1.0 INTRODUCTION

This report presents revised conceptual design plans for the closure of the above referenced waste disposal sites based on discussion with NYSDEC - Region 9 on June 16, 1992 and NYSDEC's October 30, 1992 comments on the previous submittal entitled "Conceptual Design Approach For Closure of Inactive Waste Sites No's. 915018, A, B, & C, August 1992". The remediation approach outlined reflects the limited extent of contaminant migration offsite and is consistent with an Interim Remedial Measure Closure. Results of laboratory and field testing, including a field demonstration test program utilizing onsite low permeability soil suitable for cover, are provided in support of the proposed final cover design.

2.0 EXISTING COVER ASSESSMENT

Investigation to determine the type and thickness of cover soil was performed by URS during December 1991. Shallow probe samples were obtained on a 50-foot grid spacing, located by survey, within each disposal area. Samples were collected at approximately 250 test locations using hand augers and were described in the field by the URS geologist. Thickness of soil cover and descriptions of material classification and vegetation types at individual bore locations were recorded. The location of sampling points and interpolation of cover thickness are shown in Figure 1 (Disposal Sites A and B) and Figure 2 (Disposal Area C). The thickness of fill material along the southern portion of Disposal Site C is depicted in Figure 3. Results are discussed by disposal area in the following paragraphs:

2.1 <u>Disposal Site A</u>

Major fill-area A can be characterized as consisting of a southern area containing thick (> 12 inches) clayey cover soil, and central and northern areas with minimal and discontinuous cover interspersed with isolated pockets of thicker clayey cover.

Separating the southern area from the remainder of the disposal site is a low east-west swale which becomes more pronounced along the western perimeter of the site in the vicinity of sampling locations SW-2 and SS-102. Water pended in the vicinity of SW-2, at the time of this

investigation, appeared to be derived from seepage through waste exposed in the swale which receives drainage from low areas west of Building No. 2 (Figure 1).

The presence of a 4 to 8 foot thick clay mound (from recent construction excavation activities) within the central area of the site precluded testing of this area. Samples of the clay mound soil (to be used for site cover), and undisturbed block samples of the clayey cover within the southern area of the site, were obtained for laboratory classification and permeability testing (Figure 1). The results of this testing (Appendices A.1, and A.2) indicate permeability of the existing cover to be equal to, and less than 1×10^7 cm/s demonstrating the suitability of the existing onsite soil for low-permeability cover.

2.2 **Disposal Site B**

The majority of Disposal Site B, east of survey line 2+00E and south of survey line 1+00N (north quadrant), will be covered by an asphalt parking surface which will provide an effective barrier for this area (Figure 1). Consequently, investigation of cover thickness in this area, which coincides with an existing gravel parking area, was not performed.

Cover thickness in the remaining northern and southwestern portion of the site was found to be highly variable with most test locations reporting less than 6 inches of cover. Although the surface cover appears to be continuous, waste materials were visible along the slope of the discharge drain leading to the plant settling pond. Thickest cover depths were reported toward the settling pond on the northwestern corner of Site B.

2.3 <u>Disposal Site C</u>

This area includes the main disposal mound and an outlying island of fill immediately west of the site (Figure 2). In both areas, a continuous layer of soil was found covering waste materials. In general, most of the area (approximately 65%) contains 6 inches or more of soil cover with isolated areas having up to 24 inches of soil. Thinnest cover thickness was found along the edge of the main fill area where slope grades steepen. Samples of the clayey cover were obtained for laboratory classification, which demonstrated soil properties similar to those

defined for the borrow stockpile and borrow areas (Figure 2 and Appendix A.1). Probes of waste depth along the southern margin of Area C revealed the existence of a 50 to 75 foot wide perimeter zone which contained waste material less than 12 inches thick (Figure 3).

