated future receptors in this exposure area.

9.6. Lakeshore Property Area

9.6.1. Current/Future Receptors

There are no unacceptable cancer risks or non-cancer hazards for the adolescent trespasser or adult trespasser. There are also no unacceptable cancer risks for the utility worker in this exposure area; however non-cancer hazards for this receptor exceeded the regulatory threshold. The non-cancer hazard was driven primarily by potential exposure to:

- Benzene (HQ = 9)
- Chlorobenzene (HQ = 3)

9.7. Petroleum Storage Area

9.7.1. Current/Future Receptors

There are no unacceptable cancer risks or non-cancer hazards for the adolescent trespasser or adult trespasser in this exposure area.

9.7.2. Future Receptors

There are no unacceptable cancer risks or non-cancer hazards for future industrial or utility worker. There are also no unacceptable cancer risks to the future construction worker; however, non-cancer hazards for the future construction worker exceeded the regulatory threshold of 1 and was driven primarily by exposure to:

- Manganese (HQ = 4)

9.8. Chlorobenzene Hot-Spot Area

9.8.1. Current/Future Receptors

There are no unacceptable cancer risks for the adolescent trespasser or the adult trespasser in the CHSA. Non-cancer hazard, however, did exceed the regulatory threshold and was driven by exposure to:

- PCBs (HQ = 4 and 3, respectively)

9.8.2. Future Receptors

There are no unacceptable cancer risks for future industrial worker in the CHSA. Non-cancer hazard, however, did exceed the regulatory threshold and was driven by exposure to:

- PCBs (HQ = 6)

There are no unacceptable cancer risks for future construction worker in the CHSA. Non-cancer hazards, however, did exceed the regulatory threshold and were driven primarily by exposure to:

- Manganese (HQ = 4)
- PCBs (HQ = 6)

There are no unacceptable cancer risks for future utility worker in the CHSA. Non-cancer hazard, however, did exceed the regulatory threshold and was driven primarily by exposure to:

- PCBs (HQ = 7)

9.9. Tributary 5A

9.9.1. Current/Future Receptors

There are no unacceptable cancer risks or non-cancer hazards for the adolescent trespasser or the adult trespasser in this exposure area.

9.10. Hypothetical Drinking Water Source Area

Groundwater at the Site is not suitable for use as a drinking water supply irrespective of any contributions related to waste at the Site. However, the following section describes the risk drivers that would be expected if it groundwater was used as drinking water source.

9.10.1. Future Receptors

Both cancer risk and non-cancer hazards exceeded their respective regulatory thresholds for future child and adult residents. The cancer risks are driven primarily by exposure to:

- Benzene (CR = 5×10^{-3} and 1×10^{-2}, respectively)
- Arsenic (CR = 1×10^{-3} and 2×10^{-3}, respectively)

- 1,4-Dichlorobenzene (CR = 2×10^{-4} and 4×10^{-4}, respectively)
- Benzo(b)fluoranthene (CR = 2×10^{-4} and 4×10^{-5}, respectively)

Non-cancer hazards for the future child and adult residents are driven primarily by:

- Benzene (HQ = 300 and 100, respectively)
- Chlorobenzene (HQ = 50 and 20, respectively)
- Arsenic (HQ = 30 and 10, respectively)
- Toluene ((HQ = 10 and 5, respectively)
- Chromium (HQ = 8 and 3, respectively)
- Iron (HQ = 6 and 2, respectively)
- 1,4-Dichlorobenzene (HQ = 5 and 2, respectively)

9.11. Hypothetical Future Indoor Air

Based on the discussion in Section 3.10.1 and the high vapor pressure of many of the compounds detected, a vapor intrusion evaluation will need to be conducted prior to the construction of occupied buildings at the site. Based on the vapor intrusion evaluation, preventative measures may be included in the design and construction of buildings at the Site to mitigate the risk of exposure to on-Site soil gas. Such measures may include the use of a vapor barrier or the installation of a venting system, such as at the groundwater treatment plant.

