microscopically in the other groups. Chlorobenzene produced death in rats exposed to 500 mg/kg-day (4/10 males and 3/10 females) and 750 mg/kg-day (9/10 males and 8/10 females). Body weight gain was reduced about 20% in both males and females from these groups. The most frequent histopathological lesions in these groups were moderate centrilobular hepatocellular necrosis, mild-to-moderate nephrosis (characterized by degeneration and necrosis of the proximal tubule) and minimal-to-moderate myeloid depletion of the bone marrow. Other lesions observed were hepatic degeneration and lymphoid depletions of the thymus and spleen. Further effects observed in rats from these dose groups included decreased white blood cell count, increased reticulocytes, increased serum alkaline phosphatase and gamma glutamyl transpeptidase, increased urinary output, increased urinary excretion of uroporphyrin and coproporphyrin, increased absolute and/or relative liver and kidney weights and decreased absolute and relative spleen weight. Effects in rats exposed to 250 mg/kg-day included reduced body weight gain (>20%, males only), increased absolute and relative liver weight, decreased absolute and relative spleen weight and a few observations of minimal hepatic necrosis and nephropathy. The only effects at lower doses were increased absolute and relative liver weight in females exposed to 125 mg/kg-day and decreased absolute and relative spleen weight in males exposed to 60 or 125 mg/kg-day. Taken together, the liver was identified as the most sensitive target organ. Increased liver weight was observed at $\geq$125 mg/kg-day, and hepatic necrosis occurred at $\geq$250 mg/kg-day. Although spleen weights were decreased at all doses, microscopic lesions (lymphoid depletion) were only observed at the high dose (750 mg/kg-day). Therefore, these results suggest a NOAEL and LOAEL in rats of 60 and 125 mg/kg-day, respectively (43 and 89 mg/kg-day, respectively, when adjusted for a 5 day/week dosing schedule).

Results in mice were similar in pattern to those in rats, although mice appeared to be more sensitive to chlorobenzene toxicity, as indicated by an increase in mortality in this species at 250 mg/kg-day (5/9 males and 4/10 females) and above (37/40 mice) (NTP, 1985). Body weight gain was reduced 50-80% in these groups. Histopathological lesions were generally limited in occurrence to these same dose groups; lesions included severe hepatic necrosis, moderate renal tubular necrosis, myeloid depletion of the spleen and bone marrow, lymphoid depletion of the spleen and thymus, and necrosis of the thymus. Absolute and relative liver weights were significantly increased in surviving males and females from these groups. Other changes in these dose groups were increased urinary output and increased urinary excretion of coproporphyrins. The only effect in mice exposed to 125 mg/kg was significantly increased absolute and relative liver weight in males. Based on liver toxicity in mice, NOAEL and LOAEL values of 60 and 125 mg/kg-day (duration adjusted doses of 43 and 89 mg/kg-day) can be derived.

In the chronic studies, groups of 50 rats of each sex and 50 female mice were administered chlorobenzene by gavage in corn oil at 0, 60 or 120 mg/kg-day 5 days/week for 103 weeks (NTP, 1985). Duration-adjusted doses were 0, 43, and 86 mg/kg-day, respectively. Groups of 50 male mice were similarly treated with 0, 30 or 60 mg/kg-day (duration adjusted doses of 0, 21, 43 mg/kg-day, respectively). Survival was significantly reduced in male rats in the 120 mg/kg group, but not in lower dose male rats or female rats. Body weight gain was not affected in rats of any group. From the original microscopic examination, there appeared to be a slightly increased incidence of hepatic necrosis in treated rats of both sexes (males at 60 mg/kg and females at 120 mg/kg), but a second independent review did not support these findings.

Other than effects on immune system at substantially high doses, no other chemical-related non-carcinogenic effects were identified in the rats. In mice, survival was marginally reduced in males at 30 and 60 mg/kg; however, survival trend did not follow a dose-response relationship and no effect was noted in females. Body weight gain was similar in treated and control mice and no treatment- related non-neoplastic lesions were identified.

Irish (1963) briefly reported the results of an unpublished Dow Chemical study, in which rats were treated orally with chlorobenzene 5 days per week for approximately 6 months. Doses of 144 and 288 mg/kg-day (duration adjusted doses of 103 and 206 mg/kg-day) produced significant increases in liver and kidney weight and slight liver pathology. No effects were detected in rats treated with 14.4 mg/kg-day (duration adjusted dose of 10.3 mg/kg-day). Further details regarding this study were not provided.

In contrast to the results of the studies described above, toxicity was reported at much lower doses by Varshavskaya (1967). Groups of 7 male albino rats weighing 180-200 g were treated with 0, 0.001, 0.01 or 0.1 mg/kg-day of chlorobenzene in sunflower oil by stomach tube for 9 months. Effects reported at 0.1 mg/kg-day included inhibition of higher nervous system activity (i.e., prolonged formation and accelerated loss of conditioned reflexes), a statistically significant inhibition of erythropoiesis (i.e., decreased red blood cell count and hemoglobin), increased serum alkaline phosphatase and aminotransferase levels, and immune system effects (increased leukocytes and gamma globulin). Many of these endpoints were also marginally affected by exposure to 0.01 mg/kg-day. No effects were reported at 0.001 mg/kg-day. Although some of the effects reported in this study are consistent with those observed in other studies, the effective doses are much lower. Varshavskaya (1967) also reports effects for o-dichlorobenzene that are over 3 orders of magnitude lower than other published values. Therefore, U.S. EPA (1980, 1985) considered the results of this study to be questionable.

Chlorobenzene was the subject of a developmental toxicity study in rats (IBT, 1977). Pregnant Charles River albino rats (20-22 per dose) were administered chlorobenzene at 100 or 300 mg/kg-day on gestation days 6-15 via oral gavage. Maternal body weight, mortality, and clinical signs of toxicity were recorded at regular intervals throughout exposure. All dams were sacrificed on gestation day 20 and were administered via Caesarian section. Implantation sites and the number of corpora lutea were determined, and the number of viable fetuses was recorded. All fetuses were removed from the uterus, weighed, and examined for external malformations. Two-thirds of the fetuses were examined for skeletal effects; the remaining fetuses were evaluated for internal development. No treatment-related effects were noted at any dose; however, the study did not test up to maternally toxic doses. The results of this study do not rule out developmental effects at high doses, but indicate that developmental toxicity is not likely a sensitive toxicological endpoint for chlorobenzene toxicity.

Inhalation Exposure. Several studies have examined the subchronic toxicity of inhaled chlorobenzene in animals (IBT, 1979; Roloff, 1980; Dilley, 1977; Irish, 1963; Zub, 1978). John et al. (1984) and Nair et al. (1987) have examined the developmental and reproductive toxicity, respectively, of inhaled chlorobenzene.

In a study conducted by IBT (1979), groups of male and female rats (15/sex/group) and beagle dogs (4/sex/group) were exposed to 0, 0.76, 1.47, or 2 mg/L (0, 760, 1470, or 2000 mg/m^3) of chlorobenzene 6 hours/day, 5 days/week for 90 days (62 exposure days). Controls were exposed to "clean air." All animals were observed for mortality and clinical signs of toxicity daily throughout the exposure period, and body weights were recorded weekly. Blood was taken from all surviving dogs at Day 28 (blood was taken from several dogs earlier than Day 28 because they were expected to be sacrificed moribund prior to the bleed) and from 5 control and high-concentration rats per sex at Days 39 and 91. Hematology, clinical chemistry, and urinalysis examinations were conducted at each bleed. At scheduled sacrifice, all animals were subjected to a gross pathology evaluation, the adrenal glands (dogs only), brain (cerebrum, cerebellum, and pons), lungs, pancreas, pituitary gland (dogs only), spleen, and thyroid gland (dogs only) were weighed (absolute weights and organ weight relative to the brain and terminal body weight were determined), and 29-32 tissues were microscopically examined from the control and high-concentration groups. Tissues from low- and mid-concentration animals were examined only if "significant pathologic findings" were observed at the high concentration.

No effects on rats were observed for any of the parameters evaluated (IBT, 1979). In dogs, however, a number of potential treatment-related effects were observed. An apparent concentration-related increase in mortality was observed. Mortality rates in dogs exposed at 0, 760, 1470, and 2000 mg/m^3, respectively, were 0/4, 0/4, 1/4, and 2/4 in males and 0/4, 0/4, 1/4, and 3/4 in females. Hypoactivity was observed in 0/4, 1/4, and 4/4 dogs at the low-, mid-, and high-concentrations, respectively, in both males and females (control incidences were not reported). Conjunctivitis occurred at the same incidence rates in both males and females. Also, one high-concentration female dog was observed with glazed eyes. There were no clear effects on body weight, although final mean body weights of high-concentration dogs were less than controls. No chlorobenzene-related alterations in hematological, serum clinical chemistry, or urinalysis parameters were observed. A number of statistically significant changes in absolute and relative organ weights were found; however, only pancreas weights of female dogs appeared to show a concentration-response relationship (although the lack of several organ weights from the low- and mid-concentration groups precludes a full evaluation of potential treatment-related effects). The toxicological relevance of the change in pancreas weight, however, is not clear because no microscopic lesions were observed in the pancreas.

Icterus (characterized by yellow discoloration of the aorta) and enlarged hardened livers were observed in dogs that were killed *in extremis* (IBT, 1979). Microscopic lesions were observed in the liver, kidney, testes, and bone marrow in treated dogs. At 2000 mg/m^3, slight to moderate vacuolation of the liver (2/4 males, 3/4 females), aplastic bone marrow (2/4 males, 3/4 females), epithelial cytoplasmic vacuolation in the kidneys (1/4 males, 3/4 females), and atrophy of the seminiferous epithelium in the testes (2/4 males) were observed. At 1470 mg/m^3, vacuolation of the liver (1/4 males) and juvenile testes (1/4 males) were observed. These lesions were not seen in controls. No tissues from low-concentration males or females were microscopically examined. This study was not peer-reviewed, and statements from the researchers highlighted that only a limited quality assurance review was given to this report. Therefore, reliable NOAEL or LOAEL values cannot be derived from this study. However, the study does provide suggestive evidence that the liver, kidneys, bone marrow, and testes may be target organs for chlorobenzene in dogs.

As a follow-up study, Roloff (1980) exposed beagle dogs (6 per sex and concentration) to chlorobenzene (96.5% pure) 6 hours/day, 5 days/week for 6 months at 0, 0.79, 1.59, or 2.06 mg/L (0, 790, 1590, or 2060 mg/m^3). Clinical signs of toxicity were recorded at regular intervals during the 6-hour exposure periods, detailed physical examinations were conducted weekly, and body weight was recorded weekly. After six months of exposure, animals were sacrificed, the adrenals, brain, heart, kidney, liver, pituitary, and testes were weighed, and 24 tissues were microscopically examined. A number of hematology, clinical chemistry, and urinalysis parameters were determined twice prior to study initiation, twice during the first four weeks of exposure, monthly thereafter, and at terminal sacrifice.

Body weight, food consumption, and general health of the dogs were unaffected by chlorobenzene exposure (Roloff, 1980). A concentration-related, statistically significant increase in the number of dogs observed to vomit ($p \leq 0.01$) or pass abnormal stools ($p \leq 0.01$) was reported, suggesting gastrointestinal irritation at all concentrations. However, histopathology did not reveal any treatment-related lesions of the GI tract, and other studies have not observed gastrointestinal effects. Therefore, the toxicological significance of this observation is not clear. A statistically significant ($p \leq 0.05$) increase in liver-to-body weight ratio was observed in mid- and high-concentration females and a significant ($p \leq 0.05$) decrease in absolute adrenal weight was observed in the mid- and high-concentration males. Kidney weight was not affected by treatment. In the absence of microscopic lesions in these tissues, the biological significance of the organ weight changes is not clear. Although chlorobenzene exposure has been shown to affect the liver in other studies, only relative weights in females were significantly increased compared with controls and no microscopic lesions were observed in the liver in this study. Also, relative liver weights in females did not show a clear concentration-related increase. Relative liver weights at 0, 790, 1590, and 2000 mg/m^3, respectively, were 2.4%, 3.2%, 3.1%, and 3.1%. Therefore, it does not appear that the increase in relative liver weight in female dogs was related to treatment. Statistically significant changes in various clinical chemistry parameters were observed; however, these changes appeared to be random and not related to chlorobenzene exposure. A clear LOAEL was not observed in this study.

Taken together, these 90 day and 6-month studies in dogs resulted in contradictory results and, therefore, do not allow for reliable NOAEL or LOAEL derivations. In one study, (IBT, 1979), an apparent concentration-related increase in mortality and effects on the kidney, liver, and testes were observed. In a follow-up study (Roloff, 1980), however, no effects were observed in dogs at comparable concentrations. Therefore, a clear NOAEL or LOAEL in dogs was not established.

In a study reported by Irish (1963), groups of rats, rabbits, and guinea pigs were exposed to 0, 200, 475, or 1000 ppm (0, 920, 2189, or 4604 mg/m^3) of chlorobenzene for 7 hours/day, 5 days/week for 44 days. In the guinea pigs exposed at 4604 mg/m^3, increased mortality was observed. Unspecified histological alterations were observed in the liver, kidney, and lungs in exposed animals at 4604 mg/m^3 (the study report did not specify which effects were associated with each species tested). At 2189 mg/m^3, slight histological alterations were also observed in the liver. No effects were observed at 920 mg/m^3. Additional details were not available.

Zub (1978) exposed male and female white Swiss mice (5 per sex and concentration) to chlorobenzene vapors at 100 mg/m^3 daily (7 hours per day) for 3 months or 2500 mg/m^3 daily for 3 weeks. Additional experimental design parameters were not reported. Five of 10 mice exposed at 2500 mg/m^3 died. Loss of appetite, general emaciation, marked somnolence, decreased body weight, fatty degeneration and atrophy in the liver were also observed at 2500 mg/m^3. Slight leukopenia and lymphocytosis were the only haematological effects in mice exposed to 100 mg/m^3 for 3 months. Although these data support the conclusion that chlorobenzene may affect the liver, the data are limited because sufficient detail on experimental methods and results were not reported in the published article to permit critical evaluation of the study.

Dilley (1977) exposed groups of 32 male Sprague-Dawley rats and 32 male rabbits (strain not specified) to 0, 73, or 248 ppm (0, 336, or 1142 mg/m^3, respectively) of chlorobenzene for 7 hours/day, 5 days/week for 24 weeks. Groups of 10 rats and 10 rabbits were killed after 5, 11, or 24 weeks of exposure. Animals were weighed weekly for 5 weeks, every 2 weeks for the next 4 weeks and monthly thereafter. All animals were observed daily for clinical signs of toxicity. The brain, heart, lungs, liver, spleen, kidneys, and gonads were weighed. These tissues and the adrenal glands, bone marrow, eye, skin, and abnormal tissues were microscopically examined. A number of hematology and clinical chemistry parameters were evaluated.

In rats, no deaths, unusual clinical observations or changes in body weight gain were observed (Dilley, 1977). The kidney and liver weights generally increased with increasing concentration (Table 2). Significant increases in absolute and relative liver weights were observed in male rats exposed to 248 ppm for 24 weeks (Table 2) compared with controls. Relative kidney weights were also significantly greater than controls after 24 weeks.

Hematology evaluations found decreased hematocrit and mean corpuscular volume, and increased mean corpuscular hemoglobin concentration, in rats exposed to chlorobenzene at $\geq$73 ppm after 11 weeks of exposure, consistent with microcytic anemia; however, similar effects were not observed at 24 weeks (Dilley, 1977). Therefore, the biological significance of this observation is not clear. The only consistent and significant change in the rat clinical chemistry profile was reduced serum aspartate aminotransferase (AST) activity in the high-dose group at all three sacrifice times. The toxicological significance of this observation is not clear. Histopathology revealed no consistent concentration-related increase in the incidences of any lesions. Chronic respiratory disease was observed in 8-10 rats in all treatment and control groups. It is not known if the chronic respiratory disease made the animals unusually sensitive to the toxicity of chlorobenzene or masked some aspects of chlorobenzene toxicity. Therefore, a NOAEL and LOAEL suitable for RfC derivation cannot be identified from this study. However, the organ weight data provide supportive evidence that the liver and kidneys are possible targets of chlorobenzene toxicity.

Table 2. Selected Organ Weights in Male Rats Exposed to Chlorobenzene via Inhalation for 24 Weeks (Dilley, 1977)

Organ	Absolute or Relative Weight	0 ppm	73 ppm	248 ppm
Liver	Absolute (g)	16±0.8[a]	18±0.9	21±2.0[b]
	Relative, body	34±0.6	38±1.0	44±1.9[c]
	Relative, brain	7.3±0.4	8.0±0.4	9.7±0.8
Kidneys	Absolute (g)	3.5±0.2	3.7±0.1	4.1±0.2
	Relative, body	7.5±0.2	7.9±0.2	8.5±0.2[b]
	Relative, brain	1.6±0.08	1.6±0.06	1.8±0.08

[a] mean ± standard deviation
[b] statistically significant ($p \leq 0.05$)
[c] statistically significant ($p \leq 0.01$)

In rabbits, no treatment-related deaths, unusual clinical observations, or changes in body weight gain were observed (Dilley, 1977). Overall, there were no consistent concentration-related changes in hematology, clinical chemistry, or gross or microscopic lesions. Encephalitozoonosis (caused by *Escherichia cuniculi* infection) and respiratory illness associated with atelectasis and emphysema; lymphocytic foci near bronchi and bronchioles, focal edema and congestion were observed in a number of treated and control animals that may have affected the rabbits' sensitivity to chlorobenzene-induced toxicity. Therefore, these data are not suitable for RfC derivation.

Nair et al. (1987) conducted a two-generation reproductive study in rats. In this study, groups of 30 male and 30 female CD Sprague-Dawley rats were exposed to chlorobenzene (>99.9% pure) in a dynamic air chamber at target concentrations of 0, 50, 150, or 450 ppm (0, 230, 691, or 2072 mg/m^3) for 6 hours/day, 7 days/week for 10 weeks before mating, and during mating, gestation, and lactation. The male and female F_0 rats were sacrificed after the lactation period. Groups of 30 male and 30 female F_1 rats were exposed to the same concentrations of chlorobenzene (beginning 1 week post-weaning) for 11 weeks before mating and during mating, gestation, and lactation. The F_1 rats were also sacrificed after the lactation period. The F_2 pups were sacrificed after weaning. Mortality and clinical signs of toxicity were recorded twice each day, detailed physical examinations were conducted weekly, body weights were recorded weekly except that female body weights were also recorded at additional regular intervals throughout gestation and lactation, and food consumption was recorded weekly during the growth period. Complete gross postmortem examinations were conducted on all sacrificed animals. Liver and brain weights of F_0 and F_1 adults were recorded. Liver, kidneys, pituitary gland, and reproductive organs (males: testes, epididymides, seminal vesicle, and prostate; females: vagina, uterus, and ovaries) were examined microscopically for all F_0 and F_1 adult animals in the control and high-concentration groups. Liver, kidneys, and testes of male rats in the low- and mid-

concentration groups were microscopically examined. Hematology or clinical chemistry parameters were not evaluated.

No deaths were observed in the F_0 or F_1 groups, and no significant alterations in body weight gain were observed (Nair et al., 1987). No apparent alterations in the mating, pregnancy (number of pregnant females/number mated), fertility, pup viability, pup survival, or litter survival indices were observed in the F_0 or F_1 rats. Absolute and relative liver weights were clearly and significantly increased in F_0 and F_1 male rats exposed to $\geq$150 ppm and F_0 and F_1 female rats exposed to $\geq$450 ppm (Table 3). Much smaller, but still statistically significant, increases in relative liver weight at lower doses were consistent with the observed trend, but do not themselves indicate a toxicologically significant effect at the lower doses. Histopathology examinations identified the liver, kidneys, and testes as target organs for chlorobenzene in male rats. Table 4 shows incidence data reported by the investigators and the results of statistical tests conducted for this review (statistical tests of the incidence data were not performed by the original investigators). In the liver, the incidence of centrilobular hepatocellular hypertrophy was significantly increased in the 150 and 450 ppm F_0 males in a dose-related manner, and marginally increased in the 450 ppm F_1 males. In the kidneys, significant increases in the incidences of tubular dilation, chronic interstitial nephritis, and foci of regenerative epithelium were observed at 150 and 450 ppm in the F_0 males, but primarily at 450 ppm in the F_1 males. The incidence of small and flaccid testes was significantly increased in the F_1 males at 450 ppm, and was also observed in both F_0 and F_1 males at 150 ppm. Degeneration of the testicular germinal epithelium was seen in F_0 and F_1 males at 150 and 450 ppm, and appears to have been treatment-related. Although incidence levels were low at 150 ppm and just approached statistical significance at 450 ppm, the lesion was graded as moderate or severe in 1 F_0 and 2 F_1 males at 150 ppm and in 3 F_0 and 5 F_1 males at 450 ppm. The two observations of this lesion in controls were both graded as minimal. No concentration-related microscopic lesions were observed in female rats.

The kidney lesions observed in this study included tubular dilation, chronic interstitial nephritis, and foci of regenerative epithelium (Nair et al, 1987). Because the lesions observed in this study only occurred in male rats and are consistent with those typical of alpha-$_{2u}$-globulin accumulation (U.S. EPA, 1991b), and because other chlorobenzene derivatives have been shown to cause alpha-$_{2u}$-globulin accumulation (WHO, 1991), it is possible that the kidney effects observed in this study may not be relevant to human health risk assessment. However, there is insufficient evidence to attribute the kidney effects observed in this study to alpha-$_{2u}$-globulin accumulation. The presence of alpha-$_{2u}$-globulin was not tested for in the Nair et al. (1987) study, and other studies have demonstrated the occurrence of kidney effects in animals other than male rats. Hazleton Laboratories (1967a) reported kidney effects in orally treated dogs (including tubule dilation, vacuolation, and leukocytic infiltration), and NTP (1985) reported kidney effects in male and female mice (tubular necrosis) and male and female rats (degeneration and necrosis of the proximal tubule) orally administered chlorobenzene in subchronic studies. It is possible that the absence of kidney lesions in female rats in the Nair et al. (1987) study was due to generally lower sensitivity of the females to chlorobenzene toxicity, as liver lesions were also observed only in males in this study. Therefore, there is insufficient evidence to attribute the kidney lesions observed in this study to alpha-$_{2u}$-globulin accumulation, and the kidney

Table 3. Mean Absolute and Relative Liver Weights of F_0 and F_1 Rats Exposed to Chlorobenzene Vapor (Nair et al., 1987)

Concentration (ppm)	Males		Females

effects are considered relevant to human health risk assessment until conclusive evidence is obtained indicating otherwise.

Nair et al. (1987) demonstrated dose-related effects on the liver, kidney, and testes. Male rats were more sensitive than females. In all three organs, there was some evidence for an effect at 150 ppm, and more clear evidence at 450 ppm. In the liver, significant increases in liver weight and the incidence of hepatocellular hypertrophy were seen at 150 and 450 ppm. In the kidneys, the incidences of tubular dilation, chronic interstitial nephritis, and foci of regenerative epithelium were increased at both 150 and 450 ppm. The kidney effects are considered relevant to human health risk assessment, as previously discussed. In the testes, degeneration of the germinal epithelium was not statistically increased in incidence even in the 450 ppm group, but appeared to be related to treatment in both the 150 and 450 ppm groups based on severity of the lesions observed. Although the testes appeared to be a target for chlorobenzene, reproductive

performance was not affected at any exposure level. Based on these endpoints, this study identified a LOAEL of 150 ppm (691 mg/m^3) and NOAEL of 50 ppm (230 mg/m^3).

Chlorobenzene was the subject of several developmental toxicity studies. John et al. (1984) exposed groups of 32-33 pregnant Fischer 344 rats to 0, 75, 210, or 590 ppm (0, 345, 967, or 2716 mg/m^3) of chlorobenzene 6 hours/day on gestation days (GDs) 6-15. The dams were sacrificed on GD 21. At necropsy, the uterine horns were examined for (1) number and position of fetuses; (2) number of live and dead fetuses; (3) number and position of resorption sites; (4) number of corpora lutea; (5) the sex, body weight, and crown-rump length of each fetus; and (6) gross external abnormalities. One half of each litter was examined under a dissecting microscope for soft tissue alterations, and the heads of these animals were also examined by sectioning. All fetuses were examined for skeletal alterations.

No maternal deaths or changes in general appearance or behavior were observed in the chlorobenzene-exposed rats (John et al., 1984). In dams exposed to 590 ppm, significant decreases in body weight gain were observed on GDs 6-8 (Table 5); however, weight gains over subsequent intervals and total weight gains over GDs 6-20 were not significantly affected. Significant increases in absolute and relative liver weights were observed at 590 ppm (Table 5). Mean litter size and incidence of resorptions were not affected by chlorobenzene exposure, and no alterations in the incidence of malformations were observed in the rat fetuses. The incidences of some minor skeletal variations were altered in some groups, but no consistent concentration-related changes were observed. Therefore, chlorobenzene was not considered a developmental toxicant in this study. A maternal NOAEL and LOAEL of 210 ppm and 590 ppm, respectively, was identified from this study based on increased maternal liver weight and decreased body weight. The developmental NOAEL was 590 ppm, the highest concentration tested.

Table 5. Body and Liver Weights of Female Rats Exposed to Chlorobenzene (John et al., 1984)

Concentration (ppm)	Body weight gain GD 6-8[a] (g)	Liver weight (absolute) (g)	Liver weight (relative)
0	3 ± 2[b]	9.8 ±1.1	3.8 ± 0.28
75	4 ± 3	10.0 ± 0.81	3.9 ± 0.28
210	2 ± 3	10.1 ± 0.54	3.9 ± 0.21
590	-2 ± 5[c]	11.0 ± 0.83[c]	4.3 ± 0.42[c]

[a] body weight gains at other time periods were comparable to controls and are not reported
[b] mean ± standard deviation[c] statistically significant ($p \leq 0.05$)

John et al. (1984) conducted two developmental toxicity studies in rabbits. In the first study, groups of 30 pregnant New Zealand white rabbits were exposed to 0, 75, 210, or 590 ppm (0, 345, 967, or 2716 mg/m^3) of chlorobenzene for 6 hours/day on GDs 6-18 and sacrificed on GD 29. Other details of the protocol were the same as described for rats (John et al. 1984). No

effect on body weight or weight gain was observed in the does. Absolute and relative liver weights in the does were reported to be significantly increased at 210 and 590 ppm, but the data were not shown. No effects on reproductive or fetal parameters were found. There was a statistically significant ($p \leq 0.05$) increase in the incidence of fetuses with extra rib at 590 ppm. The number of litters affected, however, was comparable to controls (Table 6). There were also several observations of historically rare malformations (head/facial anomalies, heart defects, spina bifida, acephaly) in treated rabbits that were not seen in controls (Table 6). Because it was not clear that any of these effects were directly related to chlorobenzene treatment, a second experiment was conducted in rabbits at 0, 10, 30, 75, and 590 ppm.

Table 6. Fetal Alterations in Chlorobenzene Exposed Rabbits - Experiment 1 (John et al., 1984)

Concentration (ppm)	Extra Rib	Head/Facial Anomalies	Heart Anomalies	Spina Bifida	Acephaly
0	79 (24)[a]	0	0	0	0
75	68 (19)	1 (1)	0	0	0
210	92 (33)	0	1 (1)	1 (1)	0
590	113[b] (26)	1 (1)	2 (2)	1 (1)	1 (1)

[a] number of fetuses affected (number of litters affected in parentheses)
[b] statistically significant ($p \leq 0.05$)

In the second study (John et al., 1984), groups of 30-32 pregnant New Zealand White rabbits were exposed to 0, 10, 30, 75, or 590 ppm (0, 46, 138, 345, or 2716 mg/m^3) of chlorobenzene 6 hours/day on GDs 6-18. An increase in maternal liver weight was observed in the 590 ppm group. No significant alterations in the number of litters, number of fetuses per litter, or the number of implantations resorbed were observed; however, there was a significant increase in the number of litters with resorptions at 590 ppm. This observation, however, was not considered to be related to chlorobenzene exposure by the researchers because the incidence was within the range of historical controls (details on the historical controls were not reported) and because this effect was not observed in the first rabbit study. The incidence of malformations was not altered in the chlorobenzene-exposed groups. The malformations observed in the first rabbit study were either not observed at all in the second study or were seen at comparable incidence in the control group. An increased incidence of fetuses with extra ribs was found at 10 ppm, but the number of affected litters was similar to controls. No increases in extra ribs were seen at $\geq$30 ppm. Overall, no consistent developmental effects were observed in the two studies conducted in rabbits. The NOAEL for developmental toxicity was the high concentration of 590 ppm. Increased liver weights were observed at $\geq$210 ppm in maternal animals in the first study; the second study did not test any concentration between 75 and 590 ppm. Therefore, the maternal NOAEL for these studies was 75 ppm (345 mg/m^3) and the maternal LOAEL was 210 ppm (967 mg/m^3), based on increased liver weights.

Tarkhova (1965) exposed groups of 15 male white rats (strain not specified) to 0, 0.1, or 1.0 mg/m^3 (0, 0.02, 0.2 ppm) for an "uninterrupted" 60-day period. No alterations in body weight or appearance were observed. In the 1.0 mg/m^3 group, the conduction speeds of nerve impulses to sets of flexor and extensor muscles had changed on day 39. The ratios of chronaxias of the flexor and extensor muscles in the 1 mg/m^3 exposed animals were measured every 9-10 days as the experiment progressed. Ninety-nine percent (99%) reliability of changes by comparison to the control were observed starting day 39. A significant increase in blood cholinesterase and changes in the ratio of albumin:α-globulin ratio (direction of the change can not be determined) was also observed in the 1.0 mg/m^3 group. The rise in blood cholinestrase activity was observed in the 1 mg/m^3 exposed groups of animals on the 36th day of the treatment.

Aranyi et al. (1986) tested the immunotoxicity of a number of potentially hazardous air contaminants, including chlorobenzene. Female CD_1 mice (135/group) 4-5 weeks old were exposed to either 0 or 75 ppm (0 or 345 mg/m^3) of chlorobenzene for 3 hours/day for 5 days. The mice were exposed simultaneously to an aerosol of viable *Streptococcus zooepidemicus*, and deaths over a 14-day observation period were recorded. Pulmonary bactericidal activity of *in vivo* alveolar macrophages was also monitored in animals (23/group) simultaneously exposed to ^{35}S-*Klebsiella pneumonia* and either chlorobenzene or air. The ratio of viable bacterial counts to radiolabeled bacteria was used to determine bactericidal activity. Exposure to chlorobenzene resulted in no significant increase in mortality in female CD_1 mice due to *S. zooepidemicus* challenge after 5 days of simultaneous exposure for 3 hours/day, in comparison with filtered-air controls. There was also no evidence of any adverse effect on the bactericidal activity of alveolar macrophages due to chlorobenzene exposure. The data indicate that immunotoxicity is not likely a sensitive toxicological endpoint for chlorobenzene.

DERIVATION OF A PROVISIONAL SUBCHRONIC RfD FOR CHLOROBENZENE

No relevant data were located regarding the subchronic or chronic toxicity of chlorobenzene to humans following oral exposure. Subchronic studies in dogs (Hazleton Laboratories, 1967a), rats (Hazleton Laboratories, 1967a; NTP, 1985; Irish, 1963; Varshavskaya, 1967), and mice (NTP, 1985) and chronic studies in rats and mice (NTP, 1985) were located. Overall, the data indicate that the liver and kidneys are the most sensitive target organs of orally administered chlorobenzene in experimental animals, and that the dog is the most sensitive species evaluated to chlorobenzene toxicity. In dogs, increased incidence of liver and kidney pathology was reported by Hazleton Laboratories (1967a) at ≥39.3 mg/kg-day. Effects on the bone marrow and GI tract were observed at higher chlorobenzene doses. In rodents, increased liver and kidney weights and liver pathology was observed at ≥≈100 mg/kg-day of chlorobenzene (Hazleton Laboratories, 1967b; NTP, 1985; Irish, 1963). The kidney, bone marrow, thymus, and spleen were affected by treatment at higher chlorobenzene doses (NTP, 1985). The available data indicate that the developing fetus is not a sensitive target of orally administered chlorobenzene (IBT, 1977). Although no reproductive toxicity data from oral studies were located, the available inhalation data indicate that reproductive toxicity is not the most sensitive toxicological endpoint for chlorobenzene toxicity (Nair et al., 1987). Effects on immune system tissues were observed in the study conducted by NTP (1985); however, these

effects were only observed at substantially higher doses than those that induced liver toxicity. An inhalation exposure immune function assay indicated that the immune system is not likely a sensitive indicator of chlorobenzene toxicity (Aranyi et al., 1986). No neurotoxicity studies using oral exposure were located. Inhalation data appear to indicate that neurotoxicity data could be a sensitive endpoint of chlorobenzene toxicity in humans (Rosenbaum et al., 1947; Tarkhova, 1965; Ogata et al., 1991; Girard et al., 1969; and Syrovadko and Malysheva, 1977), although none of these studies were sufficient to definitively conclude that chlorobenzene causes adverse effects on the nervous system.

The 13-week study in dogs (Hazleton Laboratories, 1967a) was chosen as the basis for the subchronic RfD because this study demonstrated that the dog is the most sensitive species that has been evaluated in subchronic studies. In this study, chlorobenzene was administered to male and female dogs (4 per sex and dose) in gelatin capsules containing 0, 27.5, 55.0, 275 mg/kg-day of chlorobenzene 5 days per week for 13 weeks (duration-adjusted doses of 0, 19.6, 39.3 or 196.4 mg/kg-day). This study revealed treatment-related effects in the liver, kidneys, GI tract, and bone marrow at 196.4 mg/kg-day. At 39.3 mg/kg-day, effects on the liver (slight bile duct proliferation, slight swelling and vacuolation and leukocytic infiltration) and kidneys (swelling of tubular epithelium and variations in cellularity) were observed. No effects were observed in dogs administered 19.6 mg/kg-day chlorobenzene. Although none of the increased incidences at 39.3 mg/kg-day were significantly greater than controls, the study used only 8 dogs (4 per sex) per dose and the small number of animals resulted in low power of statistical analysis to detect a change. The study did show a clear increase in the incidence and severity of liver and bile duct hyperplasia with increasing dose. Therefore, the marginal increase in liver lesions and bile duct hyperplasia observed at 39.3 mg/kg-day was considered related to chlorobenzene treatment. This study, then, identified a NOAEL of 19.6 mg/kg-day and a LOAEL of 39.3 mg/kg-day for liver and bile duct hyperplasia.

The provisional **subchronic RfD of 7E-2 mg/kg-day** is derived from the NOAEL of 19.6 mg/kg-day by applying an uncertainty factor of 300 (10 to extrapolate from dogs to humans, 10 to protect sensitive subpopulations, and 3 for database deficiencies, including the lack of reproductive and neurological oral toxicity studies), as follows:

subchronic p-RfD	=	NOAEL ÷ UF
	=	19.6 mg/kg-day ÷ 300
	=	0.07 or 7E-2 mg/kg-day

Confidence in the principal study is medium. This study demonstrated a progression of effects with increasing dose, enabling identification of both a NOAEL and a LOAEL. However, the study was limited by small group sizes, lack of statistical analysis and only marginally adequate reporting of results. Confidence in the database is medium. Supporting oral toxicity data are available, but reproductive effects have been studied only by inhalation exposure, and neurotoxicity, which has been identified as a potential effect of chlorobenzene in humans exposed by inhalation, has not been systematically studied by any route. Medium confidence in the p-RfD follows.

DERIVATION OF PROVISIONAL SUBCHRONIC AND CHRONIC RfCs FOR CHLOROBENZENE

Human data suggest that the nervous system may be a target for chlorobenzene toxicity (Rosenbaum et al., 1947; Girard et al., 1969; Tarkhova, 1965; Ogata et al., 1991). Headaches and drowsiness have been reported by workers and experimental subjects (Rosenbaum et al., 1947; Girard et al., 1969; Ogata et al., 1991), and tingling, numbness, and stiffness of the extremities have been observed in workers (Rosenbaum et al., 1947). However, none of these studies reported control data for these effects and the workers may have been exposed to other chemicals in addition to chlorobenzene. Thus, the observations may not have been related to chlorobenzene exposure. Tarkhova (1965) found alterations in the EEG pattern in response to rapid light flashes in humans exposed at 0.2 mg/m^3; however, the toxicological significance of these alterations is not known. Tarkhova (1965) also reported effects of unclear relevance (changes in the conduction speeds of nerve impulses to sets of flexor and extensor muscles) in rats exposed to chlorobenzene at 1.0 mg/m^3 for 60 days. The reliability of these data is uncertain because these effects have not been confirmed by other studies. Taken together, the data suggest that chlorobenzene may affect the nervous system. However, none of the data are adequate for use in risk assessment, either because the effects cannot be definitively attributed to chlorobenzene exposure, only single exposures were used, or the toxicological relevance of the effects is not clear.

The available animal data indicate that the liver and kidneys are the most sensitive target organs for chlorobenzene toxicity. Liver effects included increased weight, hepatocellular hypertrophy, fatty change, and other unspecified microscopic lesions (IBT, 1979; Nair et al., 1987; Dilley, 1977; Irish, 1963; Zub, 1978). Kidney effects included increased weights, cytoplasmic vacuolation, tubule dilation, inflammation of the interstitial cells, and regeneration of the epithelium in male rats (IBT, 1979; Irish, 1963; Nair et al., 1987; Dilley, 1977). The NOAEL and LOAEL for both liver and kidney effects were 50 and 150 ppm (230 and 691 mg/m^3, respectively) in the only adequately conducted and reported study (Nair et al., 1987). Kidney lesions have only been reported in male rats (or rats of unspecified sex) in the available inhalation studies, which suggests that the observed kidney effects may be related to alpha-$_{2u}$-globulin accumulation, a male rat-specific effect that is not predictive for health effects in humans (U.S. EPA, 1991b). Such an effect is known for other chlorinated benzene compounds (WHO, 1991). However, there does not appear to be sufficient evidence to attribute the kidney lesions observed by Nair et al. (1987) to alpha-$_{2u}$-globulin accumulation. Although the lesions were consistent with those associated with alpha-$_{2u}$-globulin, Nair et al. (1987) did not test for the presence of alpha-$_{2u}$-globulin directly. Chlorobenzene produced kidney lesions, including tubule dilation, vacuolation, and leukocytic infiltration, in dogs treated by oral exposure (Hazleton Laboratories, 1967a). NTP (1985) reported kidney effects in male and female mice (tubular necrosis) and male and female rats (degeneration and necrosis of the proximal tubule) in oral subchronic studies on chlorobenzene. The absence of kidney lesions in females (Nair et al., 1987) may reflect general lower sensitivity of females to chlorobenzene toxicity, as liver lesions were also observed only in males in this study. For these reasons, there is insufficient evidence to attribute the kidney lesions observed in this study to alpha-$_{2u}$-globulin accumulation, and the kidney effects are considered potentially relevant to human health risk assessment.

The testis was also identified as a target for chlorobenzene in male rats. Possible effects on the testes were observed in male rats exposed to chlorobenzene at 150 or 450 ppm (Nair et al., 1987). However, it does not appear that the testes are as sensitive a target as the liver and kidney because the incidence of the testicular lesions was only marginally increased in rats exposed at chlorobenzene concentrations that induced significant increases in the incidences of animals with microscopic liver and kidney lesions, and because reproductive performance was not affected.

Other studies suggested that the blood may be a potential target for chlorobenzene. Effects on the blood were observed by Zub (1978), who reported slight leukopenia and lymphocytosis in mice exposed to 100 mg/m^3 for 3 months. Dilley (1977) reported microcytic anemia in rats exposed at $\geq$ 336 mg/m^3. However, neither of these studies was adequate to base a definitive conclusion regarding effects on the blood, either because sufficient detail was not available to allow for an independent evaluation of study adequacy (Zub, 1978) or because the animals were sick during exposure (Dilley, 1977). Anemia was also reported in workers potentially exposed to unspecified concentrations of chlorobenzene; however, the workers were also exposed to other chemicals (Girard et al., 1969). Clear effects on the blood were not observed in dogs exposed to chlorobenzene for 6 months (IBT, 1979; Roloff, 1980) and blood effects have not been consistently reported in chlorobenzene exposed animals in subchronic studies; therefore, the data suggest that the blood is not likely a sensitive indicator of chlorobenzene toxicity.

Developmental toxicity studies in two species were located, which indicate that chlorobenzene is not a developmental toxicant (John et al., 1984). In a 2-generation reproductive toxicity study in rats (Nair et al., 1987), marginal increases in testicular lesions were associated with chlorobenzene exposure at concentrations that induced significant increases in the incidences of microscopic liver and kidney lesions. Reproductive impairment was not observed at any concentration. Therefore, it does not appear that reproductive toxicity is a sensitive endpoint for chlorobenzene toxicity.

Although a number of subchronic inhalation studies in animals were located (IBT, 1979; Roloff, 1980; Dilley, 1977; Irish, 1963), none of the these studies were considered adequate for RfC derivation for the following reasons: a clear LOAEL was not established (combined data from IBT, 1979 and Roloff, 1980); infection occurred in the test animals during exposure (Dilley, 1977); sufficient detail on the experimental design and results were not reported (Irish, 1963; Zub, 1978); or only one concentration was used (Zub, 1978). The only available study suitable for RfC derivation was the 2-generation study conducted by Nair et al. (1987). In this study, Sprague-Dawley rats (30 per sex and dose) were exposed to chlorobenzene (>99% pure) in a dynamic air chamber at target concentrations of 0, 50, 150, or 450 ppm (0, 230, 691, or 2072 mg/m^3) for 10 weeks before mating, then during mating, gestation, and lactation. Their offspring (F_1 rats) were exposed for 11 weeks beginning 1 week after weaning. Clear treatment-related effects were observed in the kidneys and liver of chlorobenzene exposed rats, and possible effects on the testes were observed. Kidney effects included increased weights, tubule dilation, inflammation of the interstitial cells, and regeneration of the epithelium in male rats; liver effects included increased organ weight and hepatocellular hypertrophy. The NOAEL and LOAEL for these effects was 50 and 150 ppm (230 and 691 mg/m^3, respectively). A marginal increase in the incidence of degeneration of the germinal epithelium was also observed at 150 ppm.

In order to derive the point of departure for derivation of the RfC, the LED_{10} (lower bound on dose estimated to produce a 10% increase in the extra risk of the modeled effects over background) was estimated for all kidney and liver lesions reported by Nair et al. (1987) using the U.S. EPA (2000) benchmark dose methodology. A 10% response level was modeled, as recommended for dichotomous endpoints by U.S. EPA (2000). The sensitivity of the study does not appear to warrant the use of a different response level (e.g., 1% or 5%). All available models for dichotomous data in the EPA Benchmark Dose Software (version 1.3.2) were fit to the incidence data for all treatment-related kidney and liver lesions observed in Nair et al. (1987) (incidence data reported in Table 7 below). Because each of the lesions were considered potentially relevant in human health risk assessment, the lesion that resulted in the lowest LED_{10} that was adequately described by modeling was chosen as the point of departure for the RfC. As illustrated in Table 7, renal tubular dilation resulted in the lowest LED_{10}. Tubular dilation can be caused by alpha-$_{2u}$-globulin accumulation in male rats. However, tubular dilation was observed in dogs orally administered chlorobenzene, and tubular necrosis, vacuolation, and/or regeneration was observed in male and female rats and mice orally administered chlorobenzene for 13 weeks. Therefore, tubular dilation is not necessarily a result of alpha-$_{2u}$-globulin accumulation and is potentially relevant to human health risk assessment; it was chosen as the point of departure for RfC derivation.

The dichotomous models estimated concentrations between 17 and 125 ppm associated with a 10% extra risk (ED_{10}) for tubular dilation (Table 8). As assessed by Akaike's Information Criterion (AIC), the best fitting models were the gamma, quantal linear, and Weibull models. Each of these models calculated ED_{10} values of 53.8 ppm and a lower 95% confidence interval (LED_{10}) of 39.7 ppm. Therefore, 39.7 ppm was selected as the point of departure to derive the p-RfC.

The LED_{10} of 39.7 ppm (183 mg/m^3) was converted to a human equivalent concentration using the following equations (U.S. EPA, 1994b):

$$LED_{10\ ADJ} = LED_{10} \times \text{duration adjustment}$$
$$LED_{10\ ADJ} = 183\ mg/m^3 \times 6\ hours/24\ hours \times 7\ days/7\ days$$
$$LED_{10\ ADJ} = 46\ mg/m^3$$

$$LED_{10\ HEC} = LED_{10\ ADJ} \times L_R/L_H$$

where,

L_R/L_H = rat to human blood:air partition coefficient ratio

L_R/L_H = default ratio of 1, because L_R (59.4; Gargas et al., 1989) is greater than L_H (30.0; Gargas et al., 1989)

$$LED_{10\ HEC} = 46\ mg/m^3 \times 1$$
$$LED_{10\ HEC} = 46\ mg/m^3$$

Table 7. LED_{10} Values Calculated for Chlorobenzene Based on Liver and Kidney Lesions in Nair et al. (1987)[a]

Organ, Lesion	Generation	Concentration (ppm)				LED_{10} (ppm)
		0	*50*	*150*	*450*	
Liver, hepatocellular hypertrophy	F_0	0/30[b]	0/30	5/30[c]	14/30[d]	97.3
	F_1	2/30	0/30	3/30	7/30	NA
Kidney, tubular dilation/eosinophilic material (unilateral or bilateral)	F_0	0/30	4/30	6/30[c]	18/30[d]	39.7
	F_1	8/30	7/30	14/30	22/30[d]	55.0
Kidney, chronic interstitial nephritis (unilateral or bilateral)	F_0	1/30	2/30	7/30[c]	10/30[d]	55.9
	F_1	1/30	3/30	7/30[c]	11/30[d]	49.5
Kidney, foci of regenerative epithelium (unilateral or bilateral)	F_0	0/30	1/30	5/30[c]	8/30[d]	73.0
	F_1	1/30	0/30	5/30	11/30[d]	116.7

[a] statistical analysis (Fisher Exact test) performed for this review and not by original investigators
[b] number of animals with lesion/total number of animals exposed
[c] statistically significant ($p \leq 0.05$)
[d] statistically significant ($p \leq 0.01$)
NA not assessed because statistical significance was not observed at any concentration

Table 8. ED_{10}, LED_{10}, and Selected Goodness of Fit Parameters from Modeled Incidence of Tubular Dilation/Eosinophilic Material (Unilateral or bilateral) Observed in Adult Male Rats Exposed to Chlorobenzene via Inhalation (Nair et al., 1987)

MODEL	ED_{10} (ppm)	LED_{10} (ppm)	χ^2 statistic	AIC
Gamma[a]	53.8	39.7	0.786	97.0
Quantal linear	53.8	39.7	0.786	97.0
Weibull[a]	53.8	39.7	0.786	97.0

Quantal quadratic	152.7	125.2	0.133	103.7

[a] Restrict power ≥ 1
[b] Restrict betas ≥ 0, Degree of polynomial = 2
[c] Slope restricted to >1

The $LED_{10\ HEC}$ of 46 mg/m^3 was divided by an uncertainty factor of 100 (3 to account for interspecies extrapolation using dosimetric adjustments, 10 to protect sensitive subpopulations, and 3 for database uncertainties [including the lack of adequate neurotoxicity data and the absence of a study that examined the entire respiratory tract]) to yield a provisional **subchronic RfC of 5E-1 mg/m^3**, as follows:

$$\text{subchronic p-RfC} = LED_{10\ HEC} \div UF$$
$$= 46\ \text{mg/m}^3 \div 100$$
$$= 0.5 \text{ or } 5\text{E-}1\ \text{mg/m}^3$$

Because no chronic inhalation toxicity studies were located in the literature, an additional subchronic-to-chronic uncertainty factor of 10 was applied to the provisional subchronic RfC to derive the provisional **chronic RfC of 5E-2 mg/m^3**, as follows:

$$\text{p-RfC} = \text{subchronic p-RfC} \div UF$$
$$= 5\text{E-}1\ \text{mg/m}^3 \div 10$$
$$= 5\text{E-}2\ \text{mg/m}^3$$

One area of uncertainty in the inhalation toxicity database for chlorobenzene is the lack of a study in which the entire respiratory tract was examined. None of the studies discussed in this issue paper examined the upper respiratory tract. Dilley (1977) examined the lungs, but the high incidence of chronic respiratory disease observed in the controls and chlorobenzene-exposed animals limited the ability of this study to detect chlorobenzene-related lung effects.

Data reported by Irish (1963) indicate that the lungs are not more sensitive than the liver or kidneys to chlorobenzene effects, although data from this study were not adequately reported and, therefore, cannot be independently assessed. In the Ogata et al. (1991) human study, none of the subjects complained of nose or eye irritation, although one of the subjects did complain of a sore throat following a 7-hour exposure to 60.2 ppm (277 mg/m^3). Another area of uncertainty is the lack of neurological testing. The available human data (Ogata et al., 1991) suggest that the nervous system may be a sensitive target of chlorobenzene toxicity. Headaches and drowsiness were reported by experimental subjects during exposure to 60.2 ppm (277 mg/m^3). The subchronic and chronic RfCs that were derived from Nair et al. (1987) (0.5 and 0.05 mg/m^3, respectively) are substantially lower than concentrations associated with these effects. Although Tarkhova (1965) reported changes in electroencephalographic (EEG) patterns in response to light flashes in 2/4 human subjects exposed at 0.2 mg/m^3, the toxicological relevance of this effect is not clear, and the reliability of these data is uncertain. Other studies have reported potential neurological effects in exposed humans (Rosenbaum et al., 1947; Girard et al., 1969); however, there is some uncertainty whether these effects were related to chlorobenzene exposure because neither of these studies reported data from unexposed controls. None of the repeated-dose animal studies observed overt signs of neurological effects. Tarkhova (1965) reported potential effects in rats at 0.2 ppm (1 mg/m^3); however, the toxicological significance of the reported effect (changes in the conduction speeds of nerve impulses to sets of flexor and extensor muscles on Day 39) is not clear, and these results have not been confirmed by other studies.

Confidence in the principal study (Nair et al. 1987) is high. It is a well designed two-generation study examining relevant endpoints with an adequate number of animals. Confidence in the database is low. As discussed above, the database lacks a study that adequately examined the entire respiratory tract, and also lacks an adequate neurotoxicity study. Because the available data suggest that neurotoxicity may be a sensitive toxicological endpoint for chlorobenzene, confidence in the provisional chronic and subchronic RfC is low.

PROVISIONAL PEER REVIEWED TOXICITY VALUES FOR COBALT AND COMPOUNDS (CASRN 7440-48-4)
Derivation of Subchronic and Chronic Inhalation RfCs

Background

On December 5, 2003, the U.S. Environmental Protection Agency's (EPA's) Office of Superfund Remediation and Technology Innovation (OSRTI) revised its hierarchy of human health toxicity values for Superfund risk assessments, establishing the following three tiers as the new hierarchy:

1. EPA's Integrated Risk Information System (IRIS).

2. Provisional Peer-Reviewed Toxicity Values (PPRTV) used in EPA's Superfund Program.

3. Other (peer-reviewed) toxicity values, including:

   - Minimal Risk Levels produced by the Agency for Toxic Substances and Disease Registry (ATSDR),
   - California Environmental Protection Agency (CalEPA) values, and
   - EPA Health Effects Assessment Summary Table (HEAST) values.

A PPRTV is defined as a toxicity value derived for use in the Superfund Program when such a value is not available in EPA's Integrated Risk Information System (IRIS). PPRTVs are developed according to a Standard Operating Procedure (SOP) and are derived after a review of the relevant scientific literature using the same methods, sources of data, and Agency guidance for value derivation generally used by the EPA IRIS Program. All provisional toxicity values receive internal review by two EPA scientists and external peer review by three independently selected scientific experts. PPRTVs differ from IRIS values in that PPRTVs do not receive the multi-program consensus review provided for IRIS values. This is because IRIS values are generally intended to be used in all EPA programs, while PPRTVs are developed specifically for the Superfund Program.

Because new information becomes available and scientific methods improve over time, PPRTVs are reviewed on a five-year basis and updated into the active database. Once an IRIS value for a specific chemical becomes available for Agency review, the analogous PPRTV for that same chemical is retired. It should also be noted that some PPRTV manuscripts conclude that a PPRTV cannot be derived based on inadequate data.

Disclaimers

Users of this document should first check to see if any IRIS values exist for the chemical of concern before proceeding to use a PPRTV. If no IRIS value is available, staff in the regional Superfund and RCRA program offices are advised to carefully review the information provided in this document to ensure that the PPRTVs used are appropriate for the types of exposures and circumstances at the Superfund site or RCRA facility in question. PPRTVs are periodically updated; therefore, users should ensure that the values contained in the PPRTV are current at the time of use.

It is important to remember that a provisional value alone tells very little about the adverse effects of a chemical or the quality of evidence on which the value is based. Therefore, users are strongly encouraged to read the entire PPRTV manuscript and understand the strengths and limitations of the derived provisional values. PPRTVs are developed by the EPA Office of Research and Development's National Center for Environmental Assessment, Superfund Health Risk Technical Support Center for OSRTI. Other EPA programs or external parties who may choose of their own initiative to use these PPRTVs are advised that Superfund resources will not generally be used to respond to challenges of PPRTVs used in a context outside of the Superfund Program.

Questions Regarding PPRTVs

Questions regarding the contents of the PPRTVs and their appropriate use (e.g., on chemicals not covered, or whether chemicals have pending IRIS toxicity values) may be directed to the EPA Office of Research and Development's National Center for Environmental Assessment, Superfund Health Risk Technical Support Center (513-569-7300), or OSRTI.

INTRODUCTION

IRIS (U.S. EPA, 2000) does not report an RfC for cobalt. The HEAST (U.S. EPA, 1997) likewise does not list an RfC for cobalt. The CARA lists (U.S. EPA, 1991, 1994) report a HEA for cobalt (U.S. EPA, 1987), which derived a subchronic inhalation RfD of 9E-5 mg/m^3 based on a LOAEL of 0.1 mg/m^3 for respiratory effects in a 3-month study in swine (Kerfoot et al., 1975). A chronic inhalation RfD of 9E-6 mg/m^3 was derived from the same study. An updated HEA prepared by SRC (1990) for U.S. EPA, but never finalized, dropped the RfC because, it was argued, such an RfC would not be protective for individuals already sensitized to cobalt. ATSDR (1992) has published a Toxicological Profile for cobalt and compounds. A chronic inhalation MRL was not derived, due to a lack of a suitable chronic inhalation study. A subchronic inhalation MRL of $3x10^{-5}$ mg cobalt/m^3 was derived based on a LOAEL of 0.11 mg cobalt/m^3 for metaplasia of the larynx in rats exposed for 13 weeks (6 hours/day, 5 days/week)

(NTP 1991). ACGIH (2000) has set a TLV-TWA of 0.02 mg/m^3 for cobalt and inorganic cobalt compounds, expressed as cobalt, based on respiratory and cardiovascular effects. OSHA (1989, 1993) established a PEL of 0.05 mg/m^3 for cobalt in its 1989 ruling, which has since reverted to the previous PEL of 0.1 mg/m^3 following the court-ordered vacating of the 1989 ruling; the values are based on effects in the respiratory system. The NIOSH (2000) REL (TWA) for cobalt is 0.05 mg/m^3, also based on respiratory effects. An IARC Monograph on cobalt and compounds (IARC, 1991) and the NTP Status Reports (NTP, 2000) were also searched for relevant information. The WHO (2000) has not published an Environmental Health Criteria document about cobalt. Literature searches were conducted from 1991 to November, 2000 for studies relevant to the derivation of an RfC. The databases searched were: TOXLINE, MEDLINE, CANCERLIT, and TSCATS.

REVIEW OF PERTINENT DATA

Overview

Respiratory effects, including respiratory irritation, wheezing, asthma, pneumonia and fibrosis, have been widely reported in humans exposed to cobalt by inhalation (ATSDR, 1992). Cardiomyopathy has also been reported, although this effect is better known from oral exposure. Other effects of oral exposure in humans are polycythemia and thyroid effects. Cobalt is a sensitizer in humans by any route of exposure. Sensitized individuals may react to inhalation of cobalt by developing asthma; ingestion or dermal contact with cobalt may result in development of dermatitis. Several studies have suggested that cross-sensitization may occur between cobalt and nickel (Bencko et al., 1983; Lammintausta et al., 1985; Rystedt and Fisher, 1983; Shirakawa et al., 1990).

Animal studies have generally found similar effects to those observed in humans. One additional target found in animal studies that has not been identified as a target in humans is the reproductive system.

Urinary cobalt levels are a widely used and well accepted biomarker of exposure to cobalt in humans and animals, with many studies demonstrating good correlations between cobalt concentrations in the urine and ambient air (ATSDR, 1992; Gennart and Lauwerys, 1990; Nemery et al., 1992; NTP, 1991; Swennen et al., 1993). Some researchers have concluded that measurement of urinary cobalt is a more effective and more accurate means to monitor worker exposure than monitoring of air concentrations (Cugell, 1992; Nemery et al., 1992).

Human Studies

Numerous studies have investigated health effects in workers occupationally exposed to cobalt dust (Auchincloss et al., 1992; Cugell, 1992; Davison et al., 1983; Demedts et al., 1984; Gennart and Lauwerys, 1990; Kusaka et al., 1986a,b; Meyer-Bisch et al., 1989; Nemery et al., 1992; Prescott et al., 1992; Raffn et al., 1988; Shirakawa et al., 1988, 1989; Sprince et al., 1988; Swennen et al., 1993). However, many of these studies are of limited utility for risk assessment due to inadequate characterization of exposure and/or effects. In addition, many studies were of hard metal workers exposed to tungsten carbide as well as cobalt. There is substantial evidence from animal studies that tungsten, although it acts as an inert dust by itself, can potentiate the effects of cobalt on the respiratory tract (Lasfargues et al., 1992; Swennen et al., 1993). Therefore, studies of hard metal workers were not given further consideration. Four studies were considered to be potentially suitable bases for RfC derivation. Two of these focused exclusively on respiratory effects, one studied only thyroid effects, and one considered multiple endpoints. The populations studied included diamond-cobalt saw manufacturers, diamond polishers, plate painters and cobalt production workers. All four studies were cross-sectional in design.

Gennart and Lauwerys (1990) studied ventilatory function in workers at a plant producing diamond-cobalt circular saws. The exposed population consisted of 48 workers (34 males and 14 females) who agreed to participate in the study (an additional 27 workers declined). Exposure duration for these workers ranged from 0.1 to 32 years, with an average of about 6 years. The work involved weighing and mixing cobalt powder and microdiamond particles (and possibly small amounts of other undisclosed substances), cold pressing, heating and hot pressing. After sintering, the pieces were welded onto steel disks. These operations were performed in two rooms called the mixing room and the oven room, where all the examined workers spent most of their time. Controls were 23 workers (11 males and 12 females) from other factories in the same area who were not exposed to known pneumotoxic chemicals. Personal air samples were collected at different workplaces during half of a workshift. Subjects filled out a questionnaire regarding occupational and medical histories, smoking habits and pulmonary symptoms, gave a urine sample for cobalt determination and submitted to lung function tests. Cobalt concentrations varied from 9.4-2875 $\mu g/m^3$ in the mixing room (geometric mean = 135.5 $\mu g/m^3$) and 6.2-51.2 $\mu g/m^3$ (geometric mean = 15.2 $\mu g/m^3$) in the oven room. The prevalence of respiratory symptoms, such as cough, sputum and dyspnea, were significantly increased in the exposed workers. Mean predicted values of FEV_1 (forced expiratory volume in one second) and FVC (forced vital capacity) were significantly reduced, and the prevalence of abnormal values increased, in the exposed workers (both smokers and non-smokers). Among non-smokers, the spirometric effects were greater in workers exposed for 5 years or more than in those exposed for a shorter period of time.

Nemery et al. (1992) conducted a cross-sectional study of cobalt exposure and respiratory effects in diamond polishers. The study group was composed of 194 polishers working in 10

different workshops. In two of these workshops (#1,2), the workers used cast iron polishing disks almost exclusively, and in the others they used cobalt-containing disks primarily. The number of subjects from each workshop varied from 6-28 and the participation rate varied from 56-100%. The low participation in some workshops reflects the fact that only workers who used cobalt disks were initially asked to be in the study, rather than a high refusal rate (only 8 refusals were documented). More than a year after the polishing workshops were studied, an additional three workshops with workers engaged in sawing diamonds, cleaving diamonds or drawing jewelry were studied as an unexposed control group (n=59 workers). Subjects were asked to fill out a questionnaire regarding employment history, working conditions, medical history, respiratory symptoms and smoking habits, to give a urine sample for cobalt determination, and to undergo a clinical examination and lung function tests. Both area air samples and personal air samples were collected (always on a Thursday). Sampling for area air determinations started 2 hours after work began and continued until 1 hour before the end of the work day. Personal air samples were collected from the breathing zone of a few workers per workshop for four successive one-hour periods. Air samples were analyzed for cobalt and iron. In addition, personal air samplers were used to sample the air 1 cm above the polishing disks. These samples were analyzed for the entire spectrum of mineral and metallic compounds. Air samples were not obtained at one of the polishing workshops (#4), but this workshop was reported to be almost identical to an adjoining workshop (#3) for which samples were obtained. Urinary cobalt levels were similar between workers in these two workshops, so exposure was considered to be similar as well.

There was a good correlation (R=0.92) between the results of area and personal air sampling, with area air sampling reporting lower concentrations than personal air samples in all workshops except one (#9) (Nemery et al., 1992). In this workshop, personal air samples appeared to be artificially low in comparison to area air samples and urinary cobalt levels of the workers. When this workshop was excluded, there was a good correlation (R=0.85-0.88) between urinary cobalt and cobalt in the air. Based on urinary cobalt levels, the concentration of cobalt expected in personal air samples from workshop #9 was about 45 $\mu g/m^3$ (the mean value actually reported was 6 $\mu g/m^3$). The polishing workshops were divided into two groups: those with low exposure to cobalt (#1-5, n=102) and those with high exposure to cobalt (#6-10, n=91). Mean cobalt exposure concentrations were 0.4, 1.6 and 10.2 $\mu g/m^3$ by area air sampling and 0.4, 5.3 and 15.1 $\mu g/m^3$ by personal air sampling in the control, low-exposure and high-exposure groups, respectively. The inclusion of the apparently biased personal air samples from workshop #9 means that the reported mean cobalt exposure in the high-exposure group obtained by personal air sampling (15.1 $\mu g/m^3$) may be lower than the true value. Air concentrations of iron were highest in the two polishing workshops that used iron disks and the sawing workshop (highest value = 62 $\mu g/m^3$), and were not correlated with cobalt levels. Analysis of samples taken near the disks showed the presence of cobalt, with occasional traces of copper, zinc, titanium, manganese, chromium, silicates and silicon dioxide. No tungsten was detected. There is a possibility that some workers had previously been exposed to asbestos, since pastes

containing asbestos had been used in the past to glue the diamonds onto holders. However, the degree of asbestos exposure had apparently been insufficient to produce functional impairment. The researchers considered cobalt to be the only relevant exposure. Smoking habits were similar in workers from the high-exposure, low-exposure and control groups. Duration of exposure was not discussed.