3.0 COVER CONSTRUCTION AND CERTIFICATION SUMMARY

3.1 Cover Construction

On July 21, 1992, test pads were constructed using locally available clayey soils (described in the following section) in several configurations and compaction modes. Table 1 summarizes the test data which is presented in Appendix A.3. In constructing the 18-inch test pad made from a single lift of clay, a sheepsfoot roller was employed for final compaction. That roller produced a noticeably higher result for field measurement of in-place density, as well as a lab test of 4 x 10⁻⁸ cm/sec permeability. Those results indicate that the sheepsfoot roller compactor is the equipment of choice for compacting the proposed 18" cover for these sites.

The sheepsfoot compactor used in the test pad construction weighed approximately 25,000 lbs., had 6-inch long feet, and was equipped with a vibrator. In order to achieve an average permeability coefficient of 1 x 10⁻⁷ cm/sec, or less, in the final cover, the weight of the compactor will be increased and the foot depth will be 8-inches.

3.2 Borrow Source Characterization

Clayey soil suitable for placement as low permeability cover is currently stockpiled within Disposal Site A (Figure 1). This material, consisting of approximately 1,200 cy of soil, is from a recent foundation excavation and is free of foreign material. This soil will be supplemented by the excavation of onsite sources of similar origin and quality. These sources include clay soil placed as cover within the waste areas, and excavation of borrow from an area designated east of the settling pond (Figure 1). Total estimated volume of low permeability soil from all sources is 22,000 cy.

The uniformity and consistency of the onsite clay sources is demonstrated in test boring

records (Appendix B), and laboratory test data as presented in Appendices A.1 - A.3 and summarized in Tables 2 and 3. Coarse fragments greater than 3-inches in diameter were not present in the soil. Material characterization tests performed on samples from the Area A clay stockpile, and the proposed clay borrow area east of the settling pond (Table 2), confirm the similarity of these source materials. Consequently, remolded laboratory tests and tests performed on 'undisturbed' soil cores from demonstration test pads (Table 3) are representative of both the stockpile and proposed borrow area materials.

3.3 Construction Quality Assurance (CQA) Testing:

- o Material for low permeability cover will be placed at sufficient thickness to produce a compacted layer 18 inches thick. Clay soil will be placed using a dozer or pan and subsequently compacted using a medium to heavy weight (30,000 to 50,000 pound) sheepsfoot roller with 8-9 inch depth feet. Refer to the demonstration test pad results (Appendix A.3) to substantiate the compaction of a single 18 inch lift using 4 to 6 roller passes which achieved an average permeability of 1 x 10⁻⁷ cm/sec or less.
- The moisture content of the soil and resulting compacted density will be tested during placement to insure the material lies within the window of acceptable values necessary to achieve the required permeability result. The window delineated in Figure 4 defines the acceptable moisture-density range for compaction of the onsite clay material. Limits for the test window were established based on laboratory permeability results from remolded compaction samples and were confirmed by the results from undisturbed cores taken from the field demonstration test pads (Tables 1 and 3).

The lower limit for field compaction requires a minimum 95 percent of Standard Proctor maximum density. Acceptable water content ranges from 2 to 3 percent drier than, to 3 to 6 percent wetter than optimum moisture as referenced to Standard and Modified Proctor results, respectively. For application of this approach see EPA/625/4-89/022 - Chapter 6.0 Requirements for Hazardous

Waste Landfill Design and Construction.

 Certification QA/QC testing requirements will be conducted in accordance with Table 4.

4.0 REMEDIAL ACTION APPROACH

The specifics of the Interim Remedial Measures to be implemented for each area are presented in the following sections.

4.1 <u>Disposal Site A Plan</u>

- No action is required for the southern portion of major fill-area A (Figure 5) where clay cover thickness exceeds 12 inches, vegetation is well established, and the surface is sufficiently sloped for drainage. Laboratory test data (Table 2) from undisturbed samples of the clay cover indicate hydraulic conductivities of 1×10^{-7} cm/s and less, and fine content in excess of 76 percent. The area encompasses approximately 1.2 acres.
- No action, with provision for additional groundwater monitoring and/or test pitting is required for Minor Waste Area 'A'. Investigation (including test pit excavation (URS Report 4/92) and hand auger probing, has demonstrated 2 to 3 feet of clayey cover (from settling pond excavation) throughout most of the area. The western margin of the area is diversely vegetated with mature trees. A monitoring well is to be installed downgradient of this area to monitor long-term groundwater quality and evaluate the need for future action. To determine the parameters included in the long-term monitoring program, two waste samples will be collected and analyzed for TCLP parameters.
- o Regrade the east-west swale separating the southern from the central and northern disposal areas. Low-lying areas east of the site can be effectively drained by extending the cover on the southern portion of site and diverting the drainage

southwest into the plant settling pond. Any waste materials removed from the drain are to be placed within the main fill area.

