1.0 Introduction

1.1 Site Description

This report presents findings of an investigation at the TR-3 North Wall/Stormwater Treatment Plant (SWTP) Area at the United Technologies Corporation (UTC)/Carrier facility on Thompson Road in Syracuse, Onondaga County, New York (See **Figure 1**). Historical information provided by site personnel indicates that the former TR-3 building was originally constructed in the early 1950s with two later additions. The building was used to manufacture various air conditioner components. These former manufacturing operations included the use of electrical transformers and various oils (e.g., hydraulic, compressor) which potentially contained polychlorinated biphenyls (PCBs). The former TR-3 building also contained a degreaser that used the chlorinated solvent trichloroethene (TCE).

The SWTP was constructed in the early 1990s at the northeast corner of the TR-3 building. The TR-3 building was demolished in 2010/2011. Following demolition, the floor slab and north wall of the building were left in place. The remaining portion of the wall acts as a retaining wall to accommodate the approximate 7-foot (ft) elevation drop from the south to the north side of the wall. Currently, the former TR-3 building area is used for green space, Parking Lot R, and the SWTP.

The *Former Building TR-3 North Wall Investigation Report*, prepared by EnSafe, Inc. (EnSafe), was submitted to the NYSDEC in February 2015. Findings from the EnSafe investigation confirmed the presence of chlorinated volatile organic compounds (VOCs), PCBs, and petroleum oil-related impacts in shallow subsurface soils and groundwater in the TR-3 North Wall area, including the area between the wall and Sanders Creek.

1.2 Purpose of Investigation

A Proposed Interim Remedial Measure (IRM) and IRM Predesign Investigation (PDI) Sampling and Analysis Plan (SAP), was submitted to the New York State Department of Environmental Conservation (NYSDEC) in December 2015, incorporating comments from the NYSDEC December 3, 2016 approval letter. The conceptual IRM design consists of sheet wall installation, groundwater extraction and treatment, and impacted soil removal. The sheet pile wall will function as a hydraulic barrier for containment and extraction of impacted groundwater. The SAP outlined the proposed PDI activities required to complete the design. The specific objectives of the PDI included:

- Locating utilities adjacent to TR-3 North Wall and SWTP;
- Advancing geotechnical borings along the proposed sheet pile wall alignment;
- Conducting pumping and slug tests to evaluate hydrogeologic conditions in the shallow and deep water-bearing units;
- Installing monitoring wells on the north side of Sanders Creek to investigate the presence/absence of groundwater impacts;
- Sampling for delineation of impacted soil in the immediate vicinity of the TR-3 North Wall and SWTP;
- Sampling groundwater for characterization;
- Identifying the number and locations of weep holes in the TR-3 North Wall; and
- Characterizing investigation-derived waste (IDW) for disposal requirements.

This report was prepared to summarize the results of the PDI.

2.0 Site History

This section provides a description of the site and the historical investigations and remedial actions performed at the TR-3 North Wall and the nearby area.

2.1 Site Description

The TR-3 North Wall/SWTP area is located in the north central portion of the UTC Thompson Road Campus (**Figure 1**). The area is bounded on the north by Carrier Parkway (Route 298) and New York State Department of Transportation right-of-way, and UTC property to the east, south, and west. Sanders Creek, which flows east to west, lies in the area between Route 298 and the TR-3 North Wall/SWTP.

The ground surface south of the TR-3 North Wall is approximately 7 ft higher than the north side of the wall. The area south of the North Wall is relatively flat. North of the wall the topography drops 7 to 8 ft, in varying slope, down to Sanders Creek (see **Figure 2**). The former TR-3 building was previously demolished with the exception of the north wall and floor slab. Following demolition, approximately 1 to 2 ft of clean fill was placed over the former building footprint. Weep holes were drilled into the TR-3 North Wall to drain surface water that accumulates behind the wall.

The SWTP, located in the northeastern portion of the area, is the only building present in the former TR-3 area.

2.2 History and Operation

The TR-3 building was built in the early 1950s for the manufacture of various air conditioner components. The first addition was constructed in the late 1950s and the second addition was constructed in the 1970s. Oils used in the air conditioner manufacturing operation included transformer oil, machining oil, lubricating oil, hydraulic oil, compressor oil, and degreasers. Some of the oils are suspected to have contained PCBs. The degreasers contained TCE.

Part of the TR-3 building included a transfer line, referred to as the “T-Line”, which was located along the north wall of former TR-3 building, immediately west of the current SWTP. The former T-Line was comprised of 58 machining stations, each of which utilized a lubricating oil bath. Located adjacent and connected to the T-Line was an approximately 500-gallon tank that supplied filtered oil to the machining stations.

In 2000, during limited excavation prior to building demolition, Carrier excavated oil-impacted soils adjacent to and beneath the building’s northern exterior wall. The excavation extended beneath the former TR-3 building slab and resulted in the removal of approximately 20 cubic yards of impacted soil. The excavation was limited, because of a concern for the structural integrity of the building.

2.3 Interim Measures at Outfall 001

In 2003, an IRM was completed at the outfall historically designated 011, which is located north of the SWTP. At one point, this outfall was also designated as 007, but is now designated as 001, and serves as the SWTP outfall (see **Figure 2)**. The purpose of the IRM was to prevent the migration of impacted groundwater (via outfall bedding) into Sanders Creek. The IRM included the installation of a foam wall barrier encapsulating the outfall 001 pipe and bedding, and extending out perpendicular from the pipe. The wall was constructed by placing a series of 1-inch diameter steel injection tubes

into the granular bedding material and then injecting a polyurethane grout into the bedding material through tubes. The polyurethane grout reacts with water and forms a rigid foam. This foam barrier was installed around a pipe section located between the SWTP and Sanders Creek. The IRM also included installation and operation of a groundwater recovery well in the granular bedding material of the SWTP outfall.

2.4 Previous Investigations

Previous assessments that focused on various areas of the former TR-3 building include:

- An investigation of the TR-3 degreaser in the southeast corner of the former TR-3 building;
- An investigation of the storm water detention pond (Pond 3) located outside the northwest corner of TR-3;
- An investigation of the storm sewer utility lines associated with the former TR-3 building in the central portion of what is now Parking Lot R;
- Expansion of previous assessments including a Parking Lot R investigation conducted in October and November 2013;
- Manhole 3 (MH3) oil source investigation; and
- Former Building TR-3 North Wall Investigation.

The previous EnSafe investigation performed regarding the source of oil observed in Manhole 3 (located in the SWTP) identified limited quantities of oil along the southern and westerns walls of the SWTP and the south side of the TR-3 North Wall. A subsequent investigation was then performed in 2014 to investigate the subsurface extent of VOCs, PCBs, and oils along the TR-3 North Wall. EnSafe's *Former Building TR-3 North Wall Investigation Report* was submitted to the NYSDEC in February 2015. Findings indicated chlorinated VOCs, PCBs, and petroleum oil-related impacts to subsurface soils and groundwater in the area, including the area between the TR-3 North Wall and Sanders Creek.

The key findings were:

- Impacts to soil and groundwater are vertically limited to the shallow zone above a clay aquitard located at approximately 20 ft below the former TR-3 building slab;
- Artesian conditions exist in the lower aquifer; and
- Impacted groundwater has the potential to migrate to Sanders Creek, both from potentially impacted soil north (downgradient) of the TR-3 North Wall, and by continuing flow from the potential source area behind the wall (south).

The report also recommended additional investigation and sampling to the north of Sanders Creek to determine if impacted groundwater migrated northward, beneath Sanders Creek.

The investigation included the installation of eight monitoring wells (MW-54D, MW-56, MW-57, MW-58, MW-59, MW-66, MW-67, and MW-68) between the TR-3 North Wall and Sanders Creek. Soil samples from each well boring were generally submitted for analysis of PCBs, VOCs, and Oil Range Organics and Diesel Range Organics (ORO and DRO, are collectively referred to as total petroleum hydrocarbons [TPH]). Results are summarized below:

- No VOC samples were submitted for analysis from borings MW-54D or MW-68.
- Of the nine samples submitted for PCB analysis, one sample exceeded for Title 6 New York Codes, Rules, and Regulations (NYCRR) Part 375 Unrestricted Use soil cleanup criteria for PCBs.

