MEMORANDUM

TO: Report Reviewer
FROM: Bureau of Hazardous Site Control
SUBJECT: Division of Hazardous Waste Remediation
DATE: Sleepy Hollow Campgrounds
December 20, 1989

To the reader of this report who is unfamiliar with the specifics of this site and/or who has not completed a site inspection, it may be unclear what the current site conditions are. There have been two seperate drum removals at this site. The first occured in 1981 from which 50-60 drums full of waste materials (originating from the F.N. Burt Company) were removed from an area near the entrance to the site off Siehl Road. The second drum removal occured in November 1986. A total of 17 drums of waste and 13 drums of contaminated soil were removed from a swampy area in the north portion of the site.

During the November, 1986 drum removal an additional ten drums full of unknown material were observed near the on-site maintenance building near the south entrance, as well as an estimated 100 empty drums scattered around on-site. Some of the empty drums are apparently used for refuse collection at the campsites. None of the ten full were removed at that time. During the Phase I site inspection (November 2, 1988) the 10 full and numerous empty drums were still present.

A July 6, 1989 inspection by the New York State Department of Health indicates the 10 full drums were <u>not</u> observed near the on-site maintenance building, although some drums containing an unknown waste were observed in an adjacent shed. The DEC is attempting to determine the fate of these drums. Sampling of three on-site wells by the NYSDOH indicated no contaminants above drinking water standards. Additional sampling is planned.

1.0 EXECUTIVE SUMMARY

The Sleepy Hollow Campgrounds site is located on Siehl Road in the Town of Newstead, New York, in the extreme eastern portion of Erie County (Figures 1-1, 1-2 and 1-3). This rural community is approximately 17 miles east of the City of Buffalo, New York. The estimated 104-acre site is the location of a campground which is currently owned and operated by Mario and Anthony Latello of Lancaster, New York. During the early 1970s, Fietshans and Mauer Trucking, Inc., the former owners of this property, disposed of numerous drums containing waste solvents, oils, adhesives and other liquids and sludges generated by the F. N. Burt Company, Inc. of Buffalo.

The site has the potential to impact both human health and the environment. Analyses performed on waste samples collected by the New York State Department of Environmental Conservation (NYSDEC) in 1985 indicated the presence of several hazardous compounds including toluene, xylene, chlorobenzene and others. Potential groundwater contamination is of major concern since private wells serve the majority of the population in the area with a potable water supply. Potential surface water contamination of tributaries of Ellicott Creek and on-site Sleepy Hollow Lake, which are used for recreation, are also of concern. Additionally, due to the nature of the site (i.e., campground) and lack of restrictive measures, the potential for direct contact with remaining drums and contaminated soil is a significant potential human exposure concern.

The Phase I effort involved the compilation of information gathered from several sources including, but not limited to, the following: the NYSDEC - Central Office and Region 9, the Erie County Department of Environment and Planning, and a site inspection conducted by Recra Environmental, Inc.

personnel on November 2, 1988. Photographs taken during this site inspection are presented in Appendix B.

The Sleepy Hollow Campgrounds site was evaluated and scored in accordance with the Hazard Ranking System (HRS). USEPA uses a hazard ranking system (HRS) to apply uniform technical judgement in evaluating the relative hazards presented by sites being considered for federal superfund remediation. The HRS is sometimes called the MITRE Model because it was developed by the MITRE Corporation under contract to the USEPA. HRS addresses only relative hazard. It does not assess the feasibility, desireability, or degree of cleanup required, and does not address all potential environmental or health impacts.

Under the HRS, three numerical scores are computed for each site to express the relative risk or danger from the site, taking into account: the population at risk; the hazardous potential of substances found at the site; the potential for contamination of drinking water supplies, for direct human contact, and for destruction of sensitive ecological systems; and other appropriate factors. Three scores are:

a. S_M, reflecting the potential for harm to humans or the environment from migration of a hazardous substance from the facility by groundwater, surface water or air. It is a composite of separate scores for each of the three routes.

b. S_{FE}, reflecting the potential for harm for substances that can explode or cause fires.

c. S_{DC}, reflecting the potential for harm from direct contact with hazardous substances at the facility.