To address waste contaminant migration the swale will be lined with the same compacted clay soil used for site cover, and vegetated as necessary to prevent erosion. The integrity of the protective cover, including the swale area, will be inspected and maintained throughout the closure period in accordance with the Post-Closure Maintenance/Repair Plan to be developed during design.

During construction, the Contractor will be required to submit for approval a Sedimentation Control Plan. This plan will address the problems of short term contaminant migration resulting from disturbance of the soils.

NYSDEC Division of Water will be contacted during design to address potential impacts to the existing settling pond's SPDES permit.

- A portion of the northerly and easterly parts of fill-area A will be paved to provide needed tractor-trailer staging for this expanding production facility (Figure 5). Pavement will consist of 8 inches of stone over prepared subbase with 4-inches of Type #6 binder. The existing access roadway will be expanded, covering part of the easterly portion of the area. Grades will be established to provide for surface water drainage away from unpaved areas into strategically located catch basins connected to the existing storm drain system, which leads to the settling pond.
- The northern portion of waste area 'A' will be excavated and incorporated into central waste area 'A' (Figure 5).
- O Central waste area 'A' will be contoured as necessary to facilitate site drainage, cover placement, and erosion control.
- o Sufficient clay borrow will be added to regraded central area 'A' (including

drainage swale) to constitute a continuous compacted clay soil layer 18 inches thick. This will be covered with 6 inches of soil amenable to plant growth.

- o Recontoured and disturbed areas will be seeded and mulched.
- O Due to the presence of impermeable underlying soils, the site A closure does not warrant the installation of a leachate or groundwater collection/treatment system.

4.2 <u>Disposal Site B Plan</u>

- The gravel parking area and access road to Gate No. 3 will be paved with 8" of stone overlaid with 2-inches of Type #3 binder and 1-inch of top surface. Surface drainage will be directed to catch basins and discharged into the waterway feeding the settling pond. Post-closure monitoring will be conducted to determine effectiveness.
- o Rather than, pulling back waste exposed in the drainage ditch, the discharge pipe will be extended halfway to the settling pond, the discharge drain will be backfilled with common borrow soil, and surface prepared for cover (Figure 5).
- o The waste from the southern portion of area 'B' will be excavated and incorporate it into northern area 'B' or central area 'A' (Figure 5).
- The northern waste area 'B' will be contoured for drainage and sufficient soil will be added to constitute a continuous layer of compacted clay 18 inches thick with a 6 inch cover of soil amenable to plant growth. Other suitable cover material, including use of gunite concrete applications, may be substituted for steep slopes at the time of final design.
- o Recontoured and disturbed areas will be seeded and mulched.
- o Due to the presence of impermeable underlying soils, the site B closure does not

warrant the installation of a leachate or groundwater collection/treatment system.

4.3 Disposal Site C Plan

- The shallow fill from the southern margin of the site will be removed and a swale for east-west drainage will be established (Figures 3 and 6). This swale will discharge into the north-south trending drainage ditch which flows into the Town of Tonawanda storm sewer via a culvert. The topsoil, fill, and clayey subsoil materials will be segregated for site grading and cover purposes.
- o The outlying fill pile west of the site will be excavated and incorporate it into the main fill area (Figure 6). The topsoil will be segregated for cover placement.
- The existing cover material from the main fill area will be removal and stockpiled. The area will be contoured removed and stockpiled as necessary for site drainage and the northern fill edge will be regraded to achieve an acceptable slope for cover placement and erosion control. Minimal disturbance to the adjacent wetland areas (less than one acre) is anticipated.
- o Sufficient soil will be added to constitute a continuous layer of compacted clay borrow 18 inches thick with a 6 inch cover of soil amenable to plant growth.
- o Recontoured and disturbed areas will be seeded and mulched.
- O Due to the presence of impermeable underlying soils, the site C closure does not warrant the installation of a leachate or groundwater collection/treatment system.