	Sewer and intake water	4	1997	VOCs, SVOCs, PCB/Pest, Metals	
Phase 3	Surface soil	40	1998	VOCs, SVOCs, PCB/Pest, Metals, PCDD/Fs, TOC, % Solids	Evaluate and characterize the nature and extent of Site-related constituents
	Subsurface soil	39	1998	VOCs, SVOCs, PCB/Pest, Metals, PCDD/Fs, TOC, % Solids	
Phase 4 (BERA)	Surface soil	12	1999	VOCs, SVOCs, PCB/Pest, Metals, MeHg, TOC, % Solids	Evaluate and characterize the nature and extent of Site-related constituents
	Tributary 5A surface water	4	1999	VOCs, SVOCs, PCB/Pest, Metals, MeHg, Hardness, TSS, Total Alk	Investigate Tributary 5A for the presence of Site-related constituents
	Tributary 5A sediment	4	1999	VOCs, SVOCs, PCB/Pest, Metals, MeHg, PCDD/Fs, TOC, % Solids, Grain Size	

NOTES:
Surface soil = Soil from a depth interval of 0 to 2 ft
Subsurface soil = Soil from a depth interval greater than 2 ft
BERA = Baseline Ecological Risk Assessment
Hg = Mercury
MeHg = Methyl Mercury
PCB/Pest = Polychlorinated Biphenyls/Pesticides
PCDD/Fs = Polychlorinated Dibenzo-p-dioxins/Dibenzofura
TOC = Total Organic Carbon
TSS = Total Suspended Solids
Total Alk = Total Alkalinity
SVOCs = Semivolatile Organic Compounds
VOCs = Volatile Organic Compounds
% Solids = Percent Solids

INVESTIGATION SAMPLE SUMMARY

	Sample media	No. of samples	Year collected	Exposure Area	No. of Samples	Notes
Willis Avenue Chlorobenzene Site Remedial Investigation						
Phase 1	Soil vapor	62	1991	General Plant Area	62	Includes Plant Area, FCB, and On-Site Ditches
	Surface soil	3	1992	PSA	3	
	Subsurface soil	26	1992	Plant Area	20	
				Lakeshore Area	1	
				PSA	5	
	Groundwater	63	1992, 1995	CHSA	15	
				PSA	8	
				Lakeshore Area	12	
				Plant Area	24	
				Southwest Off-Site/006	4	
Phase 2	Surface soil	16	1997	St. Fair/Northwest/004	4	
				Southwest Off-Site/006	4	
				On-Site Ditches	3	
				FCB	5	
	Subsurface soil	42	1997	Southwest Off-Site/006	2	
				General area	40	
	Subsurface utilities bedding	6	1997	St. Fair/Northwest/004	2	
				Lakeshore Area	1	
				Plant Area	2	
				FCB	1	
	Groundwater	6	1997	CHSA	5	
				Lakeshore Area	1	
	Sewer and intake water	4	1997	Lakeshore Area	1	
				Plant Area	3	Two are near the Plant Area.
Phase 3	Surface soil	40	1998	Plant Area	12	
				FCB	8	
				On-Site Ditches	2	
				Southwest Off-Site/006	7	
				St. Fair/Northwest/004	2	
				CHSA	6	
				PSA	3	
	Subsurface soil	39	1998	Plant Area	15	
				FCB	15	
				CHSA	6	
				PSA	3	
Phase 4	Surface soil	12	1999	Plant Area	1	
				FCB	1	
				On-Site Ditches	1	
				Southwest Off-Site/006	1	
				CHSA	1	
				PSA	1	
				Lakeshore Area	6	
	Tributary 5A surface water	4	1999	Tributary 5A	4	
	Tributary 5A sediment	4	1999	Tributary 5A	4	

NOTES: Surface soil = Soil from a depth interval of 0 - 2 ft
Subsurface soil = Soil from a depth interval greater than 2 ft
PSA = Petroleum Storage Area; CHSA = Chlorobenzene Hot-Spot Area; Southwest Off-Site/006 = Southwest Off-Site/Outfall 006 Exposure Area
St. Fair/004/NIMO = State Fair Boulevard/Northwest Off-Site/Outfall 004 Exposure Area; FCB = Former Chlorination Building

Notes:
* = Samples identified as QC samples from this location (samples with Sample Code WA9351)
a = Samples with Sample Codes ending in "N" (indicating NYSDEC sample) were not utilized in the HHRA.