Workers in the high-exposure group were more likely than those in the other groups to complain about respiratory symptoms; the prevalences of eye, nose and throat irritation and cough, and the fraction of these symptoms related to work, were significantly increased in the high-exposure group (Nemery et al., 1992). Workers in the high-exposure group also had significantly reduced lung function compared to controls and low-exposure group workers, as assessed by FVC (forced vital capacity), FEV_1 (forced expiratory volume in one second), MMEF (forced expiratory flow between 25 and 75% of the FVC) and mean PEF (peak expiratory flow rate), although the prevalence of abnormal values did not differ significantly between exposure categories. Results in the low-exposure group did not differ from controls. Two-way analysis of variance was used to show that the effect on spirometric parameters in the high exposure group was present in both men and women. Women seemed to be affected more than men, but the interaction between exposure and sex was not significant. Smoking was found to exert a strong effect on lung function, but lung function level remained negatively correlated with exposure to cobalt, independently of smoking.

Swennen et al. (1993) conducted a cross-sectional study of workers exposed to metallic cobalt and inorganic cobalt compounds at a cobalt plant producing these materials from cobalt metal cathodes and scrap metal. The study group included 82 male workers from the cobalt plant who had not suffered from lung disease prior to employment and who had never been exposed to other pneumotoxic chemicals. It was not reported how this group was chosen from the pool of workers meeting these criteria or how many workers meeting these criteria refused to participate in the study. The control group comprised 82 age-matched workers from the mechanical workshop of a nearby plant owned by the same company. Workers filled out a questionnaire regarding occupational history, respiratory complaints and smoking habits, received a routine clinical examination, submitted to lung function tests, had a chest radiograph taken, and gave blood and urine samples (before and after working on Monday and Friday) for determination of cobalt content as well as hematological and serum chemistry analyses. Exposure was monitored by personal air samplers worn by each cobalt worker for 6 hours on both Monday and Friday.

Workers in the cobalt plant were exposed to cobalt concentrations ranging from 1 $\mu g/m^3$ to 7772 $\mu g/m^3$ (Swennen et al., 1993). The geometric mean exposure concentration was 125 $\mu g/m^3$. Exposure duration ranged from 0.3-39.4 years, with an average exposure of 8.0 years. On the questionnaire, a significantly higher number of exposed workers reported dyspnea than controls. The increase occurred primarily among smokers, although no significant interaction was found between smoking and exposure to cobalt. A logistic regression model was used to

show that the probability of dyspnea during exercise increased as a function of cobalt concentration in the air and urine. The clinical examinations detected significantly increased prevalence of skin disorders (eczema, erythema) (51% vs 25%) and wheezing (16% vs 6%) in the exposed group compared to controls. Lung function tests did not differ between the two groups, but a few significant trends were noted: the FEV_1/VC (forced expiratory volume in one second/vital capacity) ratio decreased with increasing concentration of cobalt in the air and urine, and the RV (residual volume) and TLC (total lung capacity) increased with increasing duration of exposure. No lung abnormalities were found by chest radiographs in either group. The researchers concluded that these results demonstrate "airway involvement" in workers exposed only to cobalt and suggest there may have been thyroid effects as well. Blood analyses did not show polycythemia, and in fact there were slight, but significant, decreases in red blood cell count, hemoglobin, and hematocrit in the exposed workers. White blood cell was significantly increased. Serum levels of the thyroid hormone T3 (triiodothyronine) were slightly (7%), but significantly, decreased in the exposed group, while T4 (thyroxine) and TSH (thyrotropin) were not affected. Serum markers for cardiomyopathy were unchanged.

Prescott et al. (1992) conducted a cross-sectional study to investigate the effects of cobalt exposure on thyroid volume and function in female plate painters. The test group included 61 female plate painters exposed to cobalt blue dyes in two porcelain factories. The control group consisted of 48 unexposed women working at the same factories. The dyes used in the two factories differed; factory I (36 workers) used cobalt aluminate, which is insoluble, and factory II (25 workers) used cobalt-zinc silicate, which was reported to be "semi-soluble." Workers were exposed to cobalt during the painting procedure when the plates were spray-painted (under a fume hood) two or three times with the water-based cobalt blue underglaze and when the excess color was removed with a brush after drying. Cobalt concentrations were reported to be around 0.05 mg/m^3 in the workplaces, but no further details were provided. Duration of exposure averaged 14.6 years in group I workers and 16.2 years in group II workers. Subjects were required to fill out a questionnaire regarding health, use of medicines, day of menstrual cycle, employment information and smoking habits, to give blood and urine samples for determination of thyroid hormones and cobalt, and to undergo ultrasonography to determine volume of the thyroid gland.

Urinary cobalt levels were similar in group I exposed workers and controls (Prescott et al., 1992). Group II workers had urinary cobalt levels that were roughly ten-fold higher than controls. Group I workers did not differ from controls for any of the thyroid parameters measured, but Group II workers had a significant 22% increase in serum T4 (thyroxine) levels. Thyroid volume appeared to be reduced in this group as well, although the difference from controls (16.1 ml in group II vs 19.2 ml in controls and 18.7 ml in group I) was not statistically significant. The occurrence of respiratory effects in these workers was not discussed.

Animal Studies

In a subchronic inhalation study, groups of 10 F344/N rats and 10 B6C3F1 mice of each sex were exposed to cobalt sulfate heptahydrate aerosol (MMAD=0.83-1.10 μm) at concentrations of 0, 0.3, 1, 3, 10 or 30 mg/m^3 (0, 0.11, 0.38, 1.14, 3.8 or 11.4 mg Co/m^3) 6 hours/day, 5 days/week for 13 weeks (Bucher et al., 1990; NTP, 1991). Animals were monitored for body weight and observed for clinical signs during the exposure period. Urine samples for urinalysis and cobalt determination were collected from rats prior to sacrifice. Following termination of exposure, all animals were sacrificed and necropsied. Blood samples were collected and analyzed for hematological parameters (rats and mice) and serum chemistry and thyroid function parameters (rats only). The major organs were weighed. Animals from the control and high-dose groups received comprehensive histopathological examinations, while those from the lower dose groups received more limited examinations focused on the respiratory tissues.

All rats survived until scheduled necropsy (Bucher et al., 1990; NTP, 1991). Gross evidence of toxicity was noted only in rats exposed to 30 mg/m^3, which displayed clinical signs of toxicity (ruffled fur, hunched posture) and reduced body weights. Polycythemia, indicated by significant increases in red blood cell count, hemoglobin and hematocrit, was noted in males exposed to ≥3 mg/m^3 and females exposed to ≥10 mg/m^3. In addition, platelets were significantly reduced in rats of both sexes at ≥10 mg/m^3 and reticulocytes were increased in females at 30 mg/m^3. Leukocyte counts and differentials were unaffected. Serum cholesterol was significantly reduced in males at ≥10 mg/m^3 and females at 30 mg/m^3. No other serum chemistry parameters were affected, including creatine kinase isozymes indicative of damage to cardiac muscle cells. Among the thyroid hormones, T3 (triiodothyronine) was significantly reduced in females at ≥10 mg/m^3 and TSH (thyrotropin) was significantly reduced in males at 30 mg/m^3, but T4 (thyroxin) was not affected in either sex at any dose and the researchers concluded that thyroid function was not consistently affected in this study. Urinalysis revealed a dose-related increase in the number of epithelial cells in the urine of males rats exposed to ≥3 mg/m^3 and granular casts in the urine of many exposed male rats (3-7 per group), but no controls. The researchers interpreted this finding to indicate minimal nephropathy in exposed male rats, although histopathological lesions were not detected in the kidney. No effects on sperm counts, sperm motility or the incidence of abnormal sperm were noted. Average estrus cycle of females exposed to 30 mg/m^3 was slightly longer than controls, but the difference was not significant. Absolute and relative lung weight were significantly increased in both male and female rats at ≥1 mg/m^3. Other organ weights were not affected by treatment. Compound-related lesions were found only in the respiratory tissues of exposed rats. Degenerative, inflammatory and regenerative lesions were found throughout the respiratory tract. The lesions were concentration-related and similar in incidence and severity in males and females. The most sensitive tissue was the larynx, with squamous metaplasia present at all exposure levels.

Among mice, 2/10 males exposed to 30 mg/m^3 died during the study (Bucher et al., 1990; NTP, 1991). The only clinical signs of toxicity observed were rapid breathing and skin discoloration in one of the mice that died. Body weights were reduced throughout the study in both males and females exposed to 30 mg/m^3. No dose-related hematological effects were found. Absolute and relative lung weight were significantly increased in male and female mice exposed to ≥ 10 mg/m^3. Respiratory lesions were similar to those observed in rats. As with rats, the most sensitive tissue was the larynx, with squamous metaplasia present at all exposure levels. Reproductive system effects were more prominent in mice than rats. Males had significantly decreased testicular and epididymal weight, testicular atrophy consisting of loss of germinal epithelium in the seminiferous tubules and foci of mineralization, and an increased percentage of abnormal sperm at 30 mg/m^3, and reduced sperm motility at ≥3 mg/m^3 (lower doses not tested). Females had a significantly increased length of the estrus cycle at 30 mg/m^3.

In a subsequent chronic inhalation carcinogenicity study by the same researchers, groups of 50 F344/N rats and 50 B6C3F1 mice of each sex were exposed to cobalt sulfate heptahydrate aerosol (MMAD=1.4-1.6 μm) at concentrations of 0, 0.3, 1, or 3 mg/m^3 (0, 0.11, 0.38, or 1.14 mg Co/m^3) 6 hours/day, 5 days/week for 105 weeks (Bucher et al., 1999; NTP, 1998). Animals were monitored for body weight and observed for clinical signs during the exposure period. Following termination of exposure, all animals were sacrificed and necropsied. At necropsy, all organs and tissues were examined for gross lesions, trimmed, and examined histologically.

In F344 rats, there were no changes in survival or mean body weights in males or females of any exposure group (Bucher et al., 1999; NTP, 1998). Irregular breathing was noticed more frequently in female rats exposed to 3 mg/m^3 than in controls or other groups; no changes in clinical signs were noted in any of the treated male rats. Both male and female rats in all exposure groups showed a high incidence (94% or greater) of squamous metaplasia of the alveolar epithelium, fibrosis of the pulmonary interstitium, and granulomatous inflammation, with all lesions increasing in severity with increasing exposure. Likewise, both sexes of rats showed dose-related increases in metaplasia of the larynx, atrophy of the olfactory epithelium, and hyperplasia of the lateral nasal wall. Significant increases in alveolar/bronchiolar adenomas or carcinomas were seen in high-dose male rats, while significant increases in alveolar/bronchiolar adenomas, alveolar/bronchiolar carcinomas, or squamous cell carcinomas were seen in the mid- and high-dose female rats. Increased incidence of pheochromocytomas were seen in the mid-dose male rats, but not the high-dose males, and in high-dose female rats.

In B6C3F1 mice, no changes in survival were noticed in any exposure group (Bucher et al., 1999; NTP, 1998). Male mice exposed to 3 mg/m^3 showed a decreased mean body weight relative to controls from week 96 through the end of the study. Mean body weights of exposed female mice were generally greater than those of controls throughout the study. Irregular breathing was noted slightly more frequently in female mice exposed to 1mg/m^3 than in controls or other exposed groups. A dose-related increase in the occurrence of cytoplasmic vacuolization

of the bronchus was seen in both sexes of mice, with incidences at all exposure levels being significantly different from controls. Mice of both sexes showed significantly increased incidences of squamous metaplasia of the larynx at all exposure levels examined. The incidence of alveolar/bronchiolar adenoma or carcinoma was significantly increased in high-dose male mice, and in mid- and high-dose female mice.

Other studies in animals have also reported respiratory lesions produced by inhaled cobalt. Johansson et al. (1987) observed effects in the alveolar region of the respiratory tract in rabbits exposed to 0.4 mg Co/m^3, 6 hours/day, 5 days/week for 1-4 months. Kyono et al. (1992) observed mild pulmonary lesions in rats exposed to 2.12 mg/m^3 of cobalt aerosols 5 hours/day for 4 days. Kerfoot et al. (1975) reported decreased pulmonary function, lethargy, and wheezing following exposure of groups of 5 miniature swine to 0, 0.1, or 1.0 mg/m^3 of cobalt dust for 6 hours/day, 5 days/week for 3 months.

No developmental toxicity studies were located following inhalation exposure to cobalt. Oral developmental toxicity studies did not find evidence that cobalt is a potent developmental toxicant; one study in rats and one in mice reported no developmental effects, while a second study in rats reported developmental effects (reduced number of litters and average litter weight, increased number of dead pups/litter) that were considered by the researchers to be secondary consequences of maternal toxicity (ATSDR, 1992). The NTP (1991) study (described above) demonstrated that cobalt can produce reproductive effects in male and female mice following inhalation exposure, although the effects were produced at relatively high dose levels. Oral studies have also identified the testes as a target for cobalt toxicity. No multi-generation reproduction studies were located by inhalation or oral exposure.

DERIVATION OF PROVISIONAL RfC

Of the four epidemiology studies discussed above, the study by Nemery et al. (1992) provides the best basis for derivation of an RfC. Workers in this study were exposed to far lower concentrations of cobalt, over a much more constrained range of exposures, than in the studies by Gennart and Lauwerys (1990) and Swennen et al. (1993). As a result, discrete NOAEL and LOAEL values can be derived from the Nemery et al. (1992) study, which would not have been possible using the Gennart and Lauwerys (1990) or Swennen et al. (1993) studies. The Prescott et al. (1992) study was not considered for RfC derivation because evidence of an effect on the thyroid was marginal (22% increase in serum levels of T4) and respiratory endpoints were not investigated. The human and animal database strongly suggests that respiratory effects are the most sensitive endpoints of cobalt toxicity. Respiratory effects have been widely reported in workers exposed to cobalt, while effects on the thyroid and other tissues have not (ATSDR, 1992). In addition, Swennen et al. (1993) found only marginal evidence of thyroid effects (7% decrease in T3) and no evidence of cardiomyopathy or polycythemia in workers clearly

displaying evidence of respiratory effects. The animal data also support the conclusion that the respiratory tract is the critical target for inhaled cobalt. NTP (1991) observed respiratory lesions in rats and mice at the lowest exposure concentration tested, while polycythemia and reproductive effects were seen only at higher concentrations, thyroid function was not consistently affected at any concentration, and cardiomyopathy was undetected even at the highest concentration.

Assuming the personal air samples to be more representative of worker exposure than the area air samples, the study by Nemery et al. (1992) identified a NOAEL of 5.3 $\mu g/m^3$ and a LOAEL of 15.1 $\mu g/m^3$ for effects on lung function. Although the LOAEL may be biased low due to inclusion of data from workshop #9, this does not affect the RfC derivation. The NOAEL for occupational exposure is adjusted to continuous exposure as follows:

$$5.3\ \mu g/m^3\ (10\ m^3/d\ /\ 20\ m^3/d)\ (5\ d\ /\ 7\ d) = 1.9\ \mu g/m^3$$

Dividing the $NOAEL_{ADJ}$ of 1.9 $\mu g/m^3$ by an uncertainty factor of 100 (3 to account for the fact that exposure duration may have been subchronic in some workers, 3 for lack of inhalation developmental toxicity studies and a multi-generation reproduction study, and 10 for human variability) yields an **RfC of 2E-5 mg/m^3** for cobalt. This RfC may not be protective for people with hypersensitivity to cobalt.

STATEMENT OF CONFIDENCE

Confidence in the key study is low. This was a cross-sectional study that looked at only respiratory endpoints, included a control group that was studied more than one year after the exposed population, included a study group exposed to iron and diamond dust in addition to cobalt (and possibly to asbestos in the past), had no discussion of duration of exposure, and encountered a number of procedural difficulties during its course. Confidence in the database is medium; choice of the critical endpoint is well supported by other studies in humans and animals, but reproductive and developmental effects have not been adequately studied. Medium-to-low confidence in the RfC follows.

sq.cm.	square centimeters
TSCA	Toxic Substances Control Act
UF	uncertainty factor
µg	microgram
µmol	micromoles
VOC	volatile organic compound

PROVISIONAL PEER REVIEWED TOXICITY VALUES FOR COBALT AND COMPOUNDS (CAS NO. 7440-48-4)
Derivation of a Carcinogenicity Assessment

Background

On December 5, 2003, the U.S. Environmental Protection Agency's (EPA's) Office of Superfund Remediation and Technology Innovation (OSRTI) revised its hierarchy of human health toxicity values for Superfund risk assessments, establishing the following three tiers as the new hierarchy:

1. EPA's Integrated Risk Information System (IRIS).

2. Provisional Peer-Reviewed Toxicity Values (PPRTV) used in EPA's Superfund Program.

3. Other (peer-reviewed) toxicity values, including:

   - Minimal Risk Levels produced by the Agency for Toxic Substances and Disease Registry (ATSDR),
   - California Environmental Protection Agency (CalEPA) values, and
   - EPA Health Effects Assessment Summary Table (HEAST) values.

A PPRTV is defined as a toxicity value derived for use in the Superfund Program when such a value is not available in EPA's Integrated Risk Information System (IRIS). PPRTVs are developed according to a Standard Operating Procedure (SOP) and are derived after a review of the relevant scientific literature using the same methods, sources of data, and Agency guidance for value derivation generally used by the EPA IRIS Program. All provisional toxicity values receive internal review by two EPA scientists and external peer review by three independently selected scientific experts. PPRTVs differ from IRIS values in that PPRTVs do not receive the multi-program consensus review provided for IRIS values. This is because IRIS values are generally intended to be used in all EPA programs, while PPRTVs are developed specifically for the Superfund Program.

Because new information becomes available and scientific methods improve over time, PPRTVs are reviewed on a five-year basis and updated into the active database. Once an IRIS value for a specific chemical becomes available for Agency review, the analogous PPRTV for that same chemical is retired. It should also be noted that some PPRTV manuscripts conclude that a PPRTV cannot be derived based on inadequate data.

Disclaimers

Users of this document should first check to see if any IRIS values exist for the chemical of concern before proceeding to use a PPRTV. If no IRIS value is available, staff in the regional Superfund and RCRA program offices are advised to carefully review the information provided in this document to ensure that the PPRTVs used are appropriate for the types of exposures and

circumstances at the Superfund site or RCRA facility in question. PPRTVs are periodically updated; therefore, users should ensure that the values contained in the PPRTV are current at the time of use.

It is important to remember that a provisional value alone tells very little about the adverse effects of a chemical or the quality of evidence on which the value is based. Therefore, users are strongly encouraged to read the entire PPRTV manuscript and understand the strengths and limitations of the derived provisional values. PPRTVs are developed by the EPA Office of Research and Development's National Center for Environmental Assessment, Superfund Health Risk Technical Support Center for OSRTI. Other EPA programs or external parties who may choose of their own initiative to use these PPRTVs are advised that Superfund resources will not generally be used to respond to challenges of PPRTVs used in a context outside of the Superfund Program.

Questions Regarding PPRTVs

Questions regarding the contents of the PPRTVs and their appropriate use (e.g., on chemicals not covered, or whether chemicals have pending IRIS toxicity values) may be directed to the EPA Office of Research and Development's National Center for Environmental Assessment, Superfund Health Risk Technical Support Center (513-569-7300), or OSRTI.

INTRODUCTION

IRIS (U.S. EPA, 2000a) does not report a cancer classification, slope factor, or unit risk for cobalt. The HEAST (U.S. EPA, 1997) and Drinking Water Standards and Health Advisories list (U.S. EPA, 2000b) likewise do not report carcinogenicity assessments for cobalt. The CARA lists (U.S. EPA, 1991, 1994a) include a HEA for cobalt (U.S. EPA, 1987), which did not report a cancer classification or an estimate of the carcinogenic potency of stable cobalt compounds due to a lack of pertinent data. A draft of an updated HEA prepared by SRC (1990) for U.S. EPA, but never finalized, was also located, which likewise found insufficient data to assess the carcinogenicity of stable cobalt. An IARC Monograph on cobalt and compounds (IARC, 1991) classified cobalt and compounds as "possibly carcinogenic to humans." ACGIH (2000) has classified cobalt in category A3 - confirmed animal carcinogen with unknown relevance to humans. The ATSDR Toxicologic Profile for cobalt and compounds (ATSDR, 1992) and the NTP Status Reports (NTP, 2000) were also searched for relevant information. The WHO (2000) has not published an Environmental Health Criteria document about cobalt. Literature searches were conducted from 1991 to November, 2000 for studies relevant to the derivation of a provisional carcinogenicity assessment for cobalt. The databases searched were: TOXLINE, MEDLINE, CANCERLIT, and TSCATS.

REVIEW OF PERTINENT DATA

Human Studies

Morgan (1983) investigated the health and causes of death of 49 men occupationally exposed to cobalt salts and oxides in a manufacturing plant in South Wales. During the study period, 33 men died, 5 with lung cancer and 3 with cancer at other sites. The expected number of deaths was 0.3 for lung cancer and 4.1 for all cancers based on national statistics, resulting in mortality ratios of 16.7 and 0.73, respectively. U.S. EPA (1987) concluded that the scope of this study was too limited to demonstrate the carcinogenicity or noncarcinogenicity of occupational exposure to cobalt compounds.

Mur et al. (1987) analyzed the mortality of a cohort of 1143 workers in a plant that refined and processed cobalt and sodium. An increase in deaths resulting from lung cancer was observed in workers (SMR = 4.66 [1.46-10.64]) based on four cases observed in the exposed group and 1 case expected based on French national statistics. In a study within the cohort that controlled for age and smoking habits, 44% (four workers) in the exposed group and 17% (three workers) in the control group died of lung cancer. The authors indicated that the differences were not statistically significant and that the workers were exposed to arsenic and nickel in addition to cobalt. The exposure levels of cobalt were not reported.

Tuchsen et al. (1996) analyzed the cancer incidence of a cohort of 874 women (382 from one factory, 492 from a second factory) who worked in one of two factories applying a cobalt-based plate underglaze. 520 referents were selected from unexposed areas of factory 1. All groups were compared to statistics for all Danish women in the same calendar year. During the follow-up period, the overall cancer incidence was only slightly elevated in exposed workers, while the incidence of lung cancers was significantly increased (SIR 2.35, 95% CI 1.01-4.6). The incidence of lung cancers in the referents (not exposed to cobalt) was greater than that of all Danish women, but the difference was not significant. Exposure characterization prior to 1980 was not described, while exposures after 1980 were variable and reported as a mean concentration for a given year. Exposures were generally in the range of 0-1 mg cobalt/m^3 except for two years, during which they were greater.

Several studies examining the effects of hard metal, a mixture containing approximately 20% cobalt with the remainder being primarily tungsten carbide. Exposure of humans to hard metal has been shown to result in an increase in cancer mortality (Lasfargues et al., 1994; Moulin et al., 1998) as well as a number of other diseases, including asthma and fibrosis (for reviews, see Barceloux, 1999; Lison, 1996). There is substantial evidence from animal studies that tungsten, although it acts as an inert dust by itself, can potentiate the effects of cobalt on the respiratory tract (Lasfargues et al., 1995; Lison et al., 1995, 1996; Swennen et al., 1993). For this reason, studies of hard metal were not given further consideration.

Animal Studies

Wehner et al. (1977, 1979) exposed groups of 51 month old male Syrian golden hamsters by inhalation to cobalt oxide at 0 or 10 mg/m^3, 7 hours/day, 5 days/week for their lifetimes. The

incidence of tumors in treated hamsters was not statistically different from controls. There was "limited" histopathologic and ultrastructural examination in the study.

In a chronic inhalation carcinogenicity study, groups of 50 F344/N rats and 50 B6C3F1 mice of each sex were exposed to cobalt sulfate heptahydrate aerosol (MMAD=1.4-1.6 μm) at concentrations of 0, 0.3, 1, or 3 mg/m^3 (0, 0.11, 0.38, or 1.14 mg Co/m^3) 6 hours/day, 5 days/week for 105 weeks (Bucher et al., 1999; NTP, 1998). Animals were monitored for body weight and observed for clinical signs during the exposure period. Following termination of exposure, all animals were sacrificed and necropsied. At necropsy, all organs and tissues were examined for gross lesions, trimmed, and examined histologically.

Mortality in either sex of F344/N rats was not affected at any exposure level, nor did treatment result in alterations in body weight (Bucher et al., 1999; NTP, 1998). The combined incidence of alveolar/bronchiolar neoplasms (adenoma and carcinoma) in males were 1/50, 4/50, 4/48, and 7/50 in the control, 0.3, 1, and 3 mg/m^3 groups, respectively, while in females the incidences were 0/50, 3/49, 15/50, and 15/50, respectively. The incidences in the 3 mg/m^3 male rats and the 1 and 3 mg/m^3 female rats were significantly greater than those in controls animals, and a significant linear trend occurred in both sexes. A significant increase in the incidence of pheochromocytoma in 3 mg/m^3 females was also noted (2/48, 1/49, 4/50, and 10/50 in control, 0.3, 1, and 3 mg/m^3 groups, respectively). A marginally increased incidence of pheochromocytoma in males exposed to 1 mg/m^3, but not in those exposed to 3 mg/m^3, was not considered by the study authors to be related to treatment.

In B6C3F1 mice, no changes in survival were noticed in any exposure group (Bucher et al., 1999; NTP, 1998). Male mice exposed to 3 mg/m^3 showed a decreased mean body weight relative to controls from week 96 through the end of the study (~10 weeks). Mean body weights of exposed female mice were generally greater than those of controls throughout the study. As in rats, both sexes of mice showed a significant linear trend toward increased alveolar/bronchiolar tumors, with the 3 mg/m^3 male and the 1 and 3 mg/m^3 female groups attaining statistical significance. Incidence of combined alveolar/bronchiolar adenoma or carcinoma were 11/50, 14/50, 19/50, and 28/50 in males and 4/50, 7/50, 13/50, and 18/50 in females in the control, 0.3, 1, and 3 mg/m^3 groups, respectively. In male mice, but not in females, the incidence of hemangiosarcoma was significantly elevated in animals exposed to 1 mg/m^3, but not in other exposure groups (2/50, 4/50, 8/50, and 7/50 in the control, 0.3, 1, and 3 mg/m^3 groups, respectively).

Other Studies

Heath (1956) injected groups of 10 male and 20 female rats with a single intramuscular 28 mg dose of powdered cobalt in the thigh. Injection site sarcomas appeared in 18 (60%) of the treated rats within 5-12 months. Similar results were observed in Wistar rats by Gilman (1962) and Gilman and Ruckerbauer (1962), with single intramuscular doses of 20 mg of cobalt oxide and cobalt sulfide. Cobalt oxide and cobalt sulfide given intramuscularly at doses twice those used in rats did not induce sarcomas in mice (Gilman and Ruckerbauer, 1962). Shabaan et al. (1977) observed a high incidence of fibrosarcomas in rats given subcutaneous injections of cobalt chloride at 40 mg/kg-day for 10 days. Tumors developed in 8-12 months. Stoner et al. (1976) tested cobalt acetate in the strain A mouse pulmonary tumor test. Groups of 20 mice/sex

received three times per week intraperitoneal injections for a total of 19 cumulative doses of 0, 95, 237, or 475 mg/kg. Survival was high over the 30 week observation period, and the incidence of lung tumors in treated mice was not statistically different from controls.

The genetic toxicity of cobalt was reviewed by Beyersman and Hartwig (1992). Cobalt compounds have generally tested negative in bacterial mutagenicity assays, with the occasional positive result occurring only with the addition of an exogenous metabolic system. By contrast, cobalt compounds have generally tested positive in yeast and plant cells. In mammalian cell systems, cobalt has been shown to induce DNA strand breaks, sister-chromatid exchanges, and morphological cell transformation. Single oral exposure of male Swiss mice to 0, 4.96, 9.92, or 19.8 mg cobalt/kg as cobalt chloride resulted in significantly increased percentages of both chromosomal breaks and chromosomal aberrations, with significant linear trends toward increasing aberrations with increased exposure (Palit et al., 1991a,b,c,d). Thirty hours following single intraperitoneal injection of cobalt(II) chloride in BALB/c mice, an increase in micronucleus formation was seen at 12.4 or 22.3 mg cobalt/kg (as cobalt chloride), but not at 6.19 mg cobalt/kg (Suzuki et al., 1993). Single injection of 12.4 mg/kg $CoCl_2 \cdot 6H_2O$ resulted in significantly increased micronucleus formation at 24 hours post-injection, but not at 12, 48, 72, or 96 hours. Pedigo and Vernon (1993) reported that treatment with 400 ppm cobalt (99 mg cobalt/kg-day) in the drinking water of mice for 10 weeks resulted in an increase in dominant lethal effects.

While the precise mechanism of action of cobalt has not been determined, a number of potential mechanisms have been identified. The most likely mechanism for the carcinogenic effects of cobalt involves the generation of cobalt-induced oxidative stress. Exposure to cobalt compounds increases indices of oxidative stress, including diminished levels of reduced glutathione, increased levels of oxidized glutathione, increased levels of oxygen radicals, and increased free-radical-induced DNA damage (Kadiiska et al., 1989; Kawanishi et al., 1994; Lewis et al., 1991; Moorhouse et al., 1985; Zhang et al., 1998). The tungsten in hard metal is thought to enhance the generation of oxidants by cobalt, thus explaining the increased activity of hard metal relative to cobalt alone.

PROVISIONAL WEIGHT OF EVIDENCE CLASSIFICATION FOR COBALT

Under the 1986 Guidelines for Carcinogen Risk Assessment (U.S. EPA, 1986), cobalt is classified as group **B1 (Probable Human Carcinogen)**, based on limited evidence of carcinogenicity in humans and sufficient evidence of carcinogenicity in animals, as evidenced by increased incidence of alveolar/bronchiolar tumors in both sexes of rats and mice. Under the proposed cancer guidelines (U.S. EPA, 1999), cobalt is considered likely to be carcinogenic to humans.

While available studies in humans have been suggestive of a possible association between exposure to cobalt and respiratory tumors (Morgan et al., 1983; Mur et al., 1987; Tuchsen et al., 1996), limitations of the studies, including small numbers of subjects, inadequate exposure assessment and/or potential exposure to other chemicals, make them inadequate for assessing the carcinogenic potential of cobalt. Available chronic animal studies have demonstrated the carcinogenic potential of inhaled cobalt in male and female rats and mice, with alveolar and

bronchiolar tumors being the most prevalent (Bucher et al., 1999; NTP, 1998). No studies suitable for evaluation of the oral carcinogenic potential for cobalt were located.

The precise mechanism of cobalt-induced carcinogenicity has not been fully determined. There is evidence that cobalt is capable of eliciting genotoxic effects. While evaluations for mutagenic effects in bacteria have generally yielded negative results, results in mammalian cell systems have suggested that cobalt may be genotoxic in mammalian cells. Limited data from *in vivo* animal studies have also suggested genotoxic effects of cobalt, including chromosomal breaks, chromosomal aberrations, and micronucleus formation. The most likely mechanism for the carcinogenic effects of cobalt involves the generation of cobalt-induced oxidative stress.

QUANTITATIVE ESTIMATES OF CARCINOGENIC RISK

Provisional Oral Slope Factor for Cobalt

No human or animal studies examining the carcinogenicity of cobalt following oral exposure were located. Therefore, derivation of an oral slope factor is precluded.

Provisional Inhalation Unit Risk for Cobalt

As available human studies were not sufficiently detailed, particularly with regards to analysis of exposure, the NTP (1998; Bucher et al. 1999) 2-year carcinogenicity study in rats and mice was chosen as the key study for the derivation of an inhalation unit risk. The concentrations were first adjusted to continuous exposure as follows:

$$Conc_{[ADJ]} = Conc \times \frac{5\,days\,/\,week}{7\,days\,/\,week} \times \frac{6\,hours\,/\,day}{24\,hours\,/\,day}$$

This adjustment resulted in duration-adjusted concentrations of 0, 0.020, 0.068, and 0.20 mg cobalt/m^3 for the control, 0.3, 1, and 3 mg/m^3 groups, respectively. Using the RDDR computer program, as specified in the RfC guidelines (U.S. EPA, 1994b), human equivalent concentrations (HECs, in mg cobalt/m^3) were calculated at each exposure level for each species and sex, assuming particulate effects (MMAD=1.5 μm, σ_g=2.2) in the thoracic portion of the respiratory tract. The results are displayed below.

	Male Rat	Female Rat	Male Mouse	Female Mouse
RDDR Multiplier	0.83	0.79	1.48	1.44
Control	0	0	0	0
Low	0.017	0.016	0.030	0.029
Medium	0.056	0.054	0.10	0.098
High	0.17	0.16	0.30	0.29

The GLOBAL86 computer program was then used to fit the incidence data to the HEC for each species and sex. Calculations were based on extra risk. The results of the analysis are presented in the table below:

Species	Sex	Control	Low	Med	High	q_1^* $(mg/m^3)^{-1}$	$LEC_{10}(mg/m^3)$	P-value#
Rat	M	1/50	4/50	4/48	7/50	1.5	$7.2x10^{-2}$	0.50
Rat	F	0/50	3/49	15/50	15/50	4.4	$2.4x10^{-2}$	0.0085
Rat	F	0/50	3/49	15/50	***	8.1	$1.3x10^{-2}$	0.40
Mouse	M	11/50	14/50	19/50	28/50	2.9	$3.6x10^{-2}$	0.95
Mouse	F	4/50	7/50	13/50	18/50	2.1	$5.1x10^{-2}$	0.55

- P value describing the goodness of fit of the model. A greater p value describes a better fit, with p>0.05 being a statistically significant fit.
*** - Because of a poor fit, the group was re-analyzed without the data from the high-exposure animals.

The model did not accurately fit the data from female rats, which appeared to be the most sensitive species and gender. If the high-dose group is dropped, the model better fits the data, but likely overestimates the risk, since the incidences of tumors in both the mid- and high-dose groups were the same. The most conservative (health-protective) value obtained with adequate model fit using all dose groups, calculated from male mice, was therefore selected.

In accordance with the proposed Guidelines for Carcinogen Risk Assessment (U.S. EPA, 1999), the unit risk was also calculated by drawing a straight line between the LEC_{10} and the origin. The linear dose-response model was utilized due to the lack of understanding of the mode(s) of action of cobalt-induced carcinogenesis. This method results in unit risk for pulmonary carcinogenesis of **$2.8x10^{-3}$ $(ug\ Co/m^3)^{-1}$**, calculated as follows:

$$IUR = Incidence / Dose$$
$$= 10\% \div LEC_{10}$$
$$= 0.1 \div 3.6x10^{-2} (mg\ Co / m^3)$$
$$= 2.8 (mg\ Co / m^3)^{-1}$$
$$= 2.8 \times 10^{-3} (ug\ Co / m^3)^{-1}$$

This value is similar to that generated by directly calculating the q_1^*, which was $2.9x10^{-3}$ $(\mu g/m^3)^{-1}$. From these values, the following air concentrations were calculated for the specified risk levels:

Risk Level	Concentration
E-4 (1 in 10,000)	4E-2 ug Co/m^3
E-5 (1 in 100,000)	4E-3 ug Co/m^3
E-6 (1 in 1,000,000)	4E-4 ug Co/m^3

In summary, cobalt is provisionally classified as group B1 (Probable Human Carcinogen), based on limited evidence of carcinogenicity in humans and sufficient evidence of carcinogenicity in animals, as evidenced by increased incidence of alveolar/bronchiolar tumors in both sexes of rats and mice, under the 1986 cancer guidelines (U.S. EPA, 1986). Under the proposed cancer guidelines (U.S. EPA, 1999), cobalt is considered likely to be carcinogenic to humans. A provisional **inhalation unit risk of 2.8×10^{-3} (μg Co/m^3)$^{-1}$** was derived for cobalt, based on the increased incidence of respiratory tumors in male B6C3F1 mice. Derivation of the unit risk under the proposed guidelines (U.S. EPA, 1999) and the 1986 guidelines (U.S. EPA, 1986) resulted in very similar values. Data were inadequate to derive an oral slope factor for cobalt.

PROVISIONAL PEER REVIEWED TOXICITY VALUES FOR COBALT AND COMPOUNDS (CASRN 7440-48-4)
Derivation of Subchronic and Chronic Oral RfDs

Background

On December 5, 2003, the U.S. Environmental Protection Agency's (EPA's) Office of Superfund Remediation and Technology Innovation (OSRTI) revised its hierarchy of human health toxicity values for Superfund risk assessments, establishing the following three tiers as the new hierarchy:

1. EPA's Integrated Risk Information System (IRIS).

2. Provisional Peer-Reviewed Toxicity Values (PPRTV) used in EPA's Superfund Program.

3. Other (peer-reviewed) toxicity values, including:

   - Minimal Risk Levels produced by the Agency for Toxic Substances and Disease Registry (ATSDR),
   - California Environmental Protection Agency (CalEPA) values, and
   - EPA Health Effects Assessment Summary Table (HEAST) values.

A PPRTV is defined as a toxicity value derived for use in the Superfund Program when such a value is not available in EPA's Integrated Risk Information System (IRIS). PPRTVs are developed according to a Standard Operating Procedure (SOP) and are derived after a review of the relevant scientific literature using the same methods, sources of data, and Agency guidance for value derivation generally used by the EPA IRIS Program. All provisional toxicity values receive internal review by two EPA scientists and external peer review by three independently selected scientific experts. PPRTVs differ from IRIS values in that PPRTVs do not receive the multi-program consensus review provided for IRIS values. This is because IRIS values are generally intended to be used in all EPA programs, while PPRTVs are developed specifically for the Superfund Program.

Because new information becomes available and scientific methods improve over time, PPRTVs are reviewed on a five-year basis and updated into the active database. Once an IRIS value for a specific chemical becomes available for Agency review, the analogous PPRTV for that same chemical is retired. It should also be noted that some PPRTV manuscripts conclude that a PPRTV cannot be derived based on inadequate data.

Disclaimers

Users of this document should first check to see if any IRIS values exist for the chemical of concern before proceeding to use a PPRTV. If no IRIS value is available, staff in the regional Superfund and RCRA program offices are advised to carefully review the information provided in this document to ensure that the PPRTVs used are appropriate for the types of exposures and circumstances at the Superfund site or RCRA facility in question. PPRTVs are periodically updated; therefore, users should ensure that the values contained in the PPRTV are current at the time of use.

It is important to remember that a provisional value alone tells very little about the adverse effects of a chemical or the quality of evidence on which the value is based. Therefore, users are strongly encouraged to read the entire PPRTV manuscript and understand the strengths and limitations of the derived provisional values. PPRTVs are developed by the EPA Office of Research and Development's National Center for Environmental Assessment, Superfund Health Risk Technical Support Center for OSRTI. Other EPA programs or external parties who may choose of their own initiative to use these PPRTVs are advised that Superfund resources will not generally be used to respond to challenges of PPRTVs used in a context outside of the Superfund Program.

Questions Regarding PPRTVs

Questions regarding the contents of the PPRTVs and their appropriate use (e.g., on chemicals not covered, or whether chemicals have pending IRIS toxicity values) may be directed to the EPA Office of Research and Development's National Center for Environmental Assessment, Superfund Health Risk Technical Support Center (513-569-7300), or OSRTI.

INTRODUCTION

IRIS (U.S. EPA, 2000a) does not report an RfD for cobalt. The HEAST (U.S. EPA, 1997) and Drinking Water Standards and Health Advisories (U.S. EPA, 2000b) likewise do not list an RfD for cobalt. The CARA lists (U.S. EPA, 1991, 1994) report a HEA for cobalt (U.S. EPA, 1987). The 1987 HEA derived a chronic RfD of 0.005 mg cobalt/kg-day based on a NOAEL of 5 mg cobalt/kg-day for testicular effects in a subchronic rat study (Nation et al., 1983). An updated HEA prepared by SRC (1990) for U.S. EPA, but never finalized, dropped the RfD because, it was argued, such an RfD would not be protective for individuals already sensitized to cobalt. ATSDR (1992) has published a Toxicological Profile for cobalt and compounds, but no oral MRLs were derived due to the absence of suitable data. The WHO (2000) has not published an Environmental Health Criteria document about cobalt. An IARC Monograph on cobalt and compounds (IARC, 1991) and the NTP Status Reports (NTP, 2000)

were searched for relevant information. Literature searches were conducted from 1991 to November, 2000 for studies relevant to the derivation of an RfD. The databases searched were: TOXLINE, MEDLINE, CANCERLIT, and TSCATS.

REVIEW OF PERTINENT DATA

Cobalt has been found to stimulate the production of red blood cells in humans and, therefore, has been used as a treatment for anemia. In 12 anemic, anephric patients undergoing dialysis, treatment with 0.18 mg cobalt/kg-day as cobalt chloride for 12 weeks resulted in a significant rise in hemoglobin (Duckham and Lee, 1976). Taylor et al. (1977) reported similar effects in 8 anephric patients treated with 0.16-0.32 mg cobalt/kg-day as cobalt chloride for 12-32 weeks. In both studies, hemoglobin levels rapidly returned to pre-treatment levels following the cessation of treatment. Similar effects were reported in nonanemic humans and animals (Davis and Fields, 1958; Krasovskii and Fridlyand, 1971). Reversible polycythemia was reported in 6 normal male subjects following treatment with 1 mg cobalt/kg-day as cobalt chloride for 25 days (Davis and Fields, 1958). In normal rats, treatment with 0.5 mg cobalt/kg-day, but not 0.05 mg cobalt/kg-day, as cobalt chloride resulted in polycythemia and an increase in hemoglobin (Krasovskii and Fridlyand, 1971). An increase in hematocrit and hemoglobin levels was not observed, however, in pregnant women treated with 0.5-0.6 mg cobalt/kg-day for 90 days in an attempt to alleviate the anemia often found during pregnancy (Holly, 1955).

Much of the oral data in humans deals with the cardiomyopathy seen in people who drank large quantities of beer containing cobalt chloride (previously used to stabilize the foam) (Alexander, 1969, 1972; Morin et al., 1971). The people ingested 0.04-0.14 mg cobalt/kg-day (approximately 8-30 pints of beer daily) over a period of years (Alexander, 1969, 1972; Morin et al., 1971). The cardiomyopathy in the beer-drinkers, termed “beer-cobalt cardiomyopathy,” was fatal to 43% of the subjects within several years, with approximately 18% of these deaths occurring within the first several days following diagnosis. The beer-cobalt cardiomyopathy appeared to be similar to alcoholic cardiomyopathy and beriberi, but the onset of the beer-cobalt cardiomyopathy was much more abrupt. The practice of adding cobalt to beer to stabilize the foam has been discontinued. It should be noted, however, that the cardiomyopathy may also have been due to the fact that the beer-drinkers had protein-poor diets and may have had prior or concurrent cardiac and hepatic damage from alcohol abuse. Treatment of anemic patients, either resulting from pregnancy or other causes, with comparable or much higher doses of cobalt (0.09-1 mg cobalt/kg-day, ranging from 3-32 weeks) did not result in effects on the heart (Duckham and Lee, 1976; Davis and Fields, 1958; Holly, 1955; Taylor et al., 1977).

Studies in animals have noted cardiac effects following cobalt exposure (Haga et al., 1996; Mohiuddin et al., 1970; Pehrsson et al., 1991), though at higher exposure levels than examined in human studies. Pehrsson et al. (1991) exposed male rats (12/group) to protein-

restricted diets containing 8.4 mg Co/kg-day. Treated rats showed a significant decrease in body weight, but no differences in left ventricular function, relative to animals treated with protein-restricted diets without cobalt. In a followup study (Haga et al., 1996), in which groups of 12-16 rats were similarly exposed to 8.4 mg Co/kg-day for 16 or 24 weeks, animals exposed to cobalt showed reduced relative left ventricular weights, as well as diminished left ventricular function at both time points, with animals at the later time point demonstrating greater impairment. Groups of guinea pigs exposed to 20 mg cobalt/kg-day as cobalt sulfate in the diet for 5 weeks resulted in decreased absolute and relative heart weights and a greater incidence of abnormal electrocardiograms compared to animals not exposed to cobalt (Mohiuddin et al., 1970). Cellular alterations (observed at the light and electron microscopic level) in cardiac tissues included pericardial thickening and inflammation, myocardial degeneration and vacuolization, endocardial thickening, and myofibrillar damage.

The thyroid also appears to be a target for cobalt. Treatment of patients with 1 mg cobalt/kg/day as cobalt chloride for 2 weeks resulted in a greatly reduced uptake of radioactive iodine by the thyroid in 1 week, with uptake nearing 0 by the second week (Roche and Layrisse, 1956). When the cobalt treatment ended, the uptake values returned to normal. The decrease of radioactive iodine uptake found in patients administered 0.54 mg cobalt/kg/day for 10–25 days was found to result from cobalt blocking the organic binding of iodine (Paley et al., 1958).

Cobalt has been found to be a sensitizer in humans. Individuals are sensitized following dermal or inhalation exposure, but flares of dermatitis may be triggered following cobalt ingestion. One study was located that orally challenged cobalt-exposed workers in order to assess sensitization (Veien et al., 1987). In this study, several patients with eczema of the hands were challenged orally with 1 mg cobalt (0.014 mg cobalt/kg-day as cobalt sulfate) in tablet form once per week for 3 weeks; 28/47 patients had a flare of dermatitis following the oral challenge (Veien et al., 1987). All forty-seven patients had positive dermal patch tests to cobalt (13 to cobalt alone and 34 to nickel and cobalt) and 7 of the 13 patients that had patch-tested positive to cobalt alone reacted to the oral challenge. Comparing the results of the oral challenge and dermal patch tests, it was deduced that cobalt allergy was systemically induced. The exposure levels associated with sensitization to cobalt following inhalation or dermal exposure were not established.

Interrelationships have been found to exist between cobalt and nickel sensitization (Bencko et al., 1983; Rystedt and Fisher, 1983; Veien et al., 1987). In guinea pigs, nickel and cobalt sensitization appear to be interrelated and mutually enhancing (Lammintausta et al., 1985). Therefore, it is possible that in people sensitized by nickel, exposure to cobalt may result in an allergic reaction.

Four studies were located examining developmental effects of orally administered cobalt (given as cobalt chloride) in rodents (Domingo et al., 1985; Paternain et al., 1988; Pedigo and

Vernon, 1993; Seidenberg et al., 1986). Domingo et al. (1985) treated pregnant female rats with 5.4 to 21.8 mg cobalt/kg-day from gestation day 14 through lactation day 21. Maternal effects were not reported. Fetal effects at 5.4 mg cobalt/kg-day included stunted growth of the pups of both sexes, decreased body length and tail length in male offspring, and decreased spleen and liver weight in female offspring. Effects at the 10.9 mg cobalt/kg-day dose included decreased body weight in female pups, while at 21.8 mg cobalt/kg-day decreased survival was seen. These effects were at levels that were maternally toxic (authors did not specify the effects); therefore, the fetal effects at these levels may be a result of maternal toxicity rather than a direct effect of cobalt treatment.

No significant effects on fetal growth or survival were found in rats exposed to 6.2 to 24.8 mg cobalt/kg-day during gestation days 6-15 (Paternain et al., 1988), although a nonsignificant increase in the incidence of stunted fetuses was found in the animals treated with 12.4 or 24.8 mg cobalt/kg-day. Maternal effects, including reduced body weight gain and food consumption and altered hematological parameters, were reported at all exposure levels. No fetal effects were reported in mice exposed to 81.7 mg cobalt/kg-day during gestation days 8-12 (Seidenberg et al., 1986), but a significant decrease in maternal weight was found. Pedigo and Vernon (1993) exposed male rats to 93 mg cobalt/kg-day as cobalt chloride in the drinking water for 10 weeks, after which the males were mated with control females to examine for dominant lethal effects. Cobalt treatment resulted in a decreased percentage of pregnant females, decreased implantations per female, and increased preimplantation losses relative to controls. Recovery of reproductive function was seen by 8 weeks post-exposure.

Several studies reported testicular degeneration and atrophy in rats exposed to 6.1 to 24.4 mg cobalt/kg-day as cobalt chloride for 2-3 months in the diet or in the drinking water (Anderson et al., 1992, 1993; Corrier et al., 1985; Domingo et al., 1984; Mollenhauer et al., 1985; Nation et al., 1983; Pedigo et al., 1988). Pedigo et al. (1988) exposed male CD-1 mice to 100, 200, or 400 ppm of cobalt chloride (~6.1, 12.2, or 24.4 mg cobalt/kg-day, respectively) in the drinking water for 13 weeks. High-dose animals showed a significantly decreased testicular weight beginning at week 9 of treatment and a decreased epididymal sperm concentration by week 11 of treatment. All dose groups showed significantly decreased testicular weight and epididymal sperm concentration, and increased serum testosterone levels, by week 12 of exposure. Anderson et al. (1992, 1993) exposed groups of male CD-1 mice to 400 ppm of cobalt chloride (~24.4 mg cobalt/kg-day) in the drinking water for up to 13 weeks. A decrease in testicular weight and a progressive degeneration of the seminiferous tubules were seen beginning at 9 weeks of exposure, with no recovery seen after a 20-week non-exposure recovery period. Co-administration of 800 ppm of zinc chloride provided a partial protection against the effects of cobalt. Similar histology (degeneration of the testes, particularly the seminiferous tubules) was noted in Sprague-Dawley rats exposed to 20 mg cobalt/kg-day in the diet for up to 98 days (Corrier et al., 1985; Mollenhauer et al., 1985). Decreased testicular weight was seen in Sprague-

Dawley rats exposed to 500 ppm cobalt chloride (~17 mg cobalt/kg-day) for 3 months (Domingo et al., 1984).

Nation et al. (1983) exposed groups (n=6) of male Sprague-Dawley rats, 200-210 g, to diets containing 0, 5, or 20 mg cobalt/kg-day for a total of 69 days. Following 14 days of exposure, animals were trained for schedule (operant) or conditioned suppression neurobehavioral tests. Other than two seizures in the same high-dose animal, no overt signs of neurotoxicity were reported at any exposure level. A trend toward a decreased response rate in the schedule training behavior was observed in both the exposed groups, but only attained statistical significance in the high-dose animals near the end of the operant testing period (sessions 28-35, on exposure days 44-51). A trend toward decreased conditioned suppression behavior did not attain statistical significance in either group. Animals exposed to 20 mg cobalt/kg-day, but not 5 mg cobalt/kg-day, showed a significantly decreased weight of the testes following 69 days of exposure. This study established a NOAEL of 5 mg cobalt/kg-day and a LOAEL of 20 mg cobalt/kg-day for decreased testicular weight and changes in operant behavior in male Sprague-Dawley rats.

Several other studies have examined the effects of cobalt on neurobehavioral parameters (Bourg et al., 1985; Krasovskii and Fridlyand, 1971; Singh and Junnarkar, 1991). In groups of male Sprague-Dawley rats (n=8) exposed to 20 mg cobalt/kg/day as cobalt chloride for 57 days in the drinking water, cobalt enhanced behavioral reactivity to stress (the animals were less likely to descend from a safe platform to an electrified grid) (Bourg et al., 1985). Singh and Junnarkar (1991) reported a moderate reduction in spontaneous activity and mild hypothermia in rats exposed orally to 1/10 the LD50 of cobalt chloride or cobalt sulfate. Krasovskii and Fridlyand (1971) exposed groups of rats (number and sex not specified) to 0.05, 0.5, or 2.5 mg cobalt/kg-day for up to 7 months. Neurobehavioral tests showed that treatment with cobalt as cobalt chloride resulted in a significant increase in the latent reflex period at 0.5 mg cobalt/kg and above, and a pronounced neurotropic effect (disturbed conditioned reflexes) at 2.5 mg cobalt/kg.

DERIVATION OF A PROVISIONAL RfD FOR COBALT

The only known nutritional function of cobalt is as a vital component of vitamin B_{12}. All vitamin B_{12} is derived from bacterial synthesis, so inorganic cobalt can be considered essential for animal species, such as ruminants, that depend totally on their bacterial flora for their vitamin B_{12}. This may apply to some degree also to humans with strict vegetarian diets, whose intake of pre-formed vitamin B_{12} is severely limited (animal products are the primary source of vitamin B_{12} in the diet). However, there is no evidence that the intake of cobalt is ever limiting in the human diet, and therefore no RDA is deemed necessary for cobalt (NRC, 1989). Recent data based on a 1984 FDA Total Diet Study (Pennington and Jones, 1987) have suggested that daily cobalt intakes in humans are in the 0.003-0.011 mg cobalt/day range. A recent survey of 5 Canadian

cities also suggested dietary intakes in the range of 0.007-0.015 mg cobalt/day for all age groups (Dabeka and McKenzie, 1995). Using body weights from NRC (1989), both of these studies would suggest daily intake levels on the order of 10^{-4} mg cobalt/kg-day. Older studies suggested that the average daily intake of cobalt in humans was higher, ranging from approximately 0.002 to 0.008 mg cobalt/kg-day in adults (Tipton et al., 1966; Schroeder et al., 1967) and 0.01 to 0.06 mg cobalt/kg-day in children (NRC, 1989; Murthy et al., 1971).

The most sensitive indicators of the effects of cobalt following oral exposure appear to be the increase of hemoglobin in both humans and animals and the elicitation of dermatitis in sensitized individuals. Cardiomyopathy is an endpoint of concern for cobalt in humans, but it is highly likely that alcohol consumed in "beer-cobalt cardiomyopathy," as well as other factors, played a role in the effects that were seen. Other effects, including neurobehavioral, developmental, and testicular toxicity, were observed only in animals and at relatively high doses, and so were not considered critical for the risk assessment.

The elicitation of an allergic response in cobalt-sensitized workers was evaluated as a potential critical endpoint for the derivation of an oral RfD. However, the available data provide no information on the dose-response relationship of cobalt sensitization, nor is a NOAEL for the elicitation of the allergic response in humans defined. Interrelationships also exist between cobalt and nickel sensitization, so that people sensitized by nickel may have an allergic reaction following cobalt exposure. Sensitization was, therefore, not selected as the critical endpoint for RfD derivation.

Hematological effects of cobalt treatment (increased hemoglobin) have been reported in anemic dialysis patients (Duckham and Lee, 1976) and anephric patients (Taylor et al., 1977). In these patients, hemoglobin levels increased from levels clinically described as anemic to levels at or near "normal." Thus, the effect of cobalt administration in these patients was clinically beneficial to these patients, and not adverse. However, hematologic effects of cobalt were also found in studies of normal humans (Davis and Fields, 1958) and rats (Krasovskii and Fridlyand, 1971), indicating that the effect is not limited to anephric individuals. Davis and Fields (1958) reported hemoglobin increases of 6-11% over "normal" in healthy volunteers given 0.96 mg cobalt/kg-day as cobaltous chloride. In contrast to the situation in the anemia patients studied by Duckham and Lee (1976) and Taylor et al. (1977), polycythemia in normal people is considered to be an adverse effect. Therefore, this is considered to be a suitable endpoint for derivation of an RfD.

The study by Duckham and Lee (1976) was used as the critical study for derivation of the RfD. The study by Taylor et al. (1977) reported similar effects at similar exposure levels, but the Duckham and Lee (1976) study described the study results and methods in greater detail. The study by Davis and Fields (1958) in normal humans used a higher dose level. While the cobalt in the Duckham and Lee (1976) study was used therapeutically, it represents an effect on the most

sensitive endpoint in a sensitive population of humans, and is, therefore, appropriate for use as the critical study for derivation of an RfD. The provisional RfD was derived from the LOAEL of 0.18 mg cobalt/kg-day as follows:

RfD = LOAEL/UF x MF

Where:

LOAEL	=	0.18 mg/kg-day	
UF	=	10	Made up of component factors accounting for the use of a LOAEL (3) and deficiencies in the database (3), primarily the absence of chronic oral data leading to the use of a subchronic study.
MF	=	1	Default value for modifying factor.

Therefore:

RfD = 0.18/10 x 1

= **0.02** or **2E-2** mg/kg-day

An uncertainty factor to protect sensitive individuals was not considered to be necessary since the critical study was performed in a sensitive human population. The RfD of 0.02 mg Co/kg-day is higher than most estimates of dietary intake of cobalt, which range from 0.0001 mg/kg-day in the most recent studies (Pennington and Jones, 1987; Dabeka and McKenzie, 1995) to 0.002-0.008 mg/kg-day in older studies in adults (Tipton et al., 1966; Schroeder et al., 1967) and 0.01-0.06 in one study in children (Murthy et al., 1971). This RfD may not be protective for people with hypersensitivity to cobalt.

STATEMENT OF CONFIDENCE

Confidence in the critical study is low-to-medium. The study examined a small number of subjects over a subchronic duration, but examined what appears to be a sensitive endpoint in a group of sensitive humans. Confidence in the database is medium. There are supporting studies in both anemic and normal humans, and also in animals. However, there are no chronic oral data and only limited data on developmental effects. Low-to-medium confidence in the provisional RfD results.

bw	body weight
cc	cubic centimeters
CD	Caesarean Delivered
CERCLA	Comprehensive Environmental Response, Compensation and Liability Act of 1980
CNS	central nervous system
cu.m	cubic meter
DWEL	Drinking Water Equivalent Level
FEL	frank-effect level
FIFRA	Federal Insecticide, Fungicide, and Rodenticide Act
g	grams
GI	gastrointestinal
HEC	human equivalent concentration
Hgb	hemoglobin
i.m.	intramuscular
i.p.	intraperitoneal
IRIS	Integrated Risk Information System
IUR	inhalation unit risk
i.v.	intravenous
kg	kilogram
L	liter
LEL	lowest-effect level
LOAEL	lowest-observed-adverse-effect level
LOAEL(ADJ)	LOAEL adjusted to continuous exposure duration
LOAEL(HEC)	LOAEL adjusted for dosimetric differences across species to a human
m	meter
MCL	maximum contaminant level
MCLG	maximum contaminant level goal
MF	modifying factor
mg	milligram
mg/kg	milligrams per kilogram
mg/L	milligrams per liter
MRL	minimal risk level
MTD	maximum tolerated dose
MTL	median threshold limit
NAAQS	National Ambient Air Quality Standards
NOAEL	no-observed-adverse-effect level
NOAEL(ADJ)	NOAEL adjusted to continuous exposure duration
NOAEL(HEC)	NOAEL adjusted for dosimetric differences across species to a human
NOEL	no-observed-effect level
OSF	oral slope factor
p-IUR	provisional inhalation unit risk
p-OSF	provisional oral slope factor

p-RfC	provisional inhalation reference concentration
p-RfD	provisional oral reference dose
PBPK	physiologically based pharmacokinetic
ppb	parts per billion
ppm	parts per million
PPRTV	Provisional Peer Reviewed Toxicity Value
RBC	red blood cell(s)
RCRA	Resource Conservation and Recovery Act
RDDR	Regional deposited dose ratio (for the indicated lung region)
REL	relative exposure level
RfC	inhalation reference concentration
RfD	oral reference dose
RGDR	Regional gas dose ratio (for the indicated lung region)
s.c.	subcutaneous
SCE	sister chromatid exchange
SDWA	Safe Drinking Water Act
sq.cm.	square centimeters
TSCA	Toxic Substances Control Act
UF	uncertainty factor
µg	microgram
µmol	micromoles
VOC	volatile organic compound

6-11-2007

PROVISIONAL PEER REVIEWED TOXICITY VALUES FOR DIBENZOFURAN (CASRN 132-64-9)

Background

On December 5, 2003, the U.S. Environmental Protection Agency's (EPA's) Office of Superfund Remediation and Technology Innovation (OSRTI) revised its hierarchy of human health toxicity values for Superfund risk assessments, establishing the following three tiers as the new hierarchy:

1. EPA's Integrated Risk Information System (IRIS).

2. Provisional Peer-Reviewed Toxicity Values (PPRTV) used in EPA's Superfund Program.

3. Other (peer-reviewed) toxicity values, including:

   - Minimal Risk Levels produced by the Agency for Toxic Substances and Disease Registry (ATSDR),
   - California Environmental Protection Agency (CalEPA) values, and
   - EPA Health Effects Assessment Summary Table (HEAST) values.

A PPRTV is defined as a toxicity value derived for use in the Superfund Program when such a value is not available in EPA's Integrated Risk Information System (IRIS). PPRTVs are developed according to a Standard Operating Procedure (SOP) and are derived after a review of the relevant scientific literature using the same methods, sources of data, and Agency guidance for value derivation generally used by the EPA IRIS Program. All provisional toxicity values receive internal review by two EPA scientists and external peer review by three independently selected scientific experts. PPRTVs differ from IRIS values in that PPRTVs do not receive the multi-program consensus review provided for IRIS values. This is because IRIS values are generally intended to be used in all EPA programs, while PPRTVs are developed specifically for the Superfund Program.

Because new information becomes available and scientific methods improve over time, PPRTVs are reviewed on a five-year basis and updated into the active database. Once an IRIS value for a specific chemical becomes available for Agency review, the analogous PPRTV for that same chemical is retired. It should also be noted that some PPRTV manuscripts conclude that a PPRTV cannot be derived based on inadequate data.

Disclaimers

Users of this document should first check to see if any IRIS values exist for the chemical of concern before proceeding to use a PPRTV. If no IRIS value is available, staff in the regional Superfund and RCRA program offices are advised to carefully review the information provided in this document to ensure that the PPRTVs used are appropriate for the types of exposures and circumstances at the Superfund site or RCRA facility in question. PPRTVs are periodically updated; therefore, users should ensure that the values contained in the PPRTV are current at the time of use.

It is important to remember that a provisional value alone tells very little about the adverse effects of a chemical or the quality of evidence on which the value is based. Therefore, users are strongly encouraged to read the entire PPRTV manuscript and understand the strengths and limitations of the derived provisional values. PPRTVs are developed by the EPA Office of Research and Development's National Center for Environmental Assessment, Superfund Health Risk Technical Support Center for OSRTI. Other EPA programs or external parties who may choose of their own initiative to use these PPRTVs are advised that Superfund resources will not generally be used to respond to challenges of PPRTVs used in a context outside of the Superfund Program.

Questions Regarding PPRTVs

Questions regarding the contents of the PPRTVs and their appropriate use (e.g., on chemicals not covered, or whether chemicals have pending IRIS toxicity values) may be directed to the EPA Office of Research and Development's National Center for Environmental Assessment, Superfund Health Risk Technical Support Center (513-569-7300), or OSRTI.