- Of the six samples submitted for VOC analysis, four exceeded Unrestricted Use criteria for VOCs, however, three of the four exceeded for acetone only.
- Only one of the eight sample locations, MW-57 (adjacent to the north side of TR-3 North Wall), exhibited elevated detections (>100 milligrams per kilogram [mg/kg]) for TPH (Part 375 does not have cleanup criteria specific to TPH).

3.0 Current Field Investigation Activities

The current field investigation of the TR-3 North Wall area took place in two phases. The first was performed in January 2016 and the second was in April/May 2016. The field activities included borehole pre-clearance, drilling and installation of new groundwater monitoring wells, advancement of soil borings, pumping and slug tests, community air monitoring, equipment decontamination, IDW management, collection and analysis of soil and groundwater samples, and survey of investigation point locations and elevations.

Filed investigation activities were performed in accordance with the SAP and the Quality Assurance Project Plan (QAPP).

Prior to commencement of intrusive sampling activities, Dig Safely NY was notified for utility clearance. A geophysical contractor conducted a survey around each boring area using ground penetrating radar (GPR) equipped with a 400mHz antenna and a Radiodetection RD7000 cable and pipe locator instrument. The geophysical survey was also used to locate buried utilities on the north side of the TR-3 North Wall. Facility personnel also assisted in the assessment of buried utilities in the investigation areas. The locations of the utilities are shown in **Figure 2.**

Prior to drilling, each location was pre-cleared to a depth of approximately 5 ft by the drilling subcontractor using hand tools. IDW, including drill cuttings, development water, purge water, decontamination water, and sampling tubing, were drummed, labeled, and stored on-site pending analyses for appropriate disposal.

The field investigation included the collection and analysis of soil and groundwater samples. Analytical parameters included VOCs and PCBs. **Table 1** presents the number of samples collected per media (i.e., soil and groundwater) as well as quality assurance/quality control (QA/QC) samples. **Table 2** provides a summary of the analytical methods, as well as bottle, preservation, and holding time requirements.

An inspection of the TR-3 North Wall identified the presence of 36 equally spaced weep holes, approximately 1-inch in diameter and 5 ft above the ground surface on the north side of the wall. The inspection confirmed that the weep holes are located above the concrete slab (the former building floor) on the south side of the wall.

3.1 Drilling and Soil Sampling

Drilling services were provided by Parratt-Wolff, Inc. Track-mounted drill rigs were used in the area north of the TR-3 North Wall where the terrain is steep. A truck-mounted drill rig was used in accessible areas where the terrain was relatively flat (i.e., just north of the TR-3 North Wall and the area south of the TR-3 North Wall). The actual boring locations were adjusted in the field based on the presence of underground utilities and accessibility of the drilling equipment.

Borings were advanced for the following purposes:

- Installation of two monitoring wells;
- Installation of two pumping wells;
- Delineation of soil impacts (11 borings); and
- To obtain geotechnical information for sheet pile wall design (five borings).

The following nomenclature was used for the final borings and wells:

- Monitoring wells were designated TR3-MW-01 and TR3-MW-02;
- Pumping wells were designated TR3-PW-01 and TR3-PW-02;
- Delineation soil borings were designated as TR-3-SB-01 through TR3-SB-11; and
- Geotechnical borings were designated as TR3-GB-01 through TR3-GB-05.

Ten delineation borings were originally proposed. However, solvent orders and elevated volatile organic vapor readings were measured with the photoionization detector (PID) while drilling boring TR3-GB-01, located just north of the SWTP. Boring TR3-SB-11 was added to characterize soil contaminant conditions east of TR3-GB-01.

All borings were continuously sampled, using either direct-push or split-spoon sampling techniques. Borings advanced to obtain geotechnical information for sheet pile design and well installation were advanced while continuously collecting soil samples using a 1 $^{3}/_{8}$-in inside diameter by 2-ft long split-spoon sampler in general accordance with ASTM D1586. Undisturbed Shelby Tube samples were collected from select geotechnical boring intervals in general accordance with ASTM D1587.

Borings for delineation of soil impacts were advanced using direct-push technology and were continuously sampled using the Geoprobe Dual Tube (DT22 Liner) System.

For both sampling methods, each soil sample was inspected for evidence of contamination (e.g., staining and odors) and screened for volatile organic vapors using a calibrated miniRae photoionization detector (PID) equipped with a 10.6 eV lamp.

Generally, three soil samples were collected from each boring to bracket the vertical extent of apparent soil impacts: one soil sample collected from the interval above the interval of greatest observable impacts, one from the interval of greatest observable impacts, and one from the interval below the greatest observable impacts. If no apparent impacts were identified, three samples were collected to confirm the absence of contamination: one sample collected from the unsaturated zone, one from the interval of groundwater fluctuation, and one from the saturated zone.

Field observations were recorded in a dedicated, bound log book. Copies of boring logs prepared by the supervising AECOM geologist, are presented in **Appendix A**. Investigation locations are shown on **Figure 3**.

For each sampling interval, soil for VOC analysis was collected using TerraCore® samplers. For the remaining analytical parameters, the soil was homogenized and then transferred into the appropriate laboratory-provided sample containers.

Soil samples for geotechnical analyses of grain size were placed in glass jars provided by the driller. Shelby Tube samples were sealed in the field with wax, plastic caps, and tape immediately after collection.

3.2 Well Installation

Wells were installed for two primary purposes: to monitor groundwater levels and quality, and for characterization of hydrogeologic conditions through pumping tests. Well construction information is included in the boring logs provided in **Appendix A** and summarized in **Table 3**.

3.2.1 Pumping Test Well Construction

Pumping test wells TR3-PW-01 and TR3-PW-02 were installed in the upper water-bearing zone on the south side of the TR-3 North Wall. The borings were advanced to depths of 28 ft using a truck-mounted rig with 6 ¼-in inside diameter hollow stem augers (HSAs).

The pumping test wells were constructed with 10-slot, 4-in diameter flush-coupled polyvinyl chloride (PVC) screen and solid riser. Groundwater was observed at depths of 16.5 and ft 10.0 below ground surface (bgs), in TR3-PW-01 and TR3-PW-02, respectively. Well TR3-PW-01 was screened from 13 to 28 ft bgs and well TR3-PW-02 was screened from 11 to 16 ft bgs. A NJ #0 sand filter was placed in the annular space between the well screen/riser and the borehole wall and extended from the bottom of the well screen to approximately 2 ft above the top of the screen. Bentonite was placed above the sand filter. The sand filter and bentonite were added through the augers as the augers were slowly removed. Each well was completed with a flush-mount casing set in concrete.

3.2.2 Shallow Monitoring Well Construction

Monitoring wells TR3-MW-01 and TR3-MW-02 were installed in the upper water-bearing zone to monitor groundwater conditions on the north side of Sanders Creek. The borings were advanced to depths of 8 and 16 ft, respectively, using a track-mounted Geoprobe rig with 4 ¼-in inside diameter HSAs.

The monitoring wells were constructed with 10-slot, 2-in diameter flush-coupled PVC screen and solid riser. Groundwater was observed at depths of 3.0 and 4.0 ft bgs in TR3-MW-01 and TR3-MW-02, respectively. The wells were screened from 2 to 8 ft bgs and 2 to 12 ft bgs, respectively. A NJ #0 sand filter was placed in the annular space between the well screen/riser and borehole wall and extended from the bottom of the well screen to approximately 0.5 ft above the top of the screen. Bentonite was placed above the sand filter. The sand filter and bentonite were added through the augers as the augers were slowly removed. Each well was completed with a flush-mount casing set in concrete.

3.2.3 Deep Monitoring Well Construction

Monitoring well TR3-GB-03 was installed on the north side of the TR-3 North Wall. The boring was advanced to a depth of 50 ft using a truck-mounted rig. The upper 19 ft of the boring was advanced using 6 ¼-in inside diameter HSAs. A 4-in diameter steel separation casing was then grouted in place. Once the grout had properly cured (approximately 48 hours later), the remainder of the boring was advanced using mud rotary drilling. The drilling mud was contained and placed in 55-gallon drums for subsequent offsite disposal.

The intent of this deep well is to monitor the confined water-bearing zone. Once the drilling mud was flushed from the borehole, the well began to flow under artesian conditions. A temporary 10-ft PVC stick-up casing was added to the well to facilitate well construction. The monitoring well was constructed with 10-slot, 2-in diameter flush-coupled PVC screen with a solid riser. The well was screened from 34 to 50 ft bgs. A NJ #0 sand filter was placed in the boring around the annulus space extending from the bottom of the well screen to approximately 2 ft above the top of the screen. A bentonite seal was placed above the sand filter from 32 to 27 ft bgs. Cement bentonite grout was placed above the bentonite using 1-in tremie pipe. After the grout had time to cure, the temporary stick-up was removed and a downhole plug was installed in the well to a depth of approximately 5 ft bgs to prevent damage to the well during freezing temperatures. The well was completed with a flush-mount casing set in concrete.