Based on information gathered during this investigation of the Sleepy Hollow Campgrounds site, the following HRS scores were obtained:

S_M = 26.96 (S_{gw} = 45.10, S_{sw} = 11.89, S_a = 0.00)

S_{FE} = N.S.

S_{DC} = 25.00

The data available in several areas of this Phase I Investigation is considered inadequate for a proper site assessment; therefore, additional data gathering and evaluation are suggested. Proposed activities include subsurface investigation using borings and monitoring wells, in addition to groundwater, surface water and soil sampling and analyses.

2.0 PURPOSE

The purpose of this Phase I Investigation is to provide a preliminary characterization of hazardous substances present at the Sleepy Hollow Campgrounds site, to estimate pathways by which pollutants might be migrating from the site, to determine if populations or resources might be affected by pollutants from the site, to determine how the disposal area was used or operated, and to gather information regarding responsibility for possible site wastes.

This investigation was conducted with the following objectives:

- Collect and review available site-specific data and prepare a preliminary Hazard Ranking System (HRS) score.
- Conduct a site inspection and air monitoring survey.
- Evaluate existing data for completeness and identify environmental data needed to determine if the site poses a significant threat to the environment.
- Prepare a summary report.

The purpose of developing the Phase I report in this manner is to provide an objective assessment of the site and the potential impact it may pose on human health and the environment.

3.0 SCOPE OF WORK

The scope of work for the Phase I Investigation of the Sleepy Hollow Campgrounds site included data collection and review, site inspection and air monitoring survey, interviews with individuals who possess knowledge or information pertinent to site activities, development of a preliminary HRS score, and report preparation.

The sources contacted during this Phase I Investigation included federal, state, and local government agencies; site owners and operators; and business and/or individuals with knowledge of the site activities. These sources are listed below:

In addition to obtaining information from available literature and the data sources delineated above, Recra personnel conducted an inspection of the site on November 2, 1988. The inspection was conducted so as to identify

the present conditions of the site. During the inspection, an air monitoring survey was performed utilizing a photoionization analyzer to determine the presence of volatile emissions. No organic vapors exceeding background were detected.

4.0 SITE ASSESSMENT

4.1 Site History

The Sleepy Hollow Campgrounds site is currently owned and operated by Anthony Latello and Mario Latello of Lancaster, New York, under the name of LV & L Resort Corp. The property was purchased by the Latellos from Feitshans and Mauer Trucking, Inc. in 1976 (Ref. 9, pg. R57 and 28, pg. R128-R130).

Aerial photographs taken from 1938 through 1985 indicate the progression of the site property from undeveloped land to its current use as a campground. The 1938 photograph shows the site consisted predominantly of wooded and agricultural lands. By 1959 clearing of the property had occurred for campsites and a narrow, elongated lake is evident in the location of the present-day Sleepy Hollow Lake. The 1978 photograph illustrates that site development continued to include enlargement of the lake and installation of roadways throughout the site. A fairly large area of disturbed land is evident along the eastern side of the lake, adjacent to the site boundary. Active use of the property as a campground occurred by this time. With the exception of vegetative growth over the former disturbed area, the 1985 photograph does not indicate much, if any, change to the site (Ref. 29, pg. R131-R134).

In the early 1970s, Feitshans and Mauer Trucking, Inc. transported and disposed of numerous 55-gallon drums of waste materials at the site. The wastes included oils, solvents, adhesives and other liquids and sludges generated by the F. N. Burt Company, Inc. of Buffalo, New York (Ref. 9, pg. R57).