5.0 **CONCLUSION**

Dunlop's initial proposal of 12-inches of uncompacted subsoil and 6 inches of soil capable of supporting vegetation was protective of the environment. The additional work proposed in this Interim Remedial design is only directed at providing the Department and public with further

assurances that a protective condition will be achieved and maintained.

Moreover, the proposed cover of 18 inches of compacted clay soil and 6 inches of soil capable of supporting grass, in combination with the regrading and drainage improvements, will results in approximately 97% of all precipitation being kept from the wastes (3% annual average percolation) as shown by the HELP model infiltration analysis presented in Appendix C. The cost of this proposal is estimated to be \$500,000. If Dunlop were needlessly forced to place an additional 24 inches of uncompacted intermediate cover, it would have to spend an additional \$325,000 to purchase and place the material.

In addition, because of the resulting standing head of soil water in the intermediate cover directly overlying the compacted clay, the annual average percolation into the waste would more than double (Appendix C). There is no hydraulic benefit, therefore to the intermediate cover. Also, since a Post-Closure Maintenance/Repair Plan will be prepared and implemented, the integrity of the clay will be maintained without the need for an intermediate cover.

RE: DUNLOP TIRE CORPORATION

INVESTIGATION OF HAZARDOUS WASTE SITES

GEOTECHNICAL TESTING RESULTS

Dear Mr. Pyanowski:

Enclosed are three (3) copies of the Empire Soil Laboratory report for soil samples collected by URS on January 6, 1992. Laboratory tests were performed on the following samples to determine their suitability as capping material for Waste Site A:

DLP-A-SS #1 Undisturbed block samples of clay (cap) soil from southern DLP-A-SS #2 portions of Site A.

DLP-A-GS #1 Grab samples from clay borrow pile within northern area of DLP-A-GS #2 Site A.

The approximate locations from which these samples were obtained are shown in Figure 1. Grain size analysis of the four samples indicate a silty clay soil (USCS: CL - lean clay as per ASTM Designation 2487-85) with a moderate to low plasticity. The high percentage of fines (74 to 89 percent finer than 0.074 mm) confirms the inherent impervious nature of both the existing clay cap and recent onsite borrow material slated for use as cover on the remainder of Site A.

Permeability tests performed on the two undisturbed 'cap' samples, provided further confirmation of the low permeability of the in-place cover soil. Hydraulic conductivity values of 1 x 10^{-7} cm/sec and less are derived for test results extrapolated to an effective hydraulic gradient of 1.0 which best simulates actual field conditions.

Please let me know if you have questions or comments, or if you require additional copies.

Very truly yours,

URS CONSULTANTS, INC.

GEOTECHNICAL TESTING REPORT DUNLOP TIRE CORPORATION BUFFALO, NEW YORK

> FOR: URS CONSULTANTS, INC. BUFFALO, NEW YORK

> > JOB NO. G008.008 JANUARY, 1992

140 TELEGRAPH ROAD • P.O. BOX 297 • MIDDLEPORT, NY 11105 • 716/735-3502 FAX 716/735

January 22, 1991

Mr. Duane R. Lenhardt, PhD URS Consultants, Inc. 282 Delaware Avenue Buffalo, New York 14202-1805

Dear Mr. Lenhardt:

SUBJECT: GEOTECHNICAL TESTING

DUNLOP TIRE CORPORATION, BUFFALO, NEW YORK

Transmitted herewith are the results of geotechnical testing performed on two (2) undisturbed block samples and two (2) bag samples of soil from the subject project. The work was performed in accord with your telephone conversation and with a letter to Mr. Kevin Czaja on January 7, 1992.