3.2.4 Geotechnical Borings

Borings TR3-GB-01 through TR3-GB-05 were advanced along the north side of the TR-3 North Wall to collect geotechnical information to facilitate design of a sheet pile wall. The borings were advanced using a truck-mounted rig with 6 ¼-in inside diameter HSAs. Soil samples were collected using split-spoons and Shelby tubes.

The borings were initially advanced to a depth of 19 to 21 ft. A 4-in diameter steel separation casing was then set in grout to depths ranging from 19 to 20 ft bgs. With the exception of TR3-GB-01, after the grout cured the borings were advanced using mud rotary drilling while continuously collecting split spoon and/or Shelby tube samples to a depth of approximately 50 ft bgs. Boring TR3-GB-01 was not advanced below 20 ft because of contamination observed in the shallower soils and concern of creating a conduit for downward contaminant migration.

With the exception of TR3-GB-01 and TR3-GB-03, the borings were grouted upon completion using a cement/bentonite slurry. Boring TR3-GB-01 was not grouted, but a locking cap was installed on the steel separation casing. As mentioned above, TR3-GB-03 was completed as a deep monitoring well.

Eighteen samples were collected from these five borings for geotechnical analyses. Five of the 18 samples were Shelby tube samples collected from the confining clay layer. These samples were submitted for analysis of Atterberg Limits, water content, and unconsolidated-undrained triaxial testing by ASTM Methods D4318, D2216, and D2850, respectively. Thirteen soil samples from the sand unit beneath the clay were selected for grain size analyses using ASTM Method D422. A copy of the geotechnical lab report is provided in **Appendix B.**

3.2.5 Delineation Borings

Eleven contamination delineation borings, TR3-SB-01 through TR3-SB-11, were advanced in the area between the TR-3 North Wall and Sanders Creek using a track-mounted Geoprobe Rig. Soil sampling was performed using a 4-ft long acetate-lined sampler. Depths ranged from 4.5 to 16 ft bgs. Boring TR3-SB-05 was not completed to the planned depth of 16 ft due to shallow refusal on concrete at 4.5 ft bgs. Boring TR3-SB-06 was not completed to the planned depth due to uneven terrain, which made drilling unsafe. Only hand clearing to 4.5 and 5.0 ft bgs, respectively, was completed at these two borings. All the delineation borings were backfilled with bentonite chips upon completion.

3.3 Well Development

The monitoring wells were developed on April 12 and 13, 2016 by surging and pumping. The artesian well, TR3-GB-03, was allowed to self-purge at a flow rate of approximately 3 to 5 gallons per minute until a volume of approximately 45 gallons was removed from the well. Water quality measurements of pH, conductivity, temperature, and turbidity were periodically recorded during the development process. Copies of well development logs are provided in **Appendix C**.

3.4 Groundwater Sampling

On April 18 and 19, 2016, groundwater samples were collected from the new wells using the low-flow purge technique. The artesian well was sampled by installing a temporary riser and sampling tee. A low flow rate was maintained through the use of a gate valve on the sampling tee. Three well volumes were purged prior to sampling.

Water quality measurements of pH, conductivity, dissolved-oxygen, oxidation-reduction potential, temperature, and turbidity were frequently recorded during the purging process. Groundwater quality measurements were documented on AECOM purge logs which are provided in **Appendix D**.

The groundwater samples were analyzed for VOCs, and total and filtered PCBs. The samples for filtered PCB analyses were passed through a 0.45-micron inline filter.

3.5 Surveying

The soil boring and monitoring well locations were surveyed for location and elevation by a licensed AECOM land surveyor. Locations and elevations were measured to 0.01 ft. Location measurements were referenced to New York State Plane Central Zone North American Datum of 1983 (NAD 83) and elevations were referenced to North American Vertical Datum of 1988 (NAVD 88). Survey information is provided in **Table 3**.

3.6 Analytical Program

Soil and groundwater samples for laboratory chemical analyses were placed in pre-cleaned, laboratory-supplied glass jars, labeled, packed in a cooler with ice, and transported via courier to Accutest Laboratories under standard chain of custody procedures. The samples were submitted for analytical testing for the parameters listed in **Table 1** under standard turnaround time. Category B deliverable packages were requested for all sample delivery groups.

Samples for geotechnical analysis were hand delivered by AECOM to 3rd Rock, LLC, of East Aurora, NY.

3.7 Pumping Tests

Pumping tests were conducted using the two new 4-inch diameter unconfined water-bearing zone wells (TR3-PW-1 and TR3-PW-2), two existing 2-inch diameter unconfined water-bearing zone monitoring wells (MW-50 and MW-62), and existing confined water-bearing zone well MW-54D.

The pumping tests were performed using a Grundfos Redi-flo 2 submersible pump and In-Situ Level TROLL 700 pressure transducers to monitor water levels in the pumping well and in nearby monitoring wells.

During the tests, the water level was periodically monitored in Sanders Creek at surveyed measuring points immediately upstream and downstream of the TR-3 area.

3.7.1 Unconfined Water-Bearing Zone Pumping Tests

The tests at TR3-PW-2, MW-50, and MW-62 were conducted for approximately 7 hours with 2 hours recovery at the end of pumping. Pumping at TR3-PW-1 was terminated after 2 hours because the very low flow rate required for sustained yield could not be maintained by the pump. Water recovered during the pumping tests was conveyed to the SWTP for treatment. An abbreviated summary of pumping test details is summarized below:

Pumping Well	Observation Wells	Flow Rate (GPM)
TR3-PW-1	MW-43, MW-55, MW-56, and MW-61	Started at 0.5, reduced to 0.14
TR3-PW-2	MW-50, MW-58, MW-68, and MW-67	0.50
MW-50	TR3-PW-2, MW-58, MW-67, and MW-68	3.08
MW-62	TR3-PW-1, MW-43, MW-47, and MW-61	0.08-0.11

In addition, rising and falling head slug tests were performed on these wells to determine hydraulic conductivity and supplement the pumping test data.

3.7.2 Confined Water-Bearing Zone Pumping Test

A pumping test was performed using existing deep well MW-54D. Pressure transducers were installed to monitor water levels in the pumping well, the newly-installed nearby deep well (TR3-GB-03), and in existing deep well MW-14D. Because of artesian conditions, temporary extensions were installed on the deep well risers during the pumping test.

Also, during the deep well pumping test, nearby shallow monitoring wells MW-53 and MW-55 were monitored with pressure transducers to determine the degree of hydraulic connection, if any, between the unconfined and confined water-bearing zones.

The deep well pumping test was conducted for a total of 6 hours with 2 hours recovery at the end of pumping. The flowrate was approximately 3.2 GPM throughout the test. Water recovered during the pumping test was conveyed to the SWTP for treatment.

4.0 Investigation Results

This report section provides a summary of field screening, laboratory analytical results, and hydrogeologic evaluations.

4.1 Field Screening Results

4.1.1 Soil Observations

Wells TR3-PW-01 and TR3-PW-02 were installed on the south side of the TR-3 North Wall. Both wells were advanced to a depth of 28 ft. Drilling observations indicated that 1.8 to 2.8 ft of fill consisting of clayey silt, with trace gravel, overlies the approximately 1.5-ft thick former building concrete floor slab. The slab is underlain by interbedded sand, clay, and silt to a depth of approximately 24 to 26 ft bgs. The confining gray clay unit was encountered at this depth. Saturated conditions were encountered at 16.5 ft and 10 ft bgs in well TR3-PW-1 and TR3-PW-02, respectively.

As shown in **Figure 2**, the topography north of the TR-3 North Wall drops off towards Sanders Creek, with an approximate 7-ft drop from ground surface immediately adjacent to the wall down to the creek level. Observations made during drilling the locations on the north side of the TR-3 North Wall show that the area generally consists of topsoil underlain by as much as 14 ft of fill. The fill is underlain by an interbedded clayey silt to silty clay unit with some sand to a depth of approximately 18 ft bgs. The gray clay confining unit underlies this unit and ranges in thickness from 7 to 13 ft. The gray clay is underlain by several feet of clayey silt to silt, which is underlain by a red brown fine to medium sand unit that is approximately 2 to 6 ft thick. Below that is a dense clay/silt unit, likely a lodgment till, ranging from 4 to 12 ft thick. Red brown to green gray weathered shale underlies this unit. Geologic cross sections of the area are shown in **Figure 4**. **Figure 5** presents the line of cross section location map.