This document has passed the STSC quality review and peer review evaluation indicating that the quality is consistent with the SOPs and standards of the STSC and is suitable for use by registered users of the PPRTV system.

INTRODUCTION

RfD and RfC values for dibenzofuran (DBF) were not available on IRIS (U.S. EPA, 2007) or in the HEAST (U.S. EPA, 1997). There is a Class D cancer assessment on IRIS (U.S. EPA, 2007). Dibenzofuran was included in a Drinking Water Toxicity Profile from 1992 (U.S. EPA, 1992), although no oral toxicity value was listed. The Office of Water did not include dibenzofuran on the latest Drinking Water Regulations (U.S. EPA, 2006a) or the Drinking Water Contaminant Candidate List (U.S. EPA, 2006b). The CARA list (U.S. EPA, 1991, 1994)

included a Health Effects Assessment (HEA) (U.S. EPA, 1987) and a Reportable Quantity Document (U.S. EPA, 1989) for Dibenzofuran. The HEA concluded that additional toxicity testing was necessary and did not derive a toxicity value due to the lack of data (U.S. EPA, 1987). The 1987 HEA for Dibenzofuran neither identified nor included discussion of Thomas et al. (1940), the primary source of data used in this PPRTV document. By contrast, the 1989 Reportable Quantity Document for Dibenzofuran (U.S. EPA, 1989) used Thomas et al. (1940) as the basis for derivation of composite scores and the corresponding reportable quantities for dibenzofuran.

ATSDR had not published a Toxicological Profile for dibenzofuran (ATSDR, 2006). NTP did not study the toxicity of dibenzofuran (NTP, 2006). WHO (2006) provided no relevant information. Available data on carcinogenicity, mutagenicity, metabolism, and other biological effects were summarized for dibenzofuran by the National Cancer Institute (NCI, 2000). Data on the adverse health effects of various halogenated dibenzofurans were available; however, the biological activity varies greatly among these congeners. U.S. EPA (1986a) did not recommend risk assessment by analogy to any of these more widely studied chemicals. NCI (2000) reported that the most structurally related chemical was dibenzo-p-dioxin. NCI (1979) reported that no excess tumors were induced in rats or mice fed dibenzo-p-dioxin up to 10,000 ppm in the diet.

Updated literature searches for noncancer and cancer data were conducted for data available through April 2006. The databases searched included: TOXLINE, MEDLINE, CANCERLIT, CCRIS, TSCATS, HSDB, RTECS, GENETOX, DART/ETICBACK, and EMIC/EMICBACK. Inhalation RfC values were not derived for dibenzofuran, because no human or animal inhalation data were found and the marginal ingestion data seemed inadequate to consider for inter-route extrapolation. However, a subchronic oral p-RfD value was derived, based on a LOAEL point of departure (POD) in Thomas et al. (1940). Chronic toxicity of dibenzofuran is discussed in the appendix. No data were identified from which to derive cancer risk values.

REVIEW OF PERTINENT DATA

Human Studies

Two cross-sectional studies of exposed workers were identified in the OPPT TSCATS database (Koppers 1980a,b). However, these studies reported exposures to dibenzofuran only in complex mixtures of coal tar products. Neither report noted adverse health effects that could be attributed to dibenzofuran exposure. Existing review documents and a detailed literature search identified no other data regarding the toxicity of dibenzofuran in humans.

Animal Studies

The only long-term toxicity data available for dibenzofuran were from a 200-day rat feeding study reported by Thomas et al. (1940). However, this document also will address the NCI (1979) data for dibenzo-p-dioxin, which NCI (2000) considered to be the chemical most structurally related to dibenzofuran.

NCI (1979) reported that unsubstituted dibenzo-p-dioxin, a structural analog of dibenzofuran, exhibited very low toxicity and no evidence of carcinogenicity in Osborne-Mendel rats and B6C3F1 mice, even when the maximum tolerated dose was approached (10,000 ppm in diet). Groups of 35 rats of each gender ingested dibenzo-p-dioxin at 5000 or 10,000 ppm in diet for 110 weeks. Groups of 50 mice of each gender ingested the same doses for 87 or 90 weeks. Controls consisted of groups of 35 untreated rats of each gender and 50 untreated mice of each gender. Mean body weights of the dosed male and female rats and mice were lower than those of the corresponding controls; the depression in the amount of weight gained in the dosed male mice was, however, relatively slight. Except for the male rats, survival at the end of the bioassay was lower in the dosed groups of both rats and mice than in the corresponding control groups. At week 90, at least 57% of the rats and 54% of the mice were still alive. In some male and female rats there was a dose-related increase in the incidence of hepatotoxic alterations characterized by fatty metamorphosis or necrosis. Also in mice, toxic hepatic lesions including liver degeneration, necrosis, fibrosis and/or cirrhosis were observed in slightly increased numbers in the dosed mice ─ particularly in the high-dose females. No tumors were induced in rats or mice of either gender at incidences that were significantly higher in the dosed groups than in the corresponding control groups. The authors concluded that unsubstituted dibenzo-p-dioxin exhibited very low toxicity and was noncarcinogenic in Osborne-Mendel rats and B6C3F1 mice, even when the maximum tolerated dose was approached (10,000 ppm in diet).

The Thomas et al. (1940) report consisted of two studies, a primary 200-day dibenzofuran feeding study and a follow-up 78-day study. In the primary study, groups of five female albino rats (strain not specified), approximately 30 days old, consumed 0, 250, 500, 1000, 2000, or 4000 ppm of dibenzofuran in their food for 200 days. In addition, two female rats consumed 8000 ppm of dibenzofuran in their diet for a shorter period (approximately 100 days). According to the authors, none of the animals exhibited any abnormal activity or behavior, nor was food intake appreciably altered by dibenzofuran administration, although it was noted that the rats receiving dibenzofuran tended to consume more water than controls. The authors also reported no effect on body weight gain at any dose during the exposure period; however, decreases in body length and absolute organ weights were observed in all dibenzofuran-exposed groups at necropsy. The authors also reported that the treated animals had unusually large amounts of abdominal fat, which they interpreted as accounting for the lack of effect on body weight gain. Quantitative data were not provided to support the assertions of no appreciable

changes in food intake or body weight gain, decreases in organ weight and overall length, and excess abdominal fat. In addition, the authors did not report whether a dose-response effect was observed for changes in body length or organ weight, or for excess abdominal fat.

Histological examination of the liver, kidney, spleen, heart, and adrenals was performed in rats exposed to dibenzofuran at 500 ppm and higher, and in the control animals (Thomas et al., 1940). The low dose group (250 ppm) apparently was not examined for histopathology. In the kidney, histological examination of rats exposed to concentrations of 500 ppm and higher revealed fine, brown-pigmented granules in the epithelial cells of proximal convoluted tubules in the deeper parts of the renal cortex. This effect was noted among all rats receiving dibenzofuran, and both the amount of pigmented material within cells and the frequency of occurrence among cells increased with dose of dibenzofuran. In addition, the two rats fed diet containing 8000 ppm dibenzofuran exhibited prominent, irregular dilatation of the collecting tubules with coagulated material resembling protein; other tubules in these two rats were slightly dilated and contained more granular and amorphous material than controls. These effects were reported as occurring without cellular degeneration or glomerular abnormalities. Some (frequency not specified) of the kidneys from rats receiving 4000 ppm showed similar, but less severe, changes. These lesions were not reported among rats fed the lower doses of dibenzofuran. However, quantitative data were not reported. In the spleen, slight hyperplasia of the Malpighian bodies was reported among several rats (frequency not given) in the 4000 and 8000 ppm groups. No alterations, other than reduced organ weight, were noted in the liver, heart, or adrenals of the treated rats.

In the follow-up study to determine whether dietary dibenzofuran affected water balance, an effect noted qualitatively (increased water consumption) in female rats receiving dibenzofuran in their food, Thomas et al. (1940) exposed groups of five male rats (average initial body weight 255 grams) to 0 or 5000 ppm of dibenzofuran in the diet for 78 days. Treated rats exhibited greater water consumption and urine output than controls, suggesting that dibenzofuran altered water balance. The excess in urine output was greater than the excess in water consumption in the treated group, suggesting a slight dehydration of tissues. The authors reported that no alterations in hematological parameters were observed (hemoglobin and erythrocyte, leukocyte, and reticulocyte counts). Tables 1 and 2 have summarized the hematological data reported in the 78-day study.

TABLE 1. Blood cell types in rats exposed to DBF in normal diet for 78 days

Dose	Rats "N"	Hemoglobin	Erythrocytes	Reticulocytes	White cells
0	10	16.3%	8.12×10^6	3.0%	1.44×10^4
5000 ppm	5	16.6%	9.07×10^6	2.35%	1.65×10^4

TABLE 2. Average differential white blood cell counts in 78-day exposed rats vs. "normal rat blood"

Dose	Rats "N"	Lymphocytes	Polymorphonuclear nutrophils	Monocytes	Basophiles	Eosinophils
"Normal"	---	67.9%	27%	5.3%	0.77%	2.1%
5000 ppm	5	63.8%	33.5%	1.18%	0.64%	0.94%

In contrast to qualitative observations reported among the female rats exposed to similar concentrations in the 200-day primary study, the male rats treated for 78 days tended to consume less food than the controls and had a slightly lower rate of body weight gain than the control group. These data and water consumption data are summarized in Table 3. The authors noted that the odor and taste of dibenzofuran at 5000 ppm in the food was distinctly noticeable and may have contributed to this effect. Histological examination was not performed on tissues from these rats.

TABLE 3. Weight gain in male albino rats fed DBF for 78 days vs. controls

Dose	Rats "N"	Weight gain	Food ingestion	Water ingestion
0	5	321 g	6108 g	9652 cc
5000 ppm	5	243 g	5482 g	10,316 cc
Difference	- - - - -	78 g (24%)	626 g (10%)	664 cc (6.9%)

The literature search revealed additional, peripheral data for dibenzofuran, including those for soil nitrification organisms (Sverdrup et al., 2002), drought resistance of certain insects (Sjursen et al., 2001), plant seedling growth (Sverdrup et al., 2003), fungi-specific enzyme systems (Kurihara et al., 2002), and a study of human intellectual effects of exposure (Schantz, 2001) that mistakenly refered to unhalogenated dibenzofuran. Abstracts for these studies reported the following conclusions.

- 75 mg DBF/kg (soil) NOEL for soil nitrification and no effects on soil bacterial diversity (Sverdrup et al., 2002)

- No dose-related decrease in drought tolerance in adult soil-dwelling insects, *Folsomia fimetaria* (Sjursen et al., 2001)
- 20% reduction in plant seedling weight when exposed to 43-93 mg DBF /kg soil (Sverdrup et al., 2003)
- No change in expression of NADH-ubiquinone oxidoreductase (NUO) among DBF-exposed fungus, *Phanerochaete chrysosporium* (Kurihara et al., 2002)

DERIVATION OF A PROVISIONAL SUBCHRONIC ORAL RfD VALUE FOR DIBENZOFURAN

The only subchronic or chronic toxicity data available for dibenzofuran were from the 200-day and 78-day feeding studies described by Thomas et al. (1940). These studies, though of apparently high quality for their era, had a number of major short comings, including the following:

- only qualitative data were reported for most endpoints
- only five organs were examined in the pathology
- the lowest dose group was not subjected to pathology examinations

No pertinent developmental or reproductive data were found for dibenzofuran. The LOAEL data from the Thomas et al. (1940) 200-day feeding study provided the POD for this derivation, because no NOAEL was reported. Data from the 78-day study were used to confirm food ingestion rates estimated using default rates in U.S. EPA, 1986b. Benchmark dose modeling was considered infeasible because adverse effects and the dose-response nature of the response were reported only qualitatively.

The lowest dose tested in the 200-day Thomas et al., 1940 study, 250 ppm in diet, was selected as the LOAEL POD for the aggregate critical effects of reduced length and organ weight, and excess abdominal fat. Ingestion data from the 78-day study was used to estimate the actual doses to the animals treated at the LOAEL, as follows. The 78-day feeding study was conducted under the same conditions as the 200-day primary study. This estimation made the following assumptions.

- Data from the 78-day study (Thomas et al., 1940) were more likely to represent actual food intakes than the default reference food factor from U.S. EPA, 1986b
- Rats in the 200-day study (Thomas et al., 1940) eating a diet treated with 250 ppm dibenzofuran consumed quantities of food closer to the control amounts (6108 g/diet/5 rats) than to the quantities of food treated with 5000 ppm dibenzofuran (5482 g/5 rats) in the 78-day study

- Growth of rats eating the 250 ppm diet in the 200-day study (Thomas et al., 1940) more closely approximated controls than those eating 5000 ppm, and that the 78-day weight provided a reasonable average weight for the 200 day study period.

In the 78-day study, Thomas et al. (1940) reported that a group of 5 control rats ingested a total of 6108 grams of food over the 78 days and grew from 1.273 kg to 1.594 kg/group, while experimental rats ingested 5482 g of food treated with 5000 ppm dibenzofuran and grew from 1.274 kg to 1.517 kg/group of 5 treated rats. The following calculations used food consumption data from the 78-day study to estimate dibenzofuran consumption in the 200-day study at the POD (250 ppm) for the critical effect of reduced length and organ weight, and excess abdominal fat among the exposed rats.

(6108 g diet/5 rats) / 78 days = 78.3 g/diet/5 rats/day

(78.3 g/5 rats/day) x $(250/10^6)$ = 0.0196 g DBF/5 rats/day = 19.6 mg/5 rats/day

19.6 mg DBF/5 rats/day / (1.594 kg/5 rats) = 12.3 mg DBF/kg/day

The estimated dibenzofuran dose of 12.3 g/kg/day was essentially the same as the dose of 12.5 g/kg/day calculated using the EPA default reference food factor (U.S. EPA, 1986b).

Based on the data available, the following uncertainty factors were applied to derive a subchronic oral p-RfD.

- 10 for variability in human susceptibility
- 10 for the uncertainty in animal-to-human extrapolation
- 1 for using data from a 200-day study (in rats) to derive a subchronic p-RfD
- 3 ($10^{0.5}$) for using a minimal LOAEL instead of a NOAEL
- 10 for deficiencies in the database, including the lack of reproductive and developmental data, and the minimal data details reported in the key study

The uncertainty factors noted above provide a composite UF of 3000 ($10^{3.5}$).

In the absence of a NOAEL, a LOAEL could be several orders of magnitude above the actual no adverse effect dose, since it merely represents the lowest dose tested. Nevertheless, the uncertainty factor for using a minimal LOAEL instead of a NOAEL was reduced from 10 to 3 ($10^{0.5}$) because the following findings suggested that the smaller uncertainty factor would be more appropriate in this case. While many of the dose levels tested and the organism effects considered in the following reports would be difficult to relate to humans, together they seem to

emphasize the relatively low toxicity and mild effects of dibenzofuran across a variety of species.

- The Thomas et. al (1940) study noted relatively minor effects in rats, even at very high doses, up to thirty times the LOAEL dose selected as the POD
- Peripheral data in other species indicated very minor effects or no effects among organisms exposed to dibenzofuran
    - 75 mg DBF/kg (soil) NOEL for soil nitrification and for soil bacterial diversity (Sverdrup et al., 2002)
    - No dose-related decrease in drought tolerance in the adult soil-dwelling insects, *Folsomia fimetaria* (Sjursen et al., 2001)
    - 20% reduction in plant seedling weight when exposed to 43-93 mg DBF /kg soil (Sverdrup et al., 2003)
    - No change in expression of NADH-ubiquinone oxidoreductase (NUO) among DBF-exposed *Phanerochaete chrysosporium* fungi (Kurihara et al., 2002)
- NCI (1979) reported no tumors and relatively low toxicity among rats and mice fed diets containing 5000 ppm and 10,000 ppm dibenzo-p-dioxin, a structural analog to dibenzofuran. Effects reported were hepatic lesions, slight reductions in weight gain and nephropathy (in male rats)

Applying the composite UF of $10^{3.5}$ (~3000) to the dietary LOAEL POD of 12.3 mg DBF/kg-day for the combined critical effects of reduced length and organ weight and excess abdominal fat observed in female albino rats allowed the following calculation of the subchronic p-RfD.

Subchronic oral p-RfD = LOAEL / (UF x MF)
= (12.3 mg/kg/day) / ($10^{3.5}$ x 1)
= **$4x10^{-3}$ mg/kg-day**
= 4 µg dibenzofuran/kg-day

The data were insufficient to derive a chronic oral p-RfD value using an acceptable composite uncertainty. However, the Appendix of this document contains a Screening Value that may be useful in certain instances. Please see the attached Appendix for details.

DERIVATION OF PROVISIONAL INHALATION RfC VALUES FOR DIBENZOFURAN

Provisional inhalation RfC values were not derived for dibenzofuran because no useful inhalation exposure data were identified and data were insufficient to attempt inter-route extrapolation from the marginal ingestion data.

STATEMENT OF CONFIDENCE

Confidence in the principal study is low. Thomas et al. (1940) examined a number of endpoints, including histological examination of several major organs. The study had an adequate number of dose groups, but was limited by inclusion of only five rats in each group. Although only female rats were used for the 200-day portion of the study, male rats were used for the shorter water balance study (78 days). Thomas et al. (1940) did not report whether the critical effect selected displayed a dose-response relationship. However, the reductions in growth and organ weights, and the increase in abdominal fat were supported by histological changes noted in the kidney and impairment of water balance at higher doses. Because the critical effects were observed among rats receiving the lowest dose tested, one cannot be certain that the effects noted at 250 ppm (12.5 mg/kg-day), would not have been present at lower doses. Thus, it is uncertain whether 250 ppm is a true LOAEL. Confidence in the database and the resulting RfDs is low because of the limited toxicity data base for dibenzofuran, including lack of human studies and chronic, developmental, or reproductive oral animal studies. However, some confidence is gained from the relatively low toxicity and lack of tumors among rats and mice fed high doses of dibenzo-p-dioxin (NCI, 1979), the chemical identified by NCI (2000) as most structurally related to dibenzofuran. Nevertheless, risk managers are advised to consider any other available data before applying this p-RfD.

Suppliers and users of dibenzofuran should be encouraged to conduct toxicology studies, such as that initiated by EPA in 1978 (NCI, 2000) but then terminated because of lack of funding. The absence of inhalation, toxicokinetic, and metabolic data would justify especially encouraging studies to seek such information.

APPENDIX

DERIVATION OF A SCREENING VALUE FOR DIBENZOFURAN

For reasons noted in the main PPRTV document, it is inappropriate to derive provisional toxicity values for Dibenzofuran, chronic RfD. However, information is available for this chemical which, although insufficient to support derivation of a provisional toxicity value, under current guidelines, may be of limited use to risk assessors. In such cases, the Superfund Health Risk Technical Support Center summarizes available information in an Appendix and develops a "Screening Value." Appendices receive the same level of internal and external scientific peer review as the PPRTV documents to ensure their appropriateness within the limitations detailed in the document. In the OSRTI hierarchy, Screening Values are considered to be below Tier 3, "Other (Peer-Reviewed) Toxicity Values."

Screening Values are intended for use in limited circumstances when no Tier 1, 2, or 3 values are available. Screening Values may be used, for example, to rank relative risks of individual chemicals present at a site to determine if the risk developed from the associated exposure at the specific site is likely to be a significant concern in the overall cleanup decision. Screening Values are not defensible as the primary drivers in making cleanup decisions because they are based on limited information. Questions or concerns about the appropriate use of Screening Values should be directed to the Superfund Health Risk Technical Support Center.

The Thomas et al. (1940) study provided insufficient data to derive a chronic oral p-RfD value with uncertainty in an acceptable range. The 200-day rat minimal LOAEL POD of 12.3 mg/kg-day was considered to derive a **screening chronic oral reference dose** by applying a composite uncertainty factor of 10,000 (10^4), including 10 for variability in human susceptibility, 10 for animal-to-human extrapolation, 3 ($10^{0.5}$) for extrapolating from 200-day rat data to a chronic screening value, 3 ($10^{0.5}$) for using a minimal LOAEL instead of a NOAEL, and 10 for deficiencies in the database, including the lack of developmental data and the minimal data details reported in the key study.

Applying the minimal LOAEL dietary POD of 12.3 mg DBF/kg-day and the composite uncertainty factor of 10,000 (10^4) allowed the following calculation:

Screening chronic oral p-RfD = LOAEL/UF
= (12.3 mg/kg-day)/10^4
= **$\underline{1x10^{-3}\ mg/kg\text{-}day}$**
= 1 μg dibenzofuran/kg-day

Confidence in the key study was low, because of the lack of detail on the critical effects and other deficiencies noted in this document. Given the lack of additional studies, confidence in the database also was low, leading to low overall confidence in the screening toxicity value. Users are advised to consider any other available data and to consult with the STSC before using this screening p-RfD.

PROVISIONAL PEER REVIEWED TOXICITY VALUES FOR ENDOSULFAN (CASRN 115-29-7)
Derivation of an Oral Slope Factor

Background

On December 5, 2003, the U.S. Environmental Protection Agency's (EPA's) Office of Superfund Remediation and Technology Innovation (OSRTI) revised its hierarchy of human health toxicity values for Superfund risk assessments, establishing the following three tiers as the new hierarchy:

1. EPA's Integrated Risk Information System (IRIS).

2. Provisional Peer-Reviewed Toxicity Values (PPRTV) used in EPA's Superfund Program.

3. Other (peer-reviewed) toxicity values, including:

   - Minimal Risk Levels produced by the Agency for Toxic Substances and Disease Registry (ATSDR),
   - California Environmental Protection Agency (CalEPA) values, and
   - EPA Health Effects Assessment Summary Table (HEAST) values.

A PPRTV is defined as a toxicity value derived for use in the Superfund Program when such a value is not available in EPA's Integrated Risk Information System (IRIS). PPRTVs are developed according to a Standard Operating Procedure (SOP) and are derived after a review of the relevant scientific literature using the same methods, sources of data, and Agency guidance for value derivation generally used by the EPA IRIS Program. All provisional toxicity values receive internal review by two EPA scientists and external peer review by three independently selected scientific experts. PPRTVs differ from IRIS values in that PPRTVs do not receive the multi-program consensus review provided for IRIS values. This is because IRIS values are generally intended to be used in all EPA programs, while PPRTVs are developed specifically for the Superfund Program.

Because new information becomes available and scientific methods improve over time, PPRTVs are reviewed on a five-year basis and updated into the active database. Once an IRIS value for a specific chemical becomes available for Agency review, the analogous PPRTV for that same chemical is retired. It should also be noted that some PPRTV manuscripts conclude that a PPRTV cannot be derived based on inadequate data.

Disclaimers

Users of this document should first check to see if any IRIS values exist for the chemical of concern before proceeding to use a PPRTV. If no IRIS value is available, staff in the regional Superfund and RCRA program offices are advised to carefully review the information provided in this document to ensure that the PPRTVs used are appropriate for the types of exposures and circumstances at the Superfund site or RCRA facility in question. PPRTVs are periodically updated; therefore, users should ensure that the values contained in the PPRTV are current at the time of use.

It is important to remember that a provisional value alone tells very little about the adverse effects of a chemical or the quality of evidence on which the value is based. Therefore, users are strongly encouraged to read the entire PPRTV manuscript and understand the strengths and limitations of the derived provisional values. PPRTVs are developed by the EPA Office of Research and Development's National Center for Environmental Assessment, Superfund Health Risk Technical Support Center for OSRTI. Other EPA programs or external parties who may choose of their own initiative to use these PPRTVs are advised that Superfund resources will not generally be used to respond to challenges of PPRTVs used in a context outside of the Superfund Program.

Questions Regarding PPRTVs

Questions regarding the contents of the PPRTVs and their appropriate use (e.g., on chemicals not covered, or whether chemicals have pending IRIS toxicity values) may be directed to the EPA Office of Research and Development's National Center for Environmental Assessment, Superfund Health Risk Technical Support Center (513-569-7300), or OSRTI.

INTRODUCTION

Endosulfan (CASRN 115-29-7) is a mixture of two stereoisomers, approximately 70% endosulfan I (endosulfan α; CASRN 959-98-8) and 30% endosulfan II (endosulfan β; CASRN 33213-65-9). An assessment of the carcinogenicity of endosulfan is not available on IRIS (U.S. EPA, 2002) or in the HEAST (U.S. EPA, 1997) or Drinking Water Standards and Health Advisories list (U.S. EPA, 2000). The CARA list (U.S. EPA, 1991a, 1994) includes a Health Effects Assessment for α- and β-endosulfan (U.S. EPA, 1987) that assigned endosulfan to cancer weight-of-evidence Group D, not classifiable as to human carcinogenicity, based on inconclusive animal data. A subsequent Health and Environmental Effects Document (U.S. EPA, 1991b) also assigned endosulfan to Group D. Based on more recent adequate negative studies, the Office of Pesticide Programs has classified endosulfan in Group E (U.S. EPA, 1999). IARC (2002) has not evaluated endosulfan for carcinogenicity. Review documents by ATSDR (2000) and WHO (1984), as well as the NTP (2002) status reports, were also consulted for relevant information. Literature searches were conducted from 1998 to December 2001 for studies relevant to the

derivation of an oral slope factor for endosulfan. The databases searched were: TOXLINE, MEDLINE, CANCERLIT, RTECS, GENETOX, HSDB, CCRIS, TSCATS, EMIC/EMICBACK and DART/ETICBACK.

REVIEW OF THE PERTINENT LITERATURE

Human Studies

Case control studies of 261 patients with breast cancer (Ashengrau et al., 1998) and 30 patients with gall bladder carcinoma (Shukla et al., 2001) did not find associations between serum levels of endosulfan and cancer.

Animal Studies

The available carcinogenicity studies for endosulfan following oral exposure have been reviewed previously (U.S. EPA, 1987, 1991b, 1999; ATSDR, 2000; WHO, 1984). There was no evidence of carcinogenicity in male or female NMRI mice fed endosulfan in the diet at concentrations up to 18 ppm (2.5 mg/kg-day) for 2 years (Hoechst Celanese Corporation, 1988; Hack et al., 1995), in male or female Sprague-Dawley rats fed up to 75 ppm (3.25 mg/kg-day) for 2 years (Hoechst Celanese Corporation, 1989; Hack et al., 1995), or in male or female Wistar rats fed up to 100 ppm (8 mg/kg-day) for 2 years (Keller, 1959). Oral exposure (gavage followed by diet) of male and female B6C3F1 and B6AKF1 mice to 1.0 or 2.15 mg/kg-day of endosulfan for 73-76 weeks produced some suggestive findings (statistically significant elevations in total tumor incidence and pulmonary adenomas in all treatment groups combined), but these were not considered biologically relevant because no significant differences were apparent for individual endosulfan treatment groups, and because no pulmonary carcinomas were diagnosed in endosulfan-treated animals (Innes et al., 1969; NCI, 1968). Low survival in all treated B6C3F1 mice and high-dose B6AKF1 mice complicates interpretation of this study.

The results of a subsequent NCI (1978) study were inadequate for evaluation of carcinogenicity. No evidence of carcinogenicity was observed in male or female B6C3F1 mice fed up to 6.9 or 3.9 ppm (1.3 or 0.76 mg/kg-day), respectively, for 78 weeks, female Osborne-Mendel rats fed up to 445 ppm (39 mg/kg-day) for 71 weeks, or male Osborne-Mendel rats fed up to 952 ppm (75 mg/kg-day) for 72-82 weeks. The maximum tolerated dose was clearly exceeded, as evidenced by high mortality in male rats and mice and other serious non-neoplastic effects (weight loss, kidney and testicular damage) in all treated rat groups. A re-evaluation of the histology slides (Reuber, 1981) reported statistically significant increases in certain types of tumors grouped across tissues in female rats (total neoplasia, malignant tumors, sarcomas, lymphosarcomas and reproductive system tumors) and male rats (endocrine organ tumors). The incidence of parathyroid adenomas in male rats was also reported to be increased. In mice, the re-evaluation found a marginally significant increase in the incidence of liver carcinomas in low-dose females, but not in high-dose females or males. Reuber (1981) failed to report details

regarding definitions of neoplasia used, tissue occurrence of neoplasia observed, and how his data compare with data from the original study (NCI, 1978). The conclusions of the reevaluation have not been independently confirmed.

Other Studies

Evidence of hepatic tumor-promoting activity was observed in one of two studies in male Sprague-Dawley rats initiated by partial hepatectomy and nitrosodiethylamine treatment. Flodstrom et al. (1988) did not observe an increase in hepatic foci positive for γ-glutamyltranspeptidase in rats exposed to α-endosulfan, β-endosulfan, or technical endosulfan for 10 weeks at doses up to 5 mg/kg-day. In contrast, Fransson-Steen et al. (1992) observed statistically significant increases in the number and volume of hepatic foci positive for γ-glutamyltranspeptidase in larger test groups of male rats fed α-endosulfan, β-endosulfan, or technical endosulfan for 20 weeks up to 15 mg/kg-day. Based on observations that endosulfan has exhibited activity as an endocrine disruptor (U.S. EPA, 1999) and induced proliferation in hormone-responsive human (endometrial and breast) cancer cell lines (Coumoul et al., 2001; Soto et al., 1994; Vonier et al., 1996; others), a hypothesis has been suggested that endosulfan may promote cancer formation in humans through a mode-of-action involving endocrine disruption. However, other studies have produced conflicting results (e.g., Arcaro et al., 1998; Newbold et al., 2001) and insufficient data are available to evaluate this theory.

Reviews generally consider endosulfan to be genotoxic (U.S. EPA, 1991b, 1999; ATSDR, 2000; WHO, 1984). Extensive mutagenicity testing in *Salmonella typhimurium* and *Escherichia coli* strains reported both positive and negative results with and without metabolic activation. Conflicting positive and negative results were also seen in assays for mutation, gene conversion and chromosome aberrations in *Saccharomyces cerevisae*, although no mutations were seen in *Schizosaccharomyces pombe*. Similarly, both positive and negative tests for gene mutation have been observed in cultured mouse lymphoma cells with and without metabolic activation. Endosulfan did not induce unscheduled DNA synthesis in primary rat hepatocytes. Endosulfan induced micronuclei in cultured sheep lymphocytes and sister chromatid exchange in both preimplantation embryos of hybrid mice and human lymphoid cells *in vitro*. Endosulfan also induced chromosome aberrations in bone marrow cells of Syrian hamsters. Both positive and negative results were seen in assays measuring the formation of micronucleated polychromatic erythrocytes in mice. Endosulfan induced sex-linked recessive lethal mutations and sex-chromosome loss in *Drosophila*. Both positive and negative results have been observed in dominant lethal mutation studies in male mice. A cluster of four women living near endosulfan-contaminated areas in Florida produced five children born with evidence of mitochondrial defects (global developmental delay and hypotonia, carnitine deficiency and β-hydroxy butyrate anomalies) suggestive of mitochondrial DNA damage (Thrasher, 2000). However, it is not clear that these effects can be attributed to endosulfan exposure.

FEASIBILITY OF DERIVING A PROVISIONAL ORAL SLOPE FACTOR FOR ENDOSULFAN

No evidence of carcinogenicity resulting from endosulfan exposure was observed in epidemiology or animal studies. On the basis of the available information, it is not possible to derive a provisional oral slope factor for endosulfan.

PROVISIONAL PEER REVIEWED TOXICITY VALUES FOR HEXACHLOROBUTADIENE (CASRN 87-68-3)

Background

On December 5, 2003, the U.S. Environmental Protection Agency's (EPA's) Office of Superfund Remediation and Technology Innovation (OSRTI) revised its hierarchy of human health toxicity values for Superfund risk assessments, establishing the following three tiers as the new hierarchy:

1. EPA's Integrated Risk Information System (IRIS).

2. Provisional Peer-Reviewed Toxicity Values (PPRTV) used in EPA's Superfund Program.

3. Other (peer-reviewed) toxicity values, including:

   - Minimal Risk Levels produced by the Agency for Toxic Substances and Disease Registry (ATSDR),
   - California Environmental Protection Agency (CalEPA) values, and
   - EPA Health Effects Assessment Summary Table (HEAST) values.

A PPRTV is defined as a toxicity value derived for use in the Superfund Program when such a value is not available in EPA's Integrated Risk Information System (IRIS). PPRTVs are developed according to a Standard Operating Procedure (SOP) and are derived after a review of the relevant scientific literature using the same methods, sources of data, and Agency guidance for value derivation generally used by the EPA IRIS Program. All provisional toxicity values receive internal review by two EPA scientists and external peer review by three independently selected scientific experts. PPRTVs differ from IRIS values in that PPRTVs do not receive the multi-program consensus review provided for IRIS values. This is because IRIS values are generally intended to be used in all EPA programs, while PPRTVs are developed specifically for the Superfund Program.

Because new information becomes available and scientific methods improve over time, PPRTVs are reviewed on a five-year basis and updated into the active database. Once an IRIS value for a specific chemical becomes available for Agency review, the analogous PPRTV for that same chemical is retired. It should also be noted that some PPRTV manuscripts conclude that a PPRTV cannot be derived based on inadequate data.

Disclaimers

Users of this document should first check to see if any IRIS values exist for the chemical of concern before proceeding to use a PPRTV. If no IRIS value is available, staff in the regional Superfund and RCRA program offices are advised to carefully review the information provided in this document to ensure that the PPRTVs used are appropriate for the types of exposures and

circumstances at the Superfund site or RCRA facility in question. PPRTVs are periodically updated; therefore, users should ensure that the values contained in the PPRTV are current at the time of use.

It is important to remember that a provisional value alone tells very little about the adverse effects of a chemical or the quality of evidence on which the value is based. Therefore, users are strongly encouraged to read the entire PPRTV manuscript and understand the strengths and limitations of the derived provisional values. PPRTVs are developed by the EPA Office of Research and Development's National Center for Environmental Assessment, Superfund Health Risk Technical Support Center for OSRTI. Other EPA programs or external parties who may choose of their own initiative to use these PPRTVs are advised that Superfund resources will not generally be used to respond to challenges of PPRTVs used in a context outside of the Superfund Program.

Questions Regarding PPRTVs

Questions regarding the contents of the PPRTVs and their appropriate use (e.g., on chemicals not covered, or whether chemicals have pending IRIS toxicity values) may be directed to the EPA Office of Research and Development's National Center for Environmental Assessment, Superfund Health Risk Technical Support Center (513-569-7300), or OSRTI.

INTRODUCTION

No reference dose (RfD) or reference concentration (RfC) values are available for hexachlorobutadiene (HCBD) in the Integrated Risk Information System (IRIS) database (U.S. EPA, 2007). The Health Effects Assessment Summary Table (HEAST) lists a chronic oral RfD of 2E-4 mg/kg-day and no subchronic RfD (U.S. EPA, 1997). The source documents referenced for the RfD value in HEAST included a 2-year dietary study in rats (Kociba et al., 1977) and a 13-week dietary study in mice (NTP, 1991; Yang et al., 1989). The chronic oral RfD value cited in HEAST was derived from a LOAEL of 0.5 mg/kg-day, based on renal tubule regeneration observed in a 13-week dietary study in mice (NTP, 1991; Yang et al., 1989). The Drinking Water Standards and Health Advisories also includes an RfD of 2E-4 mg/kg-day for HCBD (U.S. EPA, 2004). The Chemical Assessments and Related Activities (CARA) list (U.S. EPA, 1991a, 1994) identifies a Health Effects Assessment (HEA) (U.S. EPA, 1984) and a Drinking Water Health Advisory report (U.S. EPA, 1987). No oral or inhalation RfD values were provided in the HEA (U.S. EPA, 1984). An RfD value of 0.002 mg/kg-day was calculated for use in the derivation of the drinking water equivalent level (DWEL) (U.S. EPA, 1987), based on kidney effects observed in the 2-year dietary study in rats (Kociba et al., 1977). A no-observed-adverse-effect level (NOAEL) of 0.2 mg/kg-day was identified from this study, based on functional and histopathological changes in the kidney, and a composite uncertainty factor (UF) of 100 was applied to account for interspecies and interindividual differences.

An Agency for Toxic Substances and Disease Registry (ATSDR) Toxicological Profile for HCBD (ATSDR, 1994) derived an intermediate-duration oral Minimal Risk Level (MRL) of 0.0002 mg/kg-day, based on the presence of kidney damage in female mice from a 13-week

dietary study (NTP, 1991). A lowest-observed-adverse-effect level (LOAEL) value of 0.2 mg/kg-day was identified, based on tubular cell degeneration and regeneration in the renal cortex, and a composite uncertainty factor (UF) of 1000 was applied to derive the intermediate-duration oral MRL (factors of 10 each to account for the interindividual variation in the human population, the uncertainty in extrapolating animal data to the case of human and uncertainty in using LOAEL data rather than NOAEL data). Because renal tubular hyperplasia was observed at 2 mg/kg-day in a chronic dietary study in rats (Kociba et al., 1977) and no effect was seen at 0.2 mg/kg-day in this study (the LOAEL for kidney effects in the 13-week mouse study), the intermediate-duration MRL was considered protective for chronic exposures and a chronic MRL was not proposed. Inhalation MRL values were not derived by ATSDR for HCBD due to the lack of sufficient data to identify a target organ or reliable NOAEL values (ATSDR, 1994). Occupational exposure standards and guidelines for HCBD, based on skin irritation and kidney effects, include American Conference of Governmental Industrial Hygienists (ACGIH) Threshold Limit Value–time-weighted average (TLV-TWA) and National Institute for Occupational Safety and Health (NIOSH) TWA values of 0.02 ppm (0.24 mg/m^3) (ACGIH, 2005; NIOSH, 2005). An Occupational Safety and Health Administration (OSHA) Permissible Exposure Limit (PEL) value is not available for HCBD (OSHA, 2006).

A cancer assessment for HCBD is available on IRIS (U.S. EPA, 2007), in the HEAST (U.S. EPA, 1997), and on the Drinking Water Standards and Health Advisories list (U.S. EPA, 2004). HCBD is considered to be a possible human carcinogen (Group C) based on kidney tumors observed in male and female rats from one study. An oral slope factor of 0.078 $(mg/kg-day)^{-1}$ was derived, based on renal tubular adenomas and adenocarcinomas observed in rats given HCBD in the diet (Kociba et al., 1977). An inhalation unit risk value of $2.2x10^{-5}$ $(\mu g/m^3)^{-1}$ was calculated based on route extrapolation from the oral data (U.S. EPA, 2007). The International Agency for Research on Cancer (IARC) assigned HCBD to Group 3 (not classifiable as to its carcinogenicity to humans), based on limited evidence for the carcinogenicity of HCBD in animals and inadequate evidence in humans (IARC, 1999). The World Health Organization (WHO) Environmental Health Criteria document (WHO, 1994) also indicated that there was limited evidence for carcinogenicity of HCBD in animals and insufficient evidence in humans. HCBD was not included in the NTP (2005) 11^{th} Report on Carcinogens.

Literature searches were performed for the time period of 1965 to May, 2006 in TOXLINE, MEDLINE (plus PubMed cancer subset) and DART/ETICBACK. An update search of the TOXCENTER (BIOSIS) database was performed for the time period of 2000 to May, 2006. Databases searched without date limitations included TSCATS, RTECS, GENETOX, HSDB and CCRIS. Search of Current Contents encompassed November 2005 to May 2006.

REVIEW OF PERTINENT DATA

Human Studies

Oral Exposure. No data were located regarding the oral toxicity or carcinogenicity of HCBD in humans.

Inhalation Exposure. Very little information pertaining to effects of inhalation of HCBD in humans is available. Howse et al. (2001) investigated biomarkers of early renal dysfunction in a cohort of subjects exposed to HCBD. This study was presented as an abstract only and few details were provided regarding the subject cohort or the nature of the exposure to HCBD. Urinary markers of renal disease were evaluated in 70 subjects known to be environmentally exposed to HCBD. Twenty-five subjects were eventually eliminated from consideration due to age, preexisting renal disease, medication use or exposure to other nephrotoxic compounds. The parameters investigated for the remaining 45 subjects included urinary albumin, total protein, γ-glutamyl transpeptidase (GGT), N-acetyl-β-glucosaminidase (NAG), leucine aminopeptidase (LAP), α- and π-glutathione transferases (GST) and retinol binding protein (RBP). Results were compared to the laboratory reference range for healthy workers. Urinary abnormalities occurred in 21 subjects, with 11 subjects exhibiting 2 or more abnormal tests. The most common effects were seen with the tubular markers LAP, GGT and α- and π-GST. No further information was provided.

Driscoll et al. (1992) carried out a study investigating liver dysfunction in workers exposed to a variety of chlorinated solvents (mainly carbon tetrachloride and perchlorethylene) and HCBD at a solvent production plant. The study included all 53 members of the workforce, but a number of individuals were excluded from the analysis because their blood samples were inadequate (6 individuals), they had not fasted before the blood samples were taken (11 individuals) or were taking antibiotics (1 individual). This left 35 subjects who were included in the analysis. Workers were categorized in relation to both HCBD exposure and overall solvent exposure at the plant. The results of repeated environmental monitoring in the plant were used to assign each worker to one of four classes of exposure to HCBD (0.0, 0.005, 0.01 or 0.02 ppm). Overall solvent exposure for all workers was low (less than 1 ppm), but varied with task; routine monitoring data from the plant records were used to assign workers to either a "lower" or "higher" solvent exposure category. Workers assigned to the various categories were similar in age and duration of employment.

Blood samples were collected from each worker after an overnight fast (Driscoll et al., 1992). Serum bile acids were assayed by high performance liquid chromatography and compared for each group. Standard tests for liver function [serum protein, albumin and bilirubin concentrations and alkaline phosphatase (AP), alanine aminotransferase (ALT), aspartate aminotransferase (AST) and GGT activities] were also carried out. Total bile acids were not significantly increased in relation to HCBD exposure, but a positive exposure-effect relationship with HCBD concentration was found for three individual bile acids (deoxycholic acid, glycine deoxycholic acid, taurine chenodeoxycholic acid) and for total deoxycholate (this includes deoxycholic acid and glycine deoxycholic acid). Using multiple linear regression and controlling for age and overall solvent exposure, these parameters had significant positive log-linear relations with exposure to HCBD. With respect to overall solvent exposure, there was no significant positive relationship for total bile acids or any individual bile acids (the researchers suggested that significant negative relationships with glycine deoxycholic acid, taurine cholate and total cholate may have resulted from misclassification of exposure for some workers).

Although liver function tests did not show any significant relationship with exposure to either HCBD or solvents overall in the Driscoll et al. (1992) study, serum bile acid

concentrations may be a more sensitive indicator of liver damage than standard tests of hepatic function. Franco et al. (1986) compared liver function in workers occupationally exposed to a mixture of organic solvents and an unexposed control group. The results from conventional tests of hepatic function were compared with those of the serum bile acid test, and the researchers concluded that the serum bile acid test had a higher sensitivity for the detection of liver dysfunction for the solvent mixture tested. The bile acid test results of Driscoll et al. (1992) suggest that exposure to HCBD may affect liver function. However, there was no supporting evidence for hepatotoxicity from standard liver function tests, workers were exposed to multiple solvents, the study did not include a control group of individuals unexposed to any solvents and the study did not assess possible confounders, such as previous hepatic disease and alcohol intake.

The only other available study of effects of HCBD in humans is a study carried out in Russia (Krasniuk et al., 1969). Krasniuk et al. (1969) recorded multiple toxic effects in vineyard workers seasonally exposed to HCBD (0.8-30 mg/m^3) and polychlorobutane-80 (0.12-6.7 mg/m^3) in the air over fumigated areas. A total of 205 workers were examined medically; 153 workers had 4 years of exposure to HCBD and polychlorobutane-80, while 52 workers had worked under the same conditions without exposure to the chemicals. The study reported multiple toxic effects in exposed workers, including the development of hypotension, cardiac disease, chronic hepatitis and disturbance of nervous function. The effects, however, are not well documented and cannot be attributed solely to HCBD.

Animal Studies

Oral Exposure.

Jonker et al., 1993 — A 4-week dietary study was conducted in Wistar rats (five/sex/group, 10 controls/sex) fed HCBD (98% pure) at concentrations of 0, 25, 100 or 400 ppm (Jonker et al., 1993). Using reference values for body weight and food consumption in Wistar rats from a subchronic study (male body weight 0.217 kg, female body weight 0.156 kg, male food consumption 0.02 kg/day, female food consumption 0.016 kg/day) (U.S. EPA, 1988), daily dose estimates were calculated to be 0, 2.3, 9.2 or 37 mg/kg-day for male rats and 0, 2.6, 10.2 or 41 mg/kg-day for female rats. During the 4^{th} week of the study, rats were deprived of water for 24 hours and food for 16 hours. Urine was collected during the last 16 hours of water deprivation and urine volume and density were measured. Urine samples were also visually inspected and analyzed for pH, protein, glucose, ketones, occult blood, urobilinogen and bilirubin. Urine samples were centrifuged and the sediment was examined microscopically. Hematology parameters, including hemoglobin, packed cell volume, red blood cells (RBCs) and total white blood cells (WBCs), were evaluated for tail vein blood samples that were obtained during the 4^{th} week of the study. Blood samples obtained at necropsy were analyzed for serum AP, AST and ALT activities, protein, albumin, bilirubin, urea, creatinine, inorganic phosphorous, calcium, sodium and potassium. The organ weights of the kidneys, adrenals and liver were recorded at necropsy and kidney tissue was prepared for histopathological evaluation.

Growth retardation and decreased food and water consumption were observed in male and female rats exposed to 100 or 400 ppm. Mean body weights measured on day 28 were

reduced by 34% in both male and female rats given 400 ppm HCBD in the diet. At 100 ppm, 28-day body weights were decreased by 10% in male rats and 15% in female rats. Increased volume and decreased density of the urine were observed in male rats receiving 100 ppm only. An increase in urinary epithelial cells was seen at 100 and 400 ppm HCBD in male and female rats and urinary ketones were increased at 400 ppm HCBD in both males and females. Clinical chemistry findings demonstrated increased AST activity (400 ppm males and females, 46% and 22% increased respectively), decreased total protein and albumin (400 ppm males only, 5% decrease), decreased urea (all female treatment groups, maximal decrease of 34%; 400 ppm males, 25% decrease), decreased creatinine (400 ppm females, 12% decrease), increased total bilirubin (6.7-fold and 2.4-fold increase in 400 ppm males and females, respectively) and decreased calcium (400 ppm males, 8% decrease). HCBD treatment resulted in a 13% decrease in absolute kidney weight in high-dose (400 ppm) male rats. Absolute kidney weights were similar to controls for all other treatment groups. An increase in relative kidney weight (organ:body weight ratio) was seen in male and female rats given 100 or 400 ppm HCBD (12 and 31% increase for male rats; 21 and 40% increase for female rats). The absolute organ weight of the adrenals was decreased in female rats given 100 or 400 ppm, while the relative adrenal weight was increased in high-dose male rats. Absolute liver weight was decreased in male rats at 400 ppm and in female rats at 100 and 400 ppm. Relative liver weight was increased in male rats given 100 ppm HCBD only. Relative organ weight increases (kidney, adrenals, and liver) are likely due to the observed decreases in body weight in male and females rats exposed to 100 ppm or 400 ppm HCBD. Kidney histopathology evaluation showed diffuse tubular cytomegaly (females at 100 ppm, males and females at 400 ppm) and focal nephrosis (males at 400 ppm). Incidence data for these lesions were not provided. Histopathological changes in the kidney were further described for a separate group of male and female rats given 100 ppm HCBD in the diet for 4 weeks. In female rats, necrosis, karyomegaly, hypercellularity and variable nuclear size were observed in inner cortex (incidence of 5/5 treated rats, 0/10 controls). NOAEL and LOAEL values of 25 and 100 ppm (2.6 and 10.2 mg/kg-day, respectively) were derived from this study, based on the kidney histopathology data in female Wistar rats.

NTP, 1991; Yang et al., 1989 — Dietary studies with HCBD were conducted in B6C3F_1 mice (NTP, 1991; Yang et al., 1989). In a 2-week study, mice (five/sex/group) received diets containing 0, 30, 100, 300, 1000 or 3000 ppm for 15 days. Animals were observed twice daily and were weighed initially and on days 7 and 15. Food consumption was measured on day 3 and every 2 days thereafter. Necropsy was performed on all animals and histopathology was evaluated in bone marrow, kidneys and liver for animals in the control, 300, 1000 and 3000 ppm groups. Organ weights were measured for the liver thymus kidneys, heart, brain, lung and testis.

All mice that were fed 1000 or 3000 ppm HCBD died before the end of the study. Growth retardation was observed in all HCBD treatment groups. Terminal body weights were 10%, 17% and 20% lower than controls for the 30, 100, and 300 ppm treatment groups, respectively. Control mice gained an average of 2.2 g over the course of the study, while mice given 30 ppm HCBD did not gain weight and mice given 100 ppm and 300 ppm experienced an average weight loss of 1.7 g and 2.1 g, respectively. The study authors indicated that it was unclear whether the observed growth retardation was treatment-related, due to the variability in the measured food consumption caused by scattering of feed by mice in the treatment groups. Daily dose estimates were calculated by the study authors based on feed consumption and body

weight measurements. Dietary concentrations of 0, 3, 30 and 300 ppm resulted in dose estimates by the study authors of 0, 3, 12 and 40 mg/kg-day in male mice and 0, 5, 16 and 49 mg/kg-day in female mice. Lower dietary intakes were reported for the 1000 and 3000 ppm dose groups (19 and 24 mg/kg-day in males; 30 and 36 mg/kg-day in females) due to the decreased food consumption occurring in these dose groups.

Clinical signs of toxicity were seen in mice given dietary concentrations ≥300 ppm. Lethargy, rough hair coat, hunched position and incoordination were observed. Decreased organ weights were seen in male and female mice from the 300 ppm dose group (28-49% decrease in thymus weight, 69-75% decrease in heart weight). Although the report does not indicate whether organ weight decreases were absolute or relative to bodyweight, the study authors suggested that the reduced organ weights were the result of stress and growth retardation and may be only secondarily related to HCDB treatment. Kidney lesions were observed in mice from each HCBD treatment group examined (300, 1000 and 3000 ppm). Severe necrosis of the cortex and outer medulla of the kidney was seen in mice from the 1000 and 3000 ppm dose groups that died prior to the end of the study. The necrosis was less severe at 300 ppm and regeneration was evident, especially in the pars recta (outer stripe of the outer medulla). Other lesions were seen in mice from the two highest dose groups, including lymphoid necrosis and atrophy in the spleen, thymus and lymph nodes, atrophy and necrosis of the red pulp of the spleen, testicular degeneration, and vacuolization and necrosis of hepatocytes. Minimal to mild depletion of the bone marrow (decrease in hematopoietic cells) was observed in mice treated with dietary concentrations of ≥300 ppm HCBD. NOAEL and LOAEL values were not identified from the 2-week study because histopathology evaluation was not performed for rats receiving 30 and 100 ppm HCBD.

In the 13-week dietary study, concentrations of 0, 1, 3, 10, 30 or 100 ppm HCBD (98% pure) were made available mixed in feed to 10 mice/sex. Body weights and food consumption rates were measured weekly. As reported by the authors, the average daily doses of HCBD were estimated to be 0, 0.1, 0.4, 1.5, 4.9 or 16.8 mg/kg-day in males and 0, 0.2, 0.5, 1.8, 4.5 or 19.2 mg/kg/day in females, when food consumption and body weight data were taken into account. Mice were observed twice daily and necropsy and histopathological evaluation of the kidneys was performed for all animals. Complete histopathology evaluation of the full range of organs and tissues was conducted for control and high-dose mice (100 ppm), and for those animals dying before the end of the study. Organ weights were measured at necropsy and samples were taken for a sperm count and motility evaluation, and for an analysis of vaginal morphology and cytology.

Although no clinical signs were evident in any of the animals in the study, one male mouse (1 ppm) died before the end of the study. HCBD treatment caused a decrease in the mean body weight in the two highest-dose groups of male mice and in the highest dose group in female mice throughout most of the study. Terminal mean body weights were 10 and 16% lower than controls for male mice in the 30 and 100 ppm dose groups, respectively, and 15% lower than controls for female mice exposed to 100 ppm HCBD. No major differences in food consumption were noted among treatment groups, suggesting that growth retardation is a toxic effect of HCBD. Absolute kidney weights were reduced (up to 24%) compared with controls in the three highest-dose male groups and the highest-dose female group (23%). Relative kidney weight was also decreased in these treatment groups (up to 19%) compared with controls. A 12% reduction

in absolute heart weight was also evident in the 100 ppm males (relative organ weight not reported). The principal histopathological finding was a compound-related increase in regeneration in the renal tubular epithelium that was most evident in the outer stripe of the outer medulla and extended into the medullary rays (pars recta) (see Table 1). Basophilic staining of the tubular cell cytoplasm and occasional mitoses were seen in regenerative cells. The necrosis that was evident at 300 ppm and above in the 2-week study was not seen after 13 weeks of exposure to 100 ppm or lower concentrations. Sperm motility was reduced in all dose groups, but the magnitude of this effect was not dose-related. No significant changes were seen in sperm count, incidence of abnormal sperm, estrous cyclicity or average length of the estrous cycle. NOAEL and LOAEL values of 0.2 and 0.5 mg/kg-day (1 and 3 ppm) were derived from this study, based on kidney lesions (renal tubule regeneration) in female rats exposed to HCBD in the diet for 13 weeks.

Table 1. The Incidence of Renal Tubule Regeneration in B6C3F$_1$ Mice Exposed to HCBD in the Diet for 13 Weeks (NTP, 1991; Yang et al., 1989)

	Incidence					
	0 ppm	**1 ppm**	**3 ppm**	**10 ppm**	**30 ppm**	**100 ppm**
Males	0/10	0/10	0/10	0/9	10/10[a]	10/10[a]
Females	0/10	1/10	9/10[a]	10/10[a]	10/10[a]	10/10[a]

[a]$p<0.05$, Fisher's Exact test performed for this analysis

Field et al. (1990) — Field et al. (1990) fed pregnant female CD rats (8-9/group) diets containing HCBD (98% purity) at concentrations of 0, 100, 200, 400, 750, 1100 or 1500 ppm on gestation day (GD) 17 through postnatal day (PND) 10. Animals were observed twice daily for clinical signs and were weighed on GD 0, 6, 11, 16 and 17 through PND 10. The reproductive and developmental parameters evaluated included litter size, sex ratio, pup body weights and percentage survival. On PND 4, litters were culled to 10 with an equivalent sex ratio, if possible. Pups were counted and weighed on PND 4, 7 and 10. On PND 10, one pup of either sex from each litter was randomly selected for urine and blood collection. Urine and blood samples were tested for glucose, urea, creatinine or total protein and osmolality was measured in the urine collected immediately following removal from the dam. One additional rat of each sex from each of the five litters was selected on PND 10 to undergo a "hydropenic test" as an indicator of renal competence. In this test, urine samples collected 4 and 6 hours following isolation from the dams were tested for osmolality. Pups were euthanized on PND 10 and liver and kidneys were weighed and prepared for histopathology. In the dams, samples of milk were collected from three dams/group, and liver and kidney tissues were weighed and processed for histopathological examination.

All dams receiving chow containing 1500 ppm HCBD became moribund and had to be terminated prematurely. Similarly, all animals (and their pups) exposed to 1100 ppm HCBD had to be terminated between PND 1 and PND 3. Clinical signs of toxicity in the two highest dose groups included excessive urination, alopecia, nasal discharge, redness of paws, tremors, piloerection, urogenital discharge, hindlimb weakness, lethargy and rough coat. Maternal body weight was decreased in all treatment groups above 100 ppm. Dams given a dietary concentration of 100 ppm HDBD had body weights similar to controls. On PND 10, maternal

body weights were decreased by 11, 21 and 31% in the 200, 400 and 750 ppm treatment groups, respectively. These reductions were accompanied by decreased food consumption during the gestational exposure period, compared with controls (43% decrease at 200 and 400 ppm and 73% decrease at 750 ppm). The study authors calculated an estimate of the daily dose using the food consumption rates for GD 20. Dose estimates of 0, 12, 22.5, 35.3 or 52.2 mg/kg-day were associated with dietary concentrations of 0, 100, 200, 400 or 750 ppm HCBD. The intake of HCBD throughout the study was considered to be variable, due to the fluctuation in food consumption. The HCBD content of maternal milk was shown to increase with increasing dietary concentration, when measured on PND 10. Relative kidney weight in dams was increased 25, 25, 44 and 78% above controls in rats from the 100, 200, 400 and 750 ppm HCBD treatment groups, respectively. Absolute kidney weights were not reported. Histopathological findings in dams demonstrated tubular regeneration of the pars recta of the proximal tubules in all treatment groups, with severity of the lesions being dose-related. At the higher dose levels, tubules were occasionally distended, appearing either empty or full of cell debris.

Three out of nine dams receiving 750 ppm HCBD delivered only dead pups, and, as a percentage, fewer pups from this group survived to PND 10 compared with controls (73% survival). In general, pups displayed dose-dependent reductions in body weight compared with controls, with those at the highest dose (750 ppm) displaying marked emaciation. Pup body weights on PND 10 were 94, 90, 59 and 51% of control pups for the 100, 200, 400 and 750 ppm HCBD treatment groups, respectively (statistical analysis not reported). Clinical chemistry results for the treated pups were similar to control. Following fluid deprivation, urine osmolality was increased in all HCBD-treated groups of dams and pups. Relative kidney weight in pups was increased by 8, 6, 12 and 21% above the control value for the 100, 200, 400 and 750 ppm HCBD treatment groups, respectively (statistical analysis was not reported). Absolute kidney weight was not reported. Histopathology examination showed kidney lesions in pups from the high-dose group only. The primary morphological changes were reduced kidney size and retention of the subscapular metanephric blastemal zone, which was considered by the study authors to reflect a delay in the postnatal development of the kidneys and apparent dehydration. The daily intake of HCBD in pups on PND 10 was calculated to range from 3 to 7% of the dose received by dams in the same dose group. The lowest dose tested (12 mg/kg-day, 100 ppm) is a LOAEL for maternal effects on the kidney (increased relative kidney weight, tubule regeneration). A NOAEL was not identified for maternal effects in this study. Effects in the offspring occurred at higher doses, with NOAEL and LOAEL values of 22.5 and 35.3 mg/kg-day (200 and 400 ppm), based on reduced pup body weight and increased relative kidney weight.

Stott et al., 1981 — Male Sprague-Dawley rats (4-6/group) were given 0, 0.2 or 20 mg/kg-day HCBD by oral gavage in corn oil for 21 consecutive days. An osmotic pump loaded with ^{3}H-thymidine was implanted 7 days prior to the end of the experiment and the rate of in vivo DNA synthesis was measured. Body weight gain was determined (frequency of measurement not indicated) and kidney weight was recorded at necropsy. Tissue samples were obtained from the central portion of the animal's left kidney and evaluated for histopathology. Rats were also given a single dose of ^{3}H-HCBD (20 mg/kg-day only) and were sacrificed 4 hours later for determination of in vivo renal DNA repair and DNA alkylation. In vitro studies conducted using HCBD included reverse mutation in *Salmonella typhimurium* and unscheduled DNA synthesis in primary rat hepatocytes.

In rats given 20 mg/kg-day for 3 weeks, body weight was decreased by 44%, kidney to body weight ratio was increased 1.3-fold, and a 1.8-fold increase was observed in the rate of renal DNA synthesis in vivo (not statistically significant due to high variability between animals). Histopathological lesions were also observed in rats from this group, occurring in the tubular epithelial cells of the inner and middle cortex. Lesions were characterized as degenerative and regenerative changes and included loss of cytoplasm, nuclear pyknosis, increased basophilia, mitotic activity and increased cellular debris located within the tubular lumen. No changes were observed in rats given 0.2 mg/kg-day (NOAEL value). The LOAEL for this study was 20 mg/kg-day.

Renal DNA repair was increased 1.27-fold and 1.54-fold (two trials) in rats given in a single oral dose of 20 mg/kg-day HCBD, as compared to controls. DNA alkylation was also observed in these rats. HCBD did not cause mutagenicity in Salmonella or unscheduled DNA synthesis in isolated rat hepatocytes.

Harleman and Seinen (1979) — Harleman and Seinen (1979) conducted a 2-week dietary study, a dietary reproduction study and a 13-week oral gavage study to evaluate the potential toxicity of HCBD in Wistar rats. In the 2-week dietary study, rats (24/sex/group) were exposed to 0, 50, 150 or 450 ppm HCBD in the diet for 14 days. Using reference values for body weight and food consumption in weanling Wistar rats (male body weight 0.053 kg, female body weight 0.052 kg, food consumption of 0.008 kg/day for both males and females) (U.S. EPA, 1988), daily dose estimates were calculated to be 0, 8, 23 or 68 mg/kg-day for male rats and 0, 8, 23 or 69 mg/kg-day for female rats. Body weights were measured at the beginning and end of the study. Liver and kidney weights were recorded at necropsy and histopathology of these organs was evaluated. Body weight was decreased in all HCBD treatment groups of female rats (10-33% decrease) and in the two highest dose groups of male rats (21 and 31% decrease at 150 or 450 ppm, respectively). Relative kidney weights were significantly increased in the two highest dose groups of male and female rats exposed to HCBD (21-28% increase in males, 7-22% increase in females). Absolute kidney weights were not reported. Histopathology findings demonstrated dose-related kidney lesions occurring in all exposed animals. These lesions were described as degeneration of the tubule epithelial cells, especially in the straight limbs of the proximal tubules located in the outer zone of the medulla. The LOAEL for the 2-week dietary study was 8 mg/kg-day (50 ppm). A NOAEL value was not identified.

In the reproduction study, female Wistar rats (six females/group) were exposed to 0, 150 or 1500 ppm for 18 weeks (4 weeks prior to mating and a 3-week mating period with untreated males). The number of pups/litter and the pup body weights were measured at partuition and the pups were culled to eight per litter. Offspring body weights were measured at PND 10 and 20 and necropsy of the adult females was conducted at 18 weeks. Organ weights were recorded for the heart, liver, kidneys, spleen, brain, adrenals, thymus and thyroid. Histopathology was performed for these organs and the lungs, pancreas, digestive tract (six segments), urinary bladder, axillary and mesenteric lymph nodes, trachea, spinal cord, and femoral nerve. No conception occurred for female rats exposed to a dietary concentration of 1500 ppm HCBD. Progressive weight loss was seen in rats from this group and an unsteady gait, hind limb weakness and ataxia occurred by 6 weeks of exposure to HCBD. Necropsies were performed during week 10, due to the moribund condition of the animals. Gross examination revealed large

pale kidneys and extensive tubule degeneration was seen by histopathology. Proliferation of bile duct epithelial cells in the liver and fragmentation and demyelination of single fibers of the femoral nerve were also seen.