The Erie County Department of Environment and Planning (ECDEP) investigated the site in June 1981 upon receipt of a complaint concerning drums at the facility. Approximately 50 to 60 drums full of wastes were found in the vicinity of Sleepy Hollow Lake and Siehl Road (the southern portion of the site). The waste material was described as glue or adhesive and waste oil generated by F. N. Burt Company. The drums were leaking and wastes were reported on the ground surface. Vegetation in the area was discolored. Approximately 100 additional, but empty, drums were also reported on-site at this time. Shortly thereafter, the drummed wastes were removed by Latello, the site owner, to a private address. Latello was charged by the NYSDEC for storage and transportation without a permit. The drums were subsequently disposed of at Frontier Chemical Services in Niagara Falls, New York under supervision of the NYSDEC (Ref. 10, pg. R69-R70).

During a site inspection conducted by the NYSDEC in May 1985, several additional drums in various stages of deterioration were reported in the swampy area north of the lake. Wastes were observed leaking from the drums. Chemical analyses performed on three waste samples detected several volatile organic compounds including, but not limited to, toluene, chlorobenzene and methylene chloride (Ref. 4, pg. R33 and 11, pg. R74-R79). (Further discussion of the waste sampling program and analytical results is presented in Section 4.4 on the Site Contamination Assessment.) A consent order was filed by the NYSDEC for the removal and proper disposal of those drums containing wastes as well as nearby contaminated soil. The consent order was executed by the Latellos and F.N. Burt Company in October 1986 (Ref. 9, pg. R63, R65-R66).

In November 1986, a total of 17 drums of waste and 13 drums of contaminated

soil were removed from the site under supervision of the NYSDEC. At this time, November 1986, ten additional drums of unknown material were reported near the on-site maintenance building, as well as an estimated 100 empty drums which were previously reported by the ECDEP (Ref. 13, Pg. R87). These drums have not been removed and were also observed during the site inspection conducted as part of this Phase I Investigation (Ref. 21, pg. R106-R110). In addition to the drums, during the Phase I site visit fuel tanks were observed behind the garage. One above-ground tank was reported to contain diesel fuel and one underground tank was reported to contain gasoline (Ref. 21, pg. R106-R110).

4.2 SITE CHARACTERISTICS

4.2.1 Environmental Setting

The site is located on the north side of Siehl Road in the extreme southeastern corner of the Town of Newstead, Erie County, New York. The estimated 104-acre site lies roughly midway between the Villages of Akron and Alden, and is less than ¼ mile west of the Genesee County border. The location lies approximately 17 miles east of the City of Buffalo, New York. Site coordinates are N42° 57' 30" latitude and W78° 28' 09" longitude (Ref. 20, pg. R105; 28, pg. R128, R129; and 30, pg. R136).

The facility is situated in a sparsely-populated, rural, residential and agricultural area. The nearest major population center is the Village of Corfu (population 689) which is located approximately 2.7 miles to the east (Ref. 31, pg. R138). A number of residences are located in proximity to the site with the closest being about 500 feet to the southeast along Siehl Road. Active farmland is also in the vicinity, including corn and

barley fields (Ref. 20, pg. R105 and 22, pg. R111).

The site is partially wooded and generally covered with grass and weeds. A long and narrow lake (Sleepy Hollow Lake) extends along the eastern site boundary. Several small buildings are located on-site, including a maintenance building, office and store, a restaurant and others. Small, gravel-covered and paved roadways accessing the campgrounds transect the site. Although use of the facility is seasonal, several camper units remain at the site year-round. Numerous, predominantly empty drums remain on-site. Various other waste debris including tires, scrap metal and construction materials were also observed. Although a lockable gate exists at the road entrance to the campground, the site is not fenced and is easily accessible (Ref. 21, pg. R106-R110).