The depth to groundwater observed during drilling ranged from as shallow as 2 ft bgs, near Sanders Creek, to 16.5 ft bgs in the area south of the TR-3 North Wall.

Elevated PID readings and solvent odors were observed in TR3-GB-01 at a depth of approximately 16 ft bgs. A single droplet of non-aqueous phase liquid (NAPL) was observed on the outside of the soil sample core in the 18- to 20-ft interval. The presence of solvent odors, elevated PID readings, and the droplet may indicate the presence of solvent in the form of dense non-aqueous phase liquid (DNAPL) in this area. Slightly elevated PID readings but no odors were observed at TR3-GB-02, TR3-PW-01, TR3-SB-01, TR3-SB-02, and TR3-SB-07.

Table 4 presents a summary of observations made during drilling.

4.1.2 Groundwater Observations

Water levels were recorded at the five newly installed wells prior to sampling on April 18, 2016. The data is included on **Table 3**. In the area south of the TR-3 North Wall, the depth to groundwater was 12.18 ft bgs in TR3-PW-01 and 11.35 ft bgs in TR3-PW-02. North of Sanders Creek, the depth to groundwater in the wells TR3-MW-01 and TR3-MW-02 was approximately 0.91 ft bgs and 2.08 ft bgs, respectively. These wells are approximately 10 ft lower in elevation than the pumping test wells located south of the TR-3 North Wall.

The water level at deep well TR3-GB-03 was recorded as 7.65 ft above ground surface indicating an upward hydraulic head from the deep to the shallow water-bearing zone.

Based on EnSafe's *Former Building TR-3 North Wall Investigation Report* and the *Corrective Measures Update Site-wide Groundwater Monitoring Report, June 2015*, the anticipated flow direction from both the south and north sides of Sanders Creek is toward Sanders Creek. Because there were only four shallow wells installed during this investigation, and these wells have not been measured contemporaneously with the side-wide groundwater monitoring network, a ground water contour map was not generated specific to this investigation.

4.2 Chemical Analytical Results

The chemical analytical results for soil and groundwater samples were validated by an AECOM chemist following NYSDEC DER-10 and USEPA Region II data validation procedures. The validated data is provided in a data usability summary report (DUSR).

The DUSR presents deviations from the relevant QC requirements and the associated qualifications to the sample data warranted by these deviations. QC issues discussed in detail in the DUSR include surrogate sample recoveries, matrix spike recoveries, duplicate sample analyses, instrument calibration and performance and method and field blank sample analyses. The report also presents copies of the laboratory reporting forms with hand written qualifications made by the data reviewer. The data presented in the summary tables included in this report reflect these qualifications.

A copy of the DUSR narrative is provided in **Appendix E**. A copy of the DUSR appendices (e.g., Form 1s), is available on request.

4.2.1 Applicable Standards, Criteria, and Guidance

Soil PCB and VOC results were compared to Part 375 Soil Cleanup Objectives (SCOs) for:

- Protection of Public Health (Residential, and Industrial);
- Protection of Ecological Resources; and
- Protection of Groundwater.

The groundwater analytical results are compared to the NYS Ambient Water Quality Standards (AWQS) and Guidance Values in Technical & Operational Guidance Series (TOGS) Version 1.1.1., June 1998, with June 2004 Addendum.

4.2.2 Soil Results

A total of 53 soil samples and two duplicate samples were collected from 18 borings and submitted to the laboratory for chemical analysis. There were no samples collected from borings TR3-SB-05 and TR3-SB-06 because those borings were terminated at shallow depths (4.5 ft. and 5 ft., respectively).

VOC Soil Analytical Results

Review of the VOC soil analytical results indicates the following:

- VOC results were compared to each of the four criteria and Protection of the Groundwater SCO resulted in the greatest number of exceedances. while comparison to Protection of Public Health, Industrial Use resulted in the smallest number of exceedances.

- Thirty two samples contained VOCs at concentrations above the Protection of Groundwater criteria. VOCs exceeding the criteria were cis-1,2-dichloroethene (cis-1,2-DCE), trans-1,2-dichloroethene (trans-1,2-DCE), acetone, tetrachloroethene (PCE), trichloroethene (TCE), and vinyl chloride.
- Only one sample contained VOCs at a concentration above the Industrial Use criteria (TCE in TR3-GB-01).
- The highest concentrations of VOCs were detected in seven borings (TR3-GB-01, TR3-GB-02, TR3-PW-01, TR3-SB-01, TR3-SB-02, TR3-SB-04, and TR3-SB-07).
- The samples from TR3-PW-02, TR3-MW-01, and TR3-MW-02 did not contain any VOCs at concentrations above either criterion.
- Acetone was detected in 16 samples with 11 of those samples containing acetone at concentrations above the Protection of Groundwater criteria. In four samples, it was the only VOC detected at concentrations above the Protection of Groundwater criteria.

It is noted that acetone is not included in Figures 6 and 7. Acetone is not believed to be a site contaminant related to past operations. Acetone is a common laboratory contaminant. Also, a 2010 report "*Acetone Production as a Result of Sodium Bisulfate Preservation of Soil Samples*" by J.L. Clausen et al. suggests that certain chemical interactions with naturally occurring organic matter can cause the formation of acetone.

The analytical results are presented in **Table 5. Figure 6** compares the results to Protection of Groundwater criteria. **Figure 7** compares the results to Industrial Use criteria**.**

PCB Soil Analytical Results

The highest detection of total PCBs was 0.442 mg/kg in TR3-SB-03. This does not exceed the restricted SCOs of Protection of Public Health; Protection of Ecological Resources; or Protection of Groundwater. However, it does exceed the Unrestricted Use Soil Cleanup Objective of 0.1 mg/kg.

4.2.3 Groundwater Results

Groundwater samples were collected from the five new wells in the TR3 North Wall area. The samples were analyzed for VOCs and total and dissolved PCBs. The analytical results are presented in **Table 6** and **Figure 8**. Only well TR3-PW-01 contained compounds at concentrations above the groundwater criteria including 1,1-dichloroethene (1,1-DCE), cis-1,2-DCE , trans-1,2-DCE, PCE, TCE, and vinyl chloride.

No PCBs were detected in groundwater in any of the five wells.

4.3 Estimated Areal Extent of Impacted Soil North of TR-3 North Wall

One of the purposes of the investigation was to delineate the extent of soils requiring remediation on the from the north side of the TR-3 North Wall to the edge of Sanders Creek. **Figures 6** and **7** compare the soil analytical results to Protection of Groundwater and Industrial Use criteria, respectively. Soil analytical results for MW-54D, MW-56, MW-57, MW-58, MW-59, MW-66, MW-67, and MW-68 from EnSafe's previous investigation are also shown on the figures. The results show apparently discontinuous areas of elevated chlorinated VOC contamination in the following areas:

- From TR3-SB-04 to TR3-SB-01 and TR3-SB-11.
- From MW-66 to TR3-SB-07.

The soil analytical results suggest that the greatest levels of contamination occur at or just above the confining gray clay unit. The results suggest that groundwater and/or DNAPL was the primary source of soil contamination and, where impacted groundwater is present, the soils are also impacted.

Because borings TR3-SB-05 and TR3-SB-06 could not be completed as planned, limited soil data exists for the area between TR3-07 and TR3-SB-04. However, groundwater data from EnSafe's 2015 site wide sampling effort shows VOC impacts in monitoring wells MW-57, MW-58, and MW-66. Based on these results, and considering that soil contamination in the area is a result of groundwater and/or DNAPL migration, it is reasonable to conclude that the soils at depth in the area between TR3-SB-07 and TR3-SB--04 are likely impacted at levels above the Protection of Groundwater SCOs. Using this assumption, **Figure 9** shows the estimated areal extent of soils considered to be impacted. However, this is not to imply that the entire volume of soil in the area is so impacted, because shallower soils may not be, as confirmed by some of the shallower soil data.