Five out of six rats in the 150 ppm dose group were fertile with a mean litter size similar to control rats. The birth weight of pups from this treatment group was lower than controls (16% decrease) and a decreased pup body weight was also observed at weaning (19% decrease). The resorption quotient was low for both control and treated rats and no gross malformations of offspring were observed. At 18 weeks, the body weight of treated dams was 15% lower than control dams (231 g for controls, 196 g for 150 ppm group). The average daily dose for the 150 ppm group was estimated to be 11 mg/kg-day, assuming a body weight of 0.196 g and a food consumption rate of 0.015 kg/day (calculated using equations in U.S. EPA, 1988). Relative kidney weight was increased by 22%, as compared with controls. Absolute kidney weights were not reported. HCBD treatment caused histopathological changes in the kidney of dams, including hypercellularity of tubule epithelial cells and hydropic necrosis of cells in the straight limbs of the proximal tubules. Treatment related effects were not observed in other organs or tissues. A LOAEL of 11 mg/kg-day (150 ppm) was derived for the reproduction study, based on maternal effects (decreased weight gain, increased kidney weights and altered kidney histopathology) and decreased fetal body weight.

In the 13-week subchronic study, 60 rats/sex/group received 0, 0.4, 1.0, 2.5, 6.3 or 15.6 mg/kg-day HCBD in arachid oil for 13 weeks. Blood samples were collected at 8 weeks (six rats/sex/group) and analyzed for hemoglobin, hematocrit, RBC count, and total and differential leukocytes. Blood samples were also obtained at study termination and tested for total protein, albumin, globulin, BUN, AST, AP and γ-glutamyl transferase activities. At 10 weeks, urine samples were collected from six rats/sex/group during the 2^{nd}-6^{th} and 7^{th}-21^{st} hour deprivation period of food and water. Urine samples were analyzed for glucose, protein, hemoglobin, ketones and pH. Urine volume and osmolarity were used as measures of the concentrating ability of the kidney. At termination, organs were weighed (heart, liver, kidney, spleen, brain, adrenals, thymus, thyroid and gonads) and a gross pathological examination was carried out on all animals. Key organs and tissues from the control and high-dose groups were processed for histopathological examination (heart, liver, kidneys, spleen, brain, adrenals, thymus, thyroid, lungs, pancreas, six sections of digestive tract, urinary bladder, axillary and mesenteric lymph nodes, trachea, spinal cord, femoral nerve, prostate, skeletal muscle, aorta, Harder's gland, skin, sternum and bone marrow). The HCBD content of kidney, liver and fat samples from high-dose female rats was measured by gas chromatography (GC) analysis.

Body weight gain and food consumption were significantly reduced at the two highest doses in male and female rats, as compared to controls (13-30% decrease in body weight at 6.3 mg/kg-day; >40% reduction in body weight at 15.6 mg/kg-day). No clinical chemistry changes were observed at any dose levels. Following a 21-hour deprivation period, a dose-related decrease in urine osmolarity was observed in female rats that were given HCBD at doses greater than 2.5 mg/kg-day. An increase in urine volume was also observed in the two highest dose groups of female rats (6.3 and 15.6 mg/kg-day), indicating an impairment in the urine concentrating ability of the kidney. No change in urine volume was observed in treated male rats, and urine osmolarity was increased only in high-dose males (15.6 mg/kg-day). Relative

kidney weight was significantly increased in all dose groups of male rats (7-31% increase) and in the two highest dose groups of female rats (19 and 32% increase for 6.3 and 15.6 mg/kg-day respectively). The relative liver weight was increased 8-24% in male rats at doses greater than 1 mg/kg-day, but was only increased in the high-dose group in female rats by 11%. In male rats, the relative weights of the brain and the spleen were increased in the 15.6 mg/kg-day dose group by 45 and 18%, respectively. Increases in the relative weight of the brain and spleen were seen at the two highest doses in female rats (21-29% increase for brain, 14-21% increase for spleen). The relative weight of the gonads was increased in male rats (12 and 40% increase at 6.3 and 15.6 mg/kg-day respectively). Absolute organ weights were not reported in the study.

Though no changes in organ appearance were seen on gross pathological examination, marked histopathological lesions were evident in the kidney, most notably in the proximal tubule, where increases in hypercellularity, necrosis and the incidence of hyperchromatic nuclei were evident. Epithelial cells in treated rats were described as small, basophilic and finely vacuolated, with large hyperchromatic nuclei. At the highest dose in female rats, changes were seen in both the straight and convoluted portions of the tubules with focal necrosis and a thin or absent epithelial brush border. The changes were similar, but less severe, in females given 6.3 mg/kg-day and were limited to the straight portion of the proximal tubule. The brush border was generally unchanged and few necrotic cells were present in the tubule lumen. Only minor effects were seen in female rats given 2.5 mg/kg-day, although tubule epithelial cells were observed to contain enlarged hyperchromatic nuclei. Kidney effects were less pronounced in male rats, as compared to females. Kidney lesions in male rats given 15.6 mg/kg-day were similar in severity to those seen in female rats given 6.3 mg/kg-day. Liver effects were seen in male rats only at doses greater than 6.3 mg/kg-day and consisted of a basophilic granulation of hepatocytes. The GC analysis of kidney, liver and adipose tissue from high-dose female rats revealed no HCBD accumulation in the liver or kidney and only slight accumulation in the fat. NOAEL and LOAEL values of 1.0 and 2.5 mg/kg-day, respectively, were derived from this study based on kidney toxicity in female rats.

Kociba et al. (1977) — Kociba et al. (1977) administered HCBD (99% purity) mixed in feed to 39-40 Sprague-Dawley rats/sex/group for 2 years. Ninety rats of each sex were used as controls. Rats were observed frequently (not quantified) for clinical signs of toxicity. Feed consumption and body weights were monitored in 15 rats/sex/group weekly for the first 3 months of the study, and then for 1 week out of each month until study termination. The average doses for either sex were calculated by the authors to be 0, 0.2, 2 or 20 mg/kg-day. Subsets of animals (5-6/sex/group) were sampled for blood and urine after approximately 12, 22 (males only) or 24 (females only) months. The hematological parameters evaluated included packed cell volume (PCV), RBC count, hemoglobin concentration, total WBC count and differential WBC count. The urinary parameters evaluated were specific gravity, pH and the presence or absence of glucose, protein, ketones, bilirubin and occult blood. Urinary creatinine, coproporphyrin and uroporphyrin were also determined from a urine sample collected over 24 hours. After 1 year, blood samples were collected from an additional subset of animals (five/sex from the high-dose and control groups only) for clinical chemistry determinations. Serum samples were also collected from all rats necropsied at the end of the study. Serum chemistry parameters included blood urea nitrogen (BUN), and AP and ALT activity. All rats (moribund and terminal sacrifice) were necropsied and pieces of all major organs and lesions were excised

and preserved. For the rats that were killed during the course of the study, histopathological evaluation was performed for the liver, kidney, stomach and all tumors or gross lesions. For those sacrificed at term, a fully comprehensive list of organs and tissues was examined microscopically for 10 females at each dose level, 10 males from the 0 and 2 mg/kg-day dose levels and 3 males at the 20 mg/kg-day dose level that survived to term. Histopathology evaluation for the remaining rats that were killed at study termination (including all male rats from the 0.2 mg/kg-day group) was limited to the kidneys, liver, stomach and any gross lesions observed during necropsy.

There was a reduction in body weight gain at the high dose level in both male and female Sprague-Dawley rats that appeared not to be associated with the sporadic changes in food consumption. This decrease in body weight was evident by 27 days in female rats and 69 days in male rats and body weight remained low throughout most of the study. A significant increase in mortality (approximately 20%, estimated from graph) occurred during the last 2 months of the study in male rats that ingested 20 mg/kg-day HCBD. Survival was not reduced in any other HCBD treatment group.

Compound-related changes in hematological parameters were limited to a 20% decrease in RBCs after 22 months in high dose male rats. Routine urinalysis parameters were not affected by HCBD treatment; however, the excretion of coproporphyrins was increased in high-dose male rats at 1 year, mid-dose female rats at 14 months and high-dose female rats at 2 years. No dose response or temporal trend was apparent from these data (see Table 2). A 57% decrease in the excretion of uroporphyrin was also seen in high-dose female rats after 2 years. Clinical chemistry parameters were generally not altered by HCBD treatment for 12 months or 2 years, with the exception of a decrease in ALT activity in high-dose (20 mg/kg-day) males at 12 months and low- and high-dose females (0.2 and 20 mg/kg-day, respectively) at 2 years. This finding in female rats was considered to result from an abnormally increased ALT activity in female control rats and was not considered to be treatment-related.

Table 2. Average Amounts of Coproporphyrins in Urine of Sprague-Dawley Rats in Response to HCBD in Feed (µg/24 hours) (Kociba et al., 1977)

HCBD in feed (mg/kg-day)	1 Year		14 Months		2 Years	
	Male	Female	Male	Female	Male	Female
0	10.2±8.5	5.0±1.3	13.1±3.0	5.6±2.4	6.8±1.8	4.5±2.4
0.2	14.2±2.6	4.7±2.1	13.0±3.8	6.2±3.3	7.1±2.3	5.4±0.8
2.0	18.8±2.4	8.9±5.2	18.3±4.0	10.6[a]±2.4	10.7±2.4	5.8±1.3
20.0	23.1[a]±11.8	9.4±3.5	17.7±12.5	8.4±2.5	14.0 ±9.5	12.3[a]±2.9

Values are means ±SD (n=5).
[a]$p<0.05$ as determined by ANOVA and Dunnett's test.

An increase in the absolute and relative weight of the kidneys was observed in male rats given 20 mg/kg-day HCBD for 22 months. An increase was also observed in relative, but not

absolute, testes weight; however, this may have been due to the observed decrease in body weight. A decrease in the absolute weight of the heart and liver and an increase in the relative weight of the brain and kidney were seen in high-dose female rats. Organ weights in the low- and mid-dose groups of male and female rats were similar to control. Histopathological examination revealed treatment-related kidney lesions in male and female rats consisting of tubular epithelial hyperplasia and proliferation, observed in the mid- and high-dose groups (2 and 20 mg/kg-day) (incidence data not provided) and tubular adenomas and adenocarcinomas in high-dose rats only. The histopathology findings in low-dose rats were similar to controls. The incidence of combined adenomas and carcinomas in kidney was 1/90, 0/40, 0/40 and 9/39 in males and 0/90, 0/40, 0/40 and 6/40 in females, for the control, low-, mid- and high-dose groups, respectively. Metastasis to the lung was noted in two cases. NOAEL and LOAEL values of 0.2 and 2 mg/kg-day, respectively, were derived from this study based on kidney lesions (tubular epithelial hyperplasia and proliferation) observed in male and female rats that ingested HCBD in the diet for 2 years.

Schwetz et al., 1977 — The same research group carried out a combined subchronic and reproductive study (Schwetz et al., 1977) in parallel to that of Kociba et al. (1977). Male and female Sprague-Dawley rats (10-12 males/treatment group, 17 male controls, 20-24 females/treatment group, 34 female controls) received 0, 0.2, 2.0 or 20 mg/kg-day HCBD (99% purity) in feed for 90 days prior to mating, throughout a 15-day mating period, and then through gestation and lactation. Blood and urine samples were collected from control and high-dose rats prior to the end of the study. At study termination, blood samples were taken from the dams prior to necropsy to measure levels of BUN, serum creatinine and ALT activity. The brain, heart, liver, kidneys and testes (males) were obtained from 10 adult rats/sex/group and organ weights were determined. For the controls and high-dose groups, many organs and tissues were excised, weighed and processed for histopathological examination (brain, heart, liver, kidneys, testes, eye, pituitary, thyroid gland, parathyroid gland, trachea, esophagus, lungs, aorta, stomach, pancreas, small intestine, colon, mesenteric lymph nodes, muscle, sciatic nerve, spinal cord, sternum, sternal bone marrow and adrenal gland). Histopathology was also carried out on kidney tissue excised from five animals from each exposure group. Standard indices of reproductive performance were evaluated, and weanling skeletons were examined after alcohol fixation and appropriate extraction and staining. Bone marrow was taken from four adults and four weanlings/sex/group for cytological examination.

No clinical signs were evident in any of the adults receiving HCBD. A decrease in food consumption was noted in high-dose male and female rats. Female rats from this group weighed significantly less than controls throughout the study (22% decrease in final body weight), while male body weights were sometimes, but not always, lower than controls (10% decrease in final body weight). There were no differences among the groups in any reproductive or survival parameters for the dams and neonates (percent pregnant, litter size, gestation survival index, sex ratio, duration of gestation); however, the mean weight of high-dose neonates was significantly reduced (13% decrease) in the 20 mg/kg-day group compared with controls at weaning (21 days of age). No gross abnormalities were observed in neonates at necropsy. Skeletal alterations were not evident in neonates at any dose level.

Among clinical chemistry parameters, BUN was decreased in male rats by 17 and 13% in the 0.2 and 2 mg/kg-day dose groups, respectively, but was similar to controls in the 20 mg/kg-day dose groups. Serum levels of creatinine and ALT did not differ from those of controls. Hematology and urinalysis results were not presented or discussed. A significant increase in the relative weights of the liver (male only, 26% increase) and kidney (27 and 19% increase in males and females, respectively) was observed at the highest dose of HCBD. Absolute liver and kidney weights were not different from control values in any treatment group. An increase in relative brain weight (31% increase) and a decrease in relative heart weight (24% decrease) were also observed in female rats from the 20 mg/kg-day dose group. No changes in absolute brain or heart weight were observed. Kidneys from male rats ingesting 2 or 20 mg/kg-day HCBD were described as roughened with a mottled cortex. No gross abnormalities were noted for female rat kidneys. Histopathological examination revealed renal tubular dilation and hypertrophy with foci of tubular epithelial degeneration and regeneration. The incidence of these kidney lesions in rats ingesting 0, 0.2, 2 or 20 mg/kg-day was 1/5, 0/5, 0/5 and 3/5 for male rats and 0/5, 0/5, 1/5 and 5/5 for female rats. No histopathological kidney lesions were evident in weanling rats. Although these findings are limited by the small number of animals examined for histopathological evaluation, NOAEL and LOAEL values of 0.2 and 2 mg/kg-day, respectively, were derived from this study, based on gross and microscopic kidney lesions in adults rats exposed to HCBD for 90 days prior to mating, 15 days during mating, and throughout gestation and lactation.

Kociba et al., 1971 - HCBD (99% pure) was administered to female Sprague-Dawley rats (4/group) in the diet for 30 days at doses of 0, 1, 3, 10, 30, 65, 100 mg/kg-day (Kociba et al., 1971). Rats were observed daily and feed consumption and body weight gain were recorded weekly throughout the study. Blood samples obtained during necropsy were analyzed for hematology parameters and ALT activity. Organ weights of heart, liver, kidney, spleen and brain were recorded and several organs and tissues were prepared for histopathology evaluation (heart, liver, kidney, spleen, brain, pituitary, thyroid, parathyroid, lung, adrenal, mesenteric lymph node, ovary uterus, stomach and intestinal tract). Clinical signs of toxicity were not observed during the study. The food consumption rate was significantly decreased in rats receiving HCBD doses greater than 30 mg/kg-day. The mean body weight values measured at 28 days were 4, 10, 22 and 28% lower than controls for the 10, 30, 65 and 100 mg/kg-day groups, respectively. A decrease in absolute organ weight was seen in the liver, heart and spleen of rats in the 65 and 100 mg/kg-day dose groups. Absolute kidney weight was increased at 3 mg/kg-day, but was similar to controls for all other treatment groups. An increase in relative organ weight (organ:body weight ratio) was seen in the brain, liver and kidneys of rats given 30, 65 or 100 mg/kg-day HCBD. Hematology results were considered to be within a normal range. No change is AST activity was observed. Gross findings revealed a depletion of abdominal fat deposits in rats given 65 or 100 mg/kg-day HCBD. Histopathology results showed hepatocellular swelling in rats given 100 mg/kg-day HCBD only (4/4 rats). Kidney lesions included tubular epithelial cell degeneration, single cell necrosis and regeneration in all rats (4/4) from the 30, 65 and 100 mg/kg-day dose groups. Liver and kidney lesions were not observed in control rats or in rats given 1 or 3 mg/kg-day (0/4 per group). NOAEL and LOAEL values of 10 and 30 mg/kg-day, respectively, were derived from this study based on renal lesions observed in female Sprague-Dawley rats.

Inhalation Exposure. Few studies were located regarding the toxicity of HCBD by inhalation exposure in animals. Saillenfait et al. (1989) conducted a developmental toxicity study in which groups of 24-25 pregnant Sprague-Dawley rats inhaled 0, 2, 5, 10 or 15 ppm of HCBD for 6 hours/day on days 6-20 of gestation. The pregnant rats were weighed prior to exposure on days 0 and 6 of gestation, and again prior to sacrifice on day 21 of gestation. After sacrifice, the uterus was removed from each female and examined for numbers of implantation and resorption sites and live and dead fetuses. Live fetuses were sexed, weighed and examined for external malformations and cleft palate. Half of the viable fetuses from each litter were examined for soft tissue alterations and the other half were examined for skeletal alterations. No deaths or changes in general behavior were noted for exposed females. There was a concentration-related reduction in maternal weight gain in animals exposed to HCBD. Weight gain was reduced by 8% at 2 ppm, 15% at 5 ppm, 12% at 10 ppm and 39% at 15 ppm. The difference from controls was statistically significant in the 5 and 15 ppm groups.

Mean numbers of implantations, total fetal loss, resorptions and live fetuses were similar in treated and control animals (Saillenfait et al., 1989). Incidence of pregnancy and fetal sex ratio were also unchanged by HCBD exposure. However, body weight of both male and female fetuses was significantly reduced in the 15 ppm group (decreased by 9.5 and 12.5% in males and females, respectively). External examination of fetuses did not find any abnormalities, and no major anomalies were found after skeletal and soft tissue examination. The only minor anomalies were a non-significant incidence of hydroureter at 15 ppm and a non-significant increase in the incidence of extra 14^{th} ribs at 10 ppm. Although there was a significant reduction in fetal weight at the greatest exposure to HCBD, there was no significant retardation of development (e.g., delayed ossification) and the change was accompanied by a reduction in maternal weight gain. This study identified a NOAEL of 2 ppm and a LOAEL of 5 ppm for maternal toxicity (decreased weight gain), and a NOAEL of 10 ppm and a LOAEL of 15 ppm for developmental effects (decreased fetal body weight).

Dow Chemical Company conducted a subchronic inhalation study of HCBD that was described by Torkelson and Rowe (1982), as follows: “small groups of rats, rabbits and guinea pigs exposed 7 hours/day, 100 times to 3 ppm in a 143 day period were adversely affected, but those exposed 129 times in 184 days to 1 ppm were not. The livers and kidneys of the animals exposed to 3 ppm were the organs most affected.” No further details of this study were located. Representatives from Dow have stated that a more detailed report of this study, which was conducted in the 1950s, is no longer available (Dow, 1992).

Respiratory irritation and renal effects were observed in short-term, repeated inhalation studies of HCBD in rats. Alderley Park SPF rats (four rats of each sex for each treatment) were exposed to concentrations of HCBD ranging from 5 to 250 ppm for durations up to 3 weeks (Gage, 1970). A day after exposure was terminated, animals were sacrificed and necropsied. The following organs were routinely examined microscopically for damage: lungs, liver, kidneys, spleen and adrenals. Blood and urine tests were normal for all treatments. At 250 ppm of HCBD (2 x 4 hours), irritation and breathing difficulties were observed (more pronounced in females). Necropsy showed degeneration of the middle renal proximal tubules and the adrenal cortex. At 100 ppm (6 hours/day, 5 days/week, 12 days) irritation and respiratory difficulties were observed; animals had poor condition and weight loss. Females had slight anemia and two

died. Necropsy showed enlarged adrenal glands and pale, enlarged kidneys with degeneration of the renal cortical tubules and epithelial regeneration. At 25 ppm (6 hours/day, 5 days/week, 3 weeks) respiratory difficulties and poor condition were observed. Females had diminished weight gain. At necropsy, kidneys were pale and enlarged with damage to the renal proximal tubules. Ten ppm (6 hours/day, 5 days/week, 3 weeks) produced diminished weight gain in females, but no organ damage. Exposure to 5 ppm (6 hours/day, 5 days/week, 3 weeks) caused no symptoms of toxicity or organ damage.

DeCeaurriz et al. (1988) assessed respiratory irritation and kidney damage after acute exposure of male Swiss OF_1 mice to HCBD. The respiratory rates of mice (six mice per treatment group) were measured during a 15-minute oronasal exposure to HCBD (83, 143, 155, 210 or 246 ppm) using individual body plethysmographs. The decreases in respiratory rate recorded for each concentration were used to calculate the concentration associated with a 50% decrease in respiratory rate (RD_{50}). The RD_{50} for HCBD was 211 ppm. In a previous study, DeCeaurriz et al. (1981) calculated the RD_{50} for a number of different chemicals. The RD_{50} for hexachlorobutadiene places it among the more potent irritants. For instance, the RD_{50} for phenol was 166 ppm and that of formaldehyde was 5.3 ppm, while the RD_{50} of toluene was 3373 ppm and that of xylene was 1467 ppm (DeCeaurriz et al., 1981).

Mice were also exposed to various concentrations of HCBD (2.75, 5, 10 and 25 ppm) or clean filtered air for 4 hours (DeCeaurriz et al., 1988). After a recovery period of 24 hours, the animals were sacrificed and their kidneys were examined microscopically for damaged tubules and alkaline phosphatase staining. There was a significant, concentration-related increase in nephrotoxicity associated with HCBD exposure. The percentage of altered renal tubular cross-sections increased from 4% in the 2.75 ppm group to 92% in the 25 ppm group (versus 0.2-1.5% in the corresponding control groups). The researchers estimated an EC_{50} of 7.2 ppm for kidney histopathology produced by HCBD. On the basis of these findings, the researchers concluded that the kidney is a more sensitive target for HCBD than the respiratory tract following acute inhalation exposure in the mouse. However, DeCeaurriz et al. (1988) did not perform a histopathological examination of the upper respiratory tract. A more recent evaluation of the applicability of sensory irritation tests (Bos et al., 1992) has described a number of compounds for which histopathological damage was observed at exposure levels more than 10 times lower than the RD_{50}.

Although respiratory tract effects of HCBD have not been studied following chronic exposure, it is reasonable to suspect that such effects may be important for this chemical. Nasal toxicity was a prominent finding in chronic bioassays of the structurally related chemical 2-chloro-1,3-butadiene (chloroprene) in rats and mice (NTP, 1998).

Other Studies

The mode of action for the kidney toxicity of HCBD has been described (reviewed in Green et al., 2003; NTP, 1991; Dekant et al., 1990). HCBD is metabolized in the liver to a glutathione conjugate, which is further transformed by γ-glutamyl transpeptidase and dipeptidase enzymes to yield a cysteine conjugate. The cysteine conjugate may be cleaved by the renal β-lyase enzymes to give toxic thiol intermediates that cause localized kidney damage. The

cysteine conjugate may also be metabolized by N-acetyl transferase to form a N-acetyl cysteine conjugate that can be excreted in the urine or converted back to the cysteine conjugate by acylase enzymes. The nephrotoxicity of HCBD is linked to the relative activity of the renal β-lyase enzyme and the amount of cysteine conjugate available to be metabolized to toxic intermediates.

Green et al. (2003) compared the key metabolic steps for HCBD in both rat and human tissues. Human liver and kidney samples were obtained as excess tissue during organ transplantation. In vitro studies were used to evaluate glutathione conjugation of HCBD (in liver microsomes), the metabolism of cysteine conjugates by renal β-lyase (in kidney cytosol and mitochondria) or N-acetyl transferase (kidney microsomes) and the metabolism of the N-acetyl cysteine conjugate by acylase enzymes (kidney cytosol). The metabolic rates (Vmax) for each of these steps were lower in humans as compared to rats (5-fold lower for glutathione conjugation, 3-fold lower for β-lyase activity and 3.5-fold lower for N-acetyl transferase activity). Acylase enzyme activity was not detected in human kidney cytosol. The metabolic rate constants obtained for rats and humans were used in a physiologically-based pharmacokinetic (PBPK) model to quantify metabolism through the β-lyase pathway to form reactive intermediates. The uptake and distribution of HCBD was estimated in the PBPK model using measured partition coefficients and standard values for physiological parameters. The PBPK model predicted that metabolism by the β-lyase pathway is approximately 20-fold lower in humans than in rats exposed to the same inhalation concentration. The predicted decrease in the formation of β-lyase metabolites was related to decreased uptake of HCBD, lower glutathione transferase and β-lyase activities and the absence of acylase activity in human kidney. Comparable model predictions for the oral exposure route were not provided in this study.

DERIVATION OF PROVISIONAL SUBCHRONIC AND CHRONIC RfDs FOR HCBD

No data were located regarding the oral toxicity of HCBD in humans. Kidney toxicity was the primary effect of oral HCBD exposure in laboratory animals. Short-term studies (2-4 weeks in duration) demonstrated necrosis and degeneration of kidney tubules at high doses (>10 mg/kg-day) (Jonker et al., 1993; NTP, 1991; Yang et al., 1989; Harleman and Seinan, 1979; Kociba et al., 1971). Necrosis was less severe at lower doses and regeneration of kidney tubules was observed. In subchronic and chronic studies, the primary histopathological change observed was renal tubule regeneration, also characterized as hyperplasia and proliferation, and necrosis was not generally seen (NTP, 1991; Yang et al., 1989; Harleman and Seinen, 1979; Kociba et al., 1977, Schwetz et al., 1977). Kidney effects were most prevalent in the straight limbs of the proximal tubule in the outer zone of the medulla; however, the convoluted portions of the proximal tubule were also involved at high doses (Harleman and Seinen, 1979). The regenerative hyperplasia observed in tubule epithelial cells (NTP, 1991; Yang et al., 1989; Harleman and Seinen, 1979; Kociba et al., 1971) may be a response to HCBD-induced cell injury and/or may be a precursor to the renal neoplasms that were observed following chronic exposure (Kociba et al., 1977). The chronic and subchronic oral toxicity studies for HCBD are summarized in Table 3.

Table 3. Chronic and Subchronic Oral Toxicity Studies for HCBD

Species	Dose/Duration	NOAEL (mg/kg-day)	LOAEL (mg/kg-day)	Effect	Reference
B6C3F$_1$ mice	13-week dietary study; 0, 0.1, 0.4, 1.5, 4.9 or 16.8 mg/kg-day in males; 0, 0.2, 0.5, 1.8, 4.5 or 19.2 mg/kg/day in females	0.2	0.5	Renal tubule regeneration	NTP (1991); Yang et al. (1989)
Wistar rats	13-week oral gavage study; 0, 0.4, 1.0, 2.5, 6.3 or 15.6 mg/kg-day HCBD in arachid oil	1.0	2.5	Tubule epithelial cell with enlarged hyperchromatic nuclei; focal necrosis at higher doses	Harleman and Seinen (1979)
Sprague-Dawley rats	2-year dietary study; 0, 0.2, 2 or 20 mg/kg-day	0.2	2	Renal tubule hyperplasia and proliferation	Kociba et al. (1977)
Sprague-Dawley rats	Dietary study, 13 weeks premating, 15 day mating period and throughout gestation and lactation; 0, 0.2, 2 or 20 mg/kg-day	0.2	2	Renal tubule degeneration and regeneration	Schwetz et al. (1977)

The quantal Benchmark Dose (BMD) models in the BMD software package (U.S. EPA, 2007; Version 1.3.2) were fit to the female mouse renal tubule regeneration data in Table 1 (NTP, 1991; Yang et al., 1989). The gamma, log-probit, Weibull and log-logistic give virtually the same fit with indistinguishable Akaike Information Criterion (AIC). The BMD and BMDL10 values were all the same at 0.2 and 0.1 mg/kg-day, respectively. The Weibull had the best fit in the region of the BMR (lowest absolute scaled residual at 0.2 mg/kg-day, although the differences among the models are minimal (see Appendix 1). The 1st-order multistage fit adequately ($p = 0.37$) but had a much higher AIC than the aforementioned model fits. Therefore, the point of departure (POD) is set equal to the common BMDL10 of 0.1 mg/kg-day.

The **subchronic p-RfD of 1E-3 mg/kg-day** is based on the $BMDL_{10}$ of 0.1 mg/kg-day for renal tubule regeneration observed in a 13-week dietary study in mice (NTP, 1991; Yang et al., 1989). Kidney toxicity was also seen in a 13-week gavage study in rats at higher doses (Harleman and Seinen, 1979).

The subchronic p-RFD is derived by dividing the $BMDL_{10}$ of 0.1 mg/kg-day by a composite UF of 100, as follows:

Subchronic p-RfD	=	NOAEL/ UF
	=	0.1 mg/kg-day / 100
	=	**0.001 or 1E-3 mg/kg-day**

The composite UF of 100 includes factors of 3 ($10^{0.5}$) each for animal-to-human extrapolation and database deficiencies, and a factor of 10 for interindividual variability.

The interspecies UF of 3 was used to account for pharmacodynamic differences across species. The role of metabolism in HCBD-induced kidney toxicity is well established. Pharmacokinetic differences between the rat and the human were investigated by Green et al. (2003). In vitro studies were used to evaluate key steps in the metabolism of HCBD (glutathione conjugation in the liver, β-lyase, N-acetyl transferase and acylase enzyme activity in the kidney). The metabolic rate for each of these steps was lower in humans as compared to rats, suggesting that humans may be less sensitive to the kidney toxicity of HCBD (no pharmacokinetic adjustment was necessary). Although comparable in vitro metabolism data are not available for mice, the dose response data suggest that rats and mice are similarly sensitive to the kidney toxicity caused by HCBD. Given the large difference (20-fold) in predicted toxic metabolite formation in the PBPK model (Green et al., 2003), there is marginal justification for reducing UF_A to unity, despite the lack of information on toxicodynamic differences between rats (or mice) and humans. However, a somewhat limiting assumption is already made about the similarity of mice and rats for the metabolism of HCBD and there is no information on the relative *in vivo* abundance of key enzymes across species, only on specific activities. These limitations preclude further reduction of UF_A. The interspecies UF of 3 was therefore considered appropriate for both rats and mice.

The interindividual variability UF of 10 is used to account for variation in sensitivity within human populations because there is limited information on the degree to which humans of varying gender, age, health status or genetic makeup might vary in the disposition of, or response to, HCBD. A partial UF of 3 for database deficiencies is selected due to the lack of a multigeneration reproductive toxicity study. Prenatal and postnatal developmental toxicity studies are available for HCBD using the oral and inhalation exposure route (Field et al., 1990; Harleman and Seinen, 1979; Saillenfait et al., 1989). There was little assessment of the immune and nervous systems in the literature. With respect to the latter, Harleman and Seinen (1979) demonstrated neuropathy in rats at 1500 ppm (150 mg/kg-day) after 18 weeks of exposure. As this LOAEL is more than 3 orders-of-magnitude greater than the BMDL of 0.1 mg/kg-day, it is probably not much of a concern, either for the subchronic p-RfD or for longer periods of exposure relative to the chronic p-RfD.

Confidence in the critical study is medium. NTP (1991)/Yang et al. (1989) was a well-conducted, 13-week dietary study with relatively small number of animals (10/group). The critical effect (kidney lesions) was well studied. Limitations include lack of hematology and clinical chemistry and lack of histopathology on organs other than the kidney. NOAEL and LOAEL values were derived from the study based on kidney toxicity. Confidence in the database is medium. An additional subchronic oral gavage study showed similar effects at doses that were approximately 5-fold higher (Harleman and Seinen, 1979). Limitations of the database

include the lack of multigeneration reproductive toxicity data. Prenatal and postnatal developmental toxicity studies have been performed (Field et al., 1990; Harleman and Seinen, 1979; Saillenfait et al., 1989). Overall, confidence in the subchronic p-RfD is medium.

The **chronic p-RfD of 1E-3 mg/kg-day** is also based on renal tubule regeneration in the 13-week dietary study in mice (NTP, 1991; Yang et al., 1989), as the BMDL of 0.1 mg/kg-day is lower than the NOAEL of 0.2 mg/kg-day for renal effects in the 2-year rat study (Kociba et al., 1977). The incidence of kidney lesions was not reported for each dose group in the 2-year study. Therefore, benchmark dose modeling could not be used to derive a point of departure. Therefore, the chronic p-RfD is derived by dividing the subchronic $BMDL_{10}$ of 0.1 mg/kg-day by a composite UF of 100, as follows:

Chronic p-RfD	=	NOAEL / UF
	=	0.1 mg/kg-day / 100
	=	**0.001 or 1E-3 mg/kg-day**

The composite UF of 100 includes factors of 3 ($10^{0.5}$) each for animal-to-human extrapolation and database deficiencies, and a factor of 10 for interindividual variability. A subchronic-to-chronic uncertainty factor is not required because the chronic 2-year rat study indicates that prolonged exposure does not result in toxicity at lower doses than for subchronic exposure. The interspecies UF of 3 was used to account for pharmacodynamic differences across species as described previously for the subchronic p-RfD. The interindividual variability UF of 10 is used to account for variation in sensitivity within human populations because there is limited information on the degree to which humans of varying gender, age, health status or genetic makeup might vary in the disposition of, or response to, HCBD. A partial UF of 3 for database deficiencies is selected due to the lack of a multigeneration reproductive toxicity study. Prenatal and postnatal developmental toxicity studies are available for HCBD using the oral and inhalation exposure route (Field et al., 1990; Harleman and Seinen, 1979; Saillenfait et al., 1989).

Overall confidence in the chronic p-RfD is medium for the same reasons as for the subchronic p-RfD.

FEASIBILITY OF DERIVING PROVISIONAL CHRONIC AND SUBCHRONIC RfCs FOR HCBD

The available data are inadequate to support derivation of a provisional inhalation RfC for HCBD. Reduced body weight gain was observed in dams following inhalation exposure in the Saillenfait et al. (1989) rat developmental toxicity study (NOAEL of 2 ppm). However, this study included limited evaluation of non-developmental endpoints, no examination of the respiratory tract and no assessment of kidney toxicity, the critical effort for oral exposure. The only other inhalation study of appropriate duration to consider for RfC derivation is the Dow Chemical study briefly described by Torkelson and Rowe (1982). However, the existing description of this study provides insufficient information to assess the study, and attempts to obtain more detailed information about the study were unsuccessful.

The database for oral toxicity of HCBD is more extensive than that for inhalation toxicity (ATSDR, 1994). The kidney appears to be the most sensitive target of HCBD by oral exposure. However, due to overt signs of respiratory irritation and uncertainty regarding the relative sensitivity of the respiratory tract as compared to the kidney with long-term inhalation exposure, an RfC is not derived.

PROVISIONAL CARCINOGENICITY ASSESSMENT FOR HEXACHLOROBUTADIENE

The carcinogenicity assessment, which includes an oral slope factor and inhalation unit risk, is on IRIS (U.S. EPA, 1991b).

PROVISIONAL PEER REVIEWED TOXICITY VALUES FOR IRON (CASRN 7439-89-6) AND COMPOUNDS
Derivation of an Inhalation RfC

Background

On December 5, 2003, the U.S. Environmental Protection Agency's (EPA's) Office of Superfund Remediation and Technology Innovation (OSRTI) revised its hierarchy of human health toxicity values for Superfund risk assessments, establishing the following three tiers as the new hierarchy:

1. EPA's Integrated Risk Information System (IRIS).

2. Provisional Peer-Reviewed Toxicity Values (PPRTV) used in EPA's Superfund Program.

3. Other (peer-reviewed) toxicity values, including:

   - Minimal Risk Levels produced by the Agency for Toxic Substances and Disease Registry (ATSDR),
   - California Environmental Protection Agency (CalEPA) values, and
   - EPA Health Effects Assessment Summary Table (HEAST) values.

A PPRTV is defined as a toxicity value derived for use in the Superfund Program when such a value is not available in EPA's Integrated Risk Information System (IRIS). PPRTVs are developed according to a Standard Operating Procedure (SOP) and are derived after a review of the relevant scientific literature using the same methods, sources of data, and Agency guidance for value derivation generally used by the EPA IRIS Program. All provisional toxicity values receive internal review by two EPA scientists and external peer review by three independently selected scientific experts. PPRTVs differ from IRIS values in that PPRTVs do not receive the multi-program consensus review provided for IRIS values. This is because IRIS values are generally intended to be used in all EPA programs, while PPRTVs are developed specifically for the Superfund Program.

Because science and available information evolve, PPRTVs are initially derived with a three-year life-cycle. However, EPA Regions (or the EPA HQ Superfund Program) sometimes request that a frequently used PPRTV be reassessed. Once an IRIS value for a specific chemical becomes available for Agency review, the analogous PPRTV for that same chemical is retired. It should also be noted that some PPRTV manuscripts conclude that a PPRTV cannot be derived based on inadequate data.

Disclaimers

Users of this document should first check to see if any IRIS values exist for the chemical of concern before proceeding to use a PPRTV. If no IRIS value is available, staff in the regional Superfund and RCRA program offices are advised to carefully review the information provided in this document to ensure that the PPRTVs used are appropriate for the types of exposures and circumstances at the Superfund site or RCRA facility in question. PPRTVs are periodically updated; therefore, users should ensure that the values contained in the PPRTV are current at the time of use.

It is important to remember that a provisional value alone tells very little about the adverse effects of a chemical or the quality of evidence on which the value is based. Therefore, users are strongly encouraged to read the entire PPRTV manuscript and understand the strengths and limitations of the derived provisional values. PPRTVs are developed by the EPA Office of Research and Development's National Center for Environmental Assessment, Superfund Health Risk Technical Support Center for OSRTI. Other EPA programs or external parties who may choose of their own initiative to use these PPRTVs are advised that Superfund resources will not generally be used to respond to challenges of PPRTVs used in a context outside of the Superfund Program.

Questions Regarding PPRTVs

Questions regarding the contents of the PPRTVs and their appropriate use (e.g., on chemicals not covered, or whether chemicals have pending IRIS toxicity values) may be directed to the EPA Office of Research and Development's National Center for Environmental Assessment, Superfund Health Risk Technical Support Center (513-569-7300), or OSRTI.

INTRODUCTION

An RfC for iron is not listed on IRIS (U.S. EPA, 2001) and was not considered by the RfD/RfC Work Group (U.S. EPA, 1995). The HEAST (U.S. EPA, 1997) reported that data regarding iron were inadequate for quantitative risk assessment. The CARA list (1991, 1994a) includes a Health Effects Assessment for Iron and Compounds (U.S. EPA, 1984) that reported negative epidemiological studies (no association between excess mortality or respiratory diseases and occupational exposure to iron oxide dusts) and no available subchronic or chronic inhalation studies in animals. In March, 2004, a literature search was also conducted using TOXLINE, MEDLINE, Chemical Abstracts and Biological Abstracts data bases.

Occupational exposure limits have been established for soluble iron salts and iron oxide, as well as for organic iron compounds not covered in this issue paper. The ACGIH (1991a,

2001) has adopted a TLV-TWA, NIOSH (2001a) has established a REL-TWA, and OSHA (2001a, 2001b) has adopted a construction industry PEL-TWA of 1 mg/m^3, as Fe, to reduce the likelihood of irritation to eyes, skin, and respiratory tract from exposure to aerosols or mists of soluble iron salts (ferrous and ferric sulfates and chlorides, and ferric nitrate). The ACGIH (1991b, 2001) has adopted a TLV-TWA and NIOSH (2001b) has established a REL-TWA of 5 mg/m^3, as Fe, for dust and fume of ferric oxide (Fe_2O_3) to protect against siderosis, a benign pneumoconiosis. OSHA (2001c) has adopted a PEL-TWA of 10 mg/m^3 for ferric oxide fume, to protect against accumulation of iron dust in the lungs.

Iron has not been the subject of a toxicological profile by ATSDR (2001) or the WHO (2001). Monographs by IARC (1972, 1984, 1987), a toxicity review on iron (Grimsley, 2001), and the NTP (2001a, 2001b) management status report and chemical repository summary were consulted for information relevant to inhalation toxicity of iron and inorganic iron compounds. The following computer searches, performed in April, 1993, were screened to identify additional pertinent studies not discussed in review documents: TOXLINE (1983-April, 1993), CANCERLIT (1990 - April, 1993), MEDLINE (1991 - April, 1993), TSCATS, RTECS, and HSDB. Update literature searches were conducted in September, 2001 in TOXLINE (1992-September, 2001), CANCERLIT (1992- September, 2001), MEDLINE (1992-September, 2001), TSCATS, RTECS, DART/ETICBACK, EMIC/EMICBACK, HSDB, GENETOX, and CCRIS.

REVIEW OF PERTINENT LITERATURE

Human Studies

A number of studies have examined the relationship between respiratory disease and inhalation exposure to iron compounds for workers employed in hematite mining or other iron-related occupations, such as welding or steel-making (U.S. EPA, 1984; IARC, 1972, 1984; Grimsley, 2001). However, since these studies involved concurrent exposure to silica and other metals, they are not suitable for the health risk assessment of iron or iron compounds. The literature search did not discover any studies that examined subchronic or chronic inhalation exposures of humans to quantified levels of iron or iron compounds alone.

In a case-control study of cancer incidence, a Swedish male worker population (1958-1971) was reported to have had a high exposure to iron oxides from the production of sulfuric acid from pyrite (FeS_2) (Axelson and Sjöberg, 1979). The workers were exposed to iron oxide (Fe_2O_3) along with 1-2% copper, 0.01-0.1% arsenic, nickel and cobalt as impurities. Exposure in the workroom was estimated as approximately 50-100 mg/m^3, and the particle size as 25% below 10 μm and 5-10% below 5 μm. However, there were no measurements of exposure levels or particle size, and exposure durations were not reported. No cases of siderosis were known from the plant.

Animal Studies

Inhalation studies for iron compounds in animals include a chronic study of hamsters exposed to ferric oxide (Fe_2O_3) dust (Nettesheim et al., 1975) and a 2-month study in rabbits exposed to aerosols of ferric chloride (Johansson et al., 1992).

In a cancer study, groups of male Syrian hamsters (132 per group) were exposed to filtered air or Fe_2O_3 (analytic grade) dust at a concentration of 40 mg/m^3, 6 hours/day, 5 days/week for life (Nettesheim et al., 1975). The particle size had a geometric mean diameter of 0.11 μm. In addition, two satellite groups (15 hamsters per treatment) were sacrificed, three animals at a time, at 2, 4, 8, 12, and 104 weeks, so that the accumulation of iron in the lung from inhaled Fe_2O_3 could be compared to background iron concentrations in heme. The animals were examined daily, before and after each exposure, for clinical signs, and body weights were recorded monthly. All animals except those cannibalized (<2%) were necropsied. Histological analyses were performed on the major organs, including heart, trachea, lungs, and nasal cavities. Examination of the satellite groups demonstrated the gradual increase in iron accumulation in the lung, reaching a total of 10 mg per lung at 104 weeks. Histological examination revealed iron deposits in the lungs and tracheal and bronchial lymph nodes of all exposed animals. Diffuse and focal alveolar fibrosis was also frequently observed in the lungs of treated animals. Results for the histological endpoints were not reported quantitatively. In this study, 40 mg/m^3 is a LOAEL for respiratory effects (alveolar fibrosis) in hamsters exposed to Fe_2O_3 dust.

Groups of 8 male rabbits (strain not reported) were exposed to aerosols of 0, 1.4, or 3.1 mg/m^3 of iron as $FeCl_3$ 6 hours/day, 5 days/week for 2 months (Johansson et al., 1992). At termination, the upper left lung lobe was examined by light microscopy, pieces of the lower left lung were analyzed by electron microscopy or used for phospholipid analysis, and the right lung was lavaged to obtain macrophages for morphological and functional analyses. The mass median aerodynamic diameter of the aerosols was ~1 μm as measured with an impactor. Treatment had no effect on survival. Lungs were spotted with black in 7/8 high-iron rabbits, in 2/8 low-iron rabbits, and in 0/8 controls. The absolute weight of the left lower lobe of the lung was significantly elevated compared to controls in the high-iron group. Exposure-related histopathology was observed in the lungs. In the high-exposure group, the lungs contained naked granulomas [large nodules (≥ 1 mm) of densely packed granular macrophages], accumulations of granular macrophages in terminal bronchioles, and foci of interstitial lymphocytic inflammatory reaction. Small granulomas were observed in one low-iron and one control rabbit. Accumulations of normal and granular macrophages were observed in the alveoli of exposed rabbits. In the control group, normal lung tissue contained some small accumulations of macrophages with occasional small inflammatory reaction. The high exposure group had a significantly higher density of alveolar type II cells than the controls. Ultrastructural analysis of macrophages showed a significantly higher number of abnormal cells, cells with enlarged lysosomes, and black inclusions in cells in both exposed groups; the high-iron group had higher

percentages of cells with laminar inclusions or with smooth cell surfaces. In functional tests, macrophages from the high-exposure group showed significantly elevated phagocytic activity, but no significant increase in oxidative metabolic activity (superoxide generation). Total phospholipids were elevated in the high-exposure group, but, as indicated by the lack of increase in phosphatidyl cholines or the percentage of 1,2-dipalmitoylphosphatidylcholine, the amount of surfactant was unchanged. In this study, the low concentration of 1.4 mg/m^3 is a NOAEL and the high concentration of 3.1 mg/m^3 is a LOAEL for adverse lung effects (nodular granulomas ≥ 1 mm in diameter, abnormal macrophages) in rabbits exposed to ferric chloride aerosols. Because of its focus on alveolar macrophage effects, this study provided no information regarding clinical signs of toxicity, body weight changes, clinical biochemistry, nasopharyngeal effects or histology of any other tissue besides the lung.

Other Studies

In a cancer study, groups of Syrian golden hamsters (24 per sex per group) received intratracheal instillations of 0 or "a maximum dose"[1] of 3 mg of Fe_2O_3 dust in 0.2 ml of saline once a week for 15 weeks, and then were observed up to week 120 (Stenbäck et al., 1976). Analysis by the sedimentation method demonstrated that 98% of the particles were less than 10 µm in diameter. Animals were weighed weekly and autopsied. Organs with gross lesions and the larynx, trachea, bronchi, and lungs were examined histologically. Treatment with ferric oxide had no effect on survival and no effect on body weight except during the final weeks of survival (data not shown). Deposited iron oxide was grossly visible as dark patches on the lung surface. Histologically, dust accumulations surrounded by cellular infiltrates were observed in the peribronchial region. Interstitial fibrosis was observed occasionally, but distinct inflammatory changes were rare. Results for the nonneoplastic endpoints were not reported quantitatively.

FEASIBILITY OF DERIVING A PROVISIONAL RfC FOR IRON

No adequate human or animal inhalation data are available for exposure to iron or inorganic iron compounds. The epidemiological study of Axelson and Sjöberg (1979) did not provide quantitative measures of exposure and did not characterize noncancer endpoints. Although Nettesheim et al. (1975) reported diffuse and focal alveolar fibrosis in the lungs of hamsters chronically exposed to iron oxide by inhalation at a concentration of 40 mg/m^3, the lack of incidence data prevents an evaluation of the significance of these findings. The subchronic study of Johansson et al. (1992), in which rabbits were exposed to aerosols of ferric chloride for

[1]The authors provided no further information regarding dosage. It is not clear whether animals were given amounts lower than 3 mg on some occasions.

2 months, demonstrated a NOAEL of 1.4 mg/m^3 and a LOAEL of 3.1 mg/m^3 for respiratory effects (granuloma nodules greater than 1 mm diameter in the lungs). However, this study does not meet the minimum standards for an inhalation bioassay as stipulated by the U.S. EPA (1994b) guidelines for derivation of an inhalation reference concentration. Inadequacies of the study include relatively small group sizes, relatively short study duration, and the failure to examine a sufficient array of endpoints. Thus this study is inadequate for the purposes of deriving a p-RfC for iron. Consequently, the available data are insufficient for derivation of a p-RfC.

PROVISIONAL PEER REVIEWED TOXICITY VALUES FOR IRON (CASRN 7439-89-6) AND COMPOUNDS
Derivation of a Carcinogenicity Assessment

Background

On December 5, 2003, the U.S. Environmental Protection Agency's (EPA's) Office of Superfund Remediation and Technology Innovation (OSRTI) revised its hierarchy of human health toxicity values for Superfund risk assessments, establishing the following three tiers as the new hierarchy:

1. EPA's Integrated Risk Information System (IRIS).

2. Provisional Peer-Reviewed Toxicity Values (PPRTV) used in EPA's Superfund Program.

3. Other (peer-reviewed) toxicity values, including:

   - Minimal Risk Levels produced by the Agency for Toxic Substances and Disease Registry (ATSDR),
   - California Environmental Protection Agency (CalEPA) values, and
   - EPA Health Effects Assessment Summary Table (HEAST) values.

A PPRTV is defined as a toxicity value derived for use in the Superfund Program when such a value is not available in EPA's Integrated Risk Information System (IRIS). PPRTVs are developed according to a Standard Operating Procedure (SOP) and are derived after a review of the relevant scientific literature using the same methods, sources of data, and Agency guidance for value derivation generally used by the EPA IRIS Program. All provisional toxicity values receive internal review by two EPA scientists and external peer review by three independently selected scientific experts. PPRTVs differ from IRIS values in that PPRTVs do not receive the multi-program consensus review provided for IRIS values. This is because IRIS values are generally intended to be used in all EPA programs, while PPRTVs are developed specifically for the Superfund Program.

Because science and available information evolve, PPRTVs are initially derived with a three-year life-cycle. However, EPA Regions (or the EPA HQ Superfund Program) sometimes request that a frequently used PPRTV be reassessed. Once an IRIS value for a specific chemical becomes available for Agency review, the analogous PPRTV for that same chemical is retired. It should also be noted that some PPRTV manuscripts conclude that a PPRTV cannot be derived based on inadequate data.

Disclaimers

Users of this document should first check to see if any IRIS values exist for the chemical of concern before proceeding to use a PPRTV. If no IRIS value is available, staff in the regional Superfund and RCRA program offices are advised to carefully review the information provided in this document to ensure that the PPRTVs used are appropriate for the types of exposures and circumstances at the Superfund site or RCRA facility in question. PPRTVs are periodically updated; therefore, users should ensure that the values contained in the PPRTV are current at the time of use.

It is important to remember that a provisional value alone tells very little about the adverse effects of a chemical or the quality of evidence on which the value is based. Therefore, users are strongly encouraged to read the entire PPRTV manuscript and understand the strengths and limitations of the derived provisional values. PPRTVs are developed by the EPA Office of Research and Development's National Center for Environmental Assessment, Superfund Health Risk Technical Support Center for OSRTI. Other EPA programs or external parties who may choose of their own initiative to use these PPRTVs are advised that Superfund resources will not generally be used to respond to challenges of PPRTVs used in a context outside of the Superfund Program.

Questions Regarding PPRTVs

Questions regarding the contents of the PPRTVs and their appropriate use (e.g., on chemicals not covered, or whether chemicals have pending IRIS toxicity values) may be directed to the EPA Office of Research and Development's National Center for Environmental Assessment, Superfund Health Risk Technical Support Center (513-569-7300), or OSRTI.

INTRODUCTION

A cancer assessment for iron is not listed on IRIS (U.S. EPA, 2005a), the HEAST (U.S. EPA, 1997), or the Drinking Water Standards and Health Advisories list (U.S. EPA, 2000), and was not considered by the CRAVE Work Group (U.S. EPA, 1995). The CARA list (1991, 1994) includes a Health Effects Assessment for Iron and Compounds (U.S. EPA, 1984) that assigned iron and its compounds to weight-of-evidence Group C, possible human carcinogen. This assessment was based on conflicting evidence of lung tumors following occupational inhalation exposure to ferric oxide (mixed exposure), and injection-site tumors in one patient and in mice treated with iron-dextran. IARC (1972, 1987) assigned ferric oxide to Group 3, not classifiable as to its carcinogenicity to humans based on inadequate data in humans (increased incidence of lung cancer following occupational exposure to iron dusts in mixtures) and apparently negative

evidence for carcinogenicity in mice, hamsters and guinea pigs exposed by inhalation or intratracheal instillation. For ferric oxide dust and fume, the ACGIH (1991, 2001) lists an A4 notation, not classifiable as a human carcinogen; this is based on mixed exposure studies in humans and primarily negative studies in animals. In March, 2004, a literature search was also conducted using TOXLINE, MEDLINE, Chemical Abstracts and Biological Abstracts data bases.

Iron has not been the subject of a toxicological review by ATSDR (2001) or the WHO (2001). Monographs by IARC (1972, 1984, 1987), a toxicity review on iron (Grimsley, 2001), and the NTP (2001a, 2001b) management status report and chemical repository summary were consulted for information relevant to the carcinogenicity of iron and inorganic iron compounds. The following computer searches, performed in April, 1993, were screened to identify additional pertinent studies not discussed in review documents: TOXLINE (1983-April, 1993), CANCERLIT (1990 - April, 1993), MEDLINE (1991 - April, 1993), TSCATS, RTECS, and HSDB. Update literature searches were conducted in September, 2001 in TOXLINE (1992-September, 2001), CANCERLIT (1992- September, 2001), MEDLINE (1992-September, 2001), TSCATS, RTECS, DART/ETICBACK, EMIC/EMICBACK, HSDB, GENETOX, and CCRIS.

REVIEW OF PERTINENT LITERATURE

Human Studies

Oral Exposure

Because iron is an essential element, the NAS (2001) has established guidelines for daily dietary intakes, based on gender, age, and physiological status, that are designed to avoid adverse effects of deficiency and excess. Individuals of northern European descent who are affected by hereditary hemochromatosis, an autosomal, recessive disorder, are not protected by these guidelines. These individuals exhibit excessive absorption of dietary iron, which results in abnormally high accumulations of iron in liver and brain tissues. When the liver consequently develops cirrhosis, the risk of developing primary hepatocellular carcinoma increases significantly. It is not clear whether these findings are relevant to excess iron intake by the general population.

Bird et al. (1996) investigated the association between plasma ferritin and iron intake and the development of adenomatous polyps, which are intermediate markers for colorectal cancer. The study population consisted of men and women between the ages of 50 and 75 years old who underwent routine screening by flexible sigmoidoscopy at one of two medical centers during 1991-1993. Individuals with cancer, inflammatory bowel disease, or familial polyposis were excluded. Cases (300 men and 167 women) were subjects diagnosed for the first time with one

or more histologically confirmed adenomatous polyps. Controls (331 men and 167 women) had no history of polyps and none discovered at sigmoidoscopy. Cases and controls were matched by sex, age (± 5 years), date of sigmoidoscopy (± 3 months), and medical center. Plasma ferritin levels, hematocrit, and certain nutritional indicators (carotenoids, ascobate, folate) were measured in blood samples drawn 6 months after examination. Iron intakes for the year preceding sigmoidoscopy were estimated by means of a semiquantitative food frequency questionnaire. After controlling for possible confounding factors, subjects with high plasma ferritin levels (>289 μg/L) had a multivariate-adjusted odds ratio for colorectal polyps of 1.5 (95% confidence interval (C.I. = 1.0-2.3) compared to subjects with low/normal levels (73-141 μg/L). The pattern for iron intake was U-shaped. Compared with subjects consuming an adequate amount of iron (11.6-13.6 mg/day), multivariate-adjusted odds ratios for colorectal polyps in men were 1.6 (95% C.I. = 1.1-2.4) for intakes below 11.6 mg/day and 1.4 (95% C.I.= 0.9-2.0) for intakes above 27.3 mg/day. The highest odds ratio of 2.1 (95% C.I. = 1.3-3.5) was found after further adjustment for smoking for men at the lowest level of iron intake. The association between iron intake and colorectal polyps disappeared when exposure group class of reaction was based on dietary intake alone (i.e., high iron supplementation ignored). The authors concluded that there was a weak positive association between iron exposure and colorectal polyps that may increase the risk of colorectal cancer but note that some factor in supplementation may have been responsible for the effect.

Inhalation Exposure

Most studies of cancer incidence following occupational exposure to iron dust are excluded from consideration because of confounding exposures to silica, radon daughters, soot, asbestos, or other types of metals in the study populations (U.S. EPA, 1984; IARC, 1972, 1984, 1987).

A case-control study examined cancer incidence in a Swedish male worker population (1958-1971) with a high exposure to iron oxides from the production of sulfuric acid from pyrite (FeS_2) (Axelson and Sjöberg, 1979). The workers were exposed to iron oxide (Fe_2O_3) along with 1-2% copper, 0.01-0.1% arsenic, nickel and cobalt as impurities. Exposure in the workroom was estimated as approximately 50-100 mg/m^3, and the particle size as 25% below 10 μm and 5-10% below 5 μm. No cases of siderosis were known from the plant. The Swedish National Cancer Register was consulted for locating cases of cancer that could have been caused by environmental exposure; the study examined cancers of the stomach, liver, lung, kidney, and bladder, and hematological malignancies. Each cancer case was matched with two controls from the local population register by matching for sex, age, and residency in the same or adjacent neighborhood block. Company files were searched to determine the length of exposure; those with less than 5 months of exposure were considered to be nonexposed. The study found no association between exposure to iron oxides and any of the selected types of cancer.

Animal Studies

Oral Exposure

Groups of F344 rats (50 per sex per group) were given ferric chloride ($FeCl_3 \cdot 6H_2O$) in drinking water at concentrations of 0, 0.25, or 0.5% (weight/volume) for 104 weeks, and then given distilled water for an 8 week recovery period (Sato et al., 1992). The intake of ferric chloride was reported to be 0, 169.7, or 319.7 mg/kg-day for males and 0, 187.9, or 336.0 mg/kg-day for females. The iron intakes were 0, 58.4, or 110 mg/kg-day in males and 0, 64.6, or 115.6 mg/kg-day in females. Rats were observed daily for clinical signs and mortality. Body weights were measured once a week for 13 weeks and every fourth week thereafter. All rats dying prematurely and survivors at week 112 were examined for gross and microscopic neoplastic and non-neoplastic lesions. There were dose-related decreases in drinking water intake and terminal body weight in both sexes. These may have been related to reduced palatability. Survival in both sexes was not significantly affected by exposure to ferric chloride. No increases in tumor incidence were observed in rats exposed to ferric chloride for two years.

Inhalation Exposure

Groups of male Syrian hamsters (132 per group) were exposed to filtered air or Fe_2O_3 (analytic grade) dust at a concentration of 40 mg/m^3, 6 hours/day, 5 days/week for life (Nettesheim et al., 1975). The particle size had a geometric mean diameter of 0.11 μm. In addition, two satellite groups (15 hamsters per treatment) were sacrificed, three animals at a time, at 2, 4, 8, 12, and 104 weeks, so that the accumulation of iron in the lung from inhaled Fe_2O_3 could be compared to background iron concentrations in heme. The animals were examined daily, before and after each exposure, for clinical signs; body weights were recorded monthly. All animals except those cannibalized (<2%) were necropsied. Histological analyses were performed for the major organs, including heart, trachea, lungs, and nasal cavities. Examination of the satellite groups demonstrated a gradual increase in iron accumulation in the lung, reaching a total of 10 mg per lung at 104 weeks. Exposure to Fe_2O_3 had no effect on survival or body weight gain and did not increase the incidence of tumors. The authors concluded that inhalation of Fe_2O_3 was not carcinogenic to hamsters.

Groups of Syrian golden hamsters (24 per sex per group) received intratracheal instillations of 0 or 3 mg[1] of Fe_2O_3 dust in 0.2 ml of saline once a week for 15 weeks, and then were observed up to week 120 (Stenbäck et al., 1976). Analysis by the sedimentation method demonstrated that 98% of the particles were less than 10 μm in diameter. Animals were weighed

[1]The authors characterized the treatment as a 'maximum dose of 3 mg'. It is not clear whether the hamsters received lower doses on some occasions.

weekly and autopsied. Organs with gross lesions and the larynx, trachea, bronchi, and lungs were examined histologically. Treatment with ferric oxide had no effect on survival and did not affect body weight except during the final weeks of survival (data not shown). Treatment did not induce tumors of the respiratory tract and the incidence of forestomach papillomas in the treatment group was less than in the control group.

Other Studies

Genotoxicity

Genotoxicity assays of inorganic iron salts were primarily negative in bacteria, but were more often positive in mammalian systems. Iron did not induce reverse mutations in *Salmonella typhimurium* strains TA98, TA102, TA1535, or TA1537, with or without activation (Wong, 1988). Ferric chloride and ferrous sulfate tested negative in strains TA98, TA100, TA1535, TA1537, and TA1538 with or without metabolic activation (Shimizu et al., 1985; Dunkel et al., 1999). Ferrous sulfate also tested negative in strains TA97 and TA102, with or without activation (Fujita et al., 1994), but positive in TA1537 and TA1538 (U.S. EPA, 1984). Ferrous and ferric chloride did not induce DNA repair in *Bacillus subtilis* (rec assay) (Leifer et al., 1981). Ferrous sulfate increased the frequency of mutations at the TK locus of mouse L5178Y lymphoma cells, with or without metabolic activation, but only at high concentrations that were likely to be cytotoxic; ferric chloride only increased the frequency of TK mutations when tested with metabolic activation (Dunkel et al., 1999). Ferrous sulfate did not induce sister chromatid exchanges *in vitro* (Ohno et al., 1982). DNA-protein cross-links were generated in mammalian cells cultured in the presence of ferrous iron (Altman et al., 1995). Single- and double-strand DNA breaks were produced in supercoiled plasmid DNA (Toyokuni and Sagripanti, 1992) and in isolated rat liver nuclei (U.S. EPA, 1984) treated with ferrous or ferric chloride. No breakage was detected electrophoretically in Chinese hamster ovary cell DNA treated with ferrous chloride (U.S. EPA, 1984). In a model of oxidative damage within cells, ferrous sulfate, in the presence of hydrogen peroxide, was demonstrated to induce double-strand breaks and intra-strand cross-links in DNA *in vitro* (Lloyd and Phillips, 1999).

Cell transformation

Iron compounds have yielded variable results in studies of cell transformation *in vitro*. Particles of magnetite (Fe_3O_4) induced transformation of cultured a Chinese hamster lung cell line (V_{79}), but only at cytotoxic concentrations (Elias et al., 1995). Ferrous chloride and ferrous sulfate induced cell transformation in viral-enhanced Syrian hamster embryo (SA7/SHE) cells (U.S. EPA, 1984).

Mechanistic Studies

Adverse effects of iron are thought to be related to the formation of reactive oxygen species via the Fenton reaction (Henle and Linn, 1997). Hydrogen peroxide can react with ferrous ion, resulting in the conversion to ferric ion and the production of hydroxyl radicals. Ferric ion can also react with hydrogen peroxide, producing superoxide radical. Reactive oxygen species may react with DNA. However, because of the complex homeostatic mechanisms involved in iron transport and metabolism, unbound ferrous iron is not likely to be present except in conditions of excessive iron intake.