Cylindrical permeability test specimens were trimmed from the block samples. The remaining portion of the block samples have been resealed with cheesecloth and wax and is currently being stored in our wet room.

Trimmings from the block samples and a portion of the material from the bag samples were used for grain size distribution test (ASTM D422) and Atterberg Limits test (ASTM D4318). Individual test reports for these tests are presented in Appendix A.

The permeability tests were performed in accordance with ASTM Designation D 5084 using a backpressure of about 80 psi. Each specimen was subjected to two successive differential pressures, the second one approximately half the magnitude of the first. For material behaving in accord with Darcy's Law, the two test runs should have resulted in close to the same permeability. For these samples compliance with Darcy's Law was not particularly good. This could be due to preferential flow along the path of rootlets noted in the specimens. Examinations of the specimens after testing also indicated a tendency to blocky structure of the soil. The results of the permeability test are contained in Appendix B.

It has been a pleasure working with your firm again on this interesting project. Should you have any questions or in case we may be of further service, do not hesitate to contact the undersigned at 716-735-3400.

Respectfully submitted,

RE: DUNLOP TIRE CORPORATION

INVESTIGATION OF HAZARDOUS WASTE SITES

GEOTECHNICAL TESTING RESULTS

Dear Mr. Pyanowski:

Enclosed are three (3) copies of the Empire Soil Laboratory report for soil samples collected by URS on January 6, 1992. Laboratory tests were performed on the following samples to determine their suitability as capping material for Waste Site A:

DLP-A-SS #1 Undisturbed block samples of clay (cap) soil from southern DLP-A-SS #2 portions of Site A.

DLP-A-GS #1 Grab samples from clay borrow pile within northern area of DLP-A-GS #2 Site A.

The approximate locations from which these samples were obtained are shown in Figure 1. Grain size analysis of the four samples indicate a silty clay soil (USCS: CL - lean clay as per ASTM Designation 2487-85) with a moderate to low plasticity. The high percentage of fines (74 to 89 percent finer than 0.074 mm) confirms the inherent impervious nature of both the existing clay cap and recent onsite borrow material slated for use as cover on the remainder of Site A.

Permeability tests performed on the two undisturbed 'cap' samples, provided further confirmation of the low permeability of the in-place cover soil. Hydraulic conductivity values of 1×10^{-7} cm/sec and less are derived for test results extrapolated to an effective hydraulic gradient of 1.0 which best simulates actual field conditions.

Please let me know if you have questions or comments, or if you require additional copies.

Very truly yours,

URS CONSULTANTS, INC.

APPENDIX A.3 CLAY BORROW COMPACTION AND TEST PAD DATA

DEMONSTRATION TEST PROGRAM SUMMARY

(A) Introduction

Demonstration tests of onsite clay soil were performed to assess construction methods and parameters for cover placement. Material used in the test program was obtained from the clay stockpile in Waste Area 'A'. Data characterizing the properties of the stockpile and borrow area soil are provided in Appendix A.2. The test program consisted of two related phases: (1) laboratory test on remolded samples, and (2) demonstration test on constructed test pads.

(B) **Program Description**

(1) Compaction and Remolded Permeability Testing:

- o Representative samples of the clay stockpile were tested for material properties and compaction response by Standard and Modified Proctor Compaction (ASTM D1557-91).
- o Permeability values were subsequently determined for each respective compaction point by maintaining corresponding unit weight in flexible wall perimeters (ASTM D5084-90).

(2) <u>Demonstration Test Pads</u>:

- Three test pads were constructed consisting of: (1) three 6-inch lifts, (2) two 9-inch lifts, and (3) one 18-inch lift. Soil placed in the 6-inch and 9-inch lifts was compacted by 10 passes of a D-6 dozer, while the 18-inch lift was compacted by the dozer and the use of a 24,000 pound vibratory sheepsfoot roller (4 to 6 passes).
- o Following compaction, the lift surface was proofrolled with a smoothdrum roller and moisture-density were measured at 2 locations using a

nuclear densimeter.

o Prior to placement of the next lift, two undisturbed cores of the lift were obtained by pushing 3" diameter Shelby tubes to the depth of the lift. Samples were sealed and forwarded to GZA's laboratory for hydraulic conductivity determination (ASTM D5084-90).