4.4 Geotechnical Analytical Results

Eighteen soil samples were submitted to 3rd Rock, LLC for geotechnical analyses. Five of the 18 samples were Shelby tube samples collected from the confining clay layer. These samples were submitted for analysis of Atterberg Limits, water content, and unconsolidated undrained triaxial testing by Methods D4318, D2216, and D2850, respectively. The remaining 13 soil samples were collected from the sand unit beneath the clay and were analyzed for grain size using Method D422. A copy of the geotechnical laboratory report is provided in **Appendix B.**

Results for the five Shelby tube samples were generally consistent with each other with the exception of the sample from TR3-GB-03 (24 to 26 ft). The plasticity index of this sample (3%) was lower than in the other four samples (which ranged from 9% to 15%). Similarly, the compressive strength of 20.4 pounds per square inch (psi) was higher than the other four samples (which ranged from 7.0 to 13.0 psi).

The grain size analytical results for the deposits below the confining clay layer indicate the unit consists primarily of fine sand with trace to some medium sand (TR3-GB-04 and TR3-GB-05 only), trace silt, and trace clay.

4.5 Pumping Test and Hydraulic Conductivity Testing Results

Pumping test and slug test data was analyzed with Aqtesolv, an industry standard program with a variety of solutions including those for confined, unconfined, and leaky aquifer conditions. Five pumping tests and four slug tests were analyzed. The pumping test and hydraulic conductivity testing results are included in **Appendix F**. The following text presents a brief summary of the pumping test and conductivity test results.

The assumptions for the analytical methods include an isotropic aquifer of infinite aerial extent, no boundaries and simple stratigraphy although vertical anisotropy can be included. The site has a complex surficial geology which complicates pump and slug test analyses. Hence, several methods were used to assess aquifer parameters.

Most of the data were analyzed using the Moench method, which utilizes wellbore storage (i.e., the column of water in the well being pumped). The following results for the shallow wells were determined based on the pumping test calculations:

- Transmissivity (T) ranged from 1.2×10^{-3} to 9.3×10^{-7} square meters per day (m^2/day);
- Hydraulic Conductivity (K) ranged from 4.5×10^{-4} to 3.5×10^{-7} meters per second (m/sec);

- Storativity (S) ranged from 0.84 to 2.7 x 10^{-9}; and
- Specific yield (S_y) ranged from 0.25 to 1.0 x 10^{-3}.

The variability of the pumping test and slug test data reflects the variability of the deposits encountered during drilling. Overall these are fairly low permeabilities. Therefore low volumes of water would be expected from the groundwater extraction system proposed in the IRM.

The deep well, MW-54D, showed indications of being in a leaky aquifer with overlying aquitard consistent with the observed stratigraphy. During the course of the test, no drawdown was observed in the nearby shallow observation wells indicating that leakage was likely emanating from aquitard storage. The following results were calculated from the MW-54D test:

- T ranged from 5.7 x 10^{-3} to 8.9 x 10^{-6} m^2/day;
- K ranged from 1.7 x 10^{-3} to 2.7 x 10^{-6} m/sec; and
- S ranged from 3.1 x 10^{-5} to 4.9 x 10^{-9}.

The water level in Sanders Creek was measured periodically during the pumping tests. There was no discernable effect on the Sanders Creek water level from the pumping tests.

The slug tests were analyzed using the Hvorslev method. Since hydraulic conductivity values were also obtained from the pumping tests and serve as a check, only the falling head portion of each test was analyzed. The slug test results produced hydraulic conductivity values ranging from 8.5 x 10^{-5} to 3.8 x 10^{-7} m/sec.

5.0 Summary

The TR-3 North Wall/SWTP Area IRM PDI was completed in accordance with the NYSDEC-approved work plan. The field work involved a geophysical survey; advancing 20 soil borings; completing four soil borings as shallow monitoring wells and one as a deep monitoring well; performing pumping and slug testing; analyzing select soil samples for VOCs, PCBs, and geotechnical parameters; and analyzing groundwater samples for VOCs and PCBs. The information obtained from the investigation provides the information required for IRM design. The information includes:

- The geophysical survey identified locations of buried utilities between Sanders Creek and the TR-3 North Wall.
- Geotechnical data (e.g., soil density, Atterberg limits, depth to bedrock, etc.) obtained from the geotechnical borings along the proposed sheet pile alignment provide the information required for the sheet pile design.
- The pumping and slug tests provide hydraulic conductivity data required to design a groundwater extraction system on the south side of the TR-3 North Wall.
- The installation and sampling of the two shallow monitoring wells on the north side of Sanders Creek confirmed the general absence of soil and groundwater contamination in that area.
- The soil boring analytical results, in combination with previous investigation results, have generally defined the areal extent of impacted soils between the TR3 North Wall and Sanders Creek (see **Figure 9**). The data indicate that the impacts are primarily in the deeper soils. A DNAPL (solvent) phase might be present in the TR3-GB-01 area.
- Groundwater analytical results from this and previous sampling events confirmed that chlorinated VOC impacts are localized to the TR-3 North Wall and SWTP area and present only in the upper water-bearing zone.

The results of the IRM PDI provide sufficient data to proceed with the design of the sheet pile groundwater barrier, and the groundwater extraction system, called for in Step 1 of the IRM.

Additional data and study may be required to complete the design of the soil remediation as called for in Step 2 of the IRM. This may include additional field sampling to refine the area of required remediation, and the evaluation of potentially applicable remedial technologies and excavation methods and procedures.

0		0-4.5			ND	Brown clayey SILT, trace coarse sand		
						Brown clayey SILT, trace coarse sand and fine gravel, occasional cobble		Refusal @ 4.5'
-5						End of boring @ 4.5' Hand Auger Refusal on concrete.		
-10								
-15								
-20								
-25								

COMMENTS: Boring hand cleared to refusal at 4.5'. Attempted to advance with track mounted 6712DT Geoprobe rig.

Concrete encountered with hand methods was confirmed to be competent with probe.

Attempted offset boring 1 foot away and refusal was also encountered at similar depth.

No samples were collected for analysis from this boring.

I. INTRODUCTION

This Data Usability Summary Report (DUSR) has been prepared following the guidelines provided in New York State Department of Environmental Conservation (NYSDEC) Division of Environmental Remediation *DER-10 Technical Guidance for Site Investigation and Remediation*, Appendix 2B - *Guidance for Data Deliverables and the Development of Data Usability Summary Reports,* May 2010.

II. ANALYTICAL METHODOLOGIES AND DATA VALIDATION PROCEDURES

The data being evaluated are from the January 12 – April 19, 2016 sampling of 54 soil samples, 2 field duplicates, 3 Matrix Spike/Matrix Spike Duplicate (MS/MSD) pairs, 5 groundwater samples, 2 equipment rinsate blanks, and 1 trip blank. All samples were sent to SGS Accutest located in Marlborough, MA and were analyzed for target compound list (TCL) volatile organic compounds (VOCs) following United States Environmental Protection Agency (USEPA) Method 8260C and TCL PCBs (total and dissolved) following USEPA Method 8082A. Not all samples were analyzed for all parameters.

A limited data validation was performed following the guidelines in the following USEPA Region II documents:

- *Validating Volatile Organic Compounds by Gas Chromatography/Mass Spectrometry, SW-846 Method 8260B*, SOP HW-24, Rev. 2, August 2008;
- *Polychlorinated Biphenyl (PCB) Aroclor Data Validation,* SOP HW-37, Rev. 3, May 2013

Qualifications applied to the data during the limited data validation include 'R' (rejected), 'J' (estimated concentration), 'U' (non-detect), and 'UJ' (estimated quantitation limit). Definitions of USEPA data qualifiers are presented at the end of this text. The validated analytical results are presented on Tables 1 – 9. Copies of marked-up laboratory analytical summaries (Form 1s) are presented in Attachment A on a per sample delivery group (SDG) basis. Documentation supporting the qualification of data is presented in Attachment B on a per sample delivery group basis. Only analytical deviations affecting data usability are discussed in this report.

III. DATA DELIVERABLE COMPLETENESS

Full deliverable data packages (i.e., NYSDEC Category B or equivalent) were provided by the laboratory, which included all reporting forms and raw data necessary to fully evaluate and verify the reported analytical results.