PROVISIONAL WEIGHT-OF-EVIDENCE CLASSIFICATION

U.S. EPA (1984) classified iron and its compounds, including ferric dextran, as possible human carcinogens (Group C). This assessment was based on reports associating an increased incidence of lung cancer with exposure to hematite dust (confounded by coincident exposures to tobacco, alcohol, silica, soot, and fumes of other metals), inconsistent reports of lung tumors in animals exposed by inhalation or tracheal instillation to ferric oxide, and reports of injection site tumors in one patient injected with iron dextran and in mice injected with iron dextran or saccharated iron oxide. The current PPRTV assessment excludes organic forms of iron and studies in which the levels of impurities are significant.

Results of the case-control study by Bird et al. (1996) provide evidence of a weak association between elevated iron intake or high plasma ferritin (a measure of body stores) and the prevalence of adenomatous colorectal polyps, a possible precursor to colorectal cancer. Weaknesses of this study include the 6-month period between examination and ferritin measurements, and the possible recall errors affecting the dietary questionnaire for the previous year. In addition, the association between iron intake and colorectal polyps was stronger at low iron intake and not related to dietary (i.e., environmental) intake. Although the association between cirrhotic hereditary hemochromatosis and hepatocellular carcinoma is well established, the evidence for dietary iron intake and hepatic cancer in the general population was characterized by the NAS (2001) as inconclusive. In a chronic rat assay, Sato et al. (1992) found no evidence of carcinogenicity of ferric chloride ingested in drinking water at concentrations up to 0.5%. In summary, the evidence for carcinogenicity of ingested inorganic iron compounds in humans and animals is inadequate.

Evidence from the case-control study of Axelson and Sjöberg (1979) suggests that inhaled iron oxide may not be carcinogenic to humans. However, uncertainty remains because levels of exposure were not measured, the durations of exposure were not reported, and individuals exposed for up to 5 months were categorized as 'nonexposed.' In addition, the lack of reported cases of siderosis in the workplace suggests that the exposure levels may have been

lower than estimated. Thus, the evidence for carcinogenicity of inhaled iron oxide in humans is considered inadequate. Results of the study of Nettesheim et al. (1975) indicate that chronic inhalation exposure to iron oxide at a concentration of 40 mg/m^3 is not carcinogenic to hamsters. This finding is supported by the negative results for carcinogenicity of iron oxide administered by intratracheal instillation to hamsters for 15 weeks (Stenbäck et al., 1976). However, as both hamster studies used single exposure concentrations, the possibility of carcinogenicity at higher exposure levels cannot be disregarded.

Following the U.S. EPA (2005b) guidelines for carcinogen risk assessment, the available data are inadequate for an assessment of the human carcinogenic potential of inhaled iron oxide or ingested iron chloride.

QUANTITATIVE ESTIMATES OF CARCINOGENIC RISK

Derivation of quantitative estimates of cancer risk for ingested or inhaled iron or iron oxide is precluded by the absence of adequate data demonstrating carcinogenicity.

PROVISONAL PEER REVIEWED TOXICITY INFORMATION FOR IRON (CASRN 7439-89-6) AND COMPOUNDS
Derivation of Subchronic and Chronic Oral RfDs

Background

On December 5, 2003, the U.S. Environmental Protection Agency's (EPA's) Office of Superfund Remediation and Technology Innovation (OSRTI) revised its hierarchy of human health toxicity values for Superfund risk assessments, establishing the following three tiers as the new hierarchy:

1. EPA's Integrated Risk Information System (IRIS).

2. Provisional Peer-Reviewed Toxicity Values (PPRTV) used in EPA's Superfund Program.

3. Other (peer-reviewed) toxicity values, including:

   - Minimal Risk Levels produced by the Agency for Toxic Substances and Disease Registry (ATSDR),
   - California Environmental Protection Agency (CalEPA) values, and
   - EPA Health Effects Assessment Summary Table (HEAST) values.

A PPRTV is defined as a toxicity value derived for use in the Superfund Program when such a value is not available in EPA's Integrated Risk Information System (IRIS). PPRTVs are developed according to a Standard Operating Procedure (SOP) and are derived after a review of the relevant scientific literature using the same methods, sources of data, and Agency guidance for value derivation generally used by the EPA IRIS Program. All provisional toxicity values receive internal review by two EPA scientists and external peer review by three independently selected scientific experts. PPRTVs differ from IRIS values in that PPRTVs do not receive the multi-program consensus review provided for IRIS values. This is because IRIS values are generally intended to be used in all EPA programs, while PPRTVs are developed specifically for the Superfund Program.

Because science and available information evolve, PPRTVs are initially derived with a three-year life-cycle. However, EPA Regions or the EPA Headquarters Superfund Program sometimes request that a frequently used PPRTV be reassessed. Once an IRIS value for a specific chemical becomes available for Agency review, the analogous PPRTV for that same chemical is retired. It should also be noted that some PPRTV manuscripts conclude that a PPRTV cannot be derived based on inadequate data.

Disclaimers

Users of this document should first check to see if any IRIS values exist for the chemical of concern before proceeding to use a PPRTV. If no IRIS value is available, staff in the regional Superfund and RCRA program offices are advised to carefully review the information provided in this document to ensure that the PPRTVs used are appropriate for the types of exposures and circumstances at the Superfund site or RCRA facility in question. PPRTVs are periodically updated; therefore, users should ensure that the values contained in the PPRTV are current at the time of use.

It is important to remember that a provisional value alone tells very little about the adverse effects of a chemical or the quality of evidence on which the value is based. Therefore, users are strongly encouraged to read the entire PPRTV manuscript and understand the strengths and limitations of the derived provisional values. PPRTVs are developed by the EPA Office of Research and Development's National Center for Environmental Assessment, Superfund Health Risk Technical Support Center for OSRTI. Other EPA programs or external parties who may choose of their own initiative to use these PPRTVs are advised that Superfund resources will not generally be used to respond to challenges of PPRTVs used in a context outside of the Superfund Program.

Questions Regarding PPRTVs

Questions regarding the contents of the PPRTVs and their appropriate use (e.g., on chemicals not covered, or whether chemicals have pending IRIS toxicity values) may be directed to the EPA Office of Research and Development's National Center for Environmental Assessment, Superfund Health Risk Technical Support Center (513-569-7300), or OSRTI

INTRODUCTION

A reference dose (RfD) for iron is not available on the Integrated Risk Information System (IRIS) (U.S. EPA, 2006) or the Drinking Water Standards and Health Advisories list (U.S. EPA, 2005). The Health Effects Assessment Summary Tables (HEAST) (U.S. EPA, 1997) reported that data regarding iron were inadequate for quantitative risk assessment. The Chemical Assessment and Related Activities (CARA) list (1991, 1994) includes a Health Effects Assessment (HEA) for Iron and Compounds (U.S. EPA, 1984) that found no reliable quantitative oral toxicity data. Iron has not been the subject of a toxicological review by the Agency for Toxic Substances Disease Registry (ATSDR) (2005) or the World Health Organization (WHO) (2005). Monographs by the International Agency for Research on Cancer (IARC) (1972, 1987), toxicity reviews by Jacobs (1977), Bothwell et al. (1979), Lauffer (1991) and Grimsley (2001), a review on dietary iron by the National Academy of Sciences (NAS) (2001), and the National Toxicology Program (NTP) (2001, 2005) management status report and chemical repository summary were consulted for relevant information. The NAS (2001) derived a Tolerable Upper Intake (TUI) level of 45 mg iron/day. The TUI is based on a minimal LOAEL of 70 mg/day (60 mg iron as ferrous fumerate plus 11 mg/day of dietary iron) identified by Frykman et al. (1994) for gastrointestinal effects and an uncertainty factor of 1.5 for use of a minimal LOAEL; a higher

uncertainty factor was not used since the nature of the observed gastrointestinal effects was considered to be self-limiting. The U.S. Food and Drug Administration (FDA) promulgated a Rule in 1997 for labeling of iron-containing dietary supplements for the prevention of accidental poisoning in children (U.S. FDA, 1997). The Rule, as modified in 2003, does not contain specific exposure limits (U.S. FDA, 2003). In general, the FDA follows the NAS guidance on exposure limits for toxicity of essential elements, such as iron. Previous literature searches were conducted through September, 2001 as follows: TOXLINE (oral and inhalation toxicity and cancer from 1983 - September, 2001); CANCERLIT (1990 - September, 2001); MEDLINE (1991 - September, 2001); TSCATS, RTECS, DART/ETICBACK, EMIC/EMICBACK, HSDB, GENETOX, and CCRIS. Update literature searches were performed in October, 2005 in MEDLINE, TOXLINE (NTIS subfile), TOXCENTER, TSCATS, CCRIS, DART/ETIC, GENETOX, HSDB, RTECS and Current Contents.

REVIEW OF PERTINENT LITERATURE

Iron is an essential element and deriving a risk assessment value for such chemicals poses a special problem in that the dose-adversity curve is "U-shaped". Thus, the risk value must be protective against deficiency as well as toxicity. The NAS (2001) has established guidelines for iron intake that take into account physiological differences during different life stages. For non-breast-fed infants aged 0-6 months, the NAS (2001) established a daily adequate intake (AI) for iron of 0.27 mg/day (0.04 mg/kg-day for infants 2-6 months old) based on the daily amount of iron secreted in human milk; breast-fed infants typically receive only 0.15 to 0.3 mg Fe/day. The NAS (2001) Dietary Reference Intakes (DRIs) for children are as follows: 11 mg/day (1.2 mg/kg-day) for infants between the ages of 7 and 12 months, 7 mg/day (0.54 mg/kg-day) for children aged 1-3 years, 10 mg/day (0.45 mg/kg-day) for ages 4-8 years, 8 mg/day (0.2 mg/kg-day) for ages 9-13 years and 11 mg/day (0.17 mg/kg-day) for boys and 15 mg/day (0.26 mg/kg-day) for girls aged 14-18 years. The DRI for men aged 19 years and above is 8 mg/day (0.11 mg/kg-day). The DRI for non-pregnant women is 18 mg/day (0.29 mg/kg-day) for ages between 19 and 50 years and 8 mg/day (0.13 mg/kg-day) for ages 51 years and older. The DRI for pregnant women is 27 mg/day (0.37 mg/kg-day for those aged 14-18 years and 0.35 mg/kg-day for those aged 19-50 years). The DRI during lactation is 10 mg/day (0.18 mg/kg-day) for women aged 14-18 years and 9 mg/day (0.15 mg/kg-day) for women aged 19-50 years.

According to the Centers for Disease Control and Prevention (CDC, 1998; CDC, 2005), iron deficiency is one of the most common known forms of nutritional deficiency. Its prevalence is highest among young children and women of childbearing age, particularly pregnant women. In children, iron deficiency causes developmental delays and behavioral disturbances, and in pregnant women, it increases the risk for a preterm delivery and delivering a low-birthweight baby. Young children are at great risk of iron deficiency because of rapid growth and increased iron requirements. Iron deficiency can occur due to lack of iron in the diet. If this continues, anemia results. Anemia is a manifestation of iron deficiency when it is relatively severe. Iron deficiency anemia significantly impairs mental and psychomotor development in infants and children. Although iron deficiency can be reversed with treatment, the reversibility of the mental and psychomotor impairment is not yet clearly understood. Thus, prevention and treatment need to be emphasized more than detection. In addition, iron deficiency increases a child's

susceptibility to lead toxicity. Lead replaces iron in the absorptive pathway when iron is unavailable.

In humans and other animals, levels in the body are regulated primarily through changes in the amount of iron absorbed by the gastrointestinal mucosa. The absorption of dietary iron is influenced by body stores, by the amount and chemical nature of iron in ingested food and by a variety of dietary factors that increase or decrease the availability of iron for absorption (Hillman, 2001; Santi and Masters, 2001). Iron contained in meat protein (hemoglobin and myoglobin) is absorbed intact without first being broken down to elemental iron. Non-heme iron must first be reduced to ferrous iron (Fe^{2+}) before it can be absorbed. Ferrous iron is transported across intestinal mucosal cells by active transport with the rate of transport inversely related to body iron stores. Depending upon the iron status of the body, iron is stored bound to ferritin within mucosal cells and macrophages in the liver, spleen and bone, or is transported in the plasma bound to transferrin. Serum levels of ferritin and transferrin, along with several red blood cell parameters, can be used clinically to evaluate iron balance. Although iron absorption is regulated, excessive accumulation of iron in the body resulting from chronic ingestion of high levels of iron cannot be prevented by intestinal regulation and humans do not have a mechanism to increase excretion of absorbed iron in response to elevated body levels (NAS, 1989, 2001).

Human Studies

Acute Exposure

Information on acute oral toxic doses of iron in humans is available from numerous case reports of ingestion by children, but values vary because it is difficult to obtain accurate estimates of the amount taken in most overdose situations. Reviews of these case reports indicate that doses in the range of 200-300 mg iron/kg are generally considered lethal (Arena, 1970; Krenzelok and Hoff, 1979; NRC, 1979; Engle et al., 1987; Mann et al., 1989; Klein-Schwartz et al., 1990).

Therapeutic Studies

Ferrous salts are administered orally for the therapeutic treatment of iron deficiency. The oral absorption of ferrous iron supplements is considered to be essentially the same for all ferrous salts (e.g., sulfate, fumarate, succinate and gluconate) and is approximately three times greater than that of ferric (Fe^{3+}) salts (Hillman, 2001); thus, ferric iron is not used therapeutically. Constipation and other gastrointestinal effects, including nausea, vomiting, diarrhea and gastrointestinal pain are commonly associated with administration of oral ferrous salt supplements (Hillman, 2001; Santi and Masters, 2001). Severity of effects is variable, ranging from mild to severe, and depends upon dose and individual susceptibility. The onset of symptoms typically occurs at the initiation of treatment and continues throughout the duration of treatment. Although there is no indication that the severity of gastrointestinal effects varies over the course of treatment, severity is decreased in some patients when iron supplements are administered with food (Hillman, 2001; Santi and Masters, 2001). For most patients, iron deficiency is reversed within six months of treatment, thus limiting the duration of exposure.

The mechanism of iron-induced gastrointestinal toxicity is not established, although it is postulated that adverse effects are due to irritant effects of the free iron ion on the gastric muscosa (Liguori, 1993). The role of absorbed iron in the development of gastrointestinal adverse effects is unknown. The adverse effects of exposure to oral iron supplements has been investigated in several studies (Blot et al., 1981; Brock et al., 1985; Coplin et al., 1991; Fryklman et al., 1994; Hallberg et al., 1966; Liguori, 1993).

Frykman et al. (1994) evaluated the adverse effects of daily oral therapy with iron fumarate in a double-blind, crossover, placebo-controlled study in Swedish male [n=25; mean age 45 years (range 40-52)] and female [n=23; mean age 41 years (range 34-45)] adult blood donors. Study subjects were administered 60 mg elemental iron as a daily dose of iron fumarate for one month, with each study subject serving as their own placebo control. Compared to the placebo treatment period, the percentage of subjects reporting constipation (placebo 20%, ferrous fumarate 35%, $p<0.05$) and total gastrointestinal symptoms (nausea, obstipation, gastric pain and diarrhea (placebo 14%, ferrous fumarate 25%, $p<0.01$) was significantly increased during ferrous fumarate treatment. Although the severity of gastrointestinal effects was graded as minor in most study subjects, four subjects withdrew from the study due to severe gastrointestinal symptoms associated with iron fumarate. In a matched group of 49 adults taking a daily combination supplement of porcine-derived heme-iron and iron fumarate containing a total daily supplement of 18 mg iron/per day, the frequency of gastrointestinal symptoms was not increased compared to placebo. No differences in therapeutic efficacy, as measured by serum ferritin and hemoglobin levels, were observed between the non-heme iron and heme-iron treatment groups.

Adverse effects of four oral iron preparations were evaluated in 1496 male and female adult blood donors in a series of double-blind, placebo controlled trials (Hallberg et al., 1966). The following treatment groups were compared: (1) placebo (195 subjects) and ferrous sulfate (198 subjects; 222 mg elemental iron/day); (2) placebo (199 subjects), ferrous sulfate (120 subjects; 222 mg elemental iron/day), ferrous fumarate (118 subjects, 222 mg elemental iron/day), and ferrous gluconate (120 subjects; 222 mg elemental iron/day); and (3) placebo (200 subjects), ferrous sulfate (195 subjects; 180 mg elemental iron/day), ferrous glycine sulfate (200 subjects; 180 mg elemental iron/day), and ferrous gluconate (196 subjects; 180 mg elemental iron/day). Treatments were administered for two weeks. For all iron treatments, the frequency of adverse gastrointestinal effects was significantly increased compared to the matched placebo group ($p<0.05$). Adverse effects reported include constipation, diarrhea, heartburn, nausea and epigastric pain. No statistically significant differences in the frequency of adverse effects were observed between iron treatments for subjects receiving 222 mg elemental iron/day or between iron treatments for subjects receiving 180 mg elemental iron/day. In the seven iron treatment groups, the percentage of subjects reporting gastrointestinal effects ranged from 22.9% in the 222 mg ferrous sulfate group to 31.5% in the 222 mg ferrous gluconate group. In the three placebo treatment groups, the percentage of subjects reporting gastrointestinal effects ranged from 12.4 to 13.6%. Although statistical comparisons were not made between the 180 and 222 mg iron/day treatments, the frequency of adverse effects was similar for all iron treatment groups.

Gastrointestinal symptoms were reported in pregnant women treated daily with oral iron supplements containing 105 mg elemental iron and 500 mg ascorbic acid (55 women) or 105 mg

elemental iron, 500 mg ascorbic acid and 350 mg folic acid (54 women) during the third trimester of pregnancy (Blot et al., 1981). The form of iron was not reported. No placebo control group was included. Gastrointestinal adverse effects reported include nausea, diarrhea, constipation and epigastric pain. Approximately 16% of all patients reported minor gastrointestinal symptoms, 14% reported severe effects and 6% stopped treatment due to adverse effects. Adverse effects occurred with approximately the same frequency in the two treatment group, although data were not reported.

The tolerability of iron protein succinylate and ferrous sulfate were compared in a double-blind clinical trial in 1095 patients with iron deficiency (Liguori, 1993). Patients received daily treatment with a controlled-release formulation of ferrous sulfate containing 105 mg elemental iron (64 males and 485 females) or iron protein succinylate containing 120 mg elemental iron (55 males and 491 females) for 60 days. No placebo control group was included. In the ferrous sulfate group, 26.3% of patients reported adverse gastrointestinal effects (heartburn, epigastric pain, constipation and abdominal pain), compared to 11.5% of patients treated with iron protein succinylate ($p<0.05$).

The adverse effects of oral treatment with a conventional ferrous sulfate tablet were compared to a ferrous sulfate wax-matrix tablet in a single-blind, parallel group study in 543 subjects (Brock et al., 1985). No placebo control group was included. Subjects were administered a conventional ferrous sulfate table containing 50 mg elemental iron/day (272 subjects) or a sulfate wax-matrix tablet containing 50 mg elemental iron/day (271 subjects) for 56 days. Approximately 45% of subjects treated with conventional ferrous sulfate reported moderate-to-severe gastrointestinal effects, including abdominal discomfort, nausea, vomiting, constipation and diarrhea, compared to approximately 17% of subjects treated with the ferrous sulfate wax-matrix preparation, a statistically significant difference ($p<0.001$).

The tolerability of ferrous sulfate (50 mg elemental iron/day) and bis-glycino iron II (50 mg elemental iron/day) was compared in a double-blind, crossover trial in 42 women (Coplin et al., 1991). The treatment period for each iron supplement was two weeks. No placebo treatment period was included. The frequency of adverse gastrointestinal effects (abdominal pain, bloating, constipation, diarrhea and nausea) was similar for the two treatments, with 54% and 59% of subjects reporting gastrointestinal symptoms during treatment with bis-glycino iron II and ferrous sulfate, respectively. The difference between treatments was not statistically significant.

Effects of iron therapy on the upper gastrointestinal tract were evaluated in 14 healthy volunteers [13 women, 1 man; mean age 29 years (range: 24-48 years)] who were instructed to ingest 325 mg tablets of ferrous sulfate (119.5 mg elemental iron) three times/day before meals (358.5 mg elemental iron/day) for 2 weeks (Laine et al., 1988). Evaluation consisted of a gastrointestinal symptom survey, qualitative (Hemoccult) and quantitative (HemoQuant; mg mercury/g stool) testing for fecal blood loss, endoscopy of the upper gastrointestinal tract and histological examination of pinch biopsies of the gastric body, antrum and duodenum. Based on actual average ingestion of 2.5 tablets/day (2-week study) and 2.6 tablets/day (1-week study) and a reference human body weight of 70 kg (U.S. EPA, 1987), the estimated doses consumed by the subjects were 4.3 and 4.4 mg iron/kg-day, respectively, in addition to dietary iron. Compared to

baseline measurements in the two weeks prior to treatment, all subjects had significantly increased ($p<0.05$) dark brown-black stools and symptoms of nausea and vomiting during the treatment period, but not abdominal pain. Hemoglobin levels in stool did not change significantly after iron treatment. Endoscopic examination showed a significant ($p=0.003$) increase in abnormalities in the stomach, but not duodenum, after therapy. These changes consisted of erythema, small areas of subepithelial hemorrhage and solitary antral erosions in nine, six and two subjects, respectively, and were considered only minimally abnormal. No treatment-related histological changes were observed. Although it was speculated that the changes in the stomach could represent a mild form of iron poisoning, the investigators concluded that the treatment caused mild endoscopic abnormalities of uncertain clinical significance in the stomach. Evidence for iron overload (tissue biopsies or hematologic iron status indices) was not examined. Considering additional dietary exposure, an exposure level of about 4.3 mg/kg-day represents, at worst, a minimal LOAEL.

Adverse developmental effects in humans have not been associated with the ingestion of supplemental iron during pregnancy. As indicated above, NAS (2001) recommended that pregnant women supplement their diets with 27 mg iron/day (0.35 mg/kg-day). McElhatton et al. (1991) reported on 49 women who took an overdose of a simple iron preparation (53%) or iron with folate preparation (47%). In 48 of the women, the amount of iron ingested was known; 28 took > 1.2 g and the remainder took $\leq$ 1.2 g. There were 25 women who received chelation treatment with desferrioxamine (DFO) and 12 who received an emetic. Maternal toxicity, consisting of nausea, vomiting, hematoemesis, abdominal pain and diarrhea, was observed in 35 of the women. Two spontaneous abortions occurred and there were three premature deliveries. One of the spontaneous abortions and the premature deliveries were not related to the iron overdose. It is not known if the other spontaneous abortion occurring at 22 weeks (3 weeks after the overdose) was caused by the iron overdose. No conclusions on the developmental toxicity of iron can be made.

Chronic Exposure

While chronic iron toxicity occurs in people with genetic metabolic disorders resulting in excessive iron absorption or abnormal hemoglobin synthesis, or who receive frequent blood transfusions (Jacobs, 1977; Bothwell et al., 1979), there is a long-standing controversy as to whether a chronic overload due to oral intake is possible in individuals with a normal ability to control iron absorption (Hillman and Finch, 1985). Nevertheless, "the cumulative experience in human subjects suffering from iron overload of various etiologies strongly suggests that iron is noxious to tissues [when]...present in parenchymal cells...for a sufficiently long period of time" (Bothwell et al., 1979).

Looker et al. (1988) made comparisons of dietary iron intake and biochemical indices of iron status based on values taken from the second National Health and Nutrition Examination Survey (NHANES II) data base[1]. NHANES II was a probability sample of the noninstitutionalized U.S. population aged 6 months to 74 years, conducted between 1976 and

[1] The latest version of this data base, NHANES III (1984-1988) evaluated 30,000 subjects aged 2 months and above (NAS, 2001). Despite minor differences in the data sets, the conclusions drawn by Looker et al. (1988) based on NHANES II appear to be valid for the NHANES III data.

1980 by the National Center for Health Statistics. These data suggest that normal intake of iron by men 16-74 years old exceeds the DRI, and that iron intake is somewhat lower than the DRI for women younger than 51 years. Concomitant with the study of dietary intake, the NHANES II measured the iron status of these populations. The percent serum transferrin saturation, a measure of the residual capacity of the iron transport system to process potential variations in iron from dietary intake or catabolized body stores, ranged from 24% saturation for pre- and post-menopausal women not using iron supplements to 29% saturation for adult male supplement users. These values are within the normal range (20-40%). The Looker et al. (1988) evaluation of the NHANES II iron status data concerned iron deficiencies, only, and did not address iron overload directly. However, iron overload conditions would likely be evidenced by increased saturation of serum transferrin and increased serum ferritin concentrations, which were also within the normal range. Therefore, the corresponding dietary intakes are presumed to represent chronic NOAELs. Looker et al. (1988) estimated daily iron intakes ranging from 10.0 for elderly women to 18.7 mg/day for young adult men in the study population. These daily intakes correspond to a range of about 0.15 to 0.27 mg/kg-day, depending on assumptions of average body weight. Taking the highest intake level of 18.7 mg/day and a body weight of 70 kg, a NOAEL of 0.27 is established for chronic iron toxicity.

Hemosiderosis (or siderosis) and iron overload are increases in tissue iron or a general increase in iron stores without associated tissue damage (Bothwell et al., 1979; Jacobs, 1977). Hemochromatosis describes massive iron overload (15 g of body iron stores or greater) together with cirrhosis and/or other tissue damage attributable to iron. Although focal deposits of iron may occur in any part of the body where red cells are extravasated, the clinical syndrome of hemochromatosis typically involves damage to the hepatic parenchyma (particularly fibrosis), heart (cardiac dysfunction including failure) and endocrine glands (particularly hypogonadism). Pancreatic iron deposition is common and massive deposits may be associated with fibrosis and diabetes. A number of studies involving chronic oral administration of iron to animals have been designed in an attempt to identify an animal model for hemochromatosis. Most of these studies have been negative (Bothwell et al., 1979; NRC, 1979). Animal studies involving parenteral administration of iron have been generally negative as well, even though parenteral routes bypass the mechanisms that regulate absorption of iron from the gastrointestinal tract.

Chronic iron toxicity has been observed in people with idiopathic hemochromatosis (a genetic metabolic disorder resulting in excessive iron absorption), abnormalities of hemoglobin synthesis (e.g., thalassemia) or various anemic states (e.g., sideroblastic anemia), frequent blood transfusions or a combination of these conditions (Jacobs, 1977; Bothwell et al., 1979). Chronic hemochromatosis has also occurred among the South African Bantu population from an excessive intake of absorbable iron in an alcoholic beverage.

Habitual excessive intake of iron by the Bantus is attributed to consumption of home-brewed Kaffir beer, which was contaminated by iron vessels during brewing (Bothwell and Bradlow, 1960; Bothwell et al., 1964). The beer's high acidity (pH 3-3.5) enhanced iron leaching from the vessels. The iron in the beer is readily assimilable (i.e., ionizable) due to the acidity and presence of iron-complexing ligands such as fructose, and is absorbed to approximately the same degree as ferric chloride. The alcohol content of the beer is also believed to contribute to the bioavailability of the iron (Jacobs, 1977; Finch and Monsen, 1972). Based

primarily on drinking habits and analyses of beer samples, the estimated average dietary iron intake of the Bantu men ranged from 50-100 mg/day from beer alone (Bothwell et al., 1964). Using a reference body weight of 70 kg (U.S. EPA, 1987), this range corresponds to 0.7-1.4 mg/kg-day. Histological examinations of the liver of 147 Bantus (129 male, 18 female) ranging in age from 11-70 years (most were between 20 and 50 years old) that died from acute traumatic causes were performed (Bothwell and Bradlow, 1960). Varying degrees of hepatic siderosis were observed in 89% of the cases; the degree tended to increase with age 40-50 years or less. The siderosis was mild in 59% and severe in 19% of the cases, respectively. There was a close correlation between hepatic iron concentration and portal fibrosis and cirrhosis. Although the overall prevalence was low (15.6% fibrosis and 1.4% cirrhosis), all 11 subjects with the highest iron concentrations (>2.0% dry weight of liver) showed either fibrosis or cirrhosis. Histological examination of the spleen (50 subjects) also showed siderosis and unspecified histological changes. Malnutrition and alcoholism could have played a role in the etiology of the hepatic and splenic siderosis in the Bantus. A NOAEL in the range of 0.7 - 1.4 mg/kg-day is indicated but may be low given the likely higher bioavailability of iron in the beer than for normal dietary exposure. Given the generally poor nutritional health status of this population, the relevance of this study for application to the U.S. population is questionable.

Ethiopia reportedly has the highest per capita iron intake in the world, with an average daily intake of 471 mg iron/day (range 98-1418 mg/day; 1.4-20.3 mg iron/kg-day assuming 70 kg body weight) (Roe, 1966; Hofvander, 1968). Increased stored iron in the liver and adverse health effects have not been observed due to low bioavailability of the iron in Ethiopian food.

A few studies have suggested that high iron intake may be a risk factor for myocardial infarction (Salonen et al., 1992; Lauffer, 1991; Sullivan, 1992). Five other large studies found no association between serum ferritin levels and coronary heart disease (NAS, 2001). Various other measures of iron status (serum transferrin saturation, serum iron concentration and total iron-binding capacity) have been examined for a possible link to cardiovascular disease in prospective cohort studies, but results overall have been characterized as contradictory (Meyers, 1996; NAS, 2001). The NAS (2001) concluded that the available evidence "does not provide convincing support for a causal relationship" between the level of dietary iron intake and the risk for coronary heart disease, although iron cannot be definitively excluded as a risk factor.

Animal Studies

Repeated-dose oral studies in experimental animals found no significant effect of treatment with inorganic iron compounds. No treatment-related adverse changes in clinical signs, body or organ weights, food consumption or histopathology were observed in male Sprague-Dawley rats that had daily dietary intakes of 35, 70 or 140 mg of iron (as $FeSO_4$ or FeEDTA) per kg for up to 61 days (Appel et al., 2001). In male and female F344 rats that were exposed to drinking water containing 0.25 or 0.5% ferric chloride ($FeCl_3 \cdot 6H_2O$) for 104 weeks, there were no dose-related effects other than reduced water intake (possibly affected by palatability) and body weight gain (Sato et al., 1992). In the latter study, the iron intakes were 58 or 110 mg/kg-day in males and 65 or 116 mg/kg-day in females.

No treatment-related teratogenic or embryotoxic effects were observed in rats given 2.7 mg iron/kg-day as ferric chloride on gestational days 6-15 (Nolen et al., 1972), or in rats and mice given 24-76 mg iron/kg-day as ferrous sulfate for 6 days during gestation (days unspecified) (Tadokoro et al., 1979). Some embryonic mortality (numbers and species not reported) occurred in the latter study at 240 mg iron/kg-day.

DERIVATION OF PROVISIONAL SUBCHRONIC AND CHRONIC RfDs FOR IRON

Iron is an essential element, as such, the RfD must be protective against both toxicity and deficiency. Using the values for dietary intake and iron status indices taken from the second National Health and Nutrition Examination Survey (NHANES II) data base, it is possible to establish a NOAEL for chronic toxicity. Looker et al. (1988) made comparisons of dietary iron intake and biochemical indices of iron status using data from NHANES II. The average intakes of iron ranged from 0.15 to 0.27 mg/kg-day. The serum ferritin levels and percent serum transferrin saturation were within the normal range. Thus, intake levels of 0.15-0.27 mg/kg-day are sufficient to protect against iron deficiency. However, the NHANES II data do not provide information to identify daily dietary iron intakes associated with toxicity. Therefore, daily dietary iron intakes were not considered as the basis for the p-RfD.

Most of the quantitative chronic oral toxicity data for iron have been obtained from studies of the Bantu population of South Africa. These data indicate that intakes in the range of 0.7-1.4 mg iron/kg-day in home-brewed beer are associated with hemosiderosis and liver cirrhosis (Bothwell and Bradlow, 1960; Bothwell et al., 1964). However, confounding factors such as malnutrition and unusually high iron bioavailability due to the high acidity and ethanol in the beer preclude use of these data for risk assessment. Much higher dietary intakes (average 6.7 mg/kg-day) of less soluble forms of iron are tolerated in non-western diets as indicated by studies of populations in Ethiopia. Thus, although toxicity associated with iron overload due to chronic oral intake can be demonstrated qualitatively or even semiquantitatively, assignment of a precise LOAEL for normal individuals consuming western diets is compromised by studies containing confounding factors.

Gastrointestinal toxicity, which is commonly associated with the therapeutic use of iron supplements, was identified as the critical effect for the basis of the provisional subchronic and chronic RfDs. The most frequently reported symptoms include epigastric pain, nausea, vomiting, constipation and diarrhea. Several prospective clinical trials in healthy subjects and iron-deficient patients identify a LOAEL for gastrointestinal toxicity of 50 to 180 mg elemental iron/day; NOAELs were not established (Blot et al., 1981; Brock et al., 1985; Coplin et al., 1991; Frykman et al., 1994; Hallberg et al., 1966; Liguori, 1993). The treatment durations in these studies range from 2 weeks to approximately 3 months. Although no chronic exposure studies reporting gastrointestinal toxicity were identified, clinical experience with iron supplements indicates that gastrointestinal effects are associated with oral iron therapy, regardless of the duration of treatment and that symptom intensity does not change over the course of treatment (Hillman, 2001; Santi and Masters, 2001). This observation suggests that the response is related to the concentration of iron in the intestinal tract and not to the time-integrated dose. Therefore,

gastrointestinal toxicity is considered as the critical effect for both the subchronic and chronic p-RfDs.

The lowest LOAEL of 50 mg elemental iron/day for gastrointestinal toxicity associated with iron supplements was reported in two studies that did not use a placebo-controlled design (Brock et al., 1985; Coplin et al., 1991); therefore, data were not considered suitable for derivation of the p-RfD. The placebo-controlled, cross-over design study by Frykman et al. (1994) reporting a LOAEL of 60 mg/day in Swedish men and women was identified as the critical study. Results of this study show that daily treatment with ferrous fumarate (60 mg elemental iron/day) for one month produced a statistically significant increase in gastrointestinal effects compared to placebo. To determine the LOAEL for total daily iron intake, the LOAEL for daily supplementation with ferrous fumarate of 60 mg elemental iron/day was added to the estimated mean dietary intake for six European countries of 11 mg elemental iron/day (NAS, 2001) for a total daily iron intake of 71 mg elemental iron/day. Based on a reference body weight of 70 kg (U.S. EPA, 1987), the LOAEL for gastrointestinal effects for total daily iron intake is 1 mg elemental iron/kg-day. This LOAEL is considered to be a minimal LOAEL because gastrointestinal effects were characterized by most study participants as minor in severity.

The provisional subchronic and chronic RfD for iron was derived from the LOAEL of 1 mg/kg-day for total daily iron intake for adverse gastrointestinal effects as follows:

$$\begin{aligned} \textbf{p-RfD (subchronic and chronic)} &= \textbf{LOAEL} \div \textbf{UF} \\ &= \textbf{1 mg/kg-day} \div \textbf{1.5} \\ &= \textbf{0.7 mg/kg-day} \end{aligned}$$

Dividing the LOAEL of 1 mg/kg-day by an uncertainty factor of 1.5 yields a subchronic and chronic p-RfD of 0.7 mg/mg-day. The uncertainty factor of 1.5 includes the individual uncertainty factors of 1.5 for use of a minimal LOAEL, 1 for sensitive individuals, 1 for less than lifetime exposure, and 1 for an adequate data base. An uncertainty factor of 1.5 was applied to account for extrapolation from a minimal LOAEL to a NOAEL for a non-serious effect. A higher uncertainty factor for use of a minimal LOAEL was not used since the observed gastrointestinal effects are not considered serious and are reversible when exposure is discontinued. Furthermore, gastrointestinal symptoms are not associated with dietary intake of similar levels of iron (NAS, 2001). Because individuals sensitive to gastrointestinal symptoms are considered to be included in the studies investigating effects of therapeutic iron; an uncertainty factor of 1 for sensitive individuals results. An uncertainty factor of 1 was used to account for less than lifetime exposure. Although exposure duration in the Frykman et al. (1994) study was only one month, there is no evidence to suggest that symptoms increase with longer exposure periods. An uncertainty factor of 1 was used to reflect an adequate database in humans, due to the extensive use of therapeutic iron.

Except for individuals with disorders of iron metabolism, little information is available on the long-term systemic toxicity of orally ingested iron. This assessment, therefore, focuses more on what is known to be a safe oral intake of iron for the general human population (i.e., apparently healthy normal individuals). The provisional reference dose is estimated to be an

intake for the general population that is adequately protective from adverse health effects. Further, it is also important to note that individual requirements for, as well as adverse reactions to, iron may be highly variable. Some individuals may, in fact, consume a diet that contributes more than the provisional reference dose, without any cause for concern. In addition, specific population subgroups may have higher nutritional requirements than the provisional RfD would provide. The p-RfD may not be protective of individuals with inherited disorders of iron metabolism or other conditions which affect iron homeostasis.

This assessment is essentially the same as that proposed by Stifelman et al. (2005).

PROVISIONAL PEER REVIEWED TOXICITY VALUES FOR *p*-ISOPROPYLTOLUENE (CASRN 99-87-6) Derivation of a Chronic Oral RfD

Background

On December 5, 2003, the U.S. Environmental Protection Agency's (EPA's) Office of Superfund Remediation and Technology Innovation (OSRTI) revised its hierarchy of human health toxicity values for Superfund risk assessments, establishing the following three tiers as the new hierarchy:

1. EPA's Integrated Risk Information System (IRIS).

2. Provisional Peer-Reviewed Toxicity Values (PPRTV) used in EPA's Superfund Program.

3. Other (peer-reviewed) toxicity values, including:

   - Minimal Risk Levels produced by the Agency for Toxic Substances and Disease Registry (ATSDR),
   - California Environmental Protection Agency (CalEPA) values, and
   - EPA Health Effects Assessment Summary Table (HEAST) values.

A PPRTV is defined as a toxicity value derived for use in the Superfund Program when such a value is not available in EPA's Integrated Risk Information System (IRIS). PPRTVs are developed according to a Standard Operating Procedure (SOP) and are derived after a review of the relevant scientific literature using the same methods, sources of data, and Agency guidance for value derivation generally used by the EPA IRIS Program. All provisional toxicity values receive internal review by two EPA scientists and external peer review by three independently selected scientific experts. PPRTVs differ from IRIS values in that PPRTVs do not receive the multi-program consensus review provided for IRIS values. This is because IRIS values are generally intended to be used in all EPA programs, while PPRTVs are developed specifically for the Superfund Program.

Because science and available information evolve, PPRTVs are initially derived with a three-year life-cycle. However, EPA Regions (or the EPA HQ Superfund Program) sometimes request that a frequently used PPRTV be reassessed. Once an IRIS value for a specific chemical becomes available for Agency review, the analogous PPRTV for that same chemical is retired. It should also be noted that some PPRTV manuscripts conclude that a PPRTV cannot be derived based on inadequate data.

Disclaimers

Users of this document should first check to see if any IRIS values exist for the chemical of concern before proceeding to use a PPRTV. If no IRIS value is available, staff in the regional Superfund and RCRA program offices are advised to carefully review the information provided in this document to ensure that the PPRTVs used are appropriate for the types of exposures and circumstances at the Superfund site or RCRA facility in question. PPRTVs are periodically updated; therefore, users should ensure that the values contained in the PPRTV are current at the time of use.

It is important to remember that a provisional value alone tells very little about the adverse effects of a chemical or the quality of evidence on which the value is based. Therefore, users are strongly encouraged to read the entire PPRTV manuscript and understand the strengths and limitations of the derived provisional values. PPRTVs are developed by the EPA Office of Research and Development's National Center for Environmental Assessment, Superfund Health Risk Technical Support Center for OSRTI. Other EPA programs or external parties who may choose of their own initiative to use these PPRTVs are advised that Superfund resources will not generally be used to respond to challenges of PPRTVs used in a context outside of the Superfund Program.

Questions Regarding PPRTVs

Questions regarding the contents of the PPRTVs and their appropriate use (e.g., on chemicals not covered, or whether chemicals have pending IRIS toxicity values) may be directed to the EPA Office of Research and Development's National Center for Environmental Assessment, Superfund Health Risk Technical Support Center (513-569-7300), or OSRTI.

INTRODUCTION

A subchronic or chronic RfD for *p*-isopropyltoluene (also known as *p*-cymene or *p*-methyl isopropyl benzene) is not available on IRIS (U.S. EPA, 2003), the HEAST (U.S. EPA, 1997), or the Drinking Water Standards and Health Advisories list (U.S. EPA, 2002). One relevant document, the Drinking Water Health Advisory for *p*-Cymene (U.S. EPA, 1987), was located in the CARA list (U.S. EPA, 1991, 1994), but no RfD was derived due to insufficient data. ATSDR (2003), NTP (2003), IARC (2003), and WHO (2003) have not produced documents for this chemical. Literature searches of the following databases were conducted for the period between 1965 through June 2003 to locate relevant studies on *p*-isopropyltoluene: TOXLINE (supplemented with BIOSIS and NTIS updates), CANCERLIT, MEDLINE, CCRIS, GENETOX, HSDB, DART/ETICBACK, EMIC/EMICBACK, RTECS and TSCATS.

Additional literature searches from June 2003 through January 2004 were conducted by NCEA-Cincinnati using MEDLINE, TOXLINE, Chemical and Biological Abstracts databases.

p-Isopropyltoluene is used as an intermediate in the manufacture of *p*-cresol and thymol (HSDB, 2003). It also serves as a component in commercial terpene solvent mixtures and as a component of paint thinners, lacquers, and varnishes. It is found to occur naturally in many arboreous plants and as a constituent of many essential oils, including oils of eucalyptus, lemon, sage, thyme, coriander, star anise, and cinnamon (Browning, 1965; Opdyke, 1974; HSDB, 2003). The FDA (2003) has approved the use of *p*-isopropyltoluene as a synthetic flavoring substance and food additive.

REVIEW OF PERTINENT DATA

Human Studies

No data regarding the toxicity of *p*-isopropyltoluene to humans following chronic or subchronic oral exposure were located. Limited information is available on the acute oral toxicity of *p*-isopropyltoluene in humans. Reports from the early literature indicate that headache, nausea and vomiting occurred in humans following ingestion of *p*-isopropyltoluene, but information on ingested dose levels was not available (Browning, 1965).

p-Isopropyltoluene appears to be a primary skin irritant. Cases of irritation of the skin and mucous membranes have been reported in workers exposed to *p*-isopropyltoluene (Browning, 1965; Carlson, 1946). Contact with the undiluted liquid has been reported to produce dermal erythema, dryness and defatting in humans (Gerarde, 1960). However, 4% *p*-isopropyltoluene in (petroleum jelly) produced no dermal irritation or sensitization in a 48-hour closed-patch maximization test with 25 human volunteers (Kligman, 1972) and no dermal irritation following daily occluded application in diethylphthalate (petroleum jelly) on the backs of 10 human subjects for 10 days (Kligman and Wooding, 1967; Kligman, 1973).

Animal Studies

No data regarding the toxicity of *p*-isopropyltoluene to animals following chronic or subchronic oral exposure were located. However, several brief reports of the effects following acute exposures to *p*-isopropyltoluene were located.

An oral LD_{50} value of 4.75 g/kg (3.72-6.06 g/kg, 95% C.I.) was reported for Osborne-Mendel rats administered single doses of undiluted chemical via intubation and observed for 14 days (Jenner et al., 1964). Clinical signs observed included CNS depression soon after dosing, coma, bloody lacrimation, and diarrhea. The exposed animals appeared irritable and scrawny

through the observation period; the time to death ranged from 4 hours to 12 days. Additional study details were not provided. An oral LD_{50} value of 3 g/kg was reported for white rats administered single doses of *p*-isopropyltoluene via gavage (Du Pont & Co., 1949). Post mortem findings revealed gross and microscopic evidence of gastritis and liver damage. Smyth et al. (1951) reported an oral LD_{50} value of 2.46 g/kg in rats administered single doses of *p*-isopropyltoluene (additional details were not reported). No gross or micropathological findings were reported for six rats given oral doses of 510 mg/kg-day of *p*-isopropyltoluene, 5 days a week, for a total of 10 treatments (Du Pont & Co., 1949). All six rats survived treatment and were sacrificed 11 days after the last treatment. No other effects or study details were provided. A study from the very early literature reported that dogs tolerated daily oral doses of 2 g of *p*-isopropyltoluene, with diarrhea as the only adverse effect (Ziegler, 1873). No other study details were provided.

Intraperitoneal administration of 2.162 g/kg of *p*-isopropyltoluene reportedly induced lethality in the guinea pig (Chassevant and Garnier, 1903). Subcutaneous injection of *p*-isopropyltoluene in rabbits produced hematological changes similar to those produced by xylene that resulted in an increase in immature white cells similar in appearance to human myeloid leukemic cells (Miyamato, 1938; Woronow, 1929). An acute dermal LD_{50} of >5 g/kg was reported for *p*-isopropyltoluene in rabbits (Moreno, 1973). Application of undiluted *p*-isopropyltoluene to intact or abraded skin of rabbits for 24 hours under occlusion was moderately irritating (Moreno, 1973).

No developmental or reproductive toxicity studies of *p*-isopropyltoluene by any route of exposure were located.

Other Studies

p-Isopropyltoluene appears to be well absorbed by the oral route. Eighty and 71% of a single 100 mg/kg gavage dose of *p*-isopropyltoluene in propylene glycol was recovered as urinary metabolites within 48 hours in 3 rats and 3 guinea pigs, respectively (Walde et al., 1983). The remainder reportedly consisted of metabolites excreted in the feces and unextracted urinary material, indicating that at least 70-80% of the administered dose was absorbed.

Studies that have examined the metabolism of *p*-isopropylbenzene in rats and guinea pigs have presented a unified picture of a compound that is subject to considerable metabolic rearrangement. Thus, Walde et al. (1983) identified 18 total urinary metabolites in the oral- and inhalation-exposed rats and guinea pigs, and found that their excretion was nearly complete within 48 hours which amounted to 60-80% of the administered dose. The principal metabolites resulting from oxidation of the isopropyl and/or methyl group in the Walde et al. (1983) study included *p*-isopropyl benzoic acid (cumic acid, 19% of administered dose), 2-*p*-carboxyphenylpropan-1-ol (11%) and 2-*p*-carboxyphenylpropionic acid (16%) in oral-exposed

rats; *p*-isopropylbenzoyl glycine (31%) and 2-*p*-tolylpropan-2-ol (14%) in oral-exposed guinea pigs; 2-*p*-carboxyphenylpropionic acid (15%) in inhalation-exposed rats; and *p*-isopropylbenzoyl glycine (31%) and 2-*p*-tolylpropionic acid (15%) in inhalation-exposed guinea pigs. The remaining metabolites identified by Walde et al. (1983) ranged from trace amounts to 6-9% of the administered dose. In general, both the methyl and isopropyl side groups have been shown to be extensively oxidized in all species tested (Bakke and Scheline, 1970; Ishida et al., 1981; Walde et al., 1983; Matsumoto et al., 1992). The numerous monohydric alcohols, diols, mono- and dicarboxylic acids and hydroxyacids identified in the urine established that oxidation to alcohol with and without further oxidation to the corresponding acid occurred at all possible aliphatic sites (i.e., the three isopropyl carbons and the methyl carbon).

Comparative studies of the *in vivo* metabolism of *p*-isopropyltoluene in Eucalyptus - eating marsupials (the brushtail possum and the koala) and the rat (Boyle et al., 1999, 2000; Southwell et al., 1980) identified a species-specific pattern with a higher level of oxidation of *p*-isopropyltoluene in the marsupials compared with the rat, and a higher level of conjugation of metabolites in the rats compared to the marsupials. *In vitro* studies of *p*-isopropyltoluene metabolism by liver microsomes of the possum, koala, and rat showed that the major metabolite in each species was cuminyl alcohol and that the possum and koala microsomes oxidized cuminyl alcohol to cumic acid (Pass et al., 2002). The rank order of the liver microsomes to metabolize *p*-isopropyltoluene, measured by intrinsic clearance (V_{max}/K_m), was terpene-pretreated possum> possum with standard diet> koala with standard diet> rat with standard diet.

FEASIBILITY OF DERIVING PROVISIONAL SUBCHRONIC AND CHRONIC ORAL RfDs FOR *p*-ISOPROPYLTOLUENE

The available oral toxicity data for *p*-isopropyltoluene indicate that the compound has a low order of acute lethality (rat LD_{50} >2000-4000 mg/kg), with symptoms of CNS depression and gastrointestinal tract irritation at lower dose levels. These findings are supported by limited acute dermal exposure data that show local irritative effects of *p*-isopropyltoluene, and are consistent with the known acute effects of alkyl benzenes in general. No adequate information is available on the subchronic or chronic toxicity of *p*-isopropyltoluene, thereby precluding derivation of a subchronic or chronic p-RfD from the oral data or from inhalation data by route-to-route extrapolation.

There are no data indicating that *p*-isopropyltoluene is metabolized to any compounds that have toxicity data sufficient for risk assessment or into the same metabolites as other alkyl benzenes that have adequate toxicity data. Therefore, in summary, derivation of a p-RfD for *p*-isopropyltoluene is precluded by insufficient toxicity data on either the subject compound or on any of its projected primary metabolites.

PROVISIONAL PEER REVIEWED TOXICITY VALUES FOR *p*-ISOPROPYLTOLUENE (CASRN 99-87-6) Derivation of a Chronic Inhalation RfC

Background

On December 5, 2003, the U.S. Environmental Protection Agency's (EPA's) Office of Superfund Remediation and Technology Innovation (OSRTI) revised its hierarchy of human health toxicity values for Superfund risk assessments, establishing the following three tiers as the new hierarchy:

1. EPA's Integrated Risk Information System (IRIS).

2. Provisional Peer-Reviewed Toxicity Values (PPRTV) used in EPA's Superfund Program.

3. Other (peer-reviewed) toxicity values, including:

   - Minimal Risk Levels produced by the Agency for Toxic Substances and Disease Registry (ATSDR),
   - California Environmental Protection Agency (CalEPA) values, and
   - EPA Health Effects Assessment Summary Table (HEAST) values.

A PPRTV is defined as a toxicity value derived for use in the Superfund Program when such a value is not available in EPA's Integrated Risk Information System (IRIS). PPRTVs are developed according to a Standard Operating Procedure (SOP) and are derived after a review of the relevant scientific literature using the same methods, sources of data, and Agency guidance for value derivation generally used by the EPA IRIS Program. All provisional toxicity values receive internal review by two EPA scientists and external peer review by three independently selected scientific experts. PPRTVs differ from IRIS values in that PPRTVs do not receive the multi-program consensus review provided for IRIS values. This is because IRIS values are generally intended to be used in all EPA programs, while PPRTVs are developed specifically for the Superfund Program.

Because science and available information evolve, PPRTVs are initially derived with a three-year life-cycle. However, EPA Regions (or the EPA HQ Superfund Program) sometimes request that a frequently used PPRTV be reassessed. Once an IRIS value for a specific chemical becomes available for Agency review, the analogous PPRTV for that same chemical is retired. It should also be noted that some PPRTV manuscripts conclude that a PPRTV cannot be derived based on inadequate data.

Disclaimers

Users of this document should first check to see if any IRIS values exist for the chemical of concern before proceeding to use a PPRTV. If no IRIS value is available, staff in the regional Superfund and RCRA program offices are advised to carefully review the information provided in this document to ensure that the PPRTVs used are appropriate for the types of exposures and circumstances at the Superfund site or RCRA facility in question. PPRTVs are periodically updated; therefore, users should ensure that the values contained in the PPRTV are current at the time of use.

It is important to remember that a provisional value alone tells very little about the adverse effects of a chemical or the quality of evidence on which the value is based. Therefore, users are strongly encouraged to read the entire PPRTV manuscript and understand the strengths and limitations of the derived provisional values. PPRTVs are developed by the EPA Office of Research and Development's National Center for Environmental Assessment, Superfund Health Risk Technical Support Center for OSRTI. Other EPA programs or external parties who may choose of their own initiative to use these PPRTVs are advised that Superfund resources will not generally be used to respond to challenges of PPRTVs used in a context outside of the Superfund Program.

Questions Regarding PPRTVs

Questions regarding the contents of the PPRTVs and their appropriate use (e.g., on chemicals not covered, or whether chemicals have pending IRIS toxicity values) may be directed to the EPA Office of Research and Development's National Center for Environmental Assessment, Superfund Health Risk Technical Support Center (513-569-7300), or OSRTI.

INTRODUCTION

A subchronic or chronic RfC for *p*-isopropyltoluene (also known as *p*-cymene or *p*-methyl isopropyl benzene) is not available on IRIS (U.S. EPA, 2003) or in the HEAST (U.S. EPA, 1997). One relevant document, the Drinking Water Health Advisory for *p*-Cymene (U.S. EPA, 1987), was located in the CARA list (U.S. EPA, 1991, 1994). ATSDR (2003), NTP (2003), IARC (2003), and WHO (2003) have not produced documents for this chemical. ACGIH (2003), NIOSH (2003), and OSHA (2003) have not recommended occupational exposure limits for *p*-isopropyltoluene. Literature searches of the following databases were conducted from 1965 through June 2003 to locate relevant studies on *p*-isopropyltoluene: TOXLINE (supplemented with BIOSIS and NTIS updates), CANCERLIT, MEDLINE, CCRIS, GENETOX, HSDB, DART/ETICBACK, EMIC/EMICBACK, RTECS and TSCATS. Additional literature searches

from June 2003 through January 2004 were conducted by NCEA-Cincinnati using MEDLINE, TOXLINE, Chemical and Biological Abstracts databases.

p-Isopropyltoluene is used as an intermediate in the manufacture of *p*-cresol and thymol (HSDB, 2003). It also serves as a component in commercial terpene solvent mixtures and as a component of paint thinners, lacquers, and varnishes. It is found to occur naturally in many arboreous plants and as a constituent of many essential oils, including oils of eucalyptus, lemon, sage, thyme, coriander, star anise, and cinnamon (Browning, 1965; Opdyke, 1974; HSDB, 2003). The FDA (2003) has approved the use of *p*-isopropyltoluene as a synthetic flavoring substance and food additive.

REVIEW OF THE PERTINENT DATA

Human Studies

Few data are available on the inhalation toxicity of *p*-isopropyltoluene in humans. The primary effects of *p*-isopropyltoluene in industrial environments were skin and mucous membrane irritation; however, information on exposure levels was unavailable (Browning, 1965). Systemic effects, including ecchymosis, severe anemia, leucopenia, thrombocytopenia and histopathologic alterations in bone marrow, were reported in a man occupationally exposed to *p*-isopropyltoluene in the paper pulp industry (Carlson, 1946). These changes were possibly indicative of aplastic anemia, but the evidence for a direct association with exposure to *p*-isopropyltoluene was inconclusive (Browning, 1965). No other cases of a "benzene-like" action on the bone marrow following exposure to *p*-isopropyltoluene were reported by Browning (1965) or located in the available literature.

Animal Studies

No toxicity studies of animals chronically exposed by inhalation to *p*-isopropyltoluene were located. Available inhalation toxicity studies are restricted to a study of dogs repeatedly exposed by inhalation and two acute inhalation studies of rats in which neurological endpoints were examined.

In repeated-exposure studies, four dogs (of unspecified breed) were exposed to vapors of *p*-isopropyltoluene at a reported concentration range of 50 to 110 ppm (average 75 ppm) for 6 hours/day, 5 days/week, for one month (Du Pont & Co., 1949). One of the dogs was withdrawn from the experiment after the 12th exposure period due to illness not related to compound exposure. After one month of exposure, the surviving 3 dogs were exposed to concentrations ranging from 75 to 155 ppm (average 100 ppm) for 6 weeks, after which the animals were sacrificed for pathological examination. Another group of four dogs was subsequently exposed

by the same protocol for a total period of 18 weeks to average concentrations of *p*-isopropyltoluene of 50 ppm for the first 40 exposures, 75 ppm for the next 24 exposures, and 160 ppm for the last 28 exposures, after which dogs were sacrificed for pathological examination. The report of the study only referred to the pathological examinations as "gross" and "micropathology," and did not further specify tissues examined or techniques employed. Blood pressure, respiration rate, and body weight were measured at unspecified intervals during exposure. Blood and urine samples were collected at unspecified intervals during exposure; hematologic and chemical parameters that were measured were not specified in the available report, other than red blood cell counts and hemoglobin concentrations. Results were reported only in a summary fashion (the magnitude of exposure-related changes was not reported). Body weights were reportedly unaffected by exposure. Blood pressure depression (compared with pre-exposure patterns) was observed in both groups of dogs during exposure, with some inter-dog variance in whether the reduction was in systolic, diastolic, or pulse pressure. Respiration rates were increased (compared with pre-exposure values) during exposure in the dogs exposed during the first experiment, but not in those exposed in the second experiment. Red blood cell counts during the exposure period were reported as normal in both groups of dogs, but hemoglobin concentrations were reported as "decreased somewhat" in the first dog experiment, but not in the second dog experiment. "No gross or micropathology" attributable to exposure was found in the three dogs that survived the first experiment or in 3 of the 4 dogs that were exposed in the second experiment. The fourth dog in the second experiment had a "filarial infestation" associated with fibrosis and slight congestion of the lungs and zones of fibrosis in the kidney.

Lam et al. (1996) exposed groups of 7, 11, or 12 male Long-Evans rats to *p*-isopropyltoluene vapor at 0, 50, or 250 ppm (0, 275 or 1370 mg/m^3), respectively, 6 hours/day, 5 days/week for 4 weeks, followed by an 8-week recovery period prior to sacrifice. However, the authors largely restricted their observations to the neurochemistry of synaptosomes isolated from whole brain (minus cerebellum), measuring specific amounts of neurotransmitters, such as noradrenaline, dopamine, and 5-hydroxytryptomine, and specific activities of enzymes, such as acetylcholinesterase, butyrylcholinesterase, and lactate dehydrogenase, as a model for *in situ* conditions at the level of the presynaptic nerve terminal. There were no overt clinical signs of toxicity in any of the animals involved in the experiment and no differences in mean body weight between the groups. Similarly, there were no treatment-induced effects on brain weight or protein concentration in whole brain minus cerebellum, cerebellum alone, or whole brain. Though the concentrations of neurotransmitters/g wet weight were the same for each brain fraction irrespective of treatment, the relative yield of synaptosomal protein/unit wet weight of brain was reduced dose-dependently and statistically significant as the concentration of *p*-isopropyltoluene increased. Similarly, potential dose-dependent fluctuations in synaptosomal enzyme activities were observed, though a constant ratio relative to the activity of LDH was maintained across all dose groups. The relative amounts of synaptosomal neurotransmitters compared to enzyme units of LDH in synaptosomal preparations appeared to be unaffected by treatment, although increases in noradrenaline and dopamine were observed relative to

synaptosomal protein. Fluctuations in the relative and absolute amounts of 5-hydroxytryptamine were also observed in relation to treatment, although, as with all these results, their relationship to the neurotoxicity of the compound is unclear. The authors interpreted their results in terms of *p*-isopropyltoluene having the capacity to reduce the density and total number of synapses *in situ*, with functional compensation by concurrent increases in the release of noradrenaline and dopamine from noradrenergic and dopaminergic neurons. However, the authors were unable to link their observed changes to manifest neurotoxicity in the whole animal, beyond the speculation that the changes in synaptosomal neurochemistry might be a reflection of "first stage affective syndrome," a condition of uncertain pathophysiology, but with possible clinical consequences marked by depression, irritability, and a general loss of interest in daily activities.

An earlier neurotoxicity evaluation was performed on male Long-Evans rats that were exposed acutely to high concentrations of *p*-isopropyltoluene vapor (Furnas and Hine, 1958). In an initial experiment, a pair of rats were exposed to 10,000 ppm for 45 minutes, i.e., until they became apneic. Clinical signs preceding the apnea were reported to be similar to those of benzene (e.g., dyspnea, ataxia, twitching and profuse salivation), but more rapid. Another experiment involved 8 rats that were successively exposed as a group to 5000-10,000 ppm of *p*-isopropyltoluene (concentrations not otherwise specified) for 50, 45, 20 and 30 minutes. The rats were removed from the exposure chamber when they showed convulsions or respiratory arrest and returned for another exposure as soon as they recovered (duration between exposures not reported). Exposure was terminated after several deaths occurred (i.e., after 4 exposures), and survivors were sacrificed 24 hours later for gross pathologic observations and histological examination of brain, spinal cord and sciatic nerve. The exposed rats showed clinical signs of respiratory irritation, CNS depression and quivering or twitching, but no convulsions, and 4 of the 8 died. No gross lesions or CNS histopathologic changes were found other than gross changes to the respiratory tract attributable to local irritation.

Subcutaneous injection of *p*-isopropyltoluene in rabbits produced hematological changes similar to those produced by xylene that resulted in an increase in immature white cells similar in appearance to human myeloid leukemic cells (Miyamato, 1938; Woronow, 1929). The lethal dose via intraperitoneal administration is 2.162 g/kg in the guinea pig (Chassevant and Garnier, 1903).

No developmental or reproductive studies by any route of exposure to *p*-isopropyltoluene were located.

Other Studies

p-Isopropyltoluene appears to be readily absorbed following inhalation. For example, at least 70% and 60% of the dose inhaled in 24 hours (reportedly 100 mg/kg) was recovered as

urinary metabolites within 48 hours in two rats and two guinea pigs, respectively (Walde et al., 1983).

Studies that have examined the metabolism of *p*-isopropylbenzene in rats and guinea pigs have presented a unified picture of a compound that is subject to considerable metabolic rearrangement. Thus, Walde et al. (1983) identified 18 total urinary metabolites in the oral- and inhalation-exposed rats and guinea pigs, and found that their excretion was nearly complete within 48 hours and amounted to 60-80% of the administered dose. The principal metabolites resulting from oxidation of the isopropyl and/or methyl group in the Walde et al. (1983) study included *p*-isopropyl benzoic acid (cumic acid, 19% of administered dose), 2-*p*-carboxyphenylpropan-1-ol (11%) and 2-*p*-carboxyphenylpropionic acid (16%) in oral-exposed rats; *p*-isopropylbenzoyl glycine (31%) and 2-*p*-tolylpropan-2-ol (14%) in oral-exposed guinea pigs; 2-*p*-carboxyphenylpropionic acid (15%) in inhalation-exposed rats; and *p*-isopropylbenzoyl glycine (31%) and 2-*p*-tolylpropionic acid (15%) in inhalation-exposed guinea pigs. The remaining metabolites identified by Walde et al. (1983) ranged from trace amounts to 6-9% of the administered dose. In general, both the methyl and isopropyl side groups have been shown to be extensively oxidized in all species tested (Walde et al., 1983; Bakke and Scheline, 1970; Ishida et al., 1981; Matsumoto et al., 1992). The numerous monohydric alcohols, diols, mono- and dicarboxylic acids and hydroxyacids identified in the urine established that oxidation to alcohol with and without further oxidation to the corresponding acid occurred at all possible aliphatic sites (i.e., the three isopropyl carbons and the methyl carbon).