4.2.2 Topography and Drainage

The site topography and that of the surrounding area is relatively flat-lying. Surface elevations at the site range from about 830 feet to 850 feet above mean sea level. The site slopes at approximately 0.5% to the northwest. Surface water runoff drains predominantly in this direction. Sleepy Hollow Lake drains into the swampy area to the north. This area is then drained by small tributaries of Ellicott Creek which lies approximately 6 or more miles downstream. Ellicott Creek eventually discharges into the Niagara River at a location north of Buffalo, New York (Ref. 20, pg. R105 and 30, pg. R136). Several Class II NYSDEC-regulated freshwater wetlands, which by classification provide important wetland benefits, lie in proximity to the site (Ref. 24, pg. R114; 26, R120; and 32, pg. R140).

4.3 SITE HYDROGEOLOGY

4.3.1 Geology

The Sleepy Hollow Campgrounds site is situated in the extreme western portion of the Erie-Ontario Lowlands physiographic province. This province consists of relatively low, flat-lying areas which rise gently to the east and south from Lake Erie and Lake Ontario, respectively. The land relief has been altered by glacial deposition which formed drumlins, recessional moraines and shoreline deposits, and also by karst features including sinkholes and swallets (Ref. 2, pg. R15-R17 and 33, pg. R143).

Regional geologic mapping indicates that bedrock underlying the site consists of Middle Devonian shale and limestone of the Hamilton Group. The site lies on the contact between the Skaneateles Formation and older rocks of the Marcellus Formation. The site lies just south of the contact with the older marine deposits of the Onondaga Limestone. The Onondaga Formation is a nearly flat-lying, massive, cherty and argillaceous limestone ranging in thickness from about 25 to 140 feet. These sedimentary rocks of Paleozoic age trend east-west, dipping gently to the south-southwest at approximately 40 feet/mile (Ref. 2, pg. R15 and 34, pg. R145-R146).

Surficial geologic mapping indicates the site is underlain by glaciolacustrine beach deposits consisting of well-sorted sand and gravel sediments deposited at a lake shoreline. The unit is generally stratified, permeable and well drained. Unit thickness generally varies in the area from about 1 to 15 feet. Also occurring in the vicinity of the site are deposits of lacustrine silt and clay which were formed in proglacial lakes.

These units are generally laminated and about 3 to 15 feet thick. A large amount of till morainal deposits also occur in the area. These sediments were deposited adjacent to the glacial ice and are generally better sorted and more permeable than till. Some till is also mapped in the area although not to a great extent. Till deposits are typically variably textured, poorly sorted and relatively impermeable. The till unit is generally not very thick in the area, with underlying bedrock frequently within 10 feet of ground surface (Ref. 2, pg. R15-R17 and 35, pg. R148-R151).

4.3.2 Groundwater

Groundwater largely occurs in the voids of the Onondaga Limestone which have been enlarged by dissolution. This secondary porosity includes bedding planes, vertical joints, and fractures, particularly those occurring within the upper 5 to 15 feet of the formation. Depth to water is commonly within 30 feet of ground surface, and frequently much less. Well yields range from 3 to 100 gallons per minute (gpm) and average 20 gpm. Groundwater is also found in the pore spaces of the unconsolidated overburden sediments, particularly glacial outwash and lacustrine sand and gravel deposits, as well as morainal sand deposits. The water-bearing unconsolidated units are generally thin with a saturated thickness ranging from 10 to 25 feet. Most of the population in the area utilize the underlying Onondaga Limestone as a source of water because it tends to be more productive. Regional groundwater flow is generally to the west, from the areas of higher elevation in the eastern portion of the Erie-Niagara Basin to lower topographic areas in the west, with eventual discharge to Lake Erie or the Niagara River. Locally, mapping indicates groundwater flow in a northwesterly direction from the site. Although relatively

impermeable lodgement till and lacustrine silt and clay units reportedly can act locally as confining layers, they are not considered continuous within the entire 3-mile radius of the site. In addition, hydrogeologic investigations conducted in an area to the west of the site report a significant downward vertical gradient in the overburden and indicate groundwater movement both laterally and downward to the underlying Onondaga Limestone. Therefore, for purposes of HRS scoring, the bedrock and overburden units are collectively considered the aquifer of concern (Ref. 1, pg. R-3-R10 and 2, pg. R18-R30).