IV. SAMPLE RECEIPT/PRESERVATION/HOLDING TIMES

All samples were received by the laboratory intact, properly preserved and under proper chain-of-custody (COC). All samples were analyzed within the required holding times, except for the following instance:

- The initial VOC analysis of soil samples TR3-MW-02 (7-7.5), TR3-SB02 (8-10), TR3-SB03 (6-8), TR3-SB03 (8-10), and TR3-SB03 (12-14) occurred within the holding time. The laboratory re-analyzed the sample outside of the holding time due to a QC issue with carbon disulfide and vinyl chloride. Only the results of carbon disulfide and vinyl chloride are being reported from the re-analysis and have been qualified 'J' or 'UJ' due to the holding time exceedance.

- The initial analysis of groundwater sample TR3-MW-02 occurred within the holding time. The laboratory re-analyzed the sample outside of the holding time due to a QC issue with acetone. Only the results for acetone are being reported from the re-analyzed and have been qualified 'UJ' due to the holding time excedeence.

- The initial analysis of groundwater sample TR3-PW1 occurred with the holding time. The laboratory re-analyzed the sample at a dilution outside of the holding time due to an elevated level of cis-1,2-dichloroethene (cis-1,2-DCE) and trichloroethene (TCE). The result for these compounds have been qualified 'J'.

V. NON-CONFORMANCES

- **Surrogates**

  The %R of VOC surrogate 4-bromofluorobenzene and/or dibromofluoromethane was above the upper QC limit in some of the samples. The detected VOC results in the associated samples as listed on the surrogate recovery summary form were qualified 'J'.

Support documentation (i.e., surrogate recovery summary form) is presented in Appendix B.

- **Instrument Calibration**

The relative response factors (RRF) for acetone and/or methyl ethyl ketone (2-butanone) in the initial calibration (ICAL) and continuing calibration standards (CCAL) were below the QC limit of 0.100. The non-detect results for these compounds in the associated samples as listed on the instrument performance check forms were qualified 'R' and the detected compounds were qualified 'J'.

The percent difference (%D) between the ICAL average RRF and the RRF in one or more of the CCALs associated with the samples exceeded the QC limit of 20% for one or more of the following VOCs: 2-butanone, 1,1-dichloroethene, 2-hexanone, 1,1,1,-trichloroethane, acetone, bromodichloromethane, bromoform, bromomethane, carbon disulfide, carbon tetrachloride, chloroethane, chloroform, chloromethane, dibromochloromethane, dichlorodifluoromethane, ethylbenzene, styrene, tetrachloroethene, trans-1,2-dichloroethene, vinyl chloride, and/or total xylenes. The results for these compounds in the associated samples as listed on the instrument performance check forms were qualified 'J' or 'UJ'.

Support documentation (i.e., instrument performance check form, continuing calibration summary form) is provided in Attachment B.

- **Method Blanks**

VOCs methylene chloride and/or toluene were detected below the reporting limit (RL) in the laboratory method blanks associated with the samples. Those associated samples that had concentrations of this compound less than the RL were qualified 'U' at the RL.

Support documentation (i.e., method blank summary form, report of analysis form) is provided in Attachment B.

- **Equipment Rinsate Blanks (EB)**

VOC trichloroethene was detected below the QL in the EB associated with the samples. Those associated samples that had concentrations of this compound less than the RL were qualified 'U' at the RL.

- **Matrix Spike Blank (MSB)**

  The VOC MSB was above the QC limit for acetone. The detected results for this compound in the associated samples as listed on the blank spike summary form have been qualified 'J'.

- **Internal Standards (VOCs only)**

  The %Rs of VOC internal standard (IS) 1,4-dichlorobenzene-d_4 were below QC limits in the samples. The compounds associated with the IS outliers in the samples listed on the internal standard area summary form have been qualified 'UJ'.

- **Chromatography**

  The laboratory noted in the case narrative that some samples exhibited interference due to multiple aroclors being present with overlapping peaks. Those samples that are affected have been noted in the laboratory case narrative and on the Form Is. The affected aroclors have been qualified 'J' in accordance with the labs notation.

  The %Ds between the dual-column analyses for the samples exceeded QC limits (>25%) for one or more PCBs. The PCB results for the affected samples have been qualified 'J', 'NJ', 'U', or 'R' in accordance with the following validation guidelines.

% Difference	Qualifier
0-25%	none
26-100%	'J'
101-200% (interference detected)	'NJ'
>50% (value is < QL on both columns)	'U'
>200%	'R'

  Support documentation (i.e., GC Identification Summary forms) is provided in Attachment B.

- **Field Duplicates**

  Field duplicates were collected at sample locations GB-05 (15-17) and TR-SB-02 (12-14) and exhibited good field and analytical precision.

VI. SAMPLE RESULTS AND REPORTING

All quantitation/detection limits were reported in accordance with method requirements and were adjusted for sample volume, moisture content, and dilution factors. Results below the quantitation limits

were qualified 'J' by the laboratory. All quantitation limits were reported in accordance with method requirements and were adjusted for dilution factors.

Several samples required dilutions due to the nature of the sample matrix and/or high levels to target compounds. Those results reported from a secondary dilutions were qualified 'D'. The quantitation limits reported for the non-detect compounds are the lowest achievable at the diluted level.

VII. SUMMARY

All sample analyses were found to be compliant with the method and validation criteria, except where previously noted. Those results qualified 'R' are considered unusable. Those results qualified 'J', 'U', and 'UJ' are considered conditionally usable. All other sample results are usable as reported. URS does not recommend the recollection of any samples at this time.

Prepared By: Ann Marie Kropovitch, Chemist AMK **Date:** 6/28/16

Reviewed By: George E. Kisluk, Senior Chemist GEK **Date:** 6/28/16

DEFINITIONS OF USEPA DATA QUALIFIERS

U –	The analyte was analyzed for, but was not detected above the level of the reported sample quantitation limit.
J –	The result is an estimated quantity. The associated numerical value is the approximate concentration of the analyte in the sample.
(J+) -	The result is an estimated quantity. The associated numerical value is biased high.
(J-) -	The result is an estimated quantity. The associated numerical value is biased low.
UJ –	The analyte was analyzed for, but not detected. The reported quantitation limit is approximate and may be inaccurate or imprecise.
R –	The data are unusable. The sample results are rejected due to serious deficiencies in meeting quality control criteria. The analyte may or may not be present in the sample.
D –	The sample result was reported from a secondary dilution analysis.
NJ –	The analysis indicates the presence of an analyte that has been "tentatively identified' and the associated numerical value represents its approximate concentration.

Pumping Test and Hydraulic Conductivity Testing Calculations

1.1 Pumping Tests

Pumping tests were conducted using the two new 4-inch diameter unconfined water-bearing zone wells (TR3-PW-1 and TR3-PW-2), two existing 2-inch diameter unconfined water-bearing zone monitoring wells (MW-50 and MW-62), and existing confined water-bearing zone well MW-54D. The pump test methods are discussed below.

Unconfined Water-Bearing Zone Pumping Tests

The pumping tests were performed using a Grundfos Redi-flo 2 submersible pump and In-Situ Level TROLL 700 pressure transducers to monitor water levels in the pumping well and in nearby monitoring wells. The tests at TR3-PW-2, MW-50, and MW-62 were run for approximately 7 hours with 2 hours recovery at the end of pumping. Pumping at TR3-PW-1 was terminated after 2 hours because the very low flow rate could not be maintained by the pump. Water recovered during the pumping tests was conveyed to the SWTB for treatment.

In addition, rising and falling head slug tests were performed on the four shallow pumping wells to determine hydraulic conductivity and supplement the pump test data.

Confined Water-Bearing Zone Pumping Test

Monitoring well MW-54D is previously installed in the confined lower water-bearing zone. The boring log from this well indicates that two sand layers underlay the confining clay layer from approximately 35 to 40 ft bgs and from 44.5 to 46 ft bgs. Similar to the unconfined water-bearing zone pumping tests, the pumping test performed in the lower water-bearing zone pumping from MW-54D used a small diameter pump capable of fitting within a 2-inch well and pressure transducers installed to monitor water levels in the pumping well, the newly-installed deep well (TR3-GB-03) and in MW-14D (an existing deep well). Because of artesian conditions, temporary extensions were installed on the deep well risers during the pump test. This pumping test was conducted for a total of 6 hours with 2 hours recovery at the end of pumping. Water recovered during the pumping test was conveyed to the SWTB for treatment.

Nearby shallow monitoring wells were also monitored with pressure transducers to determine the degree of hydraulic connection, if any, between the unconfined and confined water-bearing zones.

During these tests, the water level was also monitored in Sanders Creek both upstream and downstream using surveyed measuring points.