(C) Analysis of Test Results

(1) Compaction and Remolded Permeability:

(i) <u>Gradation - Compaction Results</u>. Grain size analysis and Atterberg limits were determined on a composite sample (DUN SP#1) taken from the area A soil stockpile. Material parameters confirmed a high content of fines (85%) and clay (35%) with low plasticity properties (ML-CL) consistent with samples obtained from the proposed borrow area (Appendix A.2).

Maximum compacted densities of 125.4 pcf at 12.2% moisture, and 116.4 pcf at 15.4% moisture, were determined by Modified and Standard Proctor compaction procedures (Figure 4).

(ii) Remolded Permeability Results. Remolded permeability tests were performed for each of the five (5) Modified and Standard compaction points to define moisture-density/permeability relationships for the proposed onsite borrow soil. Hydraulic conductivity values ranging from 8.3×10^8 to 5.2×10^9 cm/s were recorded for 9 of the 10 compaction points. Samples were remolded between 5% drier than, to 3% wetter than, optimum moisture (Figure 4). One test, prepared on the dry side of optimum, produced a permeability greater than 1×10^{-7} cm/s.

These results demonstrate that low permeabilities can be achieved over a relatively wide range of moisture-density conditions.

(2) <u>Demonstration Test Pads</u>:

performed on the test lifts during construction are summarized in Table 1. In-place moisture content ranged from 11.2% to 14.9%. In-place densities obtained by dozer compaction ranged from 113.2 pcf to 117.6 pcf, equivalent to a modified maximum density of between 90.2% and 93.7%.

Compaction of the 18-inch lift using a medium weight sheepsfoot roller with 6-inch feet produced a 3 to 4 percent increase in lift density over dozer compaction alone (Table 1). Densimeter readings recorded at 6- and 12-inch depths were equivalent using the sheepsfoot roller suggesting good compaction at depth.

tested in the lab following extrusion from the Shelby tube and sample trimming. Measurement of test core dimensions following testing indicated that the prepared lab samples were 2% to 5% less dense than corresponding densimeter measurements taken in the field. This implies possible 'bulking' of the sample during test handling, or systematic error in field measurements. Hydraulic conductivity values for the 6-inch lifts, and upper 6 inches of the 9-inch and 18-inch lifts, ranged from 10⁻⁵ to 10⁻⁷ cm/s for dozer compaction. The core sample from the sheepsfoot roller test produced a considerably lower permeability of 2 x 10⁻⁸ cm/s.

Following initial permeability testing, the density of the test specimens was increased to reflect corresponding field measurements of density, and the samples retested. All retested samples produced permeabilities in the 10⁻⁸ cm/s range representing a 2- to 3-order of magnitude reduction in permeability for an average 3 pcf increase in density.

Results of this testing confirm a significant increase in compaction and reduction of permeability using the sheepsfoot roller. The compaction data further demonstrate effective compaction of the upper 6 inches using dozer compaction, and enhanced compaction of the 18-inch lift using the sheepsfoot roller.

Attention: Mr. Duane Lenhardt

Re:

Geotechnical Sample Analysis, Dunlop Site

Dear Mr. Lenhardt:

GZA GeoEnvironmental of New York (GZA) in accordance with our proposal dated June 22, 1992 has laboratory tested one bulk sample designated as DUN SP#1 and delivered to GZA's Buffalo office by URS Consultants, Inc. (URS).

Bulk sample no. DUN SP#1 was tested for as received moisture content, liquid and plastic limits, grain size analysis, moisture-density relationship, and permeability following ASTM procedures. Enclosed are a copy of a geotechnical laboratory testing data summary sheet, associated data plots and test procedures.

After you have reviewed these data, please do not hesitate to contact the undersigned if you have any questions or require any additional information. GZA appreciates the opportunity to work with you on this project and we look forward to a continued association.