4.4 SITE CONTAMINATION ASSESSMENT

4.4.1 Waste Quantity and Type

During a site inspection conducted by the Erie County Department of Environment and Planning (ECDEP) in 1981, approximately 50 to 60 drums of wastes (described as glue or adhesive and waste oil) were reported. In addition, approximately 100 empty drums were observed on-site at this time (Ref. 10, pg. R69).

Subsequently, during a site inspection by the NYSDEC in 1985, additional drums containing wastes were observed. The contents of the drums varied, but were generally described as consisting of liquids and sludges frequently having a solvent odor. Others were described as containing a glue-like substance or motor oil (Ref. 4, pg. R33). The drums were rusted, leaking and generally in poor condition. As a result, a total of 17 drums of waste and 13 drums of contaminated soil were removed from the site in 1986 under the supervision of the NYSDEC (Ref.13, pg. R87). An additional 10 full or partially-full drums of unidentified material were observed at

this time and currently remain on-site (as well as numerous empty drums). Waste quantities were computed for the HRS score using only those drums reported as containing waste material; the empty drums were not included in the estimate since their contents, if any, are not known.

4.4.2 Previous Sampling and Analysis

On May 24, 1985 the NYSDEC collected waste samples from 3 of the drums discovered in the swampy area north of the lake. Chemical analyses performed by ERCO, a division of ENSECO, detected the following volatile organic compounds (concentrations represent the highest detected for all 3 samples): toluene (650,000 ppm); m- and p-xylene (110,000 ppm); o-xylene (45,000 ppm); ethyl benzene (28,000 ppm); chlorobenzene (1,300 ppm); trichloroethylene (800 ppm); methylene chloride (110 ppm); tetrachloroethylene (39 ppm); and, 1,2-dichloroethane (6.9 ppm) (Ref.11, pg. R74-R79). High concentrations of toluene were reported in all 3 samples.

No groundwater or surface water sampling has been conducted at the site.

4.4.3 Groundwater Quality

Groundwater contamination from the site potentially exists and is of major concern. With the exception of a few residences within and near the Village of Corfu, and a few located along Route 5 near the Village of Akron, the entire population within a 3-mile radius of the site is served by private wells. This computes to an estimated 1,098 persons who do not have an alternate, unthreatened source of potable water presently available. Although there are no wells serving community municipal water systems in the immediate area, the Village of Corfu municipal water well lies just outside of the 3-mile radius (Ref. 14, pg. R89-R92; 15, pg.

R93-R94; 16, pg. R96; 17, pg. R99; 18, pg. R101; 19, pg. R103; and 20, pg. R105).

4.4.4 Surface Water Quality

A total of 17 drums containing hazardous waste materials were observed in the swampy area in the northern portion of the site. The drums were in various stages of deterioration and some were leaking wastes, thereby constituting an observed release for HRS scoring (Ref. 4, pg. R33 and 13, pg. R87). The swampy area drains into unnamed tributaries of Ellicott Creek, which are NYSDEC-designated Class "C" surface waters (water quality standards allow them to be suitable for primary and secondary contact recreation, including fishing). There are no known surface water intakes for drinking water or irrigation within 3 miles downstream from the site (Ref. 20, pg. R105; 22, pg. R111; 23, pg. R113; 24, pg. R114; and 25, pg. R119).

4.4.5 Air Quality

As part of this Phase I Investigation, preliminary air monitoring was conducted during the site inspection. A Century OVA-128GC instrument was used for detecting organic vapors in the breathing zone. No measurements exceeding background were detected. No major population centers are situated in the site vicinity (Ref. 20, pg. R105).