1.2 Pumping and Slug Test Results

Pumping and slug test data was analyzed with Aqtesolv, an industry standard program with a variety of solutions including those for confined, unconfined, and leaky aquifer conditions. Five (5) pumping tests and four (4) slug tests were analyzed.

Assumptions

The assumptions for the analytical methods include an isotropic aquifer of infinite aerial extent, no boundaries and simple stratigraphy although vertical anisotropy can be included. The UTC Syracuse site has a complex surficial geology which makes pumping and slug test analyses a challenge. Hence, several methods have been used to assess aquifer parameters.

Results

The results of the analyses are shown in **Table 1**. Aquifer parameters derived from pumping include transmissivity T, storativity S, and specific yield (drainable porosity) S_y although not all methods produce both storage parameters. From the values of transmissivity T, hydraulic conductivity, K, is produced by dividing T by aquifer saturated thickness, b. Hydraulic conductivity, K, is derived from slug tests.

Aquifer parameters for different tests can vary for the same observation well due to the anisotropic conditions at the site. The aquifer parameters represent the conditions between the pumping well and the

observation wells. Where the same observation well is used in two (2) different tests with different pumping wells, the derived aquifer parameters can be significantly different.

Most of the data were analyzed using the Moench method which utilizes wellbore storage, which refers to the column of water in the well being pumped. At low pumping rates, this water can take significant time to be replaced by water from the aquifer resulting in less observed drawdown in both the pumping and observation wells than if wellbore storage was not occurring.

The deep well, MW54D, showed indications of being in a leaky aquifer with overlying aquitard consistent with the observed stratigraphy. During the course of the test, no drawdown was observed in the nearby shallow observation wells indicating that leakage was likely emanating from aquitard storage. It is possible, that with continued long-term pumping, there could be an effect on the shallow aquifer.

There was no discernable effect on the Sanders Creek water level from any of the pumping tests.

Hydraulic conductivity is the main parameter required for the groundwater model. Therefore, the geometric mean of the hydraulic conductivity was determined for each observation well. These are given in **Table 2**. In this table, where there was only one (1) test result, that result is presented.

WELL DATA

Pumping Wells

Well Name	X (ft)	Y (ft)
PW1	953687.2	1124816

Observation Wells

Well Name	X (ft)	Y (ft)
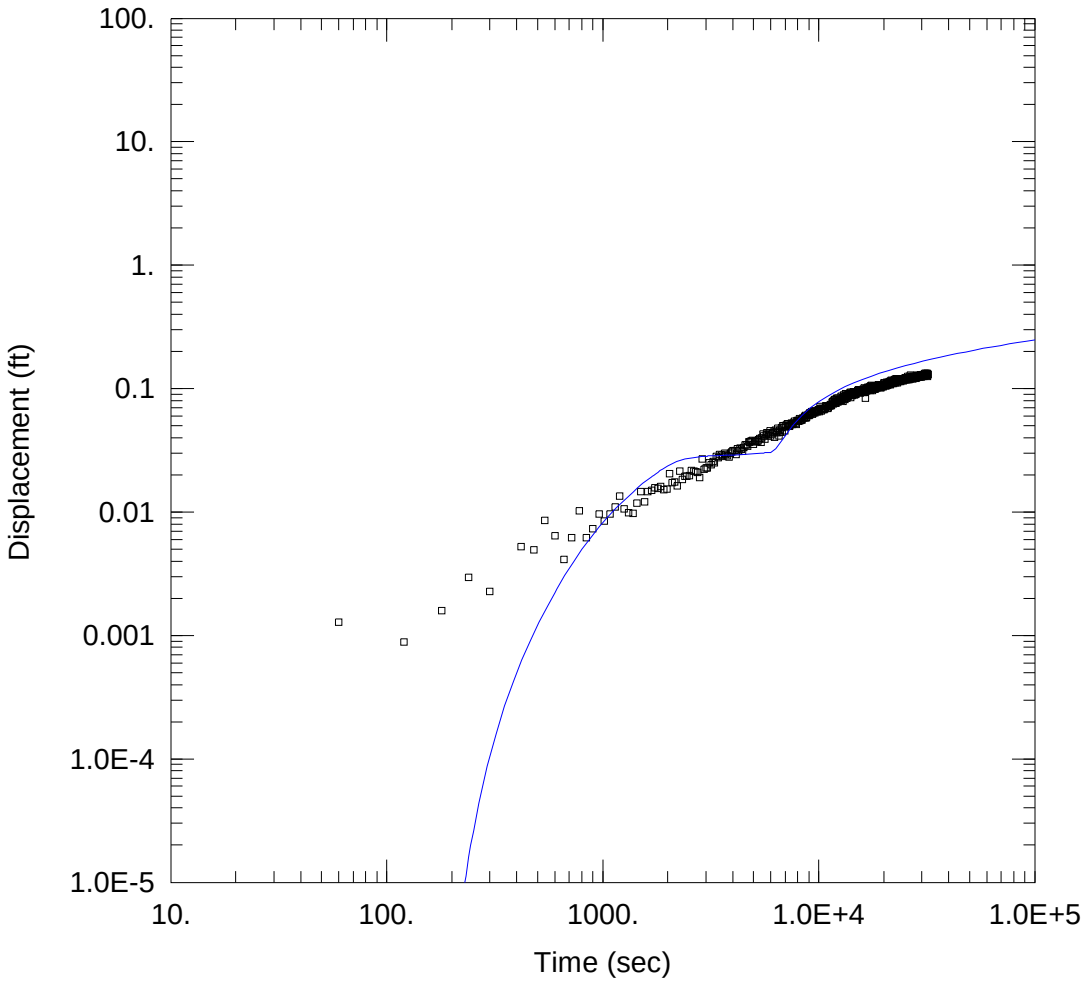
MW55	953702	1124843

SOLUTION

Aquifer Model: Unconfined Solution Method: Moench

T = 9.16E-5 m^2/sec
Sy = 0.002318
Sw = -0.825
r(c) = 0.1667 ft

S = 0.0205
Kz/Kr = 0.2596
r(w) = 0.1667 ft
alpha = 1.0E+30 sec^{-1}



WELL TEST ANALYSIS

Data Set: C:\Users\ruttand\Documents\UTC SYRACUSE\analysed pump tests\pw1\PW1 MOENCH.aqt
Date: 07/07/16 Time: 11:14:40

PROJECT INFORMATION

Company: AECOM
Client: UTC
Project: 60480273
Location: Syracuse
Test Well: PW1
Test Date: 5/16/16

AQUIFER DATA

Saturated Thickness: 15.23 ft Anisotropy Ratio (Kz/Kr): 0.2596

WELL DATA

Pumping Wells

Well Name	X (ft)	Y (ft)
PW1	953687.2	1124816

Observation Wells

Well Name	X (ft)	Y (ft)
MW56	953677	1124842

SOLUTION

Aquifer Model: Unconfined Solution Method: Moench

T = 0.0001324 m^2/sec
Sy = 0.001
Sw = -0.45
r(c) = 0.1667 ft

S = 0.008161
Kz/Kr = 0.2596
r(w) = 0.1667 ft
alpha = 1.0E+30 sec^{-1}

WELL TEST ANALYSIS

Data Set: C:\Users\ruttand\Documents\UTC SYRACUSE\analysed slug tests\mw50\MW50.aqt
Date: 06/17/16 Time: 11:30:49

PROJECT INFORMATION

Company: AECOM
Client: UTC
Project: 60480273
Location: Syracuse
Test Well: MW50
Test Date: 5/16/16