Very truly yours,

GZA GEOENVIRONMENTAL OF NEW YORK

GEOTECHNICAL LABORATORY TEST PROCEDURES

GEOTECHNICAL SAMPLE ANALYSIS DUNLOP SITE TONAWANDA, N.Y. File No. R6007.00

1. The following tests were performed with the noted ASTM test designation:

| <u>TEST</u> | ASTM DESIGNATION |
|---|---|
| Moisture Content Liquid and Plastic Limits Grain Size Analysis Moisture Density Relationships Permeability Test | D 2216-90 D 4318-84 (method A) D 422-63 (see Item 2) D 1557-91 D 5084-90 (see Item 3) |

2. Test Procedures for Combined Sieve and Hydrometer Analysis

When both sieve and hydrometer analyses are required a combined mechanical analysis is performed. This procedure is, in part, similar to ASTM's D 2217-66 (wet preparation of soil sample for grain-size analysis and determination of soil constants-B).

A representative portion of the minus No. 4 material was mixed with water so as to form a thin homogeneous slurry. The fines suspended in this slurry were then decanted over a No. 200 sieve into an empty hydrometer jar, and the mixing-decanting process repeated until most of the fines had been removed. Coarser fractions remaining after the decantation were then oven dried and sieved through a nest of sieves (Nos. 10, 20, 40, 60, 100, and 200). Any material passing the No. 200 sieve was added to the hydrometer jar containing the finer fraction.

Hydrometer analysis of these fines was performed in the conventional manner.

3. Test Procedures for Permeability Test

Permeability tests were performed on samples reconstituted to specified densities approximately equivalent to the dry density of the five points obtained from the modified Proctor test (ASTM D 1557-91 Method A) at the corresponding water content.

Reconstituted test specimens were prepared in a manner similar to that described in "Special Procedures for Testing of Soil and Rock for Engineering Purposes" STP 479, ASTM 5th Edition, pages 101-103. The specimens were reconstituted in 2.8-inch diameter by 2.5-inch long sample formers. A specific amount of soil at the appropriate water content was weighed in five equal portions. Each portion was tamped by means of a mechanical tamping foot to a specified height in the mold. After five layers were compacted the samples were weighed, dimensioned, and their

GEOTECHNICAL LABORATORY TEST PROCEDURES - FILE NO. R6007.00

unit weight verified. After verification of the unit weight, the test samples were placed on a previously de-aired, modified triaxial cell base and porous stone. A membrane was added and the samples sealed top and bottom by '0' rings.

The samples were back pressured under a small effective stress to create complete saturation of the samples. The chamber pressure was then increased such that the desired effective stress was obtained to prevent volume change of the samples. This effective stress was allowed to act for about 24 hours.

After the saturation phase, the response of the soil samples were checked by increasing the cell pressure and monitoring the pore pressure. Where required, additional back pressure was applied so as to achieve a pore pressure response equal to or greater than 95 percent. When the desired saturation was achieved, the samples were attached to the permeability apparatus and tested in accordance with ASTM procedure D 5084-90, "Measurement of Hydraulic Conductivity of Saturated Porous Materials Using a Flexible Wall Permeameter". During the test, measurements of flow vs. time were recorded with the permeability value reported being the average of several consistent values obtained during the test.