FEASIBILITY OF DERIVING PROVISIONAL SUBCHRONIC AND CHRONIC INHALATION RfCs FOR *p*-ISOPROPYLTOLUENE

The available inhalation toxicity data for *p*-isopropyltoluene indicate that acute exposure causes CNS depression and mucous membrane irritation. These findings are consistent with known acute effects of alkyl benzenes in general. However, there are no studies of the chronic-duration toxicity of *p*-isopropyltoluene in humans or animals, and there are only a few studies examining toxic endpoints in animals following repeated inhalation exposure. For example, the study by Lam et al. (1996) exposed Long-Evans rats to *p*-isopropyltoluene for a longer period of time than that of a typical acute dosing regimen (4 weeks with an 8-week recovery period). However, this remained less than a typical subchronic dosing regimen ($\geq$ 10% of the average life span of the animals being tested). Furthermore, it remains unclear whether the *ex situ* observations in synaptosomes reported by these workers represent the onset of neurotoxicological consequences of exposure to the compound (Lam et al., 1996). This points to the difficulty of assigning a NOAEL or LOAEL for neurotoxicity to either of the dose levels employed in the subject study, irrespective of its duration. A report of toxicity studies of dogs exposed for up to 18 weeks (6 hours/day, 5 days/week) in 1948 to varying concentrations of p-isopropyltoluene between 50 and160 ppm specified that exposure was associated with small

decreases in hemoglobin levels, but not with any other marked pathological changes (Du Pont & Co., 1949). However, reporting of methodological details and results was not sufficient to allow an independent evaluation of the study. Because of this deficiency, as well as the small number of animals studied and the lack of a control group, the study does not provide a suitable basis for deriving a p-RfC. In summary, no adequate information is available on the subchronic or chronic toxicity of *p*-isopropyltoluene associated with any route of exposure. This precludes the derivation of a p-RfC for the compound from inhalation data or from oral data by route-to-route extrapolation.

There are no data indicating that *p*-isopropyltoluene is metabolized to any compounds that have toxicity data sufficient for risk assessment or to the same metabolites as other alkyl benzenes that have adequate toxicity data. For example, metabolism that removes the methyl group or part or all of the isopropyl group from *p*-isopropyltoluene does not appear to occur under realistic exposure conditions (e.g., in species not adapted to diets high in *p*-isopropyltoluene), thereby preventing the use of adequately studied mono- or bifunctional alkyl benzene compounds, such as cumene (isopropylbenzene), *p*-xylene and toluene, which already have toxicity values, as surrogates. Other bifunctional alkyl benzenes, particularly compounds such as *p*-ethyltoluene and *p-tert*-butyltoluene, appear to have very limited toxicity data and have not been assessed by U.S. EPA (1997, 2003). In summary, derivation of a p-RfC for *p*-isopropyltoluene is precluded by insufficient toxicity data, as well as metabolism data that provide no basis for using a surrogate alkyl benzene for derivation of an toxicity value for the subject compound.

PROVISIONAL PEER REVIEWED TOXICITY VALUE FOR *p*-ISOPROPYLTOLUENE (CASRN 99-87-6) Derivation of a Carcinogenicity Assessment

Background

On December 5, 2003, the U.S. Environmental Protection Agency's (EPA's) Office of Superfund Remediation and Technology Innovation (OSRTI) revised its hierarchy of human health toxicity values for Superfund risk assessments, establishing the following three tiers as the new hierarchy:

1. EPA's Integrated Risk Information System (IRIS).

2. Provisional Peer-Reviewed Toxicity Values (PPRTV) used in EPA's Superfund Program.

3. Other (peer-reviewed) toxicity values, including:

   - Minimal Risk Levels produced by the Agency for Toxic Substances and Disease Registry (ATSDR),
   - California Environmental Protection Agency (CalEPA) values, and
   - EPA Health Effects Assessment Summary Table (HEAST) values.

A PPRTV is defined as a toxicity value derived for use in the Superfund Program when such a value is not available in EPA's Integrated Risk Information System (IRIS). PPRTVs are developed according to a Standard Operating Procedure (SOP) and are derived after a review of the relevant scientific literature using the same methods, sources of data, and Agency guidance for value derivation generally used by the EPA IRIS Program. All provisional toxicity values receive internal review by two EPA scientists and external peer review by three independently selected scientific experts. PPRTVs differ from IRIS values in that PPRTVs do not receive the multi-program consensus review provided for IRIS values. This is because IRIS values are generally intended to be used in all EPA programs, while PPRTVs are developed specifically for the Superfund Program.

Because science and available information evolve, PPRTVs are initially derived with a three-year life-cycle. However, EPA Regions (or the EPA HQ Superfund Program) sometimes request that a frequently used PPRTV be reassessed. Once an IRIS value for a specific chemical becomes available for Agency review, the analogous PPRTV for that same chemical is retired. It should also be noted that some PPRTV manuscripts conclude that a PPRTV cannot be derived based on inadequate data.

Disclaimers

Users of this document should first check to see if any IRIS values exist for the chemical of concern before proceeding to use a PPRTV. If no IRIS value is available, staff in the regional Superfund and RCRA program offices are advised to carefully review the information provided in this document to ensure that the PPRTVs used are appropriate for the types of exposures and circumstances at the Superfund site or RCRA facility in question. PPRTVs are periodically updated; therefore, users should ensure that the values contained in the PPRTV are current at the time of use.

It is important to remember that a provisional value alone tells very little about the adverse effects of a chemical or the quality of evidence on which the value is based. Therefore, users are strongly encouraged to read the entire PPRTV manuscript and understand the strengths and limitations of the derived provisional values. PPRTVs are developed by the EPA Office of Research and Development's National Center for Environmental Assessment, Superfund Health Risk Technical Support Center for OSRTI. Other EPA programs or external parties who may choose of their own initiative to use these PPRTVs are advised that Superfund resources will not generally be used to respond to challenges of PPRTVs used in a context outside of the Superfund Program.

Questions Regarding PPRTVs

Questions regarding the contents of the PPRTVs and their appropriate use (e.g., on chemicals not covered, or whether chemicals have pending IRIS toxicity values) may be directed to the EPA Office of Research and Development's National Center for Environmental Assessment, Superfund Health Risk Technical Support Center (513-569-7300), or OSRTI.

INTRODUCTION

A carcinogenicity assessment for *p*-isopropyltoluene (also known as *p*-cymene or *p*-methyl isopropyl benzene) is not available on IRIS (U.S. EPA, 2003), the HEAST (U.S. EPA, 1997), or the Drinking Water Standards and Health Advisories list (U.S. EPA, 2002). One relevant document, the Drinking Water Health Advisory for *p*-Cymene (U.S. EPA, 1987), was located in the CARA list (U.S. EPA, 1991, 1994). ATSDR (2003), NTP (2003), IARC (2003), and WHO (2003) have not produced documents for this chemical. Literature searches of the following databases were conducted from 1965 through June 2003 in order to locate relevant studies: TOXLINE (supplemented with BIOSIS and NTIS updates), CANCERLIT, MEDLINE, CCRIS, GENETOX, HSDB, DART/ETICBACK, EMIC/EMICBACK, RTECS and TSCATS. Additional literature searches from June 2003 through January 2004 were conducted by NCEA-Cincinnati using MEDLINE, TOXLINE, Chemical and Biological Abstracts databases.

p-Isopropyltoluene is used as an intermediate in the manufacture of *p*-cresol and thymol (HSDB, 2003). It also serves as a component in commercial terpene solvent mixtures and as a component of paint thinners, lacquers, and varnishes. It is found to occur naturally in many arboreous plants and as a constituent of many essential oils, including oils of eucalyptus, lemon, sage, thyme, coriander, star anise, and cinnamon (Browning, 1965; Opdyke, 1974; HSDB, 2003). The FDA (2003) has approved the use of *p*-isopropyltoluene as a synthetic flavoring substance and food additive.

REVIEW OF THE PERTINENT DATA

Human Studies

No data regarding the possible carcinogenicity of *p*-isopropyltoluene in humans were located.

Animal Studies

No reports of animal studies examining the carcinogenicity of *p*-isopropyltoluene by any route of exposure were located.

Other Studies

p-Isopropyltoluene was not mutagenic in *Salmonella typhimurium* strains TA98 or TA100 with metabolic activation in assays of the chemical or fractions of urine collected from rats following administration of *p*-isopropyltoluene via gavage (Rockwell and Raw, 1979). No increased frequencies of streptomycin-independent mutant colonies were found in Sd-4-73 *Escherichia coli* exposed to *p*-isopropyltoluene using the paper disk method (Iyer and Syzbalski, 1958; Syzbalski, 1958).

The metabolism of *p*-isopropyltoluene has been investigated in several studies, including oral studies in rats (Walde et al., 1983; Bakke and Scheline, 1970), guinea pigs (Walde et al., 1983) and rabbits (Ishida et al., 1981; Matsumoto et al., 1992), and inhalation studies in rats and guinea pigs (Walde et al., 1983). In general, the results suggest that the compound is readily absorbed and rapidly metabolized to a range of intermediates. For example, the compound's methyl and isopropyl side groups appeared to be extensively oxidized in all species tested. The numerous monohydric alcohols, diols, mono- and dicarboxylic acids and hydroxyacids identified in the urine established that oxidation to alcohol with and without further oxidation to the corresponding acid occurred at all possible aliphatic sites (i.e., the three isopropyl carbons and the methyl carbon).

PROVISIONAL WEIGHT-OF-EVIDENCE CLASSIFICATION

No studies examining the carcinogenic potential of *p*-isopropyltoluene in humans or animals were located. Genotoxicity data are limited to two negative mutagenicity assays in bacteria. The available data are insufficient to assess carcinogenic potential in animals or humans as specified by the proposed U.S. EPA (1999) Guidelines for Carcinogen Risk Assessment.

QUANTITATIVE ESTIMATES OF CARCINOGENIC RISK

Derivation of quantitative estimates of cancer risk for *p*-isopropyltoluene is precluded by the lack of data to assess carcinogenicity associated with *p*-isopropyltoluene exposure.

PROVISIONAL PEER REVIEWED TOXICITY VALUES FOR PYRENE (CASRN 129-00-0)

Background

On December 5, 2003, the U.S. Environmental Protection Agency's (EPA's) Office of Superfund Remediation and Technology Innovation (OSRTI) revised its hierarchy of human health toxicity values for Superfund risk assessments, establishing the following three tiers as the new hierarchy:

1. EPA's Integrated Risk Information System (IRIS).
2. Provisional Peer-Reviewed Toxicity Values (PPRTV) used in EPA's Superfund Program.
3. Other (peer-reviewed) toxicity values, including:
   - Minimal Risk Levels produced by the Agency for Toxic Substances and Disease Registry (ATSDR),
   - California Environmental Protection Agency (CalEPA) values, and
   - EPA Health Effects Assessment Summary Table (HEAST) values.

A PPRTV is defined as a toxicity value derived for use in the Superfund Program when such a value is not available in EPA's Integrated Risk Information System (IRIS). PPRTVs are developed according to a Standard Operating Procedure (SOP) and are derived after a review of the relevant scientific literature using the same methods, sources of data, and Agency guidance for value derivation generally used by the EPA IRIS Program. All provisional toxicity values receive internal review by two EPA scientists and external peer review by three independently selected scientific experts. PPRTVs differ from IRIS values in that PPRTVs do not receive the multi-program consensus review provided for IRIS values. This is because IRIS values are generally intended to be used in all EPA programs, while PPRTVs are developed specifically for the Superfund Program.

Because new information becomes available and scientific methods improve over time, PPRTVs are reviewed on a five-year basis and updated into the active database. Once an IRIS value for a specific chemical becomes available for Agency review, the analogous PPRTV for that same chemical is retired. It should also be noted that some PPRTV manuscripts conclude that a PPRTV cannot be derived based on inadequate data.

Disclaimers

Users of this document should first check to see if any IRIS values exist for the chemical of concern before proceeding to use a PPRTV. If no IRIS value is available, staff in the regional Superfund and RCRA program offices are advised to carefully review the information provided in this document to ensure that the PPRTVs used are appropriate for the types of exposures and circumstances at the Superfund site or RCRA facility in question. PPRTVs are periodically updated; therefore, users should ensure that the values contained in the PPRTV are current at the time of use.

It is important to remember that a provisional value alone tells very little about the adverse effects of a chemical or the quality of evidence on which the value is based. Therefore, users are strongly encouraged to read the entire PPRTV manuscript and understand the strengths and limitations of the derived provisional values. PPRTVs are developed by the EPA Office of Research and Development's National Center for Environmental Assessment, Superfund Health Risk Technical Support Center for OSRTI. Other EPA programs or external parties who may choose of their own initiative to use these PPRTVs are advised that Superfund resources will not generally be used to respond to challenges of PPRTVs used in a context outside of the Superfund Program.

Questions Regarding PPRTVs

Questions regarding the contents of the PPRTVs and their appropriate use (e.g., on chemicals not covered, or whether chemicals have pending IRIS toxicity values) may be directed to the EPA Office of Research and Development's National Center for Environmental Assessment, Superfund Health Risk Technical Support Center (513-569-7300), or OSRTI.

INTRODUCTION

IRIS (U.S. EPA, 1997a) provides a chronic RfD of 3E-2 mg/kg-day developed from a NOAEL of 75 mg/kg-day with a combined uncertainty factor of 3000 (10 each for intra- and interspecies variability, 10 for the use of a subchronic study for chronic RfD derivation, and an additional 3 to account for the lack of both toxicity studies in a second species and developmental/reproductive studies) using a 13 week gavage study in mice, conducted by Toxicity Research Laboratories, Muskegon, MI (U.S. EPA, 1989) for the Office of Solid Waste, Washington, DC. The critical effects were renal tubular pathology and decreased kidney weights. IRIS (U.S. EPA, 2007) did not develop an RfC. IRIS (U.S. EPA, 2007) provided a classification of D, not classifiable as to human carcinogenicity based on no human data and inadequate data from animal experiments. A subchronic RfD is currently listed on HEAST of 3E-1 mg/kg-day which will be removed when this PPRTV is activated (U.S. EPA, 1997b). It was based on the same study as this PPRTV.

A cancer classification for pyrene of Group D is listed in the Drinking water Standard and Health Advisory lists (U.S. EPA, 2000) based on an assessment of pyrene from the Drinking Water Criteria Document for polycyclic aromatic hydrocarbons (U.S. EPA, 1990). The CARA lists (U.S. EPA, 1991, 1994) report a Health Effects Assessment (U.S. EPA 1984) and a Health and Environmental Effects Profile (HEEP) U.S. EPA 1987) for pyrene. ATSDR (2001) has not published a toxicological profile for pyrene, but it is included in the profile for polycyclic aromatic hydrocarbons (ATSDR, 1995). IARC has assigned pyrene to Group 3, not classifiable as to its carcinogenicity to humans, based on no human data and limited animal data (IARC, 1983, 1987). A multimedia document for polycyclic aromatic hydrocarbons (U.S. EPA, 1992) and the NTP status reports (NTP, 2001) were also searched to identify relevant data. Literature searches for all exposure routes and effects were conducted from 1989 to December 2000 and updated to 2007. The databases searched were: TOXLINE, TSCATS, CANCERLIT,

MEDLINE, GENETOX, HSDB, EMIC/EMIC/EMICBACK, DART/ETICBACK, CCRIS AND RTECS.

This document has passed the STSC quality review and peer review evaluation indicating that the quality is consistent with the SOPs and standards of the STSC and is suitable for use by registered users of the PPRTV system.

REVIEW OF THE PERTINENT LITERATURE

Human Studies

No human studies were located regarding exposure of humans to pyrene.

Animal Studies

A U.S. EPA (1989) study conducted by Toxicity Research Laboratories, Muskegon MI for the Office of Solid Waste, Washington DC was the basis of IRIS's chronic RfD or 3E-2 mg/kg-day. Male and female CD-1 mice (20/sex/group) were gavaged with 0, 75, 125, or 250 mg/kg/day pyrene in corn oil for 13 weeks. The toxicological parameters examined in this study included body weight changes, food consumption, mortality, clinical pathological evaluations of major organs and tissues, and hematology and serum chemistry. Nephropathy, characterized by the presence of multiple foci of renal tubular regeneration, often accompanied by interstitial lymphocytic infiltrates and/or foci of interstitial fibrosis, was present in 4, 1, 1, and 9 male mice in the control, low-, medium-, and high-dose groups, respectively. Similar lesions were seen in 2, 3, 7, and 10 female mice in the 0, 75, 125, and 250 mg/kg treatment groups. The kidney lesions were described as minimal or mild in all dose groups. Relative and absolute kidney weights were reduced in the two higher dosage groups. Based on the results of this study, the low dose (75 mg/kg/day) was considered the NOAEL and 125 mg/kg/day the LOAEL for nephropathy and decreased kidney weights. The IRIS RfD of 3E-2 mg/kg-day was calculated using a composite uncertainty factor of 3000, including 10 each for intra- and interspecies variability, and an additional 3 to account for the lack of both toxicity studies in a second species and developmental/reproductive studies and 10 for extrapolation from subchronic to chronic.

White and White (1939) fed six male rats (unspecified strain) a diet containing 2000 mg pyrene/kg for 40 days. The average reported food intake for two animals was 6.1 g/day, and the average body weight for these two animals was 94.3 g. A decrease in body weight gain was observed in two animals. The authors stated that this body weight gain was representative of the whole group; although there was no change in food intake. White and White (1939) also observed enlarged livers and increased hepatic lipid content in animals treated with pyrene, benzpyrene or methylcholanthrene in the diet; however, incidence data were not reported and it is unclear whether this effect occurred in the pyrene treated rats. Interpretation of this study is further complicated by the lack of experimental controls and statistical analysis, small sample size, and incomplete reporting of histopathology results.

No other useful studies are available that examine only pyrene exposure

Other studies

Pyrene has been assayed for genotoxicity in a number of tests with both positive and negative results. These have been extensively reviewed by EPA (U.S. EPA, 1984, 1987, 2000, 2001) and only those studies published since the most recent EPA review was performed are included in the following text.

In vitro genotoxicity tests of pyrene in prokaryotic systems have produced mixed results. The consensus conclusion on the WHO international collaborative study (which involved 20 bacterial test sets) was that protocol or evaluation criteria were critical factors in individual test verdicts (WHO, 1990). Pyrene has been shown to bind to DNA (Chen, 1983) and to form DNA adducts (Segerback and Vodicka, 1993), but was not mutagenic in DNA damage assays in *Escherichia coli* and *Bacillus subtilis* (Hellmer and Bolcsfold, 1992; Kranendonk et al., 1994, 1996; Mersch-Sundermann et al., 1992, 1993; Rossman et al., 1991). Both positive (Johnson, 1992) and negative (Rexroat et al., 1995; Rusina et al., 1992; Van der Lelie et al., 1997) results have been reported in bacterial gene mutation tests. Pyrene induced increased incidence of mitotic gene conversion but not other genetic endpoints in yeast (deSerres et al., 1981).

Most *in vitro* tests in mammalian cells have given negative results. Pyrene gave mixed results in tests of unscheduled DNA synthesis (Heil and Reifferscheid, 1992; Selden et al., 1994) and was mostly negative in tests for sister chromatid exchange and negative for chromosome aberrations (Darroudi and Natarajan, 1993; Natarajan and Darroudi, 1991). Pyrene was mutagenic in the L5178Y mouse lymphoma gene mutation assay when metabolically activated (Oberly et al., 1993), but was not mutagenic in metabolically competent human lymphoblastoid cells (Busby et al., 1994; Durant et al., 1996) and did not induce micronucleus formation in a variety of mammalian cell types (Crofton-Sleigh et al., 1993; Fritzenschaf et al., 1993; Muller-Tegethoff et al., 1995; Natarajan and Darroudi, 1991; Neslany and Marzin, 1999). Results of mammalian cell transformation assays have also been negative (U.S. EPA, 2000).

In vivo genotoxicity tests of pyrene have also produced mostly negative results. Pyrene produced no increase or only a slight increase in sex-linked recessive lethals in *Drosophila* and was negative in the *Drosophila* eye mosaic assay (Fujikawa et al., 1993; Vogel and Nivard, 1993). Application of pyrene to the skin of hairless mice produced no increase in micronucleus induction in keratinocytes (He and Baker, 1991). Pyrene was positive in the newt micronucleus test (Fernandez et al., 1989).

DERIVATION OF A PROVISIONAL SUBCHRONIC OR CHRONIC RfD FOR PYRENE

A U.S. EPA (1989) study conducted by Toxicity Research Laboratories, Muskegon MI for the Office of Solid Waste, Washington DC was utilized by IRIS for development of a chronic RfD. This study was selected for development of a provisional subchronic RfD. Based on the results of this study, the low dose (75 mg/kg/day) was considered the NOAEL and 125 mg/kg/day the LOAEL for nephropathy and decreased kidney weights.

A composite uncertainty factor of 300 was applied to the NOAEL of 75 mg/kg-day; 10 each for intra- and interspecies variability, and an additional 3 to account for the lack of both toxicity studies in a second species and developmental/reproductive studies providing a **subchronic RfD of 0.25 mg/kg-day or 3E-1 mg/kg-day**.

NOAEL/ Uncertainty Factors = 75/300 = 0.25 or 3E-1 mg/kg-day

Confidence in the principal study is medium, as it was a well-designed experiment that examined a variety of toxicological endpoints and identified both a NOAEL and LOAEL for the critical effect. Confidence in the database is low, due to the lack of supporting subchronic, chronic, and developmental/reproductive studies. Accordingly, confidence in the provisional subchronic RfD is low.

DERIVATION OF A PROVISIONAL SUBCHRONIC OR CHRONIC RfC FOR PYRENE

No provisional RfC is developed due to lack of usable information.

PROVISIONAL CARCINOGENICITY ASSESSMENT FOR PYRENE

IRIS (U.S. EPA, 2007) provides no quantitative assessments (OSF or IUR) for pyrene and classifies it as classification of D, not classifiable as to human carcinogenicity based on no human data and inadequate data from animal experiments. Based on the U.S. EPA (2005) Cancer Guidelines, pyrene can be classified as “not likely to be a human carcinogen”.

No data is currently available and suitable for developing cancer values.

Acronyms and Abbreviations

bw	body weight
cc	cubic centimeters
CD	Caesarean Delivered
CERCLA	Comprehensive Environmental Response, Compensation and Liability Act of 1980
CNS	central nervous system
cu.m	cubic meter
DWEL	Drinking Water Equivalent Level
FEL	frank-effect level
FIFRA	Federal Insecticide, Fungicide, and Rodenticide Act
g	grams
GI	gastrointestinal
HEC	human equivalent concentration
Hgb	hemoglobin
i.m.	intramuscular
i.p.	intraperitoneal
i.v.	intravenous
IRIS	Integrated Risk Information System
IUR	inhalation unit risk
kg	kilogram
L	liter
LEL	lowest-effect level
LOAEL	lowest-observed-adverse-effect level
LOAEL(ADJ)	LOAEL adjusted to continuous exposure duration
LOAEL(HEC)	LOAEL adjusted for dosimetric differences across species to a human
m	meter
MCL	maximum contaminant level
MCLG	maximum contaminant level goal
MF	modifying factor
mg	milligram
mg/kg	milligrams per kilogram
mg/L	milligrams per liter
MRL	minimal risk level

MTD	maximum tolerated dose
MTL	median threshold limit
NAAQS	National Ambient Air Quality Standards
NOAEL	no-observed-adverse-effect level
NOAEL(ADJ)	NOAEL adjusted to continuous exposure duration
NOAEL(HEC)	NOAEL adjusted for dosimetric differences across species to a human
NOEL	no-observed-effect level
OSF	oral slope factor
p-IUR	**provisional inhalation unit risk**
p-OSF	**provisional oral slope factor**
p-RfC	**provisional inhalation reference concentration**
p-RfD	**provisional oral reference dose**
PBPK	physiologically based pharmacokinetic
ppb	parts per billion
ppm	parts per million
PPRTV	**Provisional Peer Reviewed Toxicity Value**
RBC	red blood cell(s)
RCRA	Resource Conservation and Recovery Act
RDDR	Regional deposited dose ratio (for the indicated lung region)
REL	relative exposure level
RfC	inhalation reference concentration
RfD	oral reference dose
RGDR	Regional gas dose ratio (for the indicated lung region)
s.c.	subcutaneous
SCE	sister chromatid exchange
SDWA	Safe Drinking Water Act
sq.cm.	square centimeters
TSCA	Toxic Substances Control Act
UF	uncertainty factor
µg	microgram
µmol	micromoles
VOC	volatile organic compound

PROVISIONAL PEER REVIEWED TOXICITY VALUES FOR n-BUTYLBENZENE (CASRN 104-51-8), sec-BUTYLBENZENE (CASRN 135-98-8) AND tert-BUTYLBENZENE (CASRN 98-06-6) Derivation of Sucbchronic and Chronic Oral RfDs

Background

On December 5, 2003, the U.S. Environmental Protection Agency's (EPA's) Office of Superfund Remediation and Technology Innovation (OSRTI) revised its hierarchy of human health toxicity values for Superfund risk assessments, establishing the following three tiers as the new hierarchy:

1. EPA's Integrated Risk Information System (IRIS).

2. Provisional Peer-Reviewed Toxicity Values (PPRTV) used in EPA's Superfund Program.

3. Other (peer-reviewed) toxicity values, including:

   - Minimal Risk Levels produced by the Agency for Toxic Substances and Disease Registry (ATSDR),
   - California Environmental Protection Agency (CalEPA) values, and
   - EPA Health Effects Assessment Summary Table (HEAST) values.

A PPRTV is defined as a toxicity value derived for use in the Superfund Program when such a value is not available in EPA's Integrated Risk Information System (IRIS). PPRTVs are developed according to a Standard Operating Procedure (SOP) and are derived after a review of the relevant scientific literature using the same methods, sources of data, and Agency guidance for value derivation generally used by the EPA IRIS Program. All provisional toxicity values receive internal review by two EPA scientists and external peer review by three independently selected scientific experts. PPRTVs differ from IRIS values in that PPRTVs do not receive the multi-program consensus review provided for IRIS values. This is because IRIS values are generally intended to be used in all EPA programs, while PPRTVs are developed specifically for the Superfund Program.

Because science and available information evolve, PPRTVs are initially derived with a three-year life-cycle. However, EPA Regions (or the EPA HQ Superfund Program) sometimes request that a frequently used PPRTV be reassessed. Once an IRIS value for a specific chemical becomes available for Agency review, the analogous PPRTV for that same chemical is retired. It should also be noted that some PPRTV manuscripts conclude that a PPRTV cannot be derived based on inadequate data.

Disclaimers

Users of this document should first check to see if any IRIS values exist for the chemical of concern before proceeding to use a PPRTV. If no IRIS value is available, staff in the regional Superfund and RCRA program offices are advised to carefully review the information provided in this document to ensure that the PPRTVs used are appropriate for the types of exposures and circumstances at the Superfund site or RCRA facility in question. PPRTVs are periodically updated; therefore, users should ensure that the values contained in the PPRTV are current at the time of use.

It is important to remember that a provisional value alone tells very little about the adverse effects of a chemical or the quality of evidence on which the value is based. Therefore, users are strongly encouraged to read the entire PPRTV manuscript and understand the strengths and limitations of the derived provisional values. PPRTVs are developed by the EPA Office of Research and Development's National Center for Environmental Assessment, Superfund Health Risk Technical Support Center for OSRTI. Other EPA programs or external parties who may choose of their own initiative to use these PPRTVs are advised that Superfund resources will not generally be used to respond to challenges of PPRTVs used in a context outside of the Superfund Program.

Questions Regarding PPRTVs

Questions regarding the contents of the PPRTVs and their appropriate use (e.g., on chemicals not covered, or whether chemicals have pending IRIS toxicity values) may be directed to the EPA Office of Research and Development's National Center for Environmental Assessment, Superfund Health Risk Technical Support Center (513-569-7300), or OSRTI.

INTRODUCTION

Subchronic or chronic RfDs for the isomeric butylbenzenes ($C_{10}H_{14}$) n-butylbenzene, sec-butylbenzene or tert-butylbenzene are not listed on IRIS (U.S. EPA, 2002a), the Drinking Water Standards and Health Advisories table (U.S. EPA, 2002b), or the HEAST (U.S. EPA, 1997). The only documents listed in the CARA database (U.S. EPA, 1991, 1994) for these chemicals are Health Advisories (U.S. EPA 1987a,b,c,d), wherein the data were considered inadequate for risk assessment for these chemicals. ATSDR (2002) has not published toxicological profiles for butylbenzenes and these chemicals were not listed in the NTP (2002) Management Status Reports. IARC (2002) and WHO (2002) have not published reviews for butylbenzenes. A review by Henderson (2001) was consulted for relevant information. Literature searches of the following databases were conducted from 1965 to July 2002 for relevant studies: TOXLINE, MEDLINE, TSCATS, GENETOX, HSDB, CANCERLIT, CCRIS, RTECS, EMIC/EMICBACK,

DART/ETICBACK and BIOSIS. An updated literature search was conducted through May 2004 and no relevant information was found.

REVIEW OF PERTINENT LITERATURE

Human Studies

No information was located regarding the adverse effects of n-butylbenzene, sec-butylbenzene, or tert-butylbenzene in humans.

Animal Studies

No studies on the chronic or subchronic toxicity of n-butylbenzene, sec-butylbenzene or tert-butylbenzene were located in the literature search. Limited acute data suggest that the branch-chained butylbenzenes are more lethal than the straight-chained butylbenzene. Gerarde (1959) observed mortality in 8/10 rats orally dosed with 4.3 g/kg of sec-butylbenzene and 7/10 at this dose of tert-butylbenzene, but only 2/10 rats treated with this dose of n-butylbenzene. Rat LD_{50} values were lower for sec-butylbenzene (2.24 g/kg) and tert-butylbenzene (2.5-5.0 g/kg) (Henderson, 2001; Dupont, 1978; Rhone-Poulenc, Inc., 1981; NIOSH, 2002; Shell Oil Company, 1979). A rat LD_{50} was not located for n-butylbenzene, but a mouse i.p. LD_{50} for this chemical of 1.995 g/kg was obtained by Tanii et al., 1995. The leading cause of death in rats in the acute oral studies conducted by Gerarde (1959) was chemical induced pneumonitis with pulmonary edema and hemorrhage, the latter often associated with hemorrhage in other tissues such as thymus, adrenal, and bladder. Hyperemia and vasodilation of the blood vessels of the gastrointestinal tract were also reported.

FEASIBILITY OF DERIVING PROVISIONAL SUBCHRONIC OR CHRONIC RfDs FOR n-BUTYLBENZENE, sec-BUTYLBENZENE AND tert-BUTYLBENZENE

Data on the oral toxicity of the three butylbenzene isomers under investigation are limited to acute lethality studies that are considered inadequate for derivation of provisional RfDs for butylbenzenes.

PROVISIONAL PEER REVIWED TOXICITY VALUES FOR n-BUTYLBENZENE (CASRN 104-51-8), sec-BUTYLBENZENE (CASRN 135-98-8) AND tert-BUTYLBENZENE (CASRN 98-06-6) Derivation of Subchronic and Chronic Inhalation RfCs

Background

On December 5, 2003, the U.S. Environmental Protection Agency's (EPA's) Office of Superfund Remediation and Technology Innovation (OSRTI) revised its hierarchy of human health toxicity values for Superfund risk assessments, establishing the following three tiers as the new hierarchy:

1. EPA's Integrated Risk Information System (IRIS).

2. Provisional Peer-Reviewed Toxicity Values (PPRTV) used in EPA's Superfund Program.

3. Other (peer-reviewed) toxicity values, including:

   - Minimal Risk Levels produced by the Agency for Toxic Substances and Disease Registry (ATSDR),
   - California Environmental Protection Agency (CalEPA) values, and
   - EPA Health Effects Assessment Summary Table (HEAST) values.

A PPRTV is defined as a toxicity value derived for use in the Superfund Program when such a value is not available in EPA's Integrated Risk Information System (IRIS). PPRTVs are developed according to a Standard Operating Procedure (SOP) and are derived after a review of the relevant scientific literature using the same methods, sources of data, and Agency guidance for value derivation generally used by the EPA IRIS Program. All provisional toxicity values receive internal review by two EPA scientists and external peer review by three independently selected scientific experts. PPRTVs differ from IRIS values in that PPRTVs do not receive the multi-program consensus review provided for IRIS values. This is because IRIS values are generally intended to be used in all EPA programs, while PPRTVs are developed specifically for the Superfund Program.

Because science and available information evolve, PPRTVs are initially derived with a three-year life-cycle. However, EPA Regions (or the EPA HQ Superfund Program) sometimes request that a frequently used PPRTV be reassessed. Once an IRIS value for a specific chemical becomes available for Agency review, the analogous PPRTV for that same chemical is retired. It should also be noted that some PPRTV manuscripts conclude that a PPRTV cannot be derived based on inadequate data.

Disclaimers

Users of this document should first check to see if any IRIS values exist for the chemical of concern before proceeding to use a PPRTV. If no IRIS value is available, staff in the regional Superfund and RCRA program offices are advised to carefully review the information provided in this document to ensure that the PPRTVs used are appropriate for the types of exposures and circumstances at the Superfund site or RCRA facility in question. PPRTVs are periodically updated; therefore, users should ensure that the values contained in the PPRTV are current at the time of use.

It is important to remember that a provisional value alone tells very little about the adverse effects of a chemical or the quality of evidence on which the value is based. Therefore, users are strongly encouraged to read the entire PPRTV manuscript and understand the strengths and limitations of the derived provisional values. PPRTVs are developed by the EPA Office of Research and Development's National Center for Environmental Assessment, Superfund Health Risk Technical Support Center for OSRTI. Other EPA programs or external parties who may choose of their own initiative to use these PPRTVs are advised that Superfund resources will not generally be used to respond to challenges of PPRTVs used in a context outside of the Superfund Program.

Questions Regarding PPRTVs

Questions regarding the contents of the PPRTVs and their appropriate use (e.g., on chemicals not covered, or whether chemicals have pending IRIS toxicity values) may be directed to the EPA Office of Research and Development's National Center for Environmental Assessment, Superfund Health Risk Technical Support Center (513-569-7300), or OSRTI.

INTRODUCTION

Subchronic or chronic RfCs the isomeric butylbenzenes ($C_{10}H_{14}$) n-butylbenzene, sec-butylbenzene or tert-butylbenzene are not listed on IRIS (U.S. EPA, 2002) or the HEAST (U.S. EPA, 1997). The only documents listed in the CARA database (U.S. EPA, 1991, 1994) for these chemicals are Health Advisories (U.S. EPA 1987a,b,c), wherein the data were considered inadequate for risk assessment for these chemicals. ATSDR (2002) has not published toxicological profiles for butylbenzenes and these chemicals were not listed in the NTP (2002) Management Status Reports. ACGIH (2001), NIOSH (2002) and OSHA (2002a,b) have not established occupational exposure limits for these chemicals. IARC (2002) and WHO (2002) have not published reviews for butylbenzenes. A review by Henderson (2001) was consulted for relevant information. Literature searches of the following databases were conducted from 1965 to July 2002 for relevant studies: TOXLINE, MEDLINE, TSCATS, GENETOX, HSDB,

CANCERLIT, CCRIS, RTECS, EMIC/EMICBACK, DART/ETICBACK and BIOSIS. An updated literature search was conducted through May 2004 and no relevant information was found.

REVIEW OF PERTINENT LITERATURE

Human Studies

No information was located regarding the adverse effects of n-butylbenzene, sec-butylbenzene, or tert-butylbenzene in humans.

Animal Studies

No studies on the subchronic or chronic inhalation toxicity of n-butylbenzene, sec-butylbenzene, or tert-butylbenzene were located in the literature search.

Available data on the toxicity of these alkylbenzenes are limited to acute duration exposures. In a review, Gerarde (1959) stated that direct contact (intratracheal instillation) of the liquid alkylbenzenes with pulmonary tissue causes chemical induced pneumonitis characterized by pulmonary edema, hemorrhage, and tissue necrosis.

n–Butylbenzene. The RD_{50} (concentration necessary to depress the respiratory rate by 50% during acute exposure in response to sensory irritation) for sensory irritation by n-butylbenzene was 710 ppm in a 30 minute exposure; the chemical did not produce pulmonary irritation (defined as a decrease in respiratory rate during exposure via tracheal cannula) at the RD_{50} (Nielsen and Alarie, 1982).

sec-Butylbenzene. Dow Chemical (1954) reported that no deaths occurred among 3 rats exposed to a saturated atmosphere (about 3400 ppm) of sec-butylbenzene for 7 hours. Slight eye irritation, drowsiness, and unsteadiness were observed, and moderate (unspecified) gross pathology of the liver and kidneys was seen at necropsy.

tert-Butylbenzene. A 4-hour LC_{50} of 4.6 mg/L (840 ppm) was reported for tert-butylbenzene in rats (Shell Oil Company, 1979). Clinical signs observed during exposure included lacrimation, salivation, tremors, and convulsions; necropsy of animals that survived the 14-day observation period revealed no gross pathological changes. The RD_{50} for tert-butylbenzene was 760 ppm in a 30 minute exposure; the chemical did not produce pulmonary irritation at the RD_{50} (Nielsen and Alarie, 1982).

FEASIBILITY OF DERIVING PROVISIONAL SUBCHRONIC OR CHRONIC RfCs FOR n-BUTYLBENZENE, sec-BUTYLBENZENE, tert-BUTYLBENZENE, and n-PROPYLBENZENE

Data on the inhalation toxicity of the butylbenzenes are limited to acute studies that are considered inadequate for derivation of provisional RfCs.

PROVISIONAL PEER REVIEWED TOXICITY VALUES FOR n-BUTYLBENZENE (CASRN 104-51-8), sec-BUTYLBENZENE (CASRN 135-98-8) AND tert-BUTYLBENZENE (CASRN 98-06-6) Derivation of a Carcinogenicity Assessment

Background

On December 5, 2003, the U.S. Environmental Protection Agency's (EPA's) Office of Superfund Remediation and Technology Innovation (OSRTI) revised its hierarchy of human health toxicity values for Superfund risk assessments, establishing the following three tiers as the new hierarchy:

1. EPA's Integrated Risk Information System (IRIS).

2. Provisional Peer-Reviewed Toxicity Values (PPRTV) used in EPA's Superfund Program.

3. Other (peer-reviewed) toxicity values, including:

   - Minimal Risk Levels produced by the Agency for Toxic Substances and Disease Registry (ATSDR),
   - California Environmental Protection Agency (CalEPA) values, and
   - EPA Health Effects Assessment Summary Table (HEAST) values.

A PPRTV is defined as a toxicity value derived for use in the Superfund Program when such a value is not available in EPA's Integrated Risk Information System (IRIS). PPRTVs are developed according to a Standard Operating Procedure (SOP) and are derived after a review of the relevant scientific literature using the same methods, sources of data, and Agency guidance for value derivation generally used by the EPA IRIS Program. All provisional toxicity values receive internal review by two EPA scientists and external peer review by three independently selected scientific experts. PPRTVs differ from IRIS values in that PPRTVs do not receive the multi-program consensus review provided for IRIS values. This is because IRIS values are generally intended to be used in all EPA programs, while PPRTVs are developed specifically for the Superfund Program.

Because science and available information evolve, PPRTVs are initially derived with a three-year life-cycle. However, EPA Regions (or the EPA HQ Superfund Program) sometimes request that a frequently used PPRTV be reassessed. Once an IRIS value for a specific chemical becomes available for Agency review, the analogous PPRTV for that same chemical is retired. It should also be noted that some PPRTV manuscripts conclude that a PPRTV cannot be derived based on inadequate data.

Disclaimers

Users of this document should first check to see if any IRIS values exist for the chemical of concern before proceeding to use a PPRTV. If no IRIS value is available, staff in the regional Superfund and RCRA program offices are advised to carefully review the information provided in this document to ensure that the PPRTVs used are appropriate for the types of exposures and circumstances at the Superfund site or RCRA facility in question. PPRTVs are periodically updated; therefore, users should ensure that the values contained in the PPRTV are current at the time of use.

It is important to remember that a provisional value alone tells very little about the adverse effects of a chemical or the quality of evidence on which the value is based. Therefore, users are strongly encouraged to read the entire PPRTV manuscript and understand the strengths and limitations of the derived provisional values. PPRTVs are developed by the EPA Office of Research and Development's National Center for Environmental Assessment, Superfund Health Risk Technical Support Center for the Office of Superfund Remediation and Technology Innovation (OSRTI). Other EPA programs or external parties who may choose of their own initiative to use these PPRTVs are advised that Superfund resources will not generally be used to respond to challenges of PPRTVs used in a context outside of the Superfund Program.

Questions Regarding PPRTVs

Questions regarding the contents of the PPRTVs and their appropriate use (e.g., on chemicals not covered, or whether chemicals have pending IRIS toxicity values) may be directed to the EPA Office of Research and Development's National Center for Environmental Assessment, Superfund Health Risk Technical Support Center (513-569-7300), or to EPA's Office of Superfund Remediation and Technology Information (OSRTI).

INTRODUCTION

Carcinogenicity assessments for the isomeric butylbenzenes ($C_{10}H_{14}$) n-butylbenzene, sec-butylbenzene or tert-butylbenzene are not listed on IRIS (U.S. EPA, 2002a), the Drinking Water Standards and Health Advisories table (U.S. EPA, 2002b), or the HEAST (U.S. EPA, 1997). The only documents listed in the CARA database (U.S. EPA, 1991, 1994) for these chemicals are Health Advisories (U.S. EPA 1987a,b,c), wherein the data were considered inadequate for risk assessment for these chemicals. ATSDR (2002) has not published toxicological profiles for butylbenzenes and these chemicals were not listed in the NTP (2002) Management Status Reports. IARC (2002) and WHO (2002) have not published reviews for butylbenzenes. A review by Henderson (2001) was consulted for relevant information. Literature searches of the following databases were conducted from 1965 to July 2002 for relevant studies: TOXLINE,

MEDLINE, TSCATS, GENETOX, HSDB, CANCERLIT, CCRIS, RTECS, EMIC/EMICBACK, DART/ETICBACK and BIOSIS. An updated literature search was conducted through May 2004 and no relevant information was found.

REVIEW OF PERTINENT LITERATURE

Human Studies

No data regarding the potential carcinogenicity of n-butylbenzene, sec-butylbenzene, or tert-butylbenzene in humans were located.

Animal Studies

No studies regarding the carcinogenicity of n-butylbenzene, sec-butylbenzene, or tert-butylbenzene in animals were located.

Other Studies

The only relevant information comes from a small number of genotoxicity studies for tert-butylbenzene.

tert-Butylbenzene. tert-Butylbenzene was not mutagenic in *Salmonella typhimurium* strains TA98, TA100, TA1535, TA1537 and TA1538 or in *Escherichia coli* strains WP2 and WP2uvrA with or without metabolic activation when tested at concentrations of 0.2-2000 µg/plate (Dean et al., 1985). tert-Butylbenzene did not affect mitotic gene conversion (inactive alleles to wild-type alleles) in *Saccharomyces cerevisiae* at concentrations between 0.01 and 5.0 mg/ml in the presence or absence of metabolic activation by induced rat liver S9 fraction (Dean et al., 1985). *In vitro* exposure of rat liver cells (RL1) to 10, 20, or 40 µg/ml of tert-butylbenzene had no significant effect on the frequency of chromatid gaps, chromatid breaks or total chromosome aberrations (Dean et al., 1985). tert-Butylbenzene did not induce morphological transformation, or potentiate the morphological transformation frequency induced by positive control benzo(a)pyrene in Syrian hamster embryo (SHE) cells in culture (Rivedal et al., 1992).

PROVISIONAL WEIGHT-OF-EVIDENCE CLASSIFICATION

No studies of the potential carcinogenicity of n-butylbenzene, sec-butylbenzene, or tert-butylbenzene in humans or animals were located. Limited genotoxicity testing of tert-butylbenzene found no genotoxic activity. Therefore, n-butylbenzene, sec-butylbenzene, and

tert-butylbenzene data, under the proposed U.S. EPA (1999) guidelines, are inadequate for an assessment of human carcinogenic potential.

QUANTITATIVE ESTIMATES OF CARCINOGENIC RISK

Derivation of quantitative estimates of cancer risk for n-butylbenzene, sec-butylbenzene, or tert-butylbenzene is precluded by the lack of data regarding carcinogenicity of these chemicals.

APPENDIX D
CALCULATION OF EXPOSURE POINT CONCENTRATIONS FOR INHALATION OF POTABLE WATER VIA SHOWERING/BATHING
EXPOSURE POINT CONCENTRATIONS (EPC)
Honeywell Wastebed B/Harbor Brook Site, Geddes and Syracuse, New York

a - Maximum air concentration in the bathroom derived by the following equation from Shaum et al. 1994.

$$C_{a\ max} = \frac{C_w\ fF_w\ t_1}{V_a}$$

b - Concentration of contaminent in the air derived by the following equation from Shaum et al. 1994.

$$C_a = \frac{(C_{a\max} / 2)t_1 + C_{a\max} t_2}{t_1 + t_2}$$

Where (all scenarios): Fraction volatilized (f) = 1, water flow rate (F_w) = 750 L/day, bathroom volume (V_a)= 12 m^3
Where (adult scenarios): time of shower (t_1) = 0.25 hr (RME), 0.1 hr (CT); time after shower (t_2) = 0.33 hr (RME), 0.15 hr (CT)
Where (child scenarios): time of shower (t_1) = 0.45 hr (RME), 0.14 hr (CT); time after shower (t_2) = 0.55 hr (RME), 0.19 hr (CT)

APPENDIX F, TABLE 2
PARTICULATE EMISSIONS FACTOR CALCULATIONS
Honeywell Wastebed B/Harbor Brook Site, Geddes and Syracuse, New York

PEF to be used for Construction & Utility worker/fugitive dust scenario

$$Q/C_{sr} = A \times \exp\left[\frac{(\ln A_s - B)^2}{C}\right]$$

Equation E-19, USEPA 2002

Variable	Value	Units	Rationale
A =	12.9351	unitless	default as per USEPA 2002
B =	5.7383	unitless	default as per USEPA 2002
C =	71.7711	unitless	default as per USEPA 2002
A_s =	0.946	acres	EU 1: Areal extent of contamination (Assumes 97.5 acre square site bisected by one construction access road 2060.85 feet long and 20 feet wide).
A_s =	0.647	acres	EU 9: Areal extent of contamination (Assumes 45.6 acre square site bisected by one construction access road feet long and 20 feet wide).

$Q/C_{sr\ EU1}$ = 20.6488 g/m^2-s per kg/m^3
$Q/C_{sr\ EU9}$ = 21.9986 g/m^2-s per kg/m^3

$$F_D = 0.1852 + \frac{5.3537}{t} + \frac{-9.6318}{t^2}$$

Equation E-16, USEPA 2002

Variable	Value	Units	Rationale
$t_{(EU\ 1)}$ =	262	hours	Time vehicles are on the road during the year. (assumes 10 vehicles traversing the length (628.13 meters) of the road 4 times per day for 250 days traveling an average of 24 kph).
$t_{(EU\ 9)}$ =	179	hours	Time vehicles are on the road during the year. (assumes 10 vehicles traversing the length (628.13 meters) of the road 4 times per day for 250 days traveling an average of 24 kph).

$F_{D\ (EU\ 1)}$ = 0.205493654 unitless
$F_{D\ (EU\ 9)}$ = 0.214809886 unitless

APPENDIX F, TABLE 2
PARTICULATE EMISSIONS FACTOR CALCULATIONS
Honeywell Wastebed B/Harbor Brook Site, Geddes and Syracuse, New York

$$PEF_{const} = Q/C_{sr} \times \frac{1}{F_D} \times \frac{T \times A_R}{556 \times (W/3)^{0.4} \times \left[\frac{(365 - p)}{365}\right] \times \sum VKT}$$

Equation 5-5, USEPA 2002

Variable	Value	Units	Rationale
T =	7200000	seconds	Total time of construction (8 hours/day X 250 days X 1 year)
$A_{R\ (EU\ 1)}$ =	3831.59	m2	Area of contaminated road (L_R = 628.13 meters, W_R = 6.1 meters)
$A_{R\ (EU\ 9)}$ =	2619.16	m2	Area of contaminated road (L_R = 429.37 meters, W_R = 6.1 meters)
W =	11.5	tons	Mean vehicle weight (average of 5 pickup trucks (3 tons) and 5 dump trucks (20 tons))
$\Sigma VKT_{(EU\ 1)}$ =	6281.3	km	Sum of vehicle km traveled (10 vehicles X 4 trips/day/vehicle X 628.13 meters/trip X 250 days)
$\Sigma VKT_{(EU\ 9)}$ =	4293.7	km	Sum of vehicle km traveled (10 vehicles X 4 trips/day/vehicle X 429.37 meters/trip X 250 days)
p =	171	days	Mean number of days with 0.01 inches precipitation or more. Data for Syracuse, NY collected by Cornell University NRCC.
$PEF_{const:\ EU1}$	**8.72E+05**	**m^3/kg**	
$PEF_{const:\ EU9}$	**8.89E+05**	**m^3/kg**

TABLE 1.1
SELECTION OF EXPOSURE PATHWAYS
EXPOSURE UNIT 1 - SITE-WIDE[a]
HONEYWELL WASTEBED B/HARBOR BROOK SITE - GEDDES AND SYRACUSE, NEW YORK

Scenario Timeframe	Medium	Exposure Medium	Exposure Point	Receptor Population	Receptor Age	Exposure Route	Type of Analysis	Rationale for Selection or Exclusion of Exposure Pathway
Current/Future	Surface Soil (0-2 ft bgs)	Surface Soil	Site-wide Surface Soil	Trespasser	Older Child (Age 12 to <18)	Ingestion	Quantitative	There is potential for trespassers to incidentally ingest soil.
						Dermal	Quantitative	There is potential for trespassers to have dermal exposure to soil.
					Adult (Age >18)	Ingestion	Quantitative	There is potential for trespassers to incidentally ingest soil.
						Dermal	Quantitative	There is potential for trespassers to have dermal exposure to soil.
		Air	Ambient Air - Fugitive Dust	Trespasser	Older Child (Age 12 to <18)	Inhalation	Quantitative	There is potential for trespassers to inhale fugitive dusts.
					Adult (Age >18)	Inhalation	Quantitative	There is potential for trespassers to inhale fugitive dusts.
			Ambient Air -Volatile Emissions	Trespasser	Older Child (Age 12 to <18)	Inhalation	Quantitative	There is potential for trespassers to inhale vapors.
					Adult (Age >18)	Inhalation	Quantitative	There is potential for trespassers to inhale vapors.
	Surface and Subsurface Soil (0-10 ft bgs)	Surface and Subsurface Soil	Site-wide Surface and Subsurface Soil	Utility Worker	Adult (Age >18)	Ingestion	Quantitative	Utility workers could incidentally ingest soil to a depth of approximately 10 ft bgs repairing or installing on-site utilities.
						Dermal	Quantitative	Utility workers could have dermal exposure to soil to a depth of approximately 10 ft bgs repairing or installing on-site utilities.
		Air	Ambient Air - Fugitive Dust	Utility Worker	Adult (Age >18)	Inhalation	Quantitative	Utility workers could inhale dust originating from soil excavations as part of repairing or installing on-site utilities.
			Ambient Air -Volatile Emissions	Utility Worker	Adult (Age >18)	Inhalation	Quantitative	Utility workers could inhale vapors originating from soil excavations as part of repairing or installing on-site utilities.
	Surface Sediment (0-1 ft)	Surface Sediment	Site-wide Surface Sediment	Trespasser	Older Child (Age 12 to <18)	Ingestion	Quantitative	There is potential for trespassers to incidentally ingest surface sediment.
						Dermal	Quantitative	There is potential for trespassers to have dermal exposure to surface sediment.
					Adult (Age >18)	Ingestion	Quantitative	There is potential for trespassers to incidentally ingest surface sediment.
						Dermal	Quantitative	There is potential for trespassers to have dermal exposure to surface sediment.
	Surface and Subsurface Sediment (0-10 ft)[b]	Surface and Subsurface Sediment	Site-wide Surface and Subsurface Sediment	Utility Worker	Adult (Age >18)	Ingestion	Quantitative	Utility workers could incidentally ingest sediment during excavations as part activities related to on-site utilities.
						Dermal	Quantitative	Utility workers could have dermal exposure to sediment during excavations as part of activities related to on-site utilities.
	Surface Water	Surface Water	Site-wide Surface Water	Trespasser	Older Child (Age 12 to <18)	Dermal	Quantitative	Trespasser could have dermal exposure to surface water.
					Adult (Age >18)	Dermal	Quantitative	Trespasser could have dermal exposure to surface water.
				Utility Worker	Adult (Age >18)	Dermal	Quantitative	Utility workers could have dermal exposure to surface water during excavations as part of activities related to on-site utilities.

TABLE 1.1
SELECTION OF EXPOSURE PATHWAYS
EXPOSURE UNIT 1 - SITE-WIDE[a]
HONEYWELL WASTEBED B/HARBOR BROOK SITE - GEDDES AND SYRACUSE, NEW YORK

Scenario Timeframe	Medium	Exposure Medium	Exposure Point	Receptor Population	Receptor Age	Exposure Route	Type of Analysis	Rationale for Selection or Exclusion of Exposure Pathway
Current/Future (cont'd)	Onondaga Lake Fish Tissue[c]	Fish Tissue	Onondaga Lake Fish Tissue	Trespasser[d]	Older Child (Age 12 to <18)	Ingestion	Quantitative	Trespasser could ingest fish if recreational angling is practiced unlawfully.
					Adult (Age >18)	Ingestion	Quantitative	Trespasser could ingest fish if recreational angling is practiced unlawfully.
	Shallow Ground Water (0-10 ft bgs)	Shallow Ground Water	Site-wide Shallow Ground Water	Utility Worker	Adult (Age >18)	Ingestion	None	Incidental ingestion of shallow ground water present during excavations as part of repairing or installing on-site utilities is expected to be *de minimis*.
						Dermal	Quantitative	Utility workers could have dermal exposure to shallow ground water present during excavations as part of repairing or installing on-site utilities.
Future	Surface and Subsurface Soil (0-10 ft bgs)	Surface and Subsurface Soil	Site-wide Surface and Subsurface Soil	Construction Worker	Adult (Age >18)	Ingestion	Quantitative	Future construction workers could incidentally ingest soil to a depth of approximately 10 ft bgs as part of construction projects.
						Dermal	Quantitative	Future construction workers could have dermal exposure to soil to a depth of approximately 10 ft bgs as part of construction projects.
		Air	Ambient Air - Fugitive Dust	Construction Worker	Adult (Age >18)	Inhalation	Quantitative	Future construction workers could inhale dust originating from soil excavations as part of construction projects.
			Ambient Air -Volatile Emissions	Construction Worker	Adult (Age >18)	Inhalation	Quantitative	Future construction workers could inhale vapors originating from soil excavations as part of construction projects.
	Surface and Subsurface Sediment (0-1 ft)[b]	Surface and Subsurface Sediment	Site-wide Surface and Subsurface Sediment	Construction Worker	Adult (Age >18)	Ingestion	Quantitative	Construction workers could incidentally ingest sediment while conducting activities.
					Adult (Age >18)	Dermal	Quantitative	Construction workers could have dermal contact with sediment while conducting activities.
	Surface Water	Surface Water	Site-wide Surface Water	Construction Worker	Adult (Age >18)	Dermal	Quantitative	Construction workers could have dermal contact with surface water while conducting activities.
	Shallow Ground Water (0-10 ft bgs)	Shallow Ground Water	Site-wide Shallow Ground Water	Construction Worker	Adult (Age >18)	Dermal	Quantitative	Future construction workers could have dermal exposure to shallow ground water present during excavations as part of construction projects.

Notes:

a = Site wide designation does not include State wetland SYW-12 area, which is evaluated seperately in this assessment (see Table 1.9).

b = Where contruction or utility workers have may contact with the sediment of Harbor Brook, a depth interval of 0 - 10 ft bgs is applied. This reflects the potential for contact with deeper sediments for bridge reconstruction, which is anticipated and unique to the Harbor Brook exposure area. In a few instances, sediment samples with start depths of 0 ft and end depths ranging from >1 to 3 ft were also incorporated in the evaluation of surface sediment.

c = Fish tissue collected from Onondaga Lake is used herein, given the lack of available fish tissue data from Harbor Brook but recognizing the hydrologic connection between Harbor Brook and Onondaga Lake.

d = Recreation is not currently allowed; a trespasser is therefore evaluated in current scenario. Trespassing includes the fish ingestion pathway and will therefore be protective of a recreator.

TABLE 1.2
SELECTION OF EXPOSURE PATHWAYS
EXPOSURE UNIT 2 - HARBOR BROOK, LAKESHORE AREA, EAST FLUME, DSA #1, AND DSA #2
HONEYWELL WASTEBED B/HARBOR BROOK SITE - GEDDES AND SYRACUSE, NEW YORK

Scenario Timeframe	Medium	Exposure Medium	Exposure Point	Receptor Population	Receptor Age	Exposure Route	Type of Analysis	Rationale for Selection or Exclusion of Exposure Pathway
Current/Future	Surface Soil (0-2 ft bgs)[a]	Surface Soil	EU-2 Surface Soils	Surveillance Worker	Adult (Age >18)	Ingestion	Quantitative	A surveillance worker may incidentally ingest surface soil while performing his/her duties.
						Dermal	Quantitative	A surveillance worker may have dermal exposure to soil while performing his/her duties.
		Air	Ambient Air - Fugitive Dust	Surveillance Worker	Adult (Age >18)	Inhalation	Quantitative	Surveillance workers could inhale fugitive dust.
			Ambient Air -Volatile Emissions	Surveillance Worker	Adult (Age >18)	Inhalation	Quantitative	Surveillance workers could inhale vapors originating from soil.

Notes:

a = Exposure to surface soil is not limited to vehicle paths of travel; soil data from the entire exposure unit is used to evaluate risk to the surveillance worker.

TABLE 1.3
SELECTION OF EXPOSURE PATHWAYS
EXPOSURE UNIT 3 - INTERSTATE 690 DRAINAGE DITCH
HONEYWELL WASTEBED B/HARBOR BROOK SITE - GEDDES AND SYRACUSE, NEW YORK

Scenario Timeframe	Medium	Exposure Medium	Exposure Point	Receptor Population	Receptor Age	Exposure Route	Type of Analysis	Rationale for Selection or Exclusion of Exposure Pathway
Current/Future	Surface Water	Storm Water	I-690 Drainage Ditch	Ditch Worker	Adult (Age >18)	Ingestion	None	Incidental ingestion of surface (storm) water is expected to be *de minimis*.
						Dermal	Quantitative	A drainage ditch worker may be dermally exposed to surface (storm) water while performing his/her duties.
	Sediment (0-1 ft bgs)	Sediment	I-690 Drainage Ditch Sediment	Ditch Worker	Adult (Age >18)	Ingestion	Quantitative	A ditch worker may incidentally ingest sediment while performing his/her duties.
						Dermal	Quantitative	A ditch worker may have dermal exposure to sediment while performing his/her duties.
		Air	Ambient Air -Volatile Emissions	Ditch Worker	Adult (Age >18)	Inhalation	Quantitative	Due to the ephemeral nature of the I-690 drainage ditch, periods of time where sediment is exposed are possible. Inhalation of volatile compounds originating from sediment could occur.

TABLE 1.4
SELECTION OF EXPOSURE PATHWAYS
EXPOSURE UNIT 4 - RAILROAD AREA
HONEYWELL WASTEBED B/HARBOR BROOK SITE - GEDDES AND SYRACUSE, NEW YORK

Scenario Timeframe	Medium	Exposure Medium	Exposure Point	Receptor Population	Receptor Age	Exposure Route	Type of Analysis	Rationale for Selection or Exclusion of Exposure Pathway
Current/Future	Surface Soil (0-2 ft bgs)	Surface Soil	EU-4 Surface Soils	Railroad Worker	Adult (Age >18)	Ingestion	Quantitative	A railroad worker may incidentally ingest soil while performing his/her duties.
						Dermal	Quantitative	A railroad worker may have dermal exposure to soil while performing his/her duties.
		Air	Ambient Air - Fugitive Dust	Railroad Worker	Adult (Age >18)	Inhalation	Quantitative	A railroad worker could inhale fugitive dust while performing his/her duties.
			Ambient Air -Volatile Emissions	Railroad Worker	Adult (Age >18)	Inhalation	Quantitative	A railroad worker could inhale vapors while performing his/her duties.

TABLE 1.5
SELECTION OF EXPOSURE PATHWAYS
EXPOSURE UNIT 5 - PENN-CAN PROPERTY
HONEYWELL WASTEBED B/HARBOR BROOK SITE - GEDDES AND SYRACUSE, NEW YORK

Scenario Timeframe	Medium	Exposure Medium	Exposure Point	Receptor Population	Receptor Age	Exposure Route	Type of Analysis	Rationale for Selection or Exclusion of Exposure Pathway
Current/Future	Surface Soil (0-2 ft bgs)	Surface Soil	EU-5 Surface Soils	Commercial/ Industrial Worker	Adult (Age >18)	Ingestion	Quantitative	A commercial/industrial worker may incidentally ingest soil while performing his/her duties.
						Dermal	Quantitative	A commercial/industrial worker may have dermal exposure to soil while performing his/her duties.
		Air	Ambient Air - Fugitive Dust	Commercial/ Industrial Worker	Adult (Age >18)	Inhalation	Quantitative	A commercial/industrial worker could inhale fugitive dust while performing his/her duties outside.
			Ambient Air -Volatile Emissions	Commercial/ Industrial Worker	Adult (Age >18)	Inhalation	Quantitative	A commercial/industrial worker could inhale vapors while performing his/her duties outside.
	Surface and Subsurface Soil (0-10 ft bgs)	Air	Indoor Air - Vapor Intrusion	Commercial/ Industrial Worker	Adult (Age >18)	Inhalation	Quantitative	Vapors originating from soil VOCs may enter building workspace. When soil vapor data is available, detected constituents are evaluated using the framework presented in USEPA (2004) Developing Indoor Air Decision Matrices for Screening and Interim Actions.
	Shallow Ground Water (0-10 ft bgs)	Air	Indoor Air - Vapor Intrusion	Commercial/ Industrial Worker	Adult (Age >18)	Inhalation	Quantitative	Constituents in ground water also have the potenial to migrate to the occupational workspace. When sub-surface soil vapor data is unavailable, ground water data will be screened with respect to USEPA OSWER (2002) ground water to indoor air critieria.