4.4.6 Soil Contamination

During the NYSDEC-supervised drum-removal program conducted at the site in 1986, a total of 13 drums of contaminated soil were also removed at this time. The excavation area was restricted to the swamp in the northern por-

tion of the site. Further soil contamination, both in the swampy area and in the southern portion of the site (ECDEP drum-discovery area) potentially exists (Ref. 13, pg. R87; and 10, pg. R69-R71). There is a lockable gate at the Siehl Road entrance to the site; however, the site is not fenced.

5.0 PRELIMINARY APPLICATION OF THE HAZARD RANKING SYSTEM

5.1 Narrative

Sleepy Hollow Campgrounds
Siehl Road
Town of Newstead, Erie County, New York

The Sleepy Hollow Campgrounds site covers approximately 104 acres in the Town of Newstead, Erie County, New York. Feitshans and Mauer Trucking, Inc. owned and operated the campground at the site until 1976, when Anthony and Mario Latello of Lancaster, New York purchased the property. The Latellos continued the operations of the campground.

In the early 1970s, Feitshans disposed of numerous drums containing waste solvents and adhesives generated by F.N. Burt Company, Inc. of Buffalo, New York at the site. The NYSDEC collected three waste samples in May 1985. Chemical analytical data indicate the presence of several volatile organic compounds including methylene chloride, trichloroethylene, toluene and others. No groundwater or surface water sampling has been conducted at the site. Potential groundwater contamination is of major concern because the majority of the population within a 3-mile radius of the site is served by private wells as the sole source of potable water. Surface water contamination is also of concern since wastes were observed leaking into the swampy area in the northern portion of the site which drains into NYSDEC-designated Class "C" surface waters.

A consent order was filed by the NYSDEC in 1986 for the removal and proper disposal of drummed wastes at the site. Although several drums of waste and contaminated soil were removed in 1986, about 10 additional drums of unidentified material currently remain on-site.

Facility name: Sleepy Hollow Campgrounds

Location: Siehl Road - Town of Newstead, Erie County, New York

EPA Region: II

Person(s) in charge of the facility: Anthony Latello and Mario Latello
146 Sheldon Avenue
Lancaster, New York 14086

Name of Reviewer: Linda Clarke, REI **Date:** April 3, 1989

General description of the facility:
(For example: landfill, surface impoundment, pile, container; types of hazardous substances; location of the facility; contamination route of major concern; types of information needed for rating; agency action; etc.

The 104 acre site is the location of an active campground at which numerous drums of waste solvents, oils, adhesives and other liquids and sludges were disposed of on the ground surface. Chemical analyses performed on waste samples detected several volatile organic compounds. No groundwater or surface water sampling has been conducted at the site. Potential groundwater contamination is of major concern because private wells are used by the majority of the population in the area. Potential surface water contamination of tributaries of Ellicott Creek and on-site Sleepy Hollow Lake, which are used for recreation.

Scores: S_M = 26.96 (S_{gw} = 45.10 S_{sw} = 11.89 S_a = 0.00)

S_{FE} = N.S.

S_{DC} = 25.00

5.4 HRS DOCUMENTATION RECORDS

DOCUMENTATION RECORDS
FOR
HAZARD RANKING SYSTEM

INSTRUCTIONS: The purpose of these records is to provide a convenient way to prepare an auditable record of the data and documentation used to apply the Hazard Ranking System to a given facility. As briefly as possible summarize the information you used to assign the score for each factor (e.g., "Waste quantity = 4,230 drums plus 800 cubic yards of sludges"). The source of information should be provided for each entry and should be a bibliographic-type reference that will make the document used for a given data point easier to find. Include the location of the document and consider appending a copy of the relevant page(s) for ease in review.