|-----------------|--|
| 8 NO | 35 24 6 07 DATE JULY 21, 19 |
| CONSTR | UCTION ACTIVITIES (Continued) |
| | BY 1:15PM, THE CONTRACTON STANTED COMPACTING TEST |
| | PAO No. 2 18, WCH LIFT BY TRACKING WITH THE DOZER |
| | (G PASSES) |
| _ - | AT 130 PM THE SMOOTH ROLLEN ANDIVED ON SITE |
| | AND THE CONTRACTOR USED THIS ROLLER TO MAKE |
| | 2 PASSES ON EACH OF THE TEST PARS TO FINISH |
| | COMPACTION THEM |
| | WHEN IT WAS FEASIGLE . I INSTRUCTED EMPIRE TO TEST |
| | BOTH TEST PAPSWITH 2 1PDS RACH. ALL FOUR (4) 1PDS |
| | PASSED AND WE PUSH A SET OF 2 SHELBY TUBES PER |
| | TEST PAD (OUR SHELBY TUBE TO BETESTED AND THE SECOND TO |
| | BE A BOCKUP). |
| | AT 2:05 PM THE CONTRACTOR PROCEDED TO PLACE AND |
| | COMPACT THE SECOND GINCH ON TEST PAD NO! AND |
| | BY 2:45PM I INSTRUCTED EMPIRE TO TAKE 21PO TEST |
| | ON THIS LIFT NO. Z. OUR OF THE TWO TESTS FAILED COMPACTION |
| | THENEFORE INSTRUCTED THE CONTRACTOR TO TAKE THO(2) |
| | MOTE APPITIONAL PASSES WITH THE SMOOTH ROLLEN. |
| | WHEN FRASIGLE , WE RETESTED FRET PAP NO ! LIFT |
| | No. 2: THIS TIME BOTH TROTO PASSED. SO WE |
| | PROCEDED TO PUSH SHELDY TUBES. |
| | ' |
| | FOLLOW THAT AT 3'00PM THE CONTRACTOR STANTED |
| | TO PLACE AND COMPACT LIFT NO.3 (THE FINAL GINCH LIFT) |
| | ON TEST PAO No.1. |
| | BY 3:43PM I HAD EMPIRE TOKE 2 IPD TESTS ON THIS |
| | LIFT; BOTH OF WHICH PASSED NEXT WE PUSHED THE |
| | FINAL SHELDY TUBED FOR THIS TEST POONS. 1. |

| | TROT OF THE SUPEGRADE. THE RESULT WAS 69% |
| | COMPACTUR AND 23070 MOISTURE BUT DUANE LENHAROT |
| | SAID THAT EVEN. WITH MONE COMPACTION THE RESULTS |
| | WOULD NOT IMPROVE OUR TO THE PORSENCE OF |
| | WASTRIN THE SUBGRADE . THEREFORE HE GAVE THE |
| | GO AHEAD FON THE CONTRACTOR TO START PLACING |
| | LIFT NOIL OF LOW PRAM SOLFOR TRST POO NO. 3. (9 INCH |
| | AT 10:30am THE CONTRACTOR STARTED TO COMPACT |
| | LIFT NO I WITH G PASSIES WITH THE DCC DOZER |
| | ALD 2 PASSES WITH THE SMOOTH ROLLEN. |
| | BY 10:45AM EMPIRE TOOK TWO (2) IPDS : THRY |
| | PASSED REFER TO EMPIREIPD TEST REPORT FOR DETAIL |
| | ON TODAY 190 TROTS. (TABLE!) THEN THE CONTRACT |
| | PROCEDE TO TAKE & ADDITIONAL PASSES WITH THIS |
| | DOZEN AND 2 PASSES WITH THE SMOOTH ROLLEN |
| | PRO DUDNE'S REQUEST. BEFORE THE CONTRACTOR |
| | PROGROED WITH THAT, WE TOOK 2 SHELBY TUBES. |
| | EMPIRE RETESTED LIFT NO. 1. THE RESULT WERE |
| | NOT MUCH DIFFERENT From THE FIRST RESULTS. |
| | |
| | AT 11:05AM THE CONTRACTOR STARTED TO PLACE |
| | LIFT NO. 2 ON TROT PAID NO. 3. WHEN THE CONTRACTOR |
| | WAS FINISHED COMPACTING THIS LIFE AT 11:35AM, |
| | EMPINE TRATED IT WE HOD ONE FAILING |
| | % COMPACTON RESULT; THEREFORE I WSTAUCTED |
| | THE CONTRACTOR TO TAKE TWO (2) ADDITIONAL |
| <u> </u> | PASSES WITH THE SMOOTH ROLLEY WHEN |
| | FRASIBLE, WE RETESTED THE LIFT AND THIS |
| | TIME BOTH IDD TROTS PASSED. THEN WE |
| | PUSHED 2 SHELBY TUBES IN THIS FINAL LIFT. |
| | |