SELECTION OF EXPOSURE PATHWAYS
EXPOSURE UNIT 6 - HARBOR BROOK, LAKESHORE AREA, EAST FLUME, DSA #1, DSA #2, AND AOS #1
HONEYWELL WASTEBED B/HARBOR BROOK SITE - GEDDES AND SYRACUSE, NEW YORK

Scenario Timeframe	Medium	Exposure Medium	Exposure Point	Receptor Population	Receptor Age	Exposure Route	Type of Analysis	Rationale for Selection or Exclusion of Exposure Pathway
Future	Surface Soil (0-2 ft bgs)	Surface Soil	EU-6 Surface Soils	Recreational Visitor	Adult (Age >18)	Ingestion	Quantitative	The potential exists for future recreational visitors to incidentally ingest surface soil.
						Dermal	Quantitative	The potential exists for future recreational visitors to have dermal contact with surface soil.
					Child (Age 0 to <6)	Ingestion	Quantitative	The potential exists for future recreational visitors to incidentally ingest surface soil.
						Dermal	Quantitative	The potential exists for future recreational visitors to have dermal contact with surface soil.
				Resident	Adult (Age >18)	Ingestion	Quantitative	Although residential use of the Site is not expected, the potential for future residents to incidentally ingest surface soil will be evaluated in the analysis of uncertainty.
						Dermal	Quantitative	Although residential use of the Site is not expected, the potential for future residents to have dermal contact with surface soil will be evaluated in the analysis of uncertianty.
					Child (Age 0 to <6)	Ingestion	Quantitative	Although residential use of the Site is not expected, the potential for future residents to incidentally ingest surface soil will be evaluated in the analysis of uncertainty.
						Dermal	Quantitative	Although residential use of the Site is not expected, the potential for future residents to have dermal contact with surface soil will be evaluated in the analysis of uncertainty.
		Air	Ambient Air - Fugitive Dust	Recreational Visitor	Adult (Age >18)	Inhalation	Quantitative	There is potential for a recreational visitor to inhale fugitive dust.
					Child (Age 0 to <6)	Inhalation	Quantitative	There is potential for a recreational visitor to inhale fugitive dust.
				Resident	Adult (Age >18)	Inhalation	Quantitative	Residential use of the Site is not expected. Nonetheless, potential inhalation of fugitive dust by a resident will be evaluated in the analysis of uncertainty.
					Child (Age 0 to <6)	Inhalation	Quantitative	Residential use of the Site is not expected. Nonetheless, potential inhalation of fugitive dust by a resident will be evaluated in the analysis of uncertainty.
			Ambient Air -Volatile Emissions	Recreational Visitor	Adult (Age >18)	Inhalation	Quantitative	There is potential for a recreational visitor to inhale vapors.
					Child (Age 0 to <6)	Inhalation	Quantitative	There is potential for a recreational visitor to inhale vapors.
				Resident	Adult (Age >18)	Inhalation	Quantitative	Residential use of the Site is not expected. Nonetheless, potential inhalation of vapors by a resident will be evaluated in the analysis of uncertainty.
					Child (Age 0 to <6)	Inhalation	Quantitative	Residential use of the Site is not expected. Nonetheless, potential inhalation of vapors by a resident will be evaluated in the analysis of uncertainty.

TABLE 1.8
SELECTION OF EXPOSURE PATHWAYS
EXPOSURE UNIT 8 - SITE-WIDE GROUND WATER[a]
HONEYWELL WASTEBED B/HARBOR BROOK SITE - GEDDES AND SYRACUSE, NEW YORK

Scenario Timeframe	Medium	Exposure Medium	Exposure Point	Receptor Population	Receptor Age	Exposure Route	Type of Analysis	Rationale for Selection or Exclusion of Exposure Pathway
Future	Ground Water	Drinking Water	Potable Water Sites	Resident	Child (Age 0 to <6)	Ingestion	Quantitative	This is a hypothetical scenario. The Site is zoned as industrial and is unlikely to be developed as a residential area. However, this pathway is being evaluated because the use designation for this aquifer is as a potable water supply and the Nation Contingency Plan states the ground water must be returned to its most beneficial use. Children may ingest ground water during the course of normal activities such drinking potable water.
						Dermal	Quantitative	This is a hypothetical scenario. The Site is zoned as industrial and is unlikely to be developed as a residential area. However, this pathway is being evaluated because the use designation for this aquifer is as a potable water supply and the Nation Contingency Plan states the ground water must be returned to its most beneficial use. Children may have dermal contact with ground water during the course of normal activities such as bathing/showering.
						Inhalation	Quantitative	This is a hypothetical scenario. The Site is zoned as industrial and is unlikely to be developed as a residential area. However, this pathway is being evaluated because the use designation for this aquifer is as a potable water supply and the Nation Contingency Plan states the ground water must be returned to its most beneficial use. Children may inhale vapors originating from potable ground water during bathing/showering.
					Adult (Age >18)	Ingestion	Quantitative	This is a hypothetical scenario. The Site is zoned as industrial and is unlikely to be developed as a residential area. However, this pathway is being evaluated because the use designation for this aquifer is as a potable water supply and the Nation Contingency Plan states the ground water must be returned to its most beneficial use. Adults may ingest ground water during the course of normal activities such drinking potable water.
						Dermal	Quantitative	This is a hypothetical scenario. The Site is zoned as industrial and is unlikely to be developed as a residential area. However, this pathway is being evaluated because the use designation for this aquifer is as a potable water supply and the Nation Contingency Plan states the ground water must be returned to its most beneficial use. Adults may have dermal contact with potable ground water during the course of normal activities such as bathing/showering.

TABLE 1.8
SELECTION OF EXPOSURE PATHWAYS
EXPOSURE UNIT 8 - SITE-WIDE GROUND WATER[a]
HONEYWELL WASTEBED B/HARBOR BROOK SITE - GEDDES AND SYRACUSE, NEW YORK

Scenario Timeframe	Medium	Exposure Medium	Exposure Point	Receptor Population	Receptor Age	Exposure Route	Type of Analysis	Rationale for Selection or Exclusion of Exposure Pathway
Future (cont'd)	Ground Water (cont'd)	Drinking Water (cont'd)	Potable Water Sites (cont'd)	Resident (cont'd)	Adult (Age >18) (cont'd)	Inhalation	Quantitative	This is a hypothetical scenario. The Site is zoned as industrial and is unlikely to be developed as a residential area. However, this pathway is being evaluated because the use designation for this aquifer is as a potable water supply and the Nation Contingency Plan states the ground water must be returned to its most beneficial use. Adults may inhale vapors originating from potable ground water during bathing/showering.
				Commercial/Industrial Worker	Adult (Age >18)	Ingestion	Quantitative	This is a hypothetical scenario. The Site is zoned as industrial and it is unlikely that ground water will be used as a potable water source. However, this pathway is being evaluated because the use designation for this aquifer is as a potable water supply and the Nation Contingency Plan states the ground water must be returned to its most beneficial use.

a = Includes SYW-12

TABLE 1.9
SELECTION OF EXPOSURE PATHWAYS
EXPOSURE UNIT 9 - STATE WETLAND SYW-12
HONEYWELL WASTEBED B/HARBOR BROOK SITE - GEDDES AND SYRACUSE, NEW YORK

Scenario Timeframe	Medium	Exposure Medium	Exposure Point	Receptor Population	Receptor Age	Exposure Route	Type of Analysis	Rationale for Selection or Exclusion of Exposure Pathway
Current/Future	Surface Soil (0-2 ft bgs)	Surface Soil	EU-9 Surface Soils	Recreational Visitor	Child (Age 0 to <6)	Ingestion	Quantitative	There is potential for recreators to incidentally ingest surface soil. An Older Child Trespasser may also ingest surface soil at SYW-12. However, the Child Recreational Visitor is protective of the Older Child Trespasser.
						Dermal	Quantitative	There is potential for recreators to have dermal exposure to surface soil. An Older Child Trespasser may also have dermal exposure to surface soil at SYW-12. However, the Child Recreational Visitor is protective of the Older Child Trespasser.
					Adult (Age >18)	Ingestion	Quantitative	There is potential for recreators to incidentally ingest surface soil. An AdultTrespasser may also ingest surface soil at SYW-12. However, the Adult Recreational Visitor is protective of the Adult Trespasser.
						Dermal	Quantitative	There is potential for recreators to have dermal exposure to surface soil. An Adult Trespasser may also have dermal expsoure to surface soil at SYW-12. However, the Adult Recreational Visitor is protective of the Adult Trespasser.
				Railroad Worker	Adult (Age >18)	Ingestion	Quantitative	There is potential for railroad workers to incidentally ingest surface soil.
						Dermal	Quantitative	There is potential for railroad workers to have dermal exposure to surface soil.
		Air	Ambient Air - Fugitive Dust	Recreational Visitor	Child (Age 0 to <6)	Inhalation	Quantitative	Recreators could inhale fugitive dust while visiting SYW-12. An Older Child Trespasser may also inhale fugitive dust while visiting SYW-12. However, the Child Recreational Visitor is protective of the Older Child Trespasser.
					Adult (Age >18)	Inhalation	Quantitative	Recreators could inhale fugitive dust while visiting SYW-12. An Adult Trespasser may also inhale fugitive dust while visiting SYW-12. However, the Adult Recreational Visitor is protective of the Adult Trespasser.
				Railroad Worker	Adult (Age >18)	Inhalation	Quantitative	A railroad worker could inhale fugitive dust while performing his/her duties.
			Ambient Air -Volatile Emissions	Recreational Visitor	Child (Age 0 to <6)	Inhalation	Quantitative	Recreators could inhale vapors while visiting SYW-12. An Older Child Trespasser may also inhale vapors while visiting SYW-12. However, the Child Recreational Visitor is protective of the Older Child Trespasser.
					Adult (Age >18)	Inhalation	Quantitative	Recreators could inhale vapors while visiting SYW-12. An Adult Trespasser may also inhale vapors while visiting SYW-12. However, the Adult Recreational Visitor is protective of the Adult Trespasser.
				Railroad Worker	Adult (Age >18)	Inhalation	Quantitative	A railroad worker could inhale vapors while performing his/her duties outside.

TABLE 1.9
SELECTION OF EXPOSURE PATHWAYS
EXPOSURE UNIT 9 - STATE WETLAND SYW-12
HONEYWELL WASTEBED B/HARBOR BROOK SITE - GEDDES AND SYRACUSE, NEW YORK

Scenario Timeframe	Medium	Exposure Medium	Exposure Point	Receptor Population	Receptor Age	Exposure Route	Type of Analysis	Rationale for Selection or Exclusion of Exposure Pathway
Current/Future (Cont'd)	Surface and Subsurface Soil (0-10 ft bgs)	Surface and Subsurface Soil	EU-9 Surface and Subsurface Soil	Utility Worker	Adult (Age >18)	Ingestion	Quantitative	Utility workers could incidentally ingest soil to a depth of approximately 10 ft bgs repairing or installing on-site utilities.
						Dermal	Quantitative	Utility workers could have dermal exposure to soil to a depth of approximately 10 ft bgs repairing or installing on-site utilities.
	Surface and Subsurface Soil (0-10 ft bgs) (cont'd)	Air	Ambient Air - Fugitive Dust	Utility Worker	Adult (Age >18)	Inhalation	Quantitative	Utility workers could inhale dust originating from soil excavations as part of repairing or installing on-site utilities.
			Ambient Air -Volatile Emissions	Utility Worker	Adult (Age >18)	Inhalation	Quantitative	Utility workers could inhale vapors originating from soil excavations as part of repairing or installing on-site utilities.
	Shallow Ground Water (0-10 ft bgs)	Shallow Ground Water	EU-9 Shallow Ground Water	Utility Worker	Adult (Age >18)	Ingestion	None	Incidental ingestion of shallow ground water present during excavations as part of repairing or installing on-site utilities is expected to be *de minimis.*
						Dermal	Quantitative	Utility workers could have dermal exposure to shallow ground water present during excavations as part of repairing or installing on-site utilities.
Future	Surface Soil (0-2 ft bgs)	Surface Soil	EU-9 Surface Soils	Resident	Child (Age 0 to <6)	Ingestion	Quantitative	Although residential use of the Site is not expected, if residental occupancy were to occur, there is potential for them to incidentally ingest surface soil.
						Dermal	Quantitative	Although residential use of the Site is not expected, if residental occupancy were to occur, there is potential for them to have dermal contact with surface soil.
					Adult (Age >18)	Ingestion	Quantitative	Although residential use of the Site is not expected, if residental occupancy were to occur, there is potential for them to incidentally ingest surface soil.
						Dermal	Quantitative	Although residential use of the Site is not expected, if residental occupancy were to occur, there is potential for them to have dermal contact with surface soil.
				Commercial/ Industrial Worker	Adult (Age >18)	Ingestion	Quantitative	If future buildings were constructed, a commercial/industrial worker may incidentally ingest surface soil while performing his/her duties outside.
						Dermal	Quantitative	If future buildings were constructed, a commercial/industrial worker may have dermal exposure to surface soil while performing his/her duties outside.
		Air	Ambient Air - Fugitive Dust	Resident	Child (Age 0 to <6)	Inhalation	Quantitative	Although residental use of the Site is not expected, if residential occupancy were to occur, a resident could inhale fugitive dust during the course of his/her activities.
					Adult (Age >18)	Inhalation	Quantitative	Although residental use of the Site is not expected, if residential occupancy were to occur, a resident could inhale fugitive dust during the course of his/her activities.
				Commercial/ Industrial Worker	Adult (Age >18)	Inhalation	Quantitative	A commercial/industrial worker could inhale fugitive dust while performing his/her duties outside.

TABLE 1.9
SELECTION OF EXPOSURE PATHWAYS
EXPOSURE UNIT 9 - STATE WETLAND SYW-12
HONEYWELL WASTEBED B/HARBOR BROOK SITE - GEDDES AND SYRACUSE, NEW YORK

Scenario Timeframe	Medium	Exposure Medium	Exposure Point	Receptor Population	Receptor Age	Exposure Route	Type of Analysis	Rationale for Selection or Exclusion of Exposure Pathway
Future (Cont'd)	Surface Soil (0-2 ft bgs) (cont'd)	Air (cont'd)	Ambient Air - Volatile Emissions	Resident	Child (Age 0 to <6)	Inhalation	Quantitative	Although residental use of the Site is not expected, if residential occupancy were to occur, a resident could inhale vapors during the course of his/her activities.
					Adult (Age >18)	Inhalation	Quantitative	Although residental use of the Site is not expected, if residential occupancy were to occur, a resident could inhale vapors during the course of his/her activities.
				Commercial/ Industrial Worker	Adult (Age >18)	Inhalation	Quantitative	A commercial/industrial worker could inhale vapors while performing his/her duties outside.
	Surface and Subsurface Soil (0-10 ft bgs)	Surface and Subsurface Soil	EU-9 Surface and Subsurface Soil	Construction Worker	Adult (Age >18)	Ingestion	Quantitative	Construction workers could incidentally ingest soil to a depth of approximately 10 ft bgs while conducting activities.
						Dermal	Quantitative	Construction workers could have dermal exposure to soil to a depth of approximately 10 ft bgs while conducting activities.
		Air	Ambient Air - Fugitive Dust	Construction Worker	Adult (Age >18)	Inhalation	Quantitative	Construction workers could inhale dust originating from soil excavations as part of construction projects.
			Ambient Air -Volatile Emissions	Construction Worker	Adult (Age >18)	Inhalation	Quantitative	Construction workers could inhale vapors originating from soil excavations as part of construction projects.
			Indoor Air - Vapor Intrusion	Resident	Adult (Age >18)	Inhalation	Qualitative	Residential use of the Site is not anticpated. However, vapors originating from soil VOCs may enter residential buildings, if they were to exist. When soil data is available, detected constituents are evaluated using the framework presented in USEPA (2004) Developing Indoor Air Decision Matrices for Screening and Interim Actions.
					Child (Age 0 to <6)	Inhalation	Qualitative	Residential use of the Site is not anticpated. However, vapors originating from soil VOCs may enter residential buildings, if they were to exist. When soil data is available, detected constituents are evaluated using the framework presented in USEPA (2004) Developing Indoor Air Decision Matrices for Screening and Interim Actions.
				Commercial/ Industrial Worker	Adult (Age >18)	Inhalation	Quantitative	Vapors originating from soil VOCs may enter building workspace. When soil data is available, detected constituents are screened using the framework presented in USEPA (2004) Developing Indoor Air Decision Matrices for Screening and Interim Actions.
	Shallow Ground Water (0-10 ft bgs)	Shallow Ground Water	EU-9 Shallow Ground Water	Construction Worker	Adult (Age >18)	Ingestion	None	Incidental ingestion of shallow ground water present during excavations is expected to be *de minimis*.
						Dermal	Quantitative	Construction workers could have dermal exposure to shallow ground water present during excavations as part of construction projects.

Footnotes:
(1) J - estimated value; N - tentatively identified at an estimated value
(2) Concentration used for screening is the maximum detected concentration.
(3) N/A - No background screening performed.
(4) United States Environmental Protection Agency. 2008. National Primary and Secondary Drinking Water Regulations.
(5) USEPA Region 3 RBCs (USEPA 2007) for tap water; C = Cancer RBC; N = Noncancer RBC; NV = No value in Region 3 RBC data set. Noncancer RBCs adjusted by multiplying RBC by 0.1.
(6) USEPA Region 9 PRGs (USEPA 2004) for tap water; ca = Cancer PRG; nc = Noncancer PRG; NV = No value in Region 9 PRG data set. Noncancer PRGs adjusted by multiplying PRG by 0.1.
(7) The Screening Toxicity Value represents the minimum of the Region 3 RBC and the Region 9 PRG.
(8) Selection Rationale: ASL - Above Screening Level; TOX - Class A Carcinogen; NTX - No Toxicity Information. Deletion Rationale: BSL - Below Screening Level
- = Compound detected in 100% of samples.
a = RBC and PRG values for chromium VI utilized.
b = Where mercury is not speciated, RBC and PRG values for methyl mercury utilized.
c = When detected, reflects summary statistics of Aroclors 1248, 1254, and 1260. RBC and PRG values for Aroclor-1254 (CAS# 11097691) utilized. Range of detection limits based on Aroclor 1254.
d = Reflects summary statistics of all detected Aroclors. RBC and PRG values for Aroclor-1254 (CAS# 11097691) utilized. Range of detection limits based on Aroclor 1254.
e = RBC value for chlordane (CAS# 57749) and PRG value for technical chlordane (CAS# 12789-03-6) utilized.
f = RBC and PRG values for endosulfan (CAS# 115297) utilized.
g = RBC and PRG values for 4-methylphenol (CAS# 106445) utilized.

Definitions:
ARAR: Applicable or Relevant and Appropriate Requirements
CAS: Chemical Abstract Service
COPC: Compound of Potential Concern
NUT: Compound is an essential nutrient and is not screened in
NV: No Value
PRG: Preliminary Remediation Goals; USEPA, 2004
RBC: Risk Based Concentration; USEPA, October 2007
TBC: To Be Considered
USEPA: United States Environmental Protection Agency

TABLE 2.2a
OCCURRENCE, DISTRIBUTION, AND SELECTION OF CHEMICALS OF POTENTIAL CONCERN
HONEYWELL WASTEBED B/HARBOR BROOK SITE - LAKESHORE AREA SURFACE SOIL
GEDDES AND SYRACUSE, NEW YORK

Scenario: Current/Future
Medium: Soil
Exposure Medium: Surface Soil (0-2 ft bgs)

Exposure Point	CAS Number	Chemical	Minimum Detected Concentration (1)	Maximum Detected Concentration (1)	Units	Location of Maximum Concentration	Detection Frequency	Range of Detection Limits	Concentration Used for Screening (2)	Background Value (3)	Potential ARAR/TBC Value (4)	USEPA RBC for Residential Soil (5)		USEPA PRG for Residential Soil (6)		Screening Toxicity Value (7)	COPC Flag (Y/N)	Rationale for Selection or Deletion (8)

Footnotes:
(1) J - estimated value; N - tentatively identified at an estimated value
(2) Concentration used for screening is the maximum detected concentration.
(3) No background screening performed.
(4) Values are from New York Subpart 375-6 Soil Cleanup Objectives. Values reflect residential restricted use for the protection of human health.
(5) USEPA Region 3 RBCs (USEPA 2007) for residential soil; C = Cancer RBC; N = Noncancer RBC; NV = No value in Region 3 RBC data set. Noncancer RBCs adjusted by multiplying RBC by 0.1.
(6) USEPA Region 9 PRGs (USEPA 2004) for residential soil; ca = Cancer PRG; nc = Noncancer PRG; NV = No value in Region 9 PRG data set. Noncancer PRGs adjusted by multiplying PRG by 0.1.
(7) The Screening Toxicity Value represents the minimum of the Region 3 RBC and the Region 9 PRG.
(8) Selection Rationale: ASL - Above Screening Level; TOX - Class A Carcinogen; NTX - No Toxicity Information. Deletion Rationale: BSL - Below Screening Level
(9) Based on use of WHO toxicity equivalency factors for dioxins and dioxin-like compounds from Van den Berg et al. (2006); see Table 2.2b.
- = Compound detected in 100% of samples.
NA = Not applicable, minimum and maximum values are calculated.
a = RBC and PRG values for chromium VI utilized.
b = RBC and PRG values for mercury compounds utilized.
c = When detected, reflects summary statistics of Aroclor 1221, 1232, 1016, and 1242. RBC and PRG values for Aroclor-1016 (CAS# 12674112) utilized. Range of detection limits based on Aroclor 1016.
d = When detected, reflects summary statistics of Aroclors 1248, 1254, and 1260. RBC and PRG values for Aroclor-1254 (CAS# 11097691) utilized. Range of detection limits based on Aroclor 1254.
e = Reflects summary statistics of all detected Aroclors. RBC and PRG values for Aroclor-1254 (CAS# 11097691) utilized. Range of detection limits based on Aroclor 1254.
f = Where criteria are not available, RBC value for chlordane (CAS# 57749) and PRG value for technical chlordane (CAS# 12789-03-6) utilized.
g = RBC and PRG values for Endosulfan (CAS# 115297) utilized.
h = RC and PRG values for Endrin (CAS# 72208) utilized.
i = RBC and PRG values for 4-methylphenol (CAS# 106445) utilized.

Definitions:
ARAR: Applicable or Relevant and Appropriate Requirements
CAS: Chemical Abstacts Service
COPC: Compound of Potential Concern
NUT: Compound is an essential nutrient and is not screened in
NV: No Value
PRG: Preliminary Remediation Goals; USEPA, 2004
RBC: Risk Based Concentration; USEPA, October 2007
TBC: To Be Considered
USEPA: United States Environmental Protection Agency

NOTES:

TCDD/F = Tetra Chlorinated Dibenzo-p-dioxins/Dibenzofurans

PECDD/F = Penta Chlorinated Dibenzo-p-dioxins/Dibenzofurans

HXCDD/F = Hexa Chlorinated Dibenzo-p-dioxins/Dibenzofurans

HPCDD/F = Hepta Chlorinated Dibenzo-p-dioxins/Dibenzofurans

OCDD/F = Octa Chlorinated Dibenzo-p-dioxins/Dibenzofurans

N/A = not applicable

EMPC = Estimated Maximum Possible Concentration

Footnotes:
(1) J - estimated value; N - tentatively identified at an estimated value
(2) Concentration used for screening is the maximum detected concentration.
(3) No background screening performed.
(4) Values are from New York Subpart 375-6 Soil Cleanup Objectives (SCO). Values reflect residential restricted use for the protection of human health.
(5) USEPA Region 3 RBCs (USEPA 2007) for residential soil; C = Cancer RBC; N = Noncancer RBC; NV = No value in Region 3 RBC data set. Noncancer RBCs adjusted by multiplying RBC by 0.1.
(6) USEPA Region 9 PRGs (USEPA 2004) for residential soil; ca = Cancer PRG; nc = Noncancer PRG; NV = No value in Region 9 PRG data set. Noncancer PRGs adjusted by multiplying PRG by 0.1.
(7) The Screening Toxicity Value represents the minimum of the Region 3 RBC and the Region 9 PRG.
(8) Selection Rationale: ASL - Above Screening Level; TOX - Class A Carcinogen; NTX - No Toxicity Information. Deletion Rationale: BSL - Below Screening Level
(9) Based on use of WHO toxicity equivalency factors for dioxins and dioxin-like compounds from Van den Berg et al. (2006); see Table 2.3b.
- = Compound detected in 100% of samples.
NA = Not applicable, minimum and maximum values are calculated.
a = RBC and PRG values for chromium VI utilized.
b = RBC and PRG values for mercury compounds utilized.
c = When detected, reflects summary statistics of Aroclor 1221, 1232, 1016, and 1242. RBC and PRG values for Aroclor-1016 (CAS# 12674112) utilized. Range of detection limits based on Aroclor 1016.
d = When detected, reflects summary statistics of Aroclors 1248, 1254, and 1260. RBC and PRG values for Aroclor-1254 (CAS# 11097691) utilized. Range of detection limits based on Aroclor 1254.
e = Reflects summary statistics of all detected Aroclors. RBC and PRG values for Aroclor-1254 (CAS# 11097691) utilized. Range of detection limits based on Aroclor 1254.
f = Where criteria are not available, RBC value for chlordane (CAS# 57749) and PRG value for technical chlordane (CAS# 12789-03-6) utilized.
g = RBC and PRG values for Endosulfan (CAS #115297) utilized.
h = RBC and PRG values for Endrin (CAS# 72208) utilized.
i = RBC and PRG values for 4-methylphenol (CAS# 106445) utilized.

Definitions:
ARAR: Applicable or Relevant and Appropriate Requirements
CAS: Chemical Abstract Service
COPC: Compound of Potential Concern
NUT: Compound is an essential nutrient and is not screened in
NV: No Value
PRG: Preliminary Remediation Goals; USEPA, 2004
RBC: Risk Based Concentration; USEPA, October, 2007
TBC: To Be Considered
USEPA: United States Environmental Protection Agency

NOTES:
TCDD/F = Tetra Chlorinated Dibenzo-p-dioxins/Dibenzofurans
PeCDD/F = Penta Chlorinated Dibenzo-p-dioxins/Dibenzofurans
HxCDD/F = Hexa Chlorinated Dibenzo-p-dioxins/Dibenzofurans
HpCDD/F = Hepta Chlorinated Dibenzo-p-dioxins/Dibenzofurans
OCDD/F = Octa Chlorinated Dibenzo-p-dioxins/Dibenzofurans
N/A = not applicable
EMPC = Estimated Maximum Possible Concentration

Notes:

* Less Chlorinated PCBs were defined as Aroclors 1221, 1232, 1016, and 1242. Highly Chlorinated PCBs were defined as Aroclors 1248, 1254, 1260, and higher if reported. Total PCBs are the sum of all detected Aroclors.

Footnotes:
* Sample start depth less than or equal to 10 ft bgs.
** Target soil gas concentration exceeds maximum possible vapor concentration (pathway incomplete)
(1) J - estimated value
(2) Concentration used for screening is the maximum detected concentration.
(3) N/A - No background screening performed.
(4) Primary and Secondary Drinking Water Regulations
(5) USEPA - OSWER Draft Guidance for Evaluating the Vapor Intrusion to Indoor Air Pathway from Groundwater and Soils (Subsurface Vapor Intrusion Guidance) Tables. November 2002. ca = Cancer; nc = Noncancer. Screening criteria correspond to a cancer risk of 10^{-6} and a noncancer hazard of 0.1. For USEPA (2002) criteria that defaulted to MCLs, criteria were derived (in italics) from USEPA (2009) RSL residential air concentration based on an attenuation factor of 10 and the Henry's Law constant for each compound at 25 deg C.
(6) Selection Rationale: ASL - Above Screening Level; TOX - Class A Carcinogen; NTX - No Toxicity Information. Deletion Rationale: BSL - Below Screening Level; INC - Pathway Incomplete
a =Target groundwater concentration for p-xylene (CAS #106-42-3) utilized.

Definitions:
ARAR: Applicable or Relevant and Appropriate Requirements
CAS: Chemical Abstract Service
COPC: Compound of Potential Concern
NV: No Value
TBC: To Be Considered
USEPA: United States Environmental Protection Agency

Footnotes:
*Sample start depth less than or equal to 10 ft bgs.
(1) J - estimated value; N - tentatively identified at an estimated value
(2) Concentration used for screening is the maximum detected concentration.
(3) N/A - No background screening performed.
(4) United States Environmental Protection Agency. 2008. National Primary and Secondary Drinking Water Regulations.
(5) USEPA Region 3 RBCs (USEPA 2007) for tap water; C = Cancer RBC; N = Noncancer RBC; NV = No value in Region 3 RBC data set. Noncancer RBCs adjusted by multiplying RBC by 0.1.
(6) USEPA Region 9 PRGs (USEPA 2004) for tap water; ca = Cancer PRG; nc = Noncancer PRG; NV = No value in Region 9 PRG data set. Noncancer PRGs adjusted by multiplying PRG by 0.1.
(7) The Screening Toxicity Value represents the minimum of the Region 3 RBC and the Region 9 PRG.
(8) Selection Rationale: ASL - Above Screening Level; TOX - Class A Carcinogen; NTX - No Toxicity Information. Deletion Rationale: BSL - Below Screening Level
- = Compound detected in 100% of samples.
a = RBC and PRG values for chromium VI utilized.
b = Where mercury is not speciated, RBC and PRG values for methyl mercury utilized.
c = When detected, reflects summary statistics of Aroclor 1221, 1232, 1016, and 1242. RBC and PRG values for Aroclor-1016 (CAS# 12674112) utilized. Range of detection limits based on Aroclor 1254.
d = Reflects summary statistics of all detected Aroclors. RBC and PRG values for Aroclor-1254 (CAS# 11097691) utilized. Range of detection limits based on Aroclor 1254.
e = RBC and PRG value for 4-methylphenol (CAS # 106445) utilized.

Definitions:

ARAR: Applicable or Relevant and Appropriate Requirements
CAS: Chemical Abstract Service
COPC: Compound of Potential Concern
NUT: Compound is an essential nutrient and not screened in
NV: No Value
PRG: Preliminary Remediation Goals; USEPA, 2004
RBC: Risk Based Concentration; USEPA, October, 2007
TBC: To Be Considered
USEPA: United States Environmental Protection Agency

TABLE 2.5b
DERIVATION OF PCB EQUIVALENTS FOR CHLORINATED CHEMICALS
HONEYWELL WASTEBED B/HARBOR BROOK SITE - LAKESHORE AREA SHALLOW GROUND WATER

Chlorination Level*	Sample Location	Start Depth (ft)	End Depth (ft)	Sample Date	Sum of Location PCB Concentration	Units
Highly Chlorinated PCBs	HB-HB-06S	3	13	5/23/2001	0.07	ug/l
Total PCBs	HB-HB-06S	3	13	5/23/2001	0.07	ug/l

Notes:

*Highly chlorinated PCBs were defined as Arorclors 1248, 1254, 1260, and higher if reported. Total PCBs are the sum of all detected Arorclors.

Footnotes:
(1) J - estimated value; N - tentatively identified at an estimated value
(2) Concentration used for screening is the maximum detected concentration.
(3) N/A - No background screening performed.
(4) United States Environmental Protection Agency. 2008. National Primary and Secondary Drinking Water Regulations.
(5) USEPA Region 3 RBCs (USEPA 2007) for tap water; C = Cancer RBC; N = Noncancer RBC; NV = No value in Region 3 RBC data set. Noncancer RBCs adjusted by multiplying RBC by 0.1.
(6) USEPA Region 9 PRGs (USEPA 2004) for tap water; ca = Cancer PRG; nc = Noncancer PRG; NV = No value in Region 9 PRG data set. Noncancer PRGs adjusted by multiplying PRG by 0.1
(7) The Screening Toxicity Value represents the minimum of the Region 3 RBC and the Region 9 PRG.
(8) Selection Rationale: ASL - Above Screening Level; TOX - Class A Carcinogen; NTX - No Toxicity Information. Deletion Rationale: BSL - Below Screening Level
- = Compound detected in 100% of samples.
a = Where mercury is not speciated, RBC and PRG values for methyl mercury utilized.
b = RBC and PRG values for 4-methylphenol (CAS # 106445) utilized.

Definitions:
ARAR: Applicable or Relevant and Appropriate Requirements
CAS: Chemical Abstract Service
COPC: Compound of Potential Concern
NUT: Compound is an essential nutrient and not screened in
NV: No Value
PRG: Preliminary Remediation Goals, USEPA, 2004
RBC: Risk Based Concentration; USEPA, October, 2007
TBC: To Be Considered
USEPA: United States Environmental Protection Agency

Footnotes:
(1) J - estimated value; N - tentatively identified at an estimated value
(2) Concentration used for screening is the maximum detected concentration.
(3) No background screening performed.
(4) Values are from New York Subpart 375-6 Soil Cleanup Objectives (SCO). Values reflect residential restricted use for the protection of human health.
(5) USEPA Region 3 RBCs (USEPA 2007) for residential soil; C = Cancer RBC; N = Noncancer RBC; NV = No value in Region 3 RBC data set. Noncancer RBCs adjusted by multiplying RBC by 0.1.
(6) USEPA Region 9 PRGs (USEPA 2004) for residential soil; ca = Cancer PRG; nc = Noncancer PRG; NV = No value in Region 9 PRG data set. Noncancer PRGs adjusted by multiplying PRG by
(7) The Screening Toxicity Value represents the minimum of the Region 3 RBC and the Region 9 PRG.
(8) Selection Rationale: ASL - Above Screening Level; TOX - Class A Carcinogen; NTX - No Toxicity Information. Deletion Rationale: BSL - Below Screening Level
- = Compound detected in 100% of samples.
NA = Not applicable, minimum and maximum values are calculated.
a = RBC and PRG values for chromium VI utilized.
b = Where mercury is not speciated, RBC and PRG values for methyl mercury utilized.
c = When detected, reflects summary statistics of Aroclors 1248, 1254, and 1260. RBC and PRG values for Aroclor-1254 (CAS# 11097691) utilized. Range of detection limits based on Aroclor 1254.
d = Reflects summary statistics of all detected Aroclors. RBC and PRG values for Aroclor-1254 (CAS# 11097691) utilized. Range of detection limits based on Aroclor 1254.
e = RBC and PRG values for Endosulfan (CAS# 115297) utilized.
f = RBC and PRG values for Endrin (CAS# 72208) utilized
g = RBC and PRG values for 4-methylphenol (CAS# 106445) utilized.

Definitions:
ARAR: Applicable or Relevant and Appropriate Requirements
CAS: Chemical Abstract Service
COPC: Compound of Potential Concern
NUT: Compound is an essential nutrient and is not screened in
NV: No Value
PRG: Preliminary Remediation Goals; USEPA, 2004
RBC: Risk Based Concentration; USEPA, October, 2007
TBC: To Be Considered
USEPA: United States Environmental Protection Agency

Footnotes:
(1) J - estimated value; N - tentatively identified at an estimated value.
(2) Concentration used for screening is the maximum detected concentration.
(3) No background screening performed.
(4) Values are from New York Subpart 375-6 Soil Cleanup Objectives (SCO). Values reflect residential restricted use for the protection of human health.
(5) USEPA Region 3 RBCs (USEPA 2007) for residential soil; C = Cancer RBC; N = Noncancer RBC; NV = No value in Region 3 RBC data set. Noncancer RBCs adjusted by multiplying RBC by 0.1.
(6) USEPA Region 9 PRGs (USEPA 2004) for residential soil; ca = Cancer PRG; nc = Noncancer PRG; NV = No value in Region 9 PRG data set. Noncancer PRGs adjusted by multiplying PRG by 0.1.
(7) The Screening Toxicity Value represents the minimum of the Region 3 RBC and the Region 9 PRG.
(8) Selection Rationale: ASL - Above Screening Level; TOX - Class A Carcinogen; NTX - No Toxicity Information. Deletion Rationale: BSL - Below Screening Level.
- = Compound detected in 100% of samples.
NA = Not applicable, minimum and maximum values are calculated.
a = RBC and PRG values for chromium VI utilized.
b = Where mercury is not speciated, RBC and PRG values for methyl mercury utilized.
c = When detected, reflects summary statistics of Aroclors 1248, 1254, and 1260. RBC and PRG values for Aroclor-1254 (CAS# 11097691) utilized. Range of detection limists based on Aroclor 1254.
d = Reflects summary statistics of all detected Aroclors. RBC and PRG values for Aroclor-1254 (CAS# 11097691) utilized. Range of detection limists based on Aroclor 1254.
e = RBC and PRG values for Endosulfan (CAS # 1115297) utilized.
f = RBC and PRG values for Endrin (CAS # 72208) utilized.
g = RBC and PRG values for 4-methylphenol (CAS # 106445) utilized.

Definitions:
ARAR: Applicable or Relevant and Appropriate Requirements
CAS: Chemical Abstract Service
COPC: Compound of Potential Concern
NUT: Compound is an essential nutrient and is not screened in
NV: No Value
PRG: Preliminary Remediation Goals; USEPA, 2004
RBC: Risk Based Concentration; USEPA, October, 2007
TBC: To Be Considered
USEPA: United States Environmental Protection Agency

Footnotes:
(1) J - estimated value; N - tentatively identified at an estimated value
(2) Concentration used for screening is the maximum detected concentration.
(3) N/A - No background screening performed.
(4) USEPA - Regional Screening Level Table. April 2009. c = Cancer; n = Noncancer. Cancer risk = 10^{-5} and Noncancer hazard = 1. Note for trichloroethene and tetrachlorethene, screening criteria are based on NYSDOH target indoor air concentration.
(5) Decision Rationale: ASL - Above Screening Level; TOX - Class A Carcinogen; NTX - No Toxicity Information. Deletion Rationale: BSL - Below Screening Level
- = Compound detected in 100% of samples.

Definitions:
ARAR: Applicable or Relevant and Appropriate Requirements
CAS: Chemical Abstract Service
COPC: Compound of Potential Concern
NV: No Value
TBC: To Be Considered
USEPA: United States Environmental Protection Agency

Footnotes:
*Sample start depth less than or equal to 10 ft bgs.
** Target soil gas concentration exceeds maximum possible vapor concentration (pathway incomplete)
(1) J - estimated value
(2) Concentration used for screening is the maximum detected concentration.
(3) N/A - No background screening performed.
(4) United States Environmental Protection Agency. 2008. National Primary and Secondary Drinking Water Regulations.
(5) USEPA - OSWER Draft Guidance for Evaluating the Vapor Intrusion to Indoor Air Pathway from Groundwater and Soils (Subsurface Vapor Intrusion Guidance) Tables. November 2002. ca = Cancer; nc = Noncancer. Screening criteria correspond to a cancer risk of 10-6 and a noncancer hazard of 0.1. For USEPA (2002) criteria that defaulted to MCLs, criteria were derived (in italics) from USEPA (2009) RSL residential air concentration based on an attenuation factor of 10 and the Henry's Law constant for each compound at 25 deg C.
(6) Selection Rationale: ASL - Above Screening Level; TOX - Class A Carcinogen; NTX - No Toxicity Information. Deletion Rationale: BSL - Below Screening Level; INC - Pathway Incomplete
a = Target groundwater concentration for p-xylene (CAS #106-42-3) utilized.

Definitions:
ARAR: Applicable or Relevant and Appropriate Requirements
CAS: Chemical Abstract Service
COPC: Compound of Potential Concern
NV: No Value
TBC: To Be Considered
USEPA: United States Environmental Protection Agency

Footnotes:
*Sample start depth less than or equal to 10 ft bgs.
(1) J - estimated value; N - tentatively identified at an estimated value
(2) Concentration used for screening is the maximum detected concentration.
(3) N/A - No background screening performed.
(4) United States Environmental Protection Agency. 2008. National Primary and Secondary Drinking Water Regulations.
(5) USEPA Region 3 RBCs (USEPA 2007) for tap water; C = Cancer RBC; N = Noncancer RBC; NV = No value in Region 3 RBC data set. Noncancer RBCs adjusted by multiplying RBC by 0.1.
(6) USEPA Region 9 PRGs (USEPA 2004) for tap water; ca = Cancer PRG; nc = Noncancer PRG; NV = No value in Region 9 PRG data set. Noncancer PRGs adjusted by multiplying PRG by 0.1.
(7) The Screening Toxicity Value represents the minimum of the Region 3 RBC and the Region 9 PRG.
(8) Selection Rationale: ASL - Above Screening Level; TOX - Class A Carcinogen; NTX - No Toxicity Information. Deletion Rationale: BSL - Below Screening Level
- = Compound detected in 100% of samples.
a = RBC and PRG values for chromium VI utilized.
b = Where mercury is not speciated, RBC and PRG values for methyl mercury utilized.
c = When detected, reflects summary statistics of Aroclors 1248, 1254, and 1260. RBC and PRG values for Aroclor-1254 (CAS# 11097691) utilized. Range of detection limits based on Aroclor 1254.
d = Reflects summary statistics of all detected Aroclors. RBC and PRG values for Aroclor-1254 (CAS# 11097691) utilized. Range of detection limits based on Aroclor 1254.
e = RBC and PRG values for 4-methylphenol (CAS # 106445) utilized.

Definitions:
ARAR: Applicable or Relevant and Appropriate Requirements
CAS: Chemical Abstract Service
COPC: Compound of Potential Concern
NUT: Compound is an essential nutrient and not screened in
NV: No Value
PRG: Preliminary Remediation Goals, USEPA, 2004
RBC: Risk Based Concentration; USEPA, October 2007
TBC: To Be Considered
USEPA: United States Environmental Protection Agency

TABLE 2.10b
DERIVATION OF PCB EQUIVALENTS FOR CHLORINATED CHEMICALS
HONEYWELL WASTEBED B/HARBOR BROOK SITE - PENN-CAN PROPERTY SHALLOW GROUND WATER

Chlorination Level*	Sample Location	Start Depth (ft)	End Depth (ft)	Sample Date	Sum of Location PCB Concentration	Units
Highly Chlorinated PCBs	HB-HB-11S	3.98	13.98	5/11/2001	0.3	ug/l
Total PCBs	HB-HB-11S	3.98	13.98	5/11/2001	0.3	ug/l

Notes:

* Highly Chlorinated PCBs were defined as Aroclors 1248, 1254, 1260, and higher if reported. Total PCBs are the sum of all detected Aroclors.

Footnotes:
(1) J - estimated value; N - tentatively identified at an estimated value
(2) Concentration used for screening is the maximum detected concentration.
(3) No background screening performed.
(4) USEPA Region 3 RBCs (USEPA 2007) for residential soil; C = Cancer RBC; N = Noncancer RBC; NV = No value in Region 3 RBC data set. Noncancer RBCs adjusted by multiplying RBC by 0.1.
(5) USEPA Region 9 PRGs (USEPA 2004) for residential soil; ca = Cancer PRG; nc = Noncancer PRG; NV = No value in Region 9 PRG data set. Noncancer PRGs adjusted by multiplying PRG by 0.1.
(6) The Screening Toxicity Value represents the minimum of the Region 3 RBC and the Region 9 PRG.
(7) Selection Rationale: ASL - Above Screening Level; TOX - Class A Carcinogen; NTX - No Toxicity Information. Deletion Rationale: BSL - Below Screening Level
(8) Based on use of WHO toxicity equivalency factors for dioxins and dioxin-like compounds from Van den Berg et al. (2006); see Table 2.11b.
- = Compound detected in 100% of samples.
NA = Not applicable, minimum and maximum values are calculated.
a = RBC and PRG values for chromium VI utilized.
b = Where mercury is not speciated, RBC and PRG values for methyl mercury utilized.
c = When detected, reflects summary statistics of Aroclors 1248, 1254, and 1260. RBC and PRG values for Aroclor-1254 (CAS# 11097691) utilized. Range of detection limits based on Aroclor 1254.
d = Reflects summary statistics of all detected Aroclors. RBC and PRG values for Aroclor-1254 (CAS# 11097691) utilized. Range of detection limits based on Aroclor 1254.

Definitions:
ARAR: Applicable or Relevant and Appropriate Requirements
CAS: Chemical Abstract Service
COPC: Compound of Potential Concern
NUT: Compound is an essential nutrient and is not screened in
NV: No Value
PRG: Preliminary Remediation Goals, USEPA, 2004
RBC: Risk Based Concentration; USEPA, October, 2007
TBC: To Be Considered
USEPA: United States Environmental Protection Agency

Footnotes:
(1) J - estimated value; N - tentatively identified at an estimated value
(2) Concentration used for screening is the maximum detected concentration.
(3) N/A - No background screening performed.
(4) United States Environmental Protection Agency. 2008. National Primary and Secondary Drinking Water Regulations.
(5) USEPA Region 3 RBCs (USEPA 2007) for tap water; C = Cancer RBC; N = Noncancer RBC; NV = No value in Region 3 RBC data set. Noncancer RBCs adjusted by multiplying RBC by 0.1.
(6) USEPA Region 9 PRGs (USEPA 2004) for tap water; ca = Cancer PRG; nc = Noncancer PRG; NV = No value in Region 9 PRG data set. Noncancer PRGs adjusted by multiplying PRG by 0.1.
(7) The Screening Toxicity Value represents the minimum of the Region 3 RBC and the Region 9 PRG.
(8) Selection Rationale: ASL - Above Screening Level; TOX - Class A Carcinogen; NTX - No Toxicity Information. Deletion Rationale: BSL - Below Screening Level
= Compound detected in 100% of samples.
a = RBC and PRG values for chromium VI utilized.
b = RBC and PRG values for methyl mercury utilized.
c = RBC and PRG values for 4-methylphenol (CAS # 106445) utilized.

Definitions:
ARAR: Applicable or Relevant and Appropriate Requirements
CAS: Chemical Abstract Service
COPC: Compound of Potential Concern
NUT: Compound is an essential nutrient and not screened in
NV: No Value
PRG: Preliminary Remediation Goals, USEPA, 2004
RBC: Risk Based Concentration; USEPA, October, 2007
TBC: To Be Considered
USEPA: United States Environmental Protection Agency

Footnotes:
(1) J - estimated value; N - tentatively identified at an estimated value
(2) Concentration used for screening is the maximum detected concentration.
(3) No background screening performed.
(4) Values are from New York Subpart 375-6 Soil Cleanup Objectives (SCO). Values reflect residential restricted use for the protection of human health.
(5) USEPA Region 3 RBCs (USEPA 2007) for residential soil; C = Cancer RBC; N = Noncancer RBC; NV = No value in Region 3 RBC data set. Noncancer RBCs adjusted by multiplying RBC by 0.1.
(6) USEPA Region 9 PRGs (USEPA 2004) for residential soil; ca = Cancer PRG; nc = Noncancer PRG; NV = No value in Region 9 PRG data set. Noncancer PRGs adjusted by multiplying PRG by 0.1.
(7) The Screening Toxicity Value represents the minimum of the Region 3 RBC and the Region 9 PRG.
(8) Selection Rationale: ASL - Above Screening Level; TOX - Class A Carcinogen; NTX - No Toxicity Information. Deletion Rationale: BSL - Below Screening Level
- = Compound detected in 100% of samples.
NA = Not applicable, minimum and maximum values are calculated.
a = RBC and PRG values for chromium VI utilized.
b = Where mercury is not speciated, RBC and PRG values for methyl mercury utilized.
c = When detected, reflects summary statistics of Aroclor 1221, 1232, 1016, and 1242. RBC and PRG values for Aroclor-1016 (CAS# 12674112) utilized. Range of detection limits based on Aroclor 1016.
d = When detected, reflects summary statistics of Aroclors 1248, 1254, and 1260. RBC and PRG values for Aroclor-1254 (CAS# 11097691) utilized. Range of detection limits based on Aroclor 1254.
e = Reflects summary statistics of all detected Aroclors. RBC and PRG values for Aroclor-1254 (CAS# 11097691) utilized. Range of detection limits based on Aroclor 1254.

Definitions:
ARAR: Applicable or Relevant and Appropriate Requirements
CAS: Chemical Abstract Service
COPC: Compound of Potential Concern
NUT: Compound is an essential nutrient and is not screened in
NV: No Value
PRG: Preliminary Remediation Goals, USEPA, 2004
RBC: Risk Based Concentration; USEPA, October, 2007
TBC: To Be Considered
USEPA: United States Environmental Protection Agency

TABLE 2.13b
DERIVATION OF PCB EQUIVALENTS FOR CHLORINATED CHEMICALS
HONEYWELL WASTEBED B/HARBOR BROOK SITE - RAILROAD AREA SURFACE SOIL (0-2 FT BGS)

Chlorination Level*	Sample Location	Start Depth (ft)	End Depth (ft)	Sample Date	Sum of Location PCB Concentration	Units
Highly Chlorinated PCBs	HB-GP-25	0	0.17	2/28/2001	0.01	mg/kg
Highly Chlorinated PCBs	HB-GP-27	0	0.17	3/1/2001	0.003	mg/kg
Highly Chlorinated PCBs	HB-GP-30	0	0.17	3/2/2001	0.006	mg/kg
Highly Chlorinated PCBs	HB-HB-08D	0	0.17	2/27/2001	0.02	mg/kg
Highly Chlorinated PCBs	HB-HB-09	0	0.17	2/26/2001	0.01	mg/kg
Highly Chlorinated PCBs	HB-RISB-09	0	0.5	3/10/2003	0.069	mg/kg
Less Chlorinated PCBs	HB-GP-25	0	0.17	2/28/2001	0.003	mg/kg
Total PCBs	HB-GP-25	0	0.17	2/28/2001	0.013	mg/kg
Total PCBs	HB-GP-27	0	0.17	3/1/2001	0.003	mg/kg
Total PCBs	HB-GP-30	0	0.17	3/2/2001	0.006	mg/kg
Total PCBs	HB-HB-08D	0	0.17	2/27/2001	0.02	mg/kg
Total PCBs	HB-HB-09	0	0.17	2/26/2001	0.01	mg/kg
Total PCBs	HB-RISB-09	0	0.5	3/10/2003	0.07	mg/kg

Notes:
* Less chlorinated PCBs were defined as Aroclors 1221, 1232, 1016, and 1242. Highly chlorinated PCBs were defined as Aroclors 1248, 1254, 1260, and higher if reported. Total PCBs are the sum of all detected Aroclors.

Footnotes:
(1) J - estimated value; N - tentatively identified at an estimated value
(2) Concentration used for screening is the maximum detected concentration.
(3) No background screening performed.
(4) Values are from New York Subpart 375-6 Soil Cleanup Objectives (SCO). Values reflect residential restricted use for the protection of human health.
(5) USEPA Region 3 RBCs (USEPA 2007) for residential soil; C = Cancer RBC; N = Noncancer RBC; NV = No value in Region 3 RBC data set. Noncancer RBCs adjusted by multiplying RBC by 0.1.
(6) USEPA Region 9 PRGs (USEPA 2004) for residential soil; ca = Cancer PRG; nc = Noncancer PRG; NV = No value in Region 9 PRG data set. Noncancer PRGs adjusted by multiplying PRG by 0.1.
(7) The Screening Toxicity Value represents the minimum of the Region 3 RBC and the Region 9 PRG.
(8) Selection Rationale: ASL - Above Screening Level; TOX - Class A Carcinogen; NTX - No Toxicity Information. Deletion Rationale: BSL - Below Screening Level
- = Compound detected in 100% of samples.
NA = Not applicable, minimum and maximum values are calculated.
a = RBC and PRG values for chromium VI utilized.
b = Where mercury is not speciated, RBC and PRG values for methyl mercury utilized.
c = When detected, reflects summary statistics of Aroclor 1221, 1232, 1016, and 1242. RBC and PRG values for Aroclor-1016 (CAS# 12674112) utilized. Range of detection limits based on Aroclor 1016.
d = When detected, reflects summary statistics of Aroclors 1248, 1254, and 1260. RBC and PRG values for Aroclor-1254 (CAS# 11097691) utilized. Range of detection limits based on Aroclor 1254.
e = Reflects summary statistics of all detected Aroclors. RBC and PRG values for Aroclor-1254 (CAS# 11097691) utilized. Range of detection limits based on Aroclor 1254.
f = RBC value for chlordane (CAS# 57749) and PRG value for technical chlordane (CAS# 12789-03-6) utilized.
g = RBC and PRG values for 4-methylphenol (CAS # 106445) utilized.

Definitions:
ARAR: Applicable or Relevant and Appropriate Requirements
CAS: Chemical Abstract Service
COPC: Compound of Potential Concern
NUT: Compound is an essential nutrient and is not screened in
NV: No Value
PRG: Preliminary Remediation Goals, USEPA, 2004
RBC: Risk Based Concentration; USEPA, October, 2007
TBC: To Be Considered
USEPA: United States Environmental Protection Agency

Footnotes:
*Sample start depth less than or equal to 10 ft bgs.
(1) J - estimated value; N - tentatively identified at an estimated value
(2) Concentration used for screening is the maximum detected concentration.
(3) N/A - No background screening performed.
(4) United States Environmental Protection Agency. 2008. National Primary and Secondary Drinking Water Regulations.
(5) USEPA Region 3 RBCs (USEPA 2007) for tap water; C = Cancer RBC; N = Noncancer RBC; NV = No value in Region 3 RBC data set. Noncancer RBCs adjusted by multiplying RBC by 0.1.
(6) USEPA Region 9 PRGs (USEPA 2004) for tap water; ca = Cancer PRG; nc = Noncancer PRG; NV = No value in Region 9 PRG data set. Noncancer PRGs adjusted by multiplying PRG by 0.1.
(7) The Screening Toxicity Value represents the minimum of the Region 3 RBC and the Region 9 PRG.
(8) Selection Rationale: ASL - Above Screening Level; TOX - Class A Carcinogen; NTX - No Toxicity Information. Deletion Rationale: BSL - Below Screening Level
- = Compound detected in 100% of samples.
a = RBC and PRG values for chromium VI utilized.

Definitions:
ARAR: Applicable or Relevant and Appropriate Requirements
CAS: Chemical Abstract Service
COPC: Compound of Potential Concern
NUT: Compound is an essential nutrient and not screened in
NV: No Value
PRG: Preliminary Remediation Goals, USEPA, 2004
RBC: Risk Based Concentration; USEPA, October, 2007
TBC: To Be Considered
USEPA: United States Environmental Protection Agency

Footnotes:
(1) J - estimated value; N - tentatively identified at an estimated value
(2) Concentration used for screening is the maximum detected concentration.
(3) No background screening performed.
(4) USEPA Region 3 RBCs (USEPA 2007) for residential soil; C = Cancer RBC; N = Noncancer RBC; NV = No value in Region 3 RBC data set. Noncancer RBCs adjusted by multiplying RBC
(5) USEPA Region 9 PRGs (USEPA 2004) for residential soil; ca = Cancer PRG; nc = Noncancer PRG; NV = No value in Region 9 PRG data set. Noncancer PRGs adjusted by multiplying PRG
(6) The Screening Toxicity Value represents the minimum of the Region 3 RBC and the Region 9 PRG.
(7) Selection Rationale: ASL - Above Screening Level; TOX - Class A Carcinogen; NTX - No Toxicity Information. Deletion Rationale: BSL - Below Screening Level
(8) Based on use of WHO toxicity equivalency factors for dioxins and dioxin-like compounds from Van den Berg et al. (2006); see Table 2.16b.
- = Compound detected in 100% of samples.
NA = Not applicable, minimum and maximum values are calculated.
a = RBC and PRG values for chromium VI utilized.
b = Where mercury is not speciated, RBC and PRG values for methyl mercury utilized.
c = When detected, reflects summary statistics of Aroclors 1248, 1254, and 1260. RBC and PRG values for Aroclor-1254 (CAS# 11097691) utilized. Range of detection limits based on Aroclor 1254.
d = Reflects summary statistics of all detected Aroclors. RBC and PRG values for Aroclor-1254 (CAS# 11097691) utilized. Range of detection limits based on Aroclor 1254.
e = RBC value for chlordane (CAS# 57749) and PRG value for technical chlordane (CAS# 12789-03-6) utilized.

Definitions:
ARAR: Applicable or Relevant and Appropriate Requirements
CAS: Chemical Abstract Service
COPC: Compound of Potential Concern
NUT: Compound is an essential nutrient and is not screened in
NV: No Value
PRG: Preliminary Remediation Goals, USEPA, 2004
RBC: Risk Based Concentration; USEPA, October, 2007
TBC: To Be Considered
USEPA: United States Environmental Protection Agency

Footnotes:
(1) J - estimated value; N - tentatively identified at an estimated value
(2) Concentration used for screening is the maximum detected concentration.
(3) N/A - No background screening performed.
(4) United States Environmental Protection Agency. 2008. National Primary and Secondary Drinking Water Regulations.
(5) USEPA Region 3 RBCs (USEPA 2007) for tap water; C = Cancer RBC; N = Noncancer RBC; NV = No value in Region 3 RBC data set. Noncancer RBCs adjusted by multiplying RBC by 0.1.
(6) USEPA Region 9 PRGs (USEPA 2004) for tap water; ca = Cancer PRG; nc = Noncancer PRG; NV = No value in Region 9 PRG data set. Noncancer PRGs adjusted by multiplying PRG by 0.1.
(7) The Screening Toxicity Value represents the minimum of the Region 3 RBC and the Region 9 PRG.
(8) Selection Rationale: ASL - Above Screening Level; TOX - Class A Carcinogen; NTX - No Toxicity Information. Deletion Rationale: BSL - Below Screening Level
- = Compound detected in 100% of samples.
a = RBC and PRG values for chromium VI utilized.
b = Where mercury is not speciated, RBC and PRG values for methyl mercury utilized.

Definitions:
ARAR: Applicable or Relevant and Appropriate Requirements
CAS: Chemical Abstract Service
COPC: Compound of Potential Concern
NUT: Compound is an essential nutrient and not screened in
NV: No Value
PRG: Preliminary Remediation Goals, USEPA, 2004
RBC: Risk Based Concentration; USEPA, October, 2007
TBC: To Be Considered
USEPA: United States Environmental Protection Agency

Footnotes:
(1) J - estimated value; N - tentatively identified at an estimated value
(2) Concentration used for screening is the maximum detected concentration.
(3) No background screening performed.
(4) USEPA Region 3 RBCs (USEPA 2007) for residential soil; C = Cancer RBC; N = Noncancer RBC; NV = No value in Region 3 RBC data set. Noncancer RBCs adjusted by multiplying RBC by 0.1.
(5) USEPA Region 9 PRGs (USEPA 2004) for residential soil; ca = Cancer PRG; nc = Noncancer PRG; NV = No value in Region 9 PRG data set. Noncancer PRGs adjusted by multiplying PRG by 0.1.
(6) The Screening Toxicity Value represents the minimum of the Region 3 RBC and the Region 9 PRG.
(7) Selection Rationale: ASL - Above Screening Level; TOX - Class A Carcinogen; NTX - No Toxicity Information. Deletion Rationale: BSL - Below Screening Level
(8) Based on use of WHO toxicity equivalency factors for dioxins and dioxin-like compounds from Van den Berg et al. (2006); see Table 2.18b.
- = Compound detected in 100% of samples.
NA = Not applicable, minimum and maximum values are calculated.
a = RBC and PRG values for chromium VI utilized.
b = Where mercury is not speciated, RBC and PRG values for methyl mercury utilized.
c = When detected, reflects summary statistics of Aroclor 1221, 1232, 1016, and 1242. RBC and PRG values for Aroclor-1016 (CAS# 12674112) utilized. Range of detection limits based on Aroclor 1016.
d = When detected, reflects summary statistics of Aroclors 1248, 1254, and 1260. RBC and PRG values for Aroclor-1254 (CAS# 11097691) utilized. Range of detection limits based on Aroclor 1254.
e = Reflects summary statistics of all detected Aroclors. RBC and PRG values for Aroclor-1254 (CAS# 11097691) utilized. Range of detection limits based on Aroclor 1254.
f = Where criteria are not available, RBC value for chlordane (CAS# 57749) and PRG value for technical chlordane (CAS# 12789-03-6) utilized.
g = RBC and PRG values for Endosulfan (CAS# 115297) utilized.
h = RBC and PRG values for Endrin (CAS # 72208) utilized.
i = RBC and PRG values for 4-methylphenol utilized.

Definitions:
ARAR: Applicable or Relevant and Appropriate Requirements
CAS: Chemical Abstract Service
COPC: Compound of Potential Concern
NUT: Compound is an essential nutrient and is not screened in
NV: No Value
PRG: Preliminary Remediation Goals, USEPA, 2004
RBC: Risk Based Concentration; USEPA, October, 2007
TBC: To Be Considered
USEPA: United States Environmental Protection Agency

Footnotes:
(1) J - estimated value; N - tentatively identified at an estimated value
(2) Concentration used for screening is the maximum detected concentration.
(3) No background screening performed.
(4) USEPA Region 3 RBCs (USEPA 2007) for residential soil; C = Cancer RBC; N = Noncancer RBC; NV = No value in Region 3 RBC data set. Noncancer RBCs adjusted by multiplying RBC by 0.1.
(5) USEPA Region 9 PRGs (USEPA 2004) for residential soil; ca = Cancer PRG; nc = Noncancer PRG; NV = No value in Region 9 PRG data set. Noncancer PRGs adjusted by multiplying PRG by 0.1.
(6) The Screening Toxicity Value represents the minimum of the Region 3 RBC and the Region 9 PRG.
(7) Selection Rationale: ASL - Above Screening Level; TOX - Class A Carcinogen; NTX - No Toxicity Information. Deletion Rationale: BSL - Below Screening Level
(8) Based on use of WHO toxicity equivalency factors for dioxins and dioxin-like compounds from Van den Berg et al. (2006); see Table 2.19b.
- = Compound detected in 100% of samples.
NA = Not applicable, minimum and maximum values are calculated.
a = RBC and PRG values for chromium VI utilized.
b = Where mercury is not speciated, RBC and PRG values for methyl mercury utilized.
c = When detected, reflects summary statistics of Aroclor 1221, 1232, 1016, and 1242. RBC and PRG values for Aroclor-1016 (CAS# 12674112) utilized. Range of detection limits based on Aroclor 1016.
d = When detected, reflects summary statistics of Aroclors 1248, 1254, and 1260. RBC and PRG values for Aroclor-1254 (CAS# 11097691) utilized. Range of detection limits based on 1254.
e = Reflects summary statistics of all detected Aroclors. RBC and PRG values for Aroclor-1254 (CAS# 11097691) utilized. Range of detection limits based on 1254.
f = Where criteria are not available, RBC value for chlordane (CAS# 57749) and PRG value for technical chlordane (CAS# 12789-03-6) utilized.
g = RBC and PRG values for Endosulfan (CAS# 115297) utilized.
h = RBC and PRG values for Endrin (CAS# 72208) utilized.
i = RBC and PRG values for 4-methylphenol utilized.