AQUIFER DATA

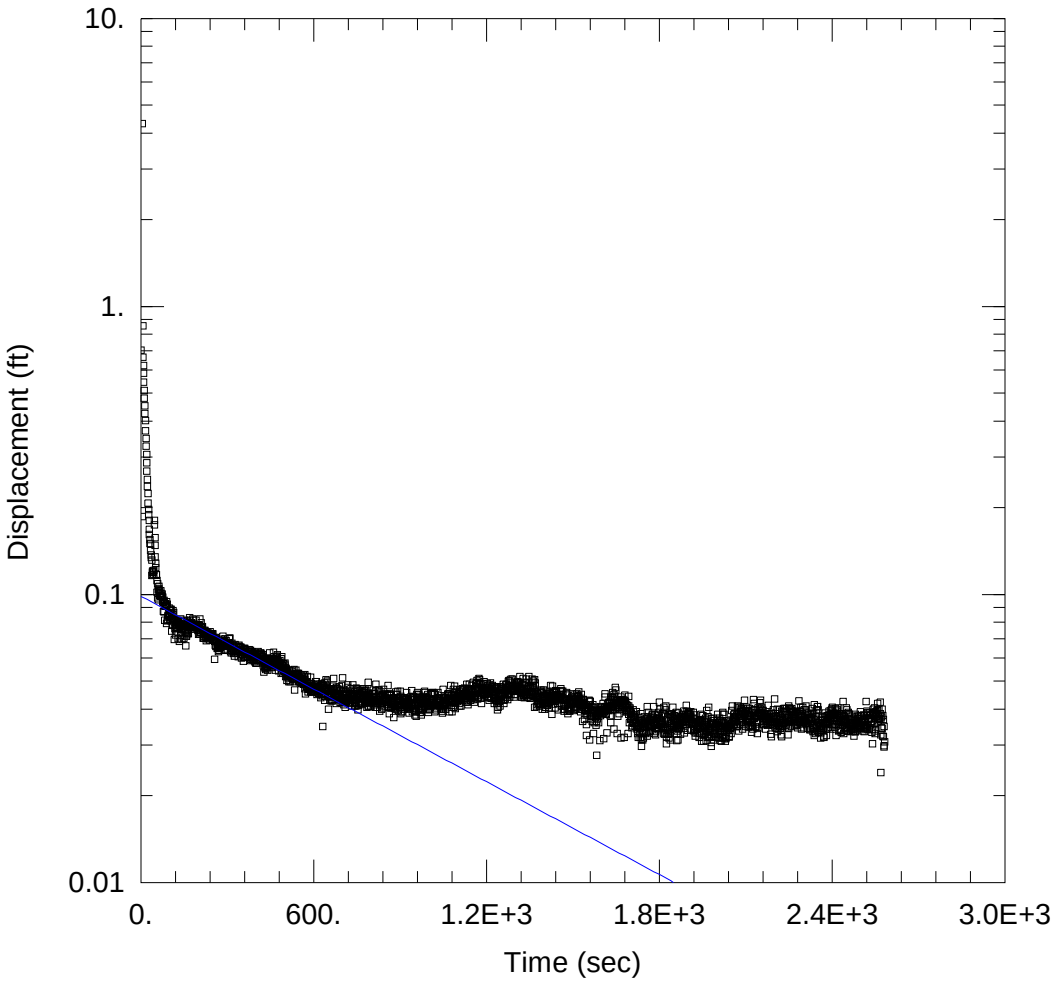
Saturated Thickness: 8.54 ft Anisotropy Ratio (Kz/Kr): 0.1

WELL DATA (MW50)

Initial Displacement: 0.086 ft
Total Well Penetration Depth: 15. ft
Casing Radius: 0.083 ft
Static Water Column Height: 1. ft
Screen Length: 15. ft
Well Radius: 0.083 ft

SOLUTION

Aquifer Model: Unconfined
Solution Method: Hvorslev
K = 8.461E-5 m/sec
y0 = 0.07831 ft



WELL TEST ANALYSIS

Data Set: C:\Users\ruttand\Documents\UTC SYRACUSE\analysed slug tests\mw62 slug\mw62slug.aqt
Date: 06/20/16 Time: 09:19:44

PROJECT INFORMATION

Company: AECOM
Client: UTC
Project: 60480273
Location: Syracuse
Test Well: MW62
Test Date: 5/16/16

AQUIFER DATA

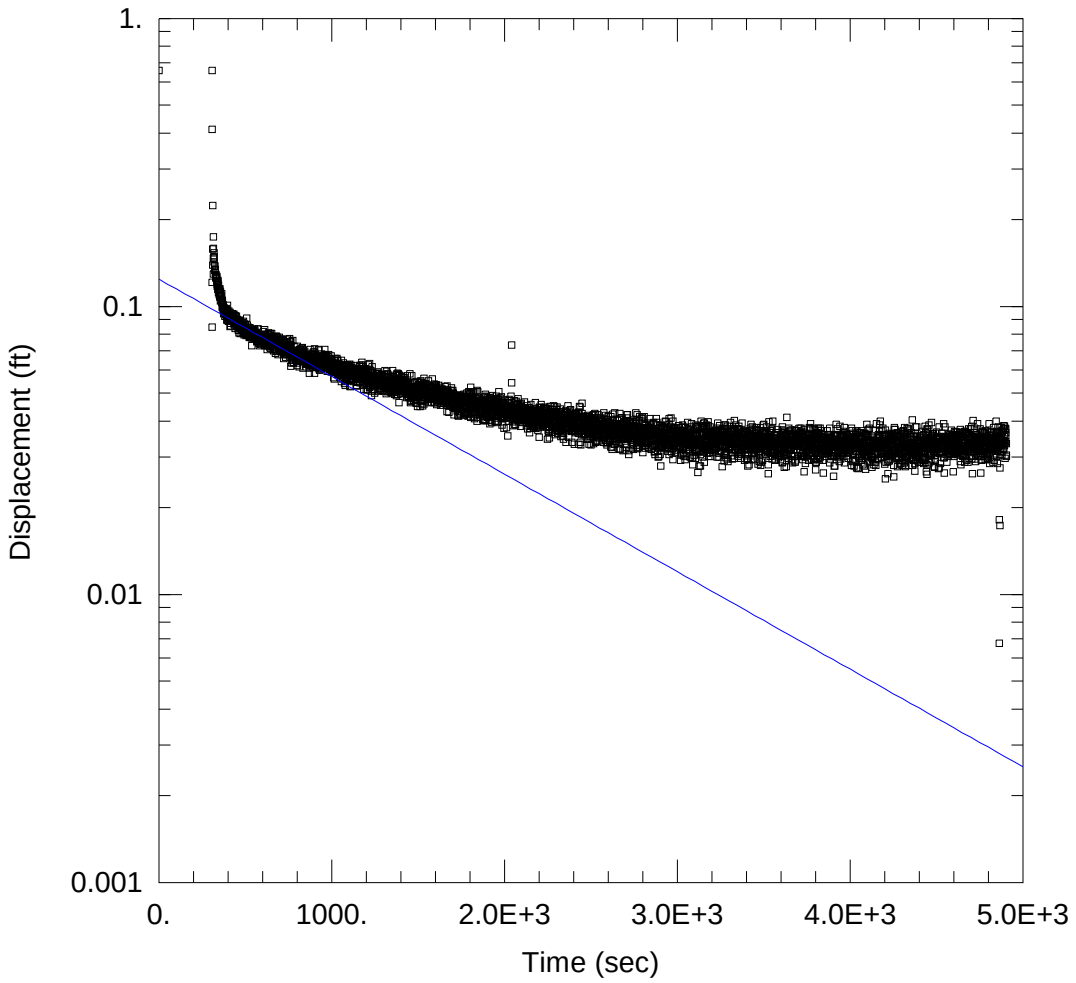
Saturated Thickness: 8.52 ft
Anisotropy Ratio (Kz/Kr): 0.1

WELL DATA (mw62)

Initial Displacement: 0.7031 ft
Total Well Penetration Depth: 15. ft
Casing Radius: 0.083 ft
Static Water Column Height: 8.52 ft
Screen Length: 15. ft
Well Radius: 0.083 ft

SOLUTION

Aquifer Model: Unconfined
K = 7.398E-7 m/sec
Solution Method: Hvorslev
y0 = 0.0938 ft



WELL TEST ANALYSIS

Data Set: C:\Users\ruttand\Documents\UTC SYRACUSE\analysed slug tests\pw1slug\PW1SUG.aqt

Date: 06/17/16 Time: 11:28:21

PROJECT INFORMATION

Company: AECOM
Client: UTC
Project: 60480273
Location: Syracuse
Test Well: PW2

AQUIFER DATA

Saturated Thickness: 13.2 ft
Anisotropy Ratio (Kz/Kr): 0.1

WELL DATA (PW2)

Initial Displacement: 0.6672 ft
Total Well Penetration Depth: 17.2 ft
Casing Radius: 0.083 ft
Static Water Column Height: 13.2 ft
Screen Length: 15. ft
Well Radius: 0.26 ft

SOLUTION

Aquifer Model: Unconfined
Solution Method: Hvorslev
K = 4.675E-6 m/sec
y0 = 0.7264 ft