Definitions:
ARAR: Applicable or Relevant and Appropriate Requirements
CAS: Chemical Abstract Service
COPC: Compound of Potential Concern
NUT: Compound is an essential nutrient and is not screened in
NV: No Value
PRG: Preliminary Remediation Goals, USEPA, 2004
RBC: Risk Based Concentration; USEPA, October, 2007
TBC: To Be Considered
USEPA: United States Environmental Protection Agency

Total PCBs	HB-T-5-2	0	0.5	1/31/2001	0.13	mg/kg

Notes:

* Less Chlorinated PCBs were defined as Aroclors 1221, 1232, 1016, and 1242. Highly Chlorinated PCBs were defined as Aroclors 1248, 1254, 1260, and higher if reported. Total PCBs are the sum of all detected Aroclors.

TABLE 2.20a
OCCURRENCE, DISTRIBUTION, AND SELECTION OF CHEMICALS OF POTENTIAL CONCERN
HONEYWELL WASTEBED B/HARBOR BROOK SITE - HARBOR BROOK SURFACE WATER
GEDDES AND SYRACUSE, NY

Scenario Timeframe: Current/Future
Medium: Water
Exposure Medium: Surface Water

Exposure Point	CAS Number	Chemical	Minimum Detected Concentration (1)	Maximum Detected Concentration (1)	Units	Location of Maximum Concentration	Detection Frequency	Range of Detection Limits	Concentration Used for Screening (2)	Background Value (3)	Potential ARAR/TBC Value (4)	USEPA RBC for Tap Water (5)		USEPA PRG for Tap Water (6)		Screening Toxicity Value (7)	COPC Flag (Y/N)	Rationale for Selection or Deletion (8)
	100-42-5	STYRENE	0.3 J	0.3 J	ug/L	HB-HBSW-06, HB-HBSW-07	2/13	0.5-5	3.00E-01		1.00E+02	1.62E+02	N	1.64E+02	nc	1.62E+02	N	BSL
	108-88-3	TOLUENE	0.3 J	4	ug/L	HB-HBSW-06	7/13	5-5	4.00E+00		1.00E+03	2.27E+02	N	7.23E+01	nc	7.23E+01	N	BSL
	1330-20-7	XYLENES, TOTAL	0.4 J	4	ug/L	HB-HBSW-06	7/13	5-5	4.00E+00		1.00E+04	2.13E+01	N	2.06E+01	nc	2.06E+01	N	BSL

Footnotes:
(1) J - estimated value; N - tentatively identified at an estimated value
(2) Concentration used for screening is the maximum detected concentration.
(3) N/A - No background screening performed.
(4) United States Environmental Protection Agency. 2008. National Primary and Secondary Drinking Water Regulations.
(5) USEPA Region 3 RBCs (USEPA 2007) for tap water; C = Cancer RBC; N = Noncancer RBC; NV = No value in Region 3 RBC data set. Noncancer RBCs adjusted by multiplying RBC by 0.1.
(6) USEPA Region 9 PRGs (USEPA 2004) for tap water; ca = Cancer PRG; nc = Noncancer PRG; NV = No value in Region 9 PRG data set. Noncancer PRGs adjusted by multiplying PRG by 0.1.
(7) The Screening Toxicity Value represents the minimum of the Region 3 RBC and the Region 9 PRG.
(8) Selection Rationale: ASL - Above Screening Level; TOX - Class A Carcinogen; NTX - No Toxicity Information. Deletion Rationale: BSL - Below Screening Level
- = Compound detected in 100% of samples.
a = RBC and PRG values for chromium VI utilized.
b = Where mercury is not speciated, RBC and PRG values for methyl mercury utilized.

Definitions:
ARAR: Applicable or Relevant and Appropriate Requirements
CAS: Chemical Abstract Service
COPC: Compound of Potential Concern
NUT: Compound is an essential nutrient and not screened in
NV: No Value
PRG: Preliminary Remediation Goals, USEPA, 2004
RBC: Risk Based Concentration; USEPA, October, 2007
TBC: To Be Considered
USEPA: United States Environmental Protection Agency

Footnotes:
(1) J - estimated value; N - tentatively identified at an estimated value
(2) Concentration used for screening is the maximum detected concentration.
(3) No background screening performed.
(4) USEPA Region 3 RBCs (USEPA 2007) for residential soil; C = Cancer RBC; N = Noncancer RBC; NV = No value in Region 3 RBC data set. Noncancer RBCs adjusted by multiplying RBC by 0.1.
(5) USEPA Region 9 PRGs (USEPA 2004) for residential soil; ca = Cancer PRG; nc = Noncancer PRG; NV = No value in Region 9 PRG data set. Noncancer PRGs adjusted by multiplying PRG by 0.1.
(6) The Screening Toxicity Value represents the minimum of the Region 3 RBC and the Region 9 PRG.
(7) Selection Rationale: ASL - Above Screening Level; TOX - Class A Carcinogen; NTX - No Toxicity Information. Deletion Rationale: BSL - Below Screening Level
(8) Based on use of WHO toxicity equivalency factors for dioxins and dioxin-like compounds from Van den Berg et al. (2006); see Table 2.21b.
- = Compound detected in 100% of samples.
NA = Not applicable, minimum and maximum values are calculated.
a = RBC and PRG values for chromium VI utilized.
b = Where mercury is not speciated, RBC and PRG values for methyl mercury utilized.
c = HB-UEF7 site used an estimated value for maximum detected concentration.
d = Sediment samples with start depths of 0 ft and end depths ranging from >1 to 3 ft were incorporated in the evaluation of surface sediment.
e = When detected, reflects summary statistics of Aroclors 1248, 1254, and 1260. RBC and PRG values for Aroclor-1254 (CAS# 11097691) utilized. Range of detection limits based on 1254.
f = Reflects summary statistics of all detected Aroclors. RBC and PRG values for Aroclor-1254 (CAS# 11097691) utilized. Range of detection limits based on 1254.
g = RBC value for chlordane (CAS# 57749) and PRG value for technical chlordane (CAS# 12789-03-6) utilized.
h = RBC and PRG values for 4-methylphenol utilized.

Definitions:
ARAR: Applicable or Relevant and Appropriate Requirements
CAS: Chemical Abstract Service
COPC: Compound of Potential Concern
NUT: Compound is an essential nutrient and is not screened in
NV: No Value
PRG: Preliminary Remediation Goals, USEPA, 2004
RBC: Risk Based Concentration; USEPA, October, 2007
TBC: To Be Considered
USEPA: United States Environmental Protection Agency

Footnotes:
(1) J - estimated value; N - tentatively identified at an estimated value
(2) Concentration used for screening is the maximum detected concentration.
(3) N/A - No background screening performed.
(4) United States Environmental Protection Agency. 2008. National Primary and Secondary Drinking Water Regulations.
(5) USEPA Region 3 RBCs (USEPA 2007) for tap water; C = Cancer RBC; N = Noncancer RBC; NV = No value in Region 3 RBC data set. Noncancer RBCs adjusted by multiplying RBC by
(6) USEPA Region 9 PRGs (USEPA 2004) for tap water; ca = Cancer PRG; nc = Noncancer PRG; NV = No value in Region 9 PRG data set. Noncancer PRGs adjusted by multiplying PRG by
(7) The Screening Toxicity Value represents the minimum of the Region 3 RBC and the Region 9 PRG.
(8) Selection Rationale: ASL - Above Screening Level; TOX - Class A Carcinogen; NTX - No Toxicity Information. Deletion Rationale: BSL - Below Screening Level
- = Compound detected in 100% of samples.

Definitions:
ARAR: Applicable or Relevant and Appropriate Requirements
CAS: Chemical Abstract Service
COPC: Compound of Potential Concern
NUT: Compound is an essential nutrient and not screened in
NV: No Value
PRG: Preliminary Remediation Goals, USEPA, 2004
RBC: Risk Based Concentration; USEPA, October, 2007
TBC: To Be Considered
USEPA: United States Environmental Protection Agency

a = Dichlorobenzene data from outfall 015 (east flume) are data that were collected as part of Honeywell's New York State Pollution Discharge Elimination System (SPDES) permit sampling program. As part of that program, Honeywell is responsible for reporting total dichlorobenzenes each month. The SPDES data constitutes the only water data available for the East Flume and was therefore utilized in the HHRA. The screening criterion for 1,4-dichlorobenzene was utilized as a conservative measure to address protection of human health.

Footnotes:
(1) J - estimated value; N - tentatively identified at an estimated value
(2) Concentration used for screening is the maximum detected concentration.
(3) No background screening performed.
(4) USEPA Region 3 RBCs (USEPA 2007) for residential soil; C = Cancer RBC; N = Noncancer RBC; NV = No value in Region 3 RBC data set. Noncancer RBCs adjusted by multiplying RBC by 0.1.
(5) USEPA Region 9 PRGs (USEPA 2004) for residential soil; ca = Cancer PRG; nc = Noncancer PRG; NV = No value in Region 9 PRG data set. Noncancer PRGs adjusted by multiplying PRG by 0.1.
(6) The Screening Toxicity Value represents the minimum of the Region 3 RBC and the Region 9 PRG.
(7) Selection Rationale: ASL - Above Screening Level; TOX - Class A Carcinogen; NTX - No Toxicity Information. Deletion Rationale: BSL - Below Screening Level
(8) Based on use of WHO toxicity equivalency factors for dioxins and dioxin-like compounds from Van den Berg et al. (2006); see Table 2.23b.
- = Compound detected in 100% of samples.
NA = Not applicable, minimum and maximum values are calculated.
a = RBC and PRG values for chromium VI utilized.
b = Where mercury is not speciated, RBC and PRG values for methyl mercury utilized.
c = When detected, reflects summary statistics of Aroclors 1248, 1254, and 1260. RBC and PRG values for Aroclor-1254 (CAS# 11097691) utilized. Range of detection limits based on Aroclor 1254.
d = Reflects summary statistics of all detected Aroclors. RBC and PRG values for Aroclor-1254 (CAS# 11097691) utilized. Range of detection limits based on Aroclor 1254.
e = RBC value for chlordane (CAS# 57749) and PRG value for technical chlordane (CAS# 12789-03-6) utilized.
f = RBC and PRG values for 4-methylphenol (CAA# 106445) utilized.

Definitions:
ARAR: Applicable or Relevant and Appropriate Requirements
CAS: Chemical Abstract Service
COPC: Compound of Potential Concern
NUT: Compound is an essential nutrient and is not screened in
NV: No Value
PRG: Preliminary Remediation Goals, USEPA, 2004
RBC: Risk Based Concentration; USEPA, October, 2007
TBC: To Be Considered
USEPA: United States Environmental Protection Agency

NOTES:

TCDD/F = Tetra Chlorinated Dibenzo-p-dioxins/Dibenzofurans

PeCDD/F = Penta Chlorinated Dibenzo-p-dioxins/Dibenzofurans

HxCDD/F = Hexa Chlorinated Dibenzo-p-dioxins/Dibenzofurans

HpCDD/F = Hepta Chlorinated Dibenzo-p-dioxins/Dibenzofurans

OCDD/F = Octa Chlorinated Dibenzo-p-dioxins/Dibenzofurans

EMPC = Estimated Maximum Possible Concentration

N/A = not applicable, J = estimated value, U = not detected, EMPC = estimated maximum possible concentration

Footnotes:
(1) J - estimated value; N - tentatively identified at an estimated value
(2) Concentration used for screening is the maximum detected concentration.
(3) N/A - No background screening performed.
(4) United States Environmental Protection Agency. 2008. National Primary and Secondary Drinking Water Regulations.
(5) USEPA Region 3 RBCs (USEPA 2007) for tap water; C = Cancer RBC; N = Noncancer RBC; NV = No value in Region 3 RBC data set. Noncancer RBCs adjusted by multiplying RBC by 0.1.
(6) USEPA Region 9 PRGs (USEPA 2004) for tap water; ca = Cancer PRG; nc = Noncancer PRG; NV = No value in Region 9 PRG data set. Noncancer PRGs adjusted by multiplying PRG by 0.1.
(7) The Screening Toxicity Value represents the minimum of the Region 3 RBC and the Region 9 PRG.
(8) Selection Rationale: ASL - Above Screening Level; TOX - Class A Carcinogen; NTX - No Toxicity Information. Deletion Rationale: BSL - Below Screening Level
- = Compound detected in 100% of samples.
a = RBC and PRG values for chromium VI utilized.
b = Where mercury is not speciated, RBC and PRG values for methyl mercury utilized.
c = RBC and PRG values for 4-methylphenol (CAS# 106445) utilized.

Definitions:
ARAR: Applicable or Relevant and Appropriate Requirements
CAS: Chemical Abstract Service
COPC: Compound of Potential Concern
NUT: Compound is an essential nutrient and not screened in
NV: No Value
PRG: Preliminary Remediation Goals
RBC: Risk Based Concentration
TBC: To Be Considered
USEPA: United States Environmental Protection Agency

Footnotes:
(1) J estimated value; N tentatively identified at an estimated value
(2) Concentration used for screening is the maximum detected concentration.
(3) No background screening performed.
(4) Values are from New York Subpart 375-6 Soil Cleanup Objectives (SCO). Values reflect residential restricted use for the protection of human health.
(5) USEPA Region 3 RBCs (USEPA 2007) for residential soil; C = Cancer RBC; N = Noncancer RBC; NV = No value in Region 3 RBC data set. Noncancer RBCs adjusted by multiplying RBC
(6) USEPA Region 9 PRGs (USEPA 2004) for residential soil; ca = Cancer PRG; nc = Noncancer PRG; NV = No value in Region 9 PRG data set. Noncancer PRGs adjusted by multiplying
(7) The Screening Toxicity Value represents the minimum of the Region 3 RBC and the Region 9 PRG.
(8) Selection Rationale: ASL Above Screening Level; TOX Class A Carcinogen; NTX No Toxicity Information. Deletion Rationale: BSL Below Screening Level
(9) Based on use of WHO toxicity equivalency factors for dioxins and dioxin-like compounds from Van den Berg et al. (2006); see Table 2.25b.
- = Compound detected in 100% of samples.
NA = Not applicable, minimum and maximum values are calculated.
a = RBC and PRG values for chromium VI utilized.
b= RBC and PRG values for mercury compounds utilized.
c = When detected, reflects summary statistics of Aroclors 1248, 1254, and 1260. RBC and PRG values for Aroclor-1254 (CAS# 11097691) utilized. Range of detection limits based on Aroclor 1254.
d = Reflects summary statistics of all detected Aroclors. RBC and PRG values for Aroclor-1254 (CAS# 11097691) utilized. Range of detection limits based on Aroclor 1254.

Definitions:
ARAR: Applicable or Relevant and Appropriate Requirements
CAS: Chemical Abstract Service
COPC: Compound of Potential Concern
NUT: Compound is an essential nutrient and is not screened in
NV: No Value
PRG: Preliminary Remediation Goals, USEPA, 2004
RBC: Risk Based Concentration; USEPA, October, 2007
TBC: To Be Considered
USEPA: United States Environmental Protection Agency
DSA #1: Dredge Soil Area #1

Footnotes:
(1) J - estimated value; N - tentatively identified at an estimated value
(2) Concentration used for screening is the maximum detected concentration.
(3) No background screening performed.
(4) USEPA Region 3 RBCs (USEPA 2007) for residential soil; C = Cancer RBC; N = Noncancer RBC; NV = No value in Region 3 RBC data set. Noncancer RBCs adjusted by multiplying RBC by 0.1.
(5) USEPA Region 9 PRGs (USEPA 2004) for residential soil; ca = Cancer PRG; nc = Noncancer PRG; NV = No value in Region 9 PRG data set. Noncancer PRGs adjusted by multiplying PRG by 0.1.
(6) The Screening Toxicity Value represents the minimum of the Region 3 RBC and the Region 9 PRG.
(7) Selection Rationale: ASL - Above Screening Level; TOX - Class A Carcinogen; NTX - No Toxicity Information. Deletion Rationale: BSL - Below Screening Level
(8) Based on use of WHO toxicity equivalency factors for dioxins and dioxin-like compounds from Van den Berg et al. (2006); see Table 2.26b.
- = Compound detected in 100% of samples.
NA = Not applicable, minimum and maximum values are calculated.
a = RBC and PRG values for chromium VI utilized.
b= RBC and PRG values for mercury compounds utilized.
c = When detected, reflects summary statistics of Aroclor 1221, 1232, 1016, and 1242. RBC and PRG values for Aroclor-1016 (CAS# 12674112) utilized. Range of detection limits based on Aroclor 1016.
d = When detected, reflects summary statistics of Aroclors 1248, 1254, and 1260. RBC and PRG values for Aroclor-1254 (CAS# 11097691) utilized. Range of detection limits based on Aroclor 1254.
e = Reflects summary statistics of all detected Aroclors. RBC and PRG values for Aroclor-1254 (CAS# 11097691) utilized. Range of detection limits based on Aroclor 1254.
f = RBC and PRG values for isopropylbenzene are referred to as cumene (CAS # 98-82-8).

Definitions:
ARAR: Applicable or Relevant and Appropriate Requirements
CAS: Chemical Abstract Service
COPC: Compound of Potential Concern
NUT: Compound is an essential nutrient and is not screened in
NV: No Value
PRG: Preliminary Remediation Goals, USEPA, 2004
RBC: Risk Based Concentration; USEPA, October, 2007
TBC: To Be Considered
USEPA: United States Environmental Protection Agency
DSA #1: Dredge Spoil Area #1
SCO = Soil Cleanup Objective

Footnotes:
(1) J estimated value; N tentatively identified at an estimated value
(2) Concentration used for screening is the maximum detected concentration.
(3) No background screening performed.
(4) Values are from New York Subpart 375-6 Soil Cleanup Objectives (SCO). Values reflect residential restricted use for the protection of human health.
(5) USEPA Region 3 RBCs (USEPA 2007) for residential soil; C = Cancer RBC; N = Noncancer RBC; NV = No value in Region 3 RBC data set. Noncancer RBCs adjusted by multiplying RBC by 0.1.
(6) USEPA Region 9 PRGs (USEPA 2004) for residential soil; ca = Cancer PRG; nc = Noncancer PRG; NV = No value in Region 9 PRG data set. Noncancer PRGs adjusted by multiplying PRG by 0.1.
(7) The Screening Toxicity Value represents the minimum of the Region 3 RBC and the Region 9 PRG.
(8) Selection Rationale: ASL Above Screening Level; TOX Class A Carcinogen; NTX No Toxicity Information. Deletion Rationale: BSL Below Screening Level
(9) Based on use of WHO toxicity equivalency factors for dioxins and dioxin-like compounds from Van den Berg et al. (2006); see Table 2.27b.
= Compound detected in 100% of samples.
NA = Not applicable, minimum and maximum values are calculated.
a = RBC and PRG values for chromium VI utilized
b = Where mercury is not speciated, RBC and PRG values for methyl mercury utilized.
c = When detected, reflects summary statistics of Aroclor 1221, 1232, 1016, and 1242. RBC and PRG values for Aroclor-1016 (CAS# 12674112) utilized. Range of detection limits based on Aroclor 1016.
d = When detected, reflects summary statistics of Aroclors 1248, 1254, and 1260. RBC and PRG values for Aroclor-1254 (CAS# 11097691) utilized. Range of detection limits based on Aroclor 1254.
e = Reflects summary statistics of all detected Aroclors. RBC and PRG values for Aroclor-1254 (CAS# 11097691) utilized. Range of detection limits based on Aroclor 1254.
f = RBC value for chlordane (CAS# 57749) and PRG value for technical chlordane (CAS# 12789-03-6) utilized.

Definitions:
ARAR: Applicable or Relevant and Appropriate Requirements
CAS: Chemical Abstract Service
COPC: Compound of Potential Concern
NUT: Compound is an essential nutrient and is not screened in
NV: No Value
PRG: Preliminary Remediation Goals, USEPA, 2004
RBC: Risk Based Concentration; USEPA, October, 2007
TBC: To Be Considered
USEPA: United States Environmental Protection Agency
DSA #1: Dredge Soil Area #1

NOTES:

TCDD/F = Tetra Chlorinated Dibenzo-p-dioxins/Dibenzofurans

PeCDD/F = Penta Chlorinated Dibenzo-p-dioxins/Dibenzofurans

HxCDD/F = Hexa Chlorinated Dibenzo-p-dioxins/Dibenzofurans

HpCDD/F = Hepta Chlorinated Dibenzo-p-dioxins/Dibenzofurans

OCDD/F = Octa Chlorinated Dibenzo-p-dioxins/Dibenzofurans

EMPC = Estimated Maximum Possible Concentration

N/A = not applicable, J = estimated value, U = non detect, EMPC = estimated maximum possible concentration

TABLE 2.27c
DERIVATION OF PCB EQUIVALENTS FOR CHLORINATED CHEMICALS
HONEYWELL WASTEBED B/HARBOR BROOK SITE - DREDGE SPOIL AREA #2 SURFACE SOIL (0-2 ft)

Chlorination Level*	Sample Location	Start Depth (ft)	End Depth (ft)	Sample Date	Sum of Location PCB Concentration	Units
Highly Chlorinated PCBs	HB-HB-01D	0	0.17	7/21/2000	3	mg/kg
Highly Chlorinated PCBs	HB-HB-01S	0	0.17	7/25/2000	0.4	mg/kg
Less Chlorinated PCBs	HB-HB-01D	0	0.17	7/21/2000	2	mg/kg
Less Chlorinated PCBs	HB-HB-01S	0	0.17	7/25/2000	0.3	mg/kg
Total PCBs	HB-HB-01D	0	0.17	7/21/2000	5	mg/kg
Total PCBs	HB-HB-01S	0	0.17	7/25/2000	0.7	mg/kg

Notes:

* Less Chlorinated PCBs were defined as Aroclors 1221, 1232, 1016, and 1242. Highly Chlorinated PCBs were defined as Aroclors 1248, 1254, 1260, and higher if reported. Total PCBs are the sum of all detected Aroclors.

Footnotes:
(1) J - estimated value; N - tentatively identified at an estimated value
(2) Concentration used for screening is the maximum detected concentration.
(3) No background screening performed.
(4) Values are from New York Subpart 375-6 Soil Cleanup Objectives (SCO). Values reflect residential restricted use for the protection of human health.
(5) USEPA Region 3 RBCs (USEPA 2007) for residential soil; C = Cancer RBC; N = Noncancer RBC; NV = No value in Region 3 RBC data set. Noncancer RBCs adjusted by multiplying RBC by 0.1.
(6) USEPA Region 9 PRGs (USEPA 2004) for residential soil; ca = Cancer PRG; nc = Noncancer PRG; NV = No value in Region 9 PRG data set. Noncancer PRGs adjusted by multiplying PRG by 0.1.
(7) The Screening Toxicity Value represents the minimum of the Region 3 RBC and the Region 9 PRG.
(8) Selection Rationale: ASL - Above Screening Level; TOX - Class A Carcinogen; NTX - No Toxicity Information. Deletion Rationale: BSL - Below Screening Level
(9) Based on use of WHO toxicity equivalency factors for dioxins and dioxin-like compounds from Van den Berg et al. (2006); see Table 2.28b.
- = Compound detected in 100% of samples.
NA = Not applicable, minimum and maximum values are calculated.
a = RBC and PRG values for chromium VI utilized.
b = Where mercury is not speciated, RBC and PRG values for methyl mercury utilized.
c = RBC and PRG values for Endosulfan (CAS #115297) utilized.
d = RBC value for chlordane (CAS# 57749) and PRG value for technical chlordane (CAS# 12789-03-6) utilized.
e = When detected, reflects summary statistics of Aroclor 1221, 1232, 1016, and 1242. RBC and PRG values for Aroclor-1016 (CAS# 12674112) utilized. Range of detection limits based on Aroclor 1016.
f = When detected, reflects summary statistics of Aroclors 1248, 1254, and 1260. RBC and PRG values for Aroclor-1254 (CAS# 11097691) utilized. Range of detection limits based on Aroclor 1254.
g = Reflects summary statistics of all detected Aroclors. RBC and PRG values for Aroclor-1254 (CAS# 11097691) utilized. Range of detection limits based on Aroclor 1254.
h = RBC and PRG values for isopropylbenzene are referred to as cumene (CAS # 98-82-8).

Definitions:
ARAR: Applicable or Relevant and Appropriate Requirements
CAS: Chemical Abstract Service
COPC: Compound of Potential Concern
NUT: Compound is an essential nutrient and is not screened in
NV: No Value
PRG: Preliminary Remediation Goals, USEPA, 2004
RBC: Risk Based Concentration; USEPA, October, 2007
TBC: To Be Considered
USEPA: United States Environmental Protection Agency
DSA #2: Dredge Spoil Area #2

Footnotes:
*Sample start depth less than or equal to 10 ft bgs.
(1) J - estimated value; N - tentatively identified at an estimated value
(2) Concentration used for screening is the maximum detected concentration.
(3) N/A - No background screening performed.
(4) United States Environmental Protection Agency. 2008. National Primary and Secondary Drinking Water Regulations.
(5) USEPA Region 3 RBCs (USEPA 2007) for tap water; C = Cancer RBC; N = Noncancer RBC; NV = No value in Region 3 RBC data set. Noncancer RBCs adjusted by multiplying RBC by
(6) USEPA Region 9 PRGs (USEPA 2004) for tap water; ca = Cancer PRG; nc = Noncancer PRG; NV = No value in Region 9 PRG data set. Noncancer PRGs adjusted by multiplying PRG
(7) The Screening Toxicity Value represents the minimum of the Region 3 RBC and the Region 9 PRG.
(8) Selection Rationale: ASL - Above Screening Level; TOX - Class A Carcinogen; NTX - No Toxicity Information. Deletion Rationale: BSL - Below Screening Level
- = Compound detected in 100% of samples.
a = RBC and PRG values for chromium VI utilized.
b = Where mercury is not speciated, RBC and PRG values for methyl mercury utilized.
c = RBC and PRG values for Endosulfan (CAS# 115297) utilized.

Definitions:
ARAR: Applicable or Relevant and Appropriate Requirements
CAS: Chemical Abstract Service
COPC: Compound of Potential Concern
NUT: Compound is an essential nutrient and not screened in
NV: No Value
PRG: Preliminary Remediation Goals, USEPA, 2004
RBC: Risk Based Concentration; USEPA, October, 2007
TBC: To Be Considered
USEPA: United States Environmental Protection Agency

Footnotes:
*Sample start depth less than or equal to 10 ft bgs.
**Target soil gas concentration exceeds maximum possible vapor concentration (pathway incomplete)
(1) J - estimated value
(2) Concentration used for screening is the maximum detected concentration.
(3) N/A - No background screening performed.
(4) Primary and Secondary Drinking Water Regulations
(5) USEPA - OSWER Draft Guidance for Evaluating the Vapor Intrusion to Indoor Air Pathway from Groundwater and Soils (Subsurface Vapor Intrusion Guidance) Tables. November 2002. ca = Cancer; nc = Noncancer. Screening criteria correspond to a cancer risk of 10^{-6} and a noncancer hazard of 0.1. For USEPA (2002) criteria that defaulted to MCLs, criteria were derived (in italics) from USEPA (2009) RSL residential air concentration based on an attenuation factor of 10 and the Henry's Law constant for each compound at 25 deg C.
(6) Selection Rationale: ASL - Above Screening Level; TOX - Class A Carcinogen; NTX - No Toxicity Information. Deletion Rationale: BSL - Below Screening Level; INC - Pathway Incomplete
- = Compound detected in 100% of samples.
a = Target groundwater concentration for p-xylene (CAS #106-42-3) utilized.

Definitions:
ARAR: Applicable or Relevant and Appropriate Requirements
CAS: Chemical Abstract Service
COPC: Compound of Potential Concern
NV: No Value
TBC: To Be Considered
USEPA: United States Environmental Protection Agency

Footnotes:
(1) J - estimated value; N - tentatively identified at an estimated value
(2) Concentration used for screening is the maximum detected concentration.
(3) No background screening performed.
(4) Values are from New York Subpart 375-6 Soil Cleanup Objectives (SCO). Values reflect residential restricted use for the protection of human health.
(5) USEPA Region 3 RBCs (USEPA 2007) for residential soil; C = Cancer RBC; N = Noncancer RBC; NV = No value in Region 3 RBC data set. Noncancer RBCs adjusted by multiplying RBC by 0.1.
(6) USEPA Region 9 PRGs (USEPA 2004) for residential soil; ca = Cancer PRG; nc = Noncancer PRG; NV = No value in Region 9 PRG data set. Noncancer PRGs adjusted by multiplying PRG by 0.1.
(7) The Screening Toxicity Value represents the minimum of the Region 3 RBC and the Region 9 PRG.
(8) Selection Rationale: ASL - Above Screening Level; TOX - Class A Carcinogen; NTX - No Toxicity Information. Deletion Rationale: BSL - Below Screening Level
(9) Based on use of WHO toxicity equivalency factors for dioxins and dioxin-like compounds from Van den Berg et al. (2006); see Table 2.31b.
- = Compound detected in 100% of samples.
NA = Not applicable, minimum and maximum values are calculated.
a = RBC and PRG values for chromium VI utilized.
b = RBC and PRG values for mercury compounds utlized.
c = When detected, reflects summary statistics of Aroclors 1248, 1254, and 1260. RBC and PRG values for Aroclor 1254 (CAS# 11097691) utilized. Range of detection limits based on Aroclor-1254.
d = Reflects summary statistics of all detected Aroclors. RBC and PRG values for Aroclor-1254 (CAS# 11097691) utilized. Range of detection limits based on Aroclor 1254.
e = RBC value for chlordane (CAS# 57749) and PRG value for technical chlordane (CAS# 12789-03-6) utilized.

Definitions:
ARAR: Applicable or Relevant and Appropriate Requirements
CAS: Chemical Abstract Service
COPC: Compound of Potential Concern
NUT: Compound is an essential nutrient and is not screened in
NV: No Value
PRG: Preliminary Remediation Goals, USEPA, 2004
RBC: Risk Based Concentration; USEPA, October, 2007
TBC: To Be Considered
USEPA: United States Environmental Protection Agency
AOS #1: Additional Area of Study #1

Footnotes:
(1) J - estimated value; N - tentatively identified at an estimated value
(2) Concentration used for screening is the maximum detected concentration.
(3) No background screening performed.
(4) Values are from New York Subpart 375-6 Soil Cleanup Objectives. Values reflect residential restricted use for the protection of human health.
(5) USEPA Region 3 RBCs (USEPA 2007) for residential soil; C = Cancer RBC; N = Noncancer RBC; NV = No value in Region 3 RBC data set. Noncancer RBCs adjusted by multiplying RBC by 0.1.
(6) USEPA Region 9 PRGs (USEPA 2004) for residential soil; ca = Cancer PRG; nc = Noncancer PRG; NV = No value in Region 9 PRG data set. Noncancer PRGs adjusted by multiplying PRG by 0.1.
(7) The Screening Toxicity Value represents the minimum of the Region 3 RBC and the Region 9 PRG.
(8) Selection Rationale: ASL - Above Screening Level; TOX - Class A Carcinogen; NTX - No Toxicity Information. Deletion Rationale: BSL - Below Screening Level
(9) Based on use of WHO toxicity equivalency factors for dioxins and dioxin-like compounds from Van den Berg et al. (2006); see Table 2.32b.
- = Compound detected in 100% of samples.
NA = Not applicable, minimum and maximum values are calculated.
a = RBC and PRG values for chromium VI utilized.
b= RBC and PRG values for mercury compounds utilized.
c = When detected, reflects summary statistics of Aroclors 1248, 1254, and 1260. RBC and PRG values for Aroclor-1254 (CAS# 11097691) utilized. Range of detection limits based on Aroclor 1254.
d = Reflects summary statistics of all detected Aroclors. RBC and PRG values for Aroclor-1254 (CAS# 11097691) utilized. Range of detection limits based on Aroclor 1254.
e = RBC value for chlordane (CAS# 57749) and PRG value for technical chlordane (CAS# 12789-03-6) utilized.

Definitions:
ARAR: Applicable or Relevant and Appropriate Requirements
CAS: Chemical Abstract Service
COPC: Compound of Potential Concern
NUT: Compound is an essential nutrient and is not screened in
NV: No Value
PRG: Preliminary Remediation Goals
PRG: Preliminary Remediation Goals, USEPA, 2004
RBC: Risk Based Concentration; USEPA, October, 2007
USEPA: United States Environmental Protection Agency
AOS #1: Additional Area of Study #1

Footnotes:
*Sample start depth less than or equal to 10 ft bgs.
(1) J - estimated value; N - tentatively identified at an estimated value
(2) Concentration used for screening is the maximum detected concentration.
(3) N/A - No background screening performed.
(4) United States Environmental Protection Agency. 2008. National Primary and Secondary Drinking Water Regulations.
(4) USEPA Region 3 RBCs (USEPA 2007) for tap water; C = Cancer RBC; N = Noncancer RBC; NV = No value in Region 3 RBC data set. Noncancer RBCs adjusted by multiplying RBC by 0.1.
(5) USEPA Region 9 PRGs (USEPA 2004) for tap water; ca = Cancer PRG; nc = Noncancer PRG; NV = No value in Region 9 PRG data set. Noncancer PRGs adjusted by multiplying PRG by 0.1.
(6) The Screening Toxicity Value represents the minimum of the Region 3 RBC and the Region 9 PRG.
(7) Selection Rationale: ASL - Above Screening Level; TOX - Class A Carcinogen; NTX - No Toxicity Information. Deletion Rationale: BSL - Below Screening Level
- = Compound detected in 100% of samples.
a = RBC and PRG values for chromium VI utilized.
b = Where mercury is not speciated, RBC and PRG values for methyl mercury utilized.
c = RBC and PRG values for 4-methylphenol utilized.

Footnotes:
* Sample start depth less than or equal to 10 ft bgs.
** Target soil gas concentration exceeds maximum possible vapor concentration (pathway incomplete)
(1) J - estimated value; N - tentatively identified at an estimated value
(2) Concentration used for screening is the maximum detected concentration.
(3) N/A - No background screening performed.
(4) Primary and Secondary Drinking Water Regulations
(5) USEPA - OSWER Draft Guidance for Evaluating the Vapor Intrusion to Indoor Air Pathway from Groundwater and Soils (Subsurface Vapor Intrusion Guidance) Tables. November 2002. ca = Cancer; nc = Noncancer. Screening criteria correspond to a cancer risk of 10-6 and a noncancer hazard of 0.1. For USEPA (2002) criteria that defaulted to MCLs, criteria were derived (in italics) from USEPA (2009) RSL residential air concentration based on an attenuation factor of 10 and the Henry's Law constant for each compound at 25 deg C.
(6) Selection Rationale: ASL - Above Screening Level; TOX - Class A Carcinogen; NTX - No Toxicity Information. Deletion Rationale: BSL - Below Screening Level
- = Compound detected in 100% of samples.
a = Target groundwater concentration for p-xylene (CAS #106-42-3) utilized.

Footnotes:
(1) J - estimated value; N - tentatively identified at an estimated value
(2) Concentration used for screening is the maximum detected concentration.
(3) No background screening performed.
(4) Values are from New York Subpart 375-6 Soil Cleanup Objectives (SCO). Values reflect residential restricted use for the protection of human health.
(5) USEPA Region 3 RBCs (USEPA 2007) for residential soil; C = Cancer RBC; N = Noncancer RBC; NV = No value in Region 3 RBC data set. Noncancer RBCs adjusted by multiplying RBC by 0.1.
(6) USEPA Region 9 PRGs (USEPA 2004) for residential soil; ca = Cancer PRG; nc = Noncancer PRG; NV = No value in Region 9 PRG data set. Noncancer PRGs adjusted by multiplying PRG by 0.1.
(7) The Screening Toxicity Value represents the minimum of the Region 3 RBC and the Region 9 PRG.
(8) Selection Rationale: ASL - Above Screening Level; TOX - Class A Carcinogen; NTX - No Toxicity Information. Deletion Rationale: BSL - Below Screening Level
- = Compound detected in 100% of samples.
NA = Not applicable, minimum and maximum values are calculated.
a = RBC and PRG values for chromium VI utilized.
b = Where mercury is not speciated, RBC and PRG values for methyl mercury utilized.

Footnotes:
*SYW-12 wetland sediment is considered hydric soil and was evaluated as surface soil.
(1) J - estimated value; N - tentatively identified at an estimated value
(2) Concentration used for screening is the maximum detected concentration.
(3) No background screening performed.
(4) Values are from New York Subpart 375-6 Soil Cleanup Objectives (SCO). Values reflect residential restricted use for the protection of human health.
(5) USEPA Region 3 RBCs (USEPA 2007) for residential soil; C = Cancer RBC; N = Noncancer RBC; NV = No value in Region 3 RBC data set. Noncancer RBCs adjusted by multiplying RBC by 0.1.
(6) USEPA Region 9 PRGs (USEPA 2004) for residential soil; ca = Cancer PRG; nc = Noncancer PRG; NV = No value in Region 9 PRG data set. Noncancer PRGs adjusted by multiplying PRG by 0.1.
(7) The Screening Toxicity Value represents the minimum of the Region 3 RBC and the Region 9 PRG.
(8) Selection Rationale: ASL - Above Screening Level; TOX - Class A Carcinogen; NTX - No Toxicity Information. Deletion Rationale: BSL - Below Screening Level
(9) Based on use of WHO toxicity equivalency factors for dioxins and dioxin-like compounds from Van den Berg et al. (2006); see Table 2.37b.
- = Compound detected in 100% of samples.
NA = Not applicable, minimum and maximum values are calculated.
a = RBC and PRG values for chromium VI utilized.
b = RBC and PRG values for mercury compounds utilized.
c = When detected, reflects summary statistics of Aroclors 1248, 1254, and 1260. RBC and PRG values for Aroclor-1254 (CAS# 11097691) utilized. Range of detection limits based on Aroclor 1254.
d = Reflects summary statistics of all detected Aroclors. RBC and PRG values for Aroclor-1254 (CAS# 11097691) utilized. Range of detection limits based on Aroclor 1254.
e = RBC value for chlordane (CAS# 57749) and PRG value for technical chlordane (CAS# 12789-03-6) utilized.
f = RBC and PRG values for Endrin (CAS # 72208) utilized.

Definitions:
ARAR: Applicable or Relevant and Appropriate Requirements
CAS: Chemical Abstract Service
COPC: Compound of Potential Concern
NUT: Compound is an essential nutrient and is not screened in
NV: No Value
PRG: Preliminary Remediation Goals, USEPA, 2004
RBC: Risk Based Concentration; USEPA, October, 2007
TBC: To Be Considered
USEPA: United States Environmental Protection Agency

Footnotes:
(1) J - estimated value; N - tentatively identified at an estimated value
(2) Concentration used for screening is the maximum detected concentration.
(3) No background screening performed.
(4) Values are from New York Subpart 375-6 Soil Cleanup Objectives (SCO). Values reflect residential restricted use for the protection of human health.
(5) USEPA Region 3 RBCs (USEPA 2007) for residential soil; C = Cancer RBC; N = Noncancer RBC; NV = No value in Region 3 RBC data set. Noncancer RBCs adjusted by multiplying RBC by 0.1.
(6) USEPA Region 9 PRGs (USEPA 2004) for residential soil; ca = Cancer PRG; nc = Noncancer PRG; NV = No value in Region 9 PRG data set. Noncancer PRGs adjusted by multiplying PRG by 0.1.
(7) The Screening Toxicity Value represents the minimum of the Region 3 RBC and the Region 9 PRG.
(8) Selection Rationale: ASL - Above Screening Level; TOX - Class A Carcinogen; NTX - No Toxicity Information. Deletion Rationale: BSL - Below Screening Level
(9) Based on use of WHO toxicity equivalency factors for dioxins and dioxin-like compounds from Van den Berg et al. (2006); see Table 2.38b.
- = Compound detected in 100% of samples.
NA = Not applicable, minimum and maximum values are calculated.
a = RBC and PRG values for chromium VI utilized.
b = RBC and PRG values for mercury compounds utilized.
c = When detected, reflects summary statistics of Aroclor 1221, 1232, 1016, and 1242. RBC and PRG values for Aroclor-1016 (CAS# 12674112) utilized. Range of detection limits based on Aroclor 1016.
d = When detected, reflects summary statistics of Aroclors 1248, 1254, and 1260. RBC and PRG values for Aroclor-1254 (CAS# 11097691) utilized. Range of detection limits based on Aroclor 1254.
e = Reflects summary statistics of all detected Aroclors. RBC and PRG values for Aroclor-1254 (CAS# 11097691) utilized. Range of detection limits based on Aroclor 1254.
f = RBC value for chlordane (CAS# 57749) and PRG value for technical chlordane (CAS# 12789-03-6) utilized.
g = RBC and PRG values for Endrin (CAS# 72208) utilized.

Definitions:
ARAR: Applicable or Relevant and Appropriate Requirements
CAS: Chemical Abstract Service
COPC: Compound of Potential Concern
NUT: Compound is an essential nutrient and is not screened in
NV: No Value
PRG: Preliminary Remediation Goals, USEPA, 2004
RBC: Risk Based Concentration; USEPA, October, 2007
TBC: To Be Considered
USEPA: United States Environmental Protection Agency

TABLE 2.38b
DERIVATION OF TOXIC EQUIVALENTS FOR DIOXINS

Notes:

* Less Chlorinated PCBs were defined as Aroclors 1221, 1232, 1016, and 1242. Highly Chlorinated PCBs were defined as Aroclors 1248, 1254, 1260, and higher if reported. Total PCBs are the sum of all detected Aroclors.

Footnotes:
*Sample start depth less than or equal to 10 ft bgs.
(1) J - estimated value; N - tentatively identified at an estimated value
(2) Concentration used for screening is the maximum detected concentration.
(3) N/A - No background screening performed.
(4) United States Environmental Protection Agency. 2008. National Primary and Secondary Drinking Water Regulations.
(5) USEPA Region 3 RBCs (USEPA 2007) for tap water; C = Cancer RBC; N = Noncancer RBC; NV = No value in Region 3 RBC data set. Noncancer RBCs adjusted by multiplying RBC by 0.1.
(6) USEPA Region 9 PRGs (USEPA 2004) for tap water; ca = Cancer PRG; nc = Noncancer PRG; NV = No value in Region 9 PRG data set. Noncancer PRGs adjusted by multiplying PRG by 0.1.
(7) The Screening Toxicity Value represents the minimum of the Region 3 RBC and the Region 9 PRG.
(8) Selection Rationale: ASL - Above Screening Level; TOX - Class A Carcinogen; NTX - No Toxicity Information. Deletion Rationale: BSL - Below Screening Level
- = Compound detected in 100% of samples.
a = RBC and PRG values for chromium VI utilized.
b = Where mercury is not speciated, RBC and PRG values for methyl mercury utilized.

Definitions:
ARAR: Applicable or Relevant and Appropriate Requirements
CAS: Chemical Abstract Service
COPC: Compound of Potential Concern
NUT: Compound is an essential nutrient and not screened in
NV: No Value
PRG: Preliminary Remediation Goals, USEPA, 2004
RBC: Risk Based Concentration; USEPA, October, 2007
TBC: To Be Considered
USEPA: United States Environmental Protection Agency

Footnotes:
* Sample start depth less than or equal to 10 ft bgs.
** Target soil gas concentration exceeds maximum possible vapor concentration (pathway incomplete)
(1) J - estimated value
(2) Concentration used for screening is the maximum detected concentration.
(3) N/A - No background screening performed.
(4) Primary and Secondary Drinking Water Regulations
(5) USEPA - OSWER Draft Guidance for Evaluating the Vapor Intrusion to Indoor Air Pathway from Groundwater and Soils (Subsurface Vapor Intrusion Guidance) Tables. November 2002. ca = Cancer; nc = Noncancer. Screening criteria correspond to a cancer risk of 10-6 and a noncancer hazard of 0.1. For USEPA (2002) criteria that defaulted to MCLs, criteria were derived (in italics) from USEPA (2009) RSL residential air concentration based on an attenuation factor of 10 and the Henry's Law constant for each compound at 25 deg C.
(6) Selection Rationale: ASL - Above Screening Level; TOX - Class A Carcinogen; NTX - No Toxicity Information. Deletion Rationale: BSL - Below Screening Level; INC - Pathway Incomplete

Definitions:
ARAR: Applicable or Relevant and Appropriate Requirements
CAS: Chemical Abstract Service
COPC: Compound of Potential Concern
NV: No Value
TBC: To Be Considered
USEPA: United States Environmental Protection Agency

Footnotes:
a = Aroclor-1248,-1254, -1260 samples were combined for analysis by ProUCL 4.0 and determination of an EPC.
b = All aroclor samples were combined for analysis by ProUCL 4.0 and the determination of an EPC.
c = Max - maximum detected concentration; %UCL - % upper confidence limit. KM - Kaplan-Meier method.
Chebyshev UCL or Student's-t UCL for nonparametric distribution based on ProUCL (V. 4.0) recommendation; Gamma UCL for gamma distribution; Nonparametric Bootstrap UCLs introduce some standard error and may not be reproduced precisely.
NA = UCL could not be calculated because there were too few samples or too few detected samples among many non-detected samples
It is possible that in certain instances, the calculated 95% UCL is smaller than the mean detected concentration. This reflects a low detection frequency and non-detect samples largely outnumbering detected samples, causing the 95% UCL recommended by ProUCL v4.0 to be smaller than the mean detected concentration, since it reflects the large number of non-detect samples.
H-UCL = (1-α)100% UCL of the mean based upon H-statistic (H-UCL) (parametric).
KM (BCA) UCL = UCL based upon Kaplan-Meier estimates using the bias corrected accelerated percentile bootstrap method. (non-parametric).
KM (Chebyshev) UCL = UCL based upon Kaplan-Meier estimates using the Chebyshev inequality (non-paarmetric).
KM (t) UCL = UCL based upon Kaplan-Meier estimates using student's t-distribution critical value (non-parametric).
Student's-t UCL = Computation method based upon student's t-distribution (parametric).

Footnotes:
UCL based on USEPA ProUCL (V. 4.0) recommendation, using Regression on Order Statistics (ROS) for evaluating data with non-detect (ND) samples.
a = Aroclor-1248,-1254, -1260 samples were combined for analysis by ProUCL 4.0 and determination of an EPC.
b = All aroclor samples were combined for analysis by ProUCL 4.0 and the determination of an EPC.
c = Max - maximum detected concentration; %UCL - % upper confidence limit.
NA = UCL could not be calculated because of low sample number or low detection frequency.
It is possible that in certain instances, the calculated 95% UCL is smaller than the mean detected concentration. This reflects a low detection frequency and non-detect samples largely outnumbering detected samples, causing the 95% UCL recommended by ProUCL v4.0 to be smaller than the mean detected concentration, since it reflects the large number of non-detect samples.
* = ProUCL does not provide 95% UCLs when there is insufficient data, as defined by fewer than 3 samples or fewer than 2 unique detected samples. In these cases, the EPC is obtained by using the maximum detected concentration.
KM (BCA) UCL = UCL based upon Kaplan-Meier estimates using the bias corrected accelerated percentile bootstrap method. (non-parametric).
KM (Chebyshev) UCL = UCL based upon Kaplan-Meier estimates using the Chebyshev inequality (non-parametric).
KM (Percentile Bootstrap) UCL - (1-α) 100% UCL of the Mean Based Upon Simple Percentile Bootstrap Method (non-parametric).
KM (t) UCL = UCL based upon Kaplan-Meier estimates using student's t-distribution critical value (non-parametric).

Footnotes:
Table modified from RAGS Table 3.1 Onondaga Lake Human Health Risk Assessment prepared by TAMS Consultants, Inc. & YEC, Inc.
a = Aroclor-1016,-1221,-1232,-1242 samples were combined for analysis by ProUCL 4.0 and determination of an EPC.
b = Aroclor-1248,-1254, -1260 samples were combined for analysis by ProUCL 4.0 and determination of an EPC.
c = All aroclor samples were combined for analysis by ProUCL 4.0 and the determination of an EPC.
d = Max - maximum detected concentration; %UCL - % upper confidence limit.
NA = UCL could not be calculated because of low sample number or low detection frequency.
* = Insufficient data to calculate a UCL, according to the Onondaga Lake Human Health Risk Assessment. In these cases, the EPC is obtained by using the maximum detected concentration.
D'Agostino (Y) UCL = Distributional fit for sample sets containing greater than 50 samples.
Shapiro-Wilk (W) UCL = Distributional fit for sample sets contaig less than 50 samples.

Footnotes:
UCL based on USEPA ProUCL (V. 4.0) recommendation, using Regression on Order Statistics (ROS) for evaluating data with non-detect (ND) samples.
a = Aroclor-1016,-1221,-1232,-1242 samples were combined for analysis by ProUCL 4.0 and determination of an EPC.
b = Aroclor-1248,-1254, -1260 samples were combined for analysis by ProUCL 4.0 and determination of an EPC.
c = All aroclor samples were combined for analysis by ProUCL 4.0 and the determination of an EPC.
d = Max - maximum detected concentration; %UCL - % upper confidence limit.
NA = UCL could not be calculated because of low sample number or low detection frequency.
It is possible that in certain instances, the calculated 95% UCL is smaller than the mean detected concentration. This reflects a low detection frequency and non-detect samples largely outnumbering detected samples, causing the 95% UCL recommended by ProUCL v4.0 to be smaller than the mean detected concentration, since it reflects the large number of non-detect samples.
* = ProUCL does not provide 95% UCLs when there is insufficient data, as defined by fewer than 3 samples or fewer than 2 unique detected samples. In these cases, the EPC is obtained by using the maximum detected concentration.
Chebyshev (Mean, Sd) UCL = (1-α)100% UCL of the mean based upon the chebyshev theorem (using the sample mean and sample standard deviation - non-parametric).
Chebyshev (MVUE) UCL = (1-α) 100% UCL of the Mean of a Lognormal Population Based Upon the Chebyshev Theorem (Using the MVUE of the Mean and its Standard Error - parametric).
Gamma UCL = Computation of UCL of the mean of a Gamma, G(k,θ) distribution (parametric).
H-UCL = (1-α)100% UCL of the mean based upon H-statistic (H-UCL) (parametric).
KM (BCA) UCL = UCL based upon Kaplan-Meier estimates using the bias corrected accelerated percentile bootstrap method. (non-parametric).
KM (Chebyshev) UCL = UCL based upon Kaplan-Meier estimates using the Chebyshev inequality (non-parametric).
KM (t) UCL = UCL based upon Kaplan-Meier estimates using student's t-distribution critical value (non-parametric).
Student's-t UCL = Computation method based upon student's t-distribution (parametric).

It is possible that in certain instances, the calculated 95% UCL is smaller than the mean detected concentration. This reflects a low detection frequency and non-detect samples largely outnumbering detected samples, causing the 95% UCL recommended by ProUCL v4.0 to be smaller than the mean detected concentration, since it reflects the large number of non-detect samples.
* = ProUCL does not provide 95% UCLs when there is insufficient data, as defined by fewer than 3 samples or fewer than 2 unique detected samples. In these cases, the EPC is obtained by using the maximum detected concentration.
Chebyshev (Mean, Sd) UCL = (1-α)100% UCL of the mean based upon the chebyshev theorem (using the sample mean and sample standard deviation - non-parametric).
Gamma UCL = Computation of UCL of the mean of a Gamma, G(k,θ) distribution (parametric).
KM (BCA) UCL = UCL based upon Kaplan-Meier estimates using the bias corrected accelerated percentile bootstrap method. (non-parametric).
KM (Chebyshev) UCL = UCL based upon Kaplan-Meier estimates using the Chebyshev inequality (non-parametric).
KM (Percentile Bootstrap) UCL - (1-α) 100% UCL of the Mean Based Upon Simple Percentile Bootstrap Method (non-parametric)
KM (t) UCL = UCL based upon Kaplan-Meier estimates using student's t-distribution critical value (non-parametric).
Student's-t UCL = Computation method based upon student's t-distribution (parametric).

Footnotes:
UCL based on USEPA ProUCL (V. 4.0) recommendation, using Regression on Order Statistics (ROS) for evaluating data with non-detect (ND) samples.
a = Aroclor-1248,-1254, -1260 samples were combined for analysis by ProUCL 4.0 and determination of an EPC.
b = All aroclor samples were combined for analysis by ProUCL 4.0 and the determination of an EPC.
c = Max - maximum detected concentration; %UCL - % upper confidence limit. KM - Kaplan-Meier method.
NA = UCL could not be calculated because of low sample number or low detection frequency.
It is possible that in certain instances, the calculated 95% UCL is smaller than the mean detected concentration. This reflects a low detection frequency and non-detect samples largely outnumbering detected samples, causing the 95% UCL recommended by ProUCL v4.0 to be smaller than the mean detected concentration, since it reflects the large number of non-detect samples.
* = ProUCL does not provide 95% UCLs when there is insufficient data, as defined by fewer than 3 samples or fewer than 2 unique detected samples. In these cases, the EPC is obtained by using the maximum detected concentration.
95% H-UCL = (1-α)100% UCL of the mean based upon H-statistic (H-UCL) (parametric).
Chebyshev (Mean, Sd) UCL = (1-α)100% UCL of the mean based upon the chebyshev theorem (using the sample mean and sample standard deviation - non-parametric).
Gamma UCL = Computation of UCL of the mean of a Gamma, G(k,θ) distribution (parametric).
KM (Chebyshev) UCL = UCL based upon Kaplan-Meier estimates using the Chebyshev inequality (non-parametric).
KM (t) UCL = UCL based upon Kaplan-Meier estimates using student's t-distribution critical value (non-parametric).
Student's-t UCL = Computation method based upon student's t-distribution (parametric).

	1330-20-7	XYLENES, TOTAL	mg/kg	11.48	67.72	314	6.77E+01	mg/kg	% UCL	99% KM (Chebyshev) UCL

Footnotes:
Chebyshev UCL or Student's-t UCL for nonparametric distribution based on ProUCL (V. 4.0) recommendation; Gamma UCL for gamma distribution; Nonparametric Bootstrap UCLs introduce some standard error and may not be reproduced precisely.
a = Aroclor-1248,-1254, -1260 samples were combined for analysis by ProUCL 4.0 and determination of an EPC.
b = All aroclor samples were combined for analysis by ProUCL 4.0 and the determination of an EPC.
c = Max - maximum detected concentration; %UCL - % upper confidence limit.
It is possible that in certain instances, the calculated 95% UCL is smaller than the mean detected concentration. This reflects a low detection frequency and non-detect samples largely outnumbering detected samples, causing the 95% UCL recommended by ProUCL v4.0 to be smaller than the mean detected concentration, since it reflects the large number of non-detect samples.
Chebyshev (Mean, Sd) UCL = (1-α)100% UCL of the mean based upon the chebyshev theorem (using the sample mean and sample standard deviation - non-parametric).
Chebyshev (MVUE) UCL = (1-α) 100% UCL of the Mean of a Lognormal Population Based Upon the Chebyshev Theorem (Using the MVUE of the Mean and its Standard Error - parametric).
KM (BCA) UCL = UCL based upon Kaplan-Meier estimates using the bias corrected accelerated percentile bootstrap method. (non-parametric).
KM (Chebyshev) UCL = UCL based upon Kaplan-Meier estimates using the Chebyshev inequality (non-parametric).
KM (t) UCL = UCL based upon Kaplan-Meier estimates using student's t-distribution critical value (non-parametric).
Student's-t UCL = Computation method based upon student's t-distribution (parametric).
95% H-UCL = (1- α)100% UCL of the mean based upon H-statistic (H-UCL) (parametric).

Footnotes:
UCL based on USEPA ProUCL (V. 4.0) recommendation, using Regression on Order Statistics (ROS) for evaluating data with non-detect (ND) samples.
a = Max - maximum detected concentration; %UCL - % upper confidence limit. KM - Kaplan-Meier method.
NA = UCL could not be calculated because of low sample number or low detection frequency.
It is possible that in certain instances, the calculated 95% UCL is smaller than the mean detected concentration. This reflects a low detection frequency and non-detect samples largely outnumbering detected samples, causing the 95% UCL recommended by ProUCL v4.0 to be smaller than the mean detected concentration, since it reflects the large number of non-detect samples.
* = ProUCL does not provide 95% UCLs when there is insufficient data, as defined by fewer than 3 samples or fewer than 2 unique detected samples. In these cases, the EPC is obtained by using the maximum detected concentration.
KM (Chebyshev) UCL = UCL based upon Kaplan-Meier estimates using the Chebyshev inequality (non-parmetric).
KM (t) UCL = UCL based upon Kaplan-Meier estimates using student's t-distribution critical value (non-parametric).

Footnotes:
Table modified from Table 3.1 Onondaga Lake Human Health Risk Assessment prepared by TAMS Consultants, Inc. & YEC, Inc.
a = Aroclor-1016,-1221,-1232,-1242 samples were combined for analysis by ProUCL 4.0 and determination of an EPC.
b = Aroclor-1248,-1254, -1260 samples were combined for analysis by ProUCL 4.0 and determination of an EPC.
c = All aroclor samples were combined for analysis by ProUCL 4.0 and the determination of an EPC.
d = Max - maximum detected concentration; %UCL - % upper confidence limit.
NA = UCL could not be calculated because of low sample number or low detection frequency.
* = Insufficient data to calculate a UCL, according to the Onondaga Lake Human Health Risk Assessment. In these cases, the EPC is obtained by using the maximum detected concentration.
D'Agostino (Y) UCL = Distributional fit for sample sets containing greater than 50 samples.
Shapiro-Wilk (W) UCL = Distributional fit for sample sets contaig less than 50 samples.

Footnotes:
UCL based on USEPA ProUCL (V. 4.0) recommendation, using Regression on Order Statistics (ROS) for evaluating data with non-detect (ND) samples.
a = Aroclor-1016,-1221,-1232,-1242 samples were combined for analysis by ProUCL 4.0 and determination of an EPC.
b = Aroclor-1248,-1254, -1260 samples were combined for analysis by ProUCL 4.0 and determination of an EPC.
c = All aroclor samples were combined for analysis by ProUCL 4.0 and the determination of an EPC.
d = Max - maximum detected concentration; %UCL - % upper confidence limit.
NA = UCL could not be calculated because of low sample number or low detection frequency.
It is possible that in certain instances, the calculated 95% UCL is smaller than the mean detected concentration. This reflects a low detection frequency and non-detect samples largely outnumbering detected samples, causing the 95% UCL recommended by ProUCL v4.0 to be smaller than the mean detected concentration, since it reflects the large number of non-detect samples.
* = ProUCL does not provide 95% UCLs when there is insufficient data, as defined by fewer than 3 samples or fewer than 2 unique detected samples. In these cases, the EPC is obtained by using the maximum detected concentration.
Chebyshev (Mean, Sd) UCL = (1-α)100% UCL of the mean based upon the chebyshev theorem (using the sample mean and sample standard deviation - non-parametric).
Chebyshev (MVUE) UCL = (1-α) 100% UCL of the Mean of a Lognormal Population Based Upon the Chebyshev Theorem (Using the MVUE of the Mean and its Standard Error - parametric).
Gamma UCL = Computation of UCL of the mean of a Gamma, G(k,θ) distribution (parametric).
H-UCL = (1-α)100% UCL of the mean based upon H-statistic (H-UCL) (parametric).
KM (BCA) UCL = UCL based upon Kaplan-Meier estimates using the bias corrected accelerated percentile bootstrap method. (non-parametric).
KM (Chebyshev) UCL = UCL based upon Kaplan-Meier estimates using the Chebyshev inequality (non-parametric).
KM (t) UCL = UCL based upon Kaplan-Meier estimates using student's t-distribution critical value (non-parametric).

Footnotes:
UCL based on USEPA ProUCL (V. 4.0) recommendation, using Regression on Order Statistics (ROS) for evaluating data with non-detect (ND) samples.
a = Aroclor-1248,-1254, -1260 samples were combined for analysis by ProUCL 4.0 and determination of an EPC.
b = All aroclor samples were combined for analysis by ProUCL 4.0 and the determination of an EPC.
c = Max - maximum detected concentration; %UCL - % upper confidence limit.
NA = UCL could not be calculated because of low sample number or low detection frequency.
It is possible that in certain instances, the calculated 95% UCL is smaller than the mean detected concentration. This reflects a low detection frequency and non-detect samples largely outnumbering detected samples, causing the 95% UCL recommended by ProUCL v4.0 to be smaller than the mean detected concentration, since it reflects the large number of non-detect samples.
Approximate Gamma UCL = Computation of UCL of the mean of a Gamma, G(k,θ) distribution (parametric).
KM (BCA) UCL = UCL based upon Kaplan-Meier estimates using the bias corrected accelerated percentile bootstrap method. (non-parametric).
KM (Chebyshev) UCL = UCL based upon Kaplan-Meier estimates using the Chebyshev inequality (non-parametric).
KM (t) UCL = UCL based upon Kaplan-Meier estimates using student's t-distribution critical value (non-parametric).
Student's-t UCL = Computation method based upon student's t-distribution (parametric).

[2] EPA 1997. Exposure Factors Handbook. Table 3-30 - Summary of Recommended Drinking Water Intake Rates. 95th Percentile (90th Percentile was used when 95th Percentile is not listed).

[3] EPA 1991. Standard Default Exposure Factors. Default for resident child and adult.

[4] EPA 1997. Exposure Factors Handbook. Table 5-23 - Summary of Recommended Values for Inhalation. Mean of male and female. Values were given as (m^3 / day) and were then divided by 24 hours to give an hourly rate.

[5] SSAF-Adj to be used with the Child Resident exposed to surface soils. Derived from the Soil SSAF.

[6] SSAF-Adj to be used with the Older Child Trespasser and Child Recreator exposed to surface soils and sediment. Derived from the Sediment SSAF.

[7] EPA 2004. Risk Assessment Guidance for Superfund Volume I: Human Health Evaluation Manual (Part E, Supplemental Guidance for Dermal Risk Assessment).
Recommended default adherence factor for a child resident (0.2) and adult resident (0.07). For older children, the geometric mean weighted adherence factor for children playing in wet soil of was used for children 6 - 12, as a central tendency estimate of a high end soil contact activity (see Exhibit 3-3).

[8] EPA 2004. Risk Assessment Guidance for Superfund Volume I: Human Health Evaluation Manual (Part E, Supplemental Guidance for Dermal Risk Assessment)
Calculated from Exhibit C-1 - Body Part-Specific Surface Area Calculations (Children). Data from Exposure Factors Handbook, Tables 6-6, 6-7 and 6-8.
Surface area of head, forearms, hands, lower legs and feet (for child <6 years); feet excluded from surface area calculation for >6 years.
Surface area for >18 is recommended default for adult resident (EPA 2004).