FACILITY NAME: Sleepy Hollow Campgrounds (FEITSHANS)

LOCATION: Siehl Road, Town of Newstead, Erie County, New York

DATE: March 1989

PERSON SCORING: Linda Clark

PRIMARY SOURCE(S) OF INFORMATION (e.g. EPA Regions, State, FIT, etc.):

NYSDEC Region 9 and Albany; NYSDOH - Albany; ECDEP; USEPA Region II

FACTORS NOT SCORED DUE TO INSUFFICIENT INFORMATION:

COMMENTS OR QUALIFICATIONS:

GROUND WATER ROUTE

1 OBSERVED RELEASE

Contaminants detected (5 maximum):

No groundwater sampling has been conducted at the site.

Rationale for attributing the contaminants to the facility:

N/A

Assigned Value = 0

* * *

2 ROUTE CHARACTERISTICS

Depth to Aquifer of Concern

Name/description of aquifer(s) of concern:

Groundwater largely occurs within the fractures, solution openings and along bedding planes of the Middle Devonian Onondaga Limestone, and to a lesser extent within the pore spaces of the unconsolidated overburden sediments (primarily glacio-lacustrine beach and glacial moraine deposits of sand and gravel). Collectively, these units are considered the aquifer of concern.
(Ref. 1, pg. R3-R10; and 2, pg. R18-R30)

Depth(s) from the ground surface to the highest seasonal level of the saturated zone [water table(s)] of the aquifer of concern:

Known highest level occurs at a depth of 4.5 feet below ground surface.
(Ref. 2, pg. R18-R30)

Depth from the ground surface to the lowest point of waste disposal/storage:

Wastes were observed on ground surface and drummed waste reportedly disposed of in swamp area. Depths of subsurface wastes are not known; therefore, allowable depth of 6 feet is assumed.
(Ref. 3, pg. R32 and 4, pg. R33)

Assigned Value = 3

Net Precipitation

Mean annual or seasonal precipitation (list months for seasonal):

33.00 inches mean annual precipitation
(Ref. 5, pg. R35 and 6, pg. R37)

Mean annual lake or seasonal evaporation (list months for seasonal):

26.8 inches mean annual lake evaporation
(Ref. 5, pg. R35 and 6, pg. R39)

Net precipitation (subtract the above figures):

6.2 inches

Assigned Value = 2

Permeability of Unsaturated Zone

Soil type in unsaturated zone:

On-site soils consist of Palms muck (Pa) which is typically underlain by clay loam to fine sand loam; Pu which has a high sand and gravel content (generally moderately high to high permeability); and various silty loams to fine gravelly loams (primarily located in the northern portion of the site).
(Ref. 7, pg. R43-R45, R51-R52)

Permeability associated with soil type:

Approximately 10^{-4} to 10^{-5}
(Ref. 5, pg. R35)

Assigned Value = 2

Physical State

Physical state of substances at time of disposal (or at present time for generated gases):

Liquids and sludges
(Ref. 8, pg. R53 and 9, pg. R57)

Assigned Value = 3

* * *

3 CONTAINMENT

Containment

Method(s) of waste or leachate containment evaluated:

Drums were observed on the unlined ground surface. Drums were rusted and in unsound condition, many reportedly leaking their contents.
(Ref 4, pg. R33 and 10, pg. R70)

Method with highest score:

Containers - leaking, no liner.

Assigned Value = 3

4 WASTE CHARACTERISTICS

Toxicity and Persistence

Compound(s) evaluated:

Methylene chloride, trichloroethylene, tetrachloroethylene, chlorobenzene, toluene, ethyl benzene, xylene (o, m and p), and 1,2-dichloroethane.
(Ref. 8, pg. R53 and 11, pg. R74-R79)

Compound with highest score:

Methylene chloride and trichloroethylene.
(Ref. 5, pg. R35 and 12, pg. R81-R86)

	Toxicity	Persistence	Matrix Value
methylene chloride	3	2	15
trichloroethylene	3	2	15
tetrachloroethylene	3	1	12
chlorobenzene	2	2	12
toluene	2	1	9
ethyl benzene	2	1	9
xylene	2	1	9
1,2-dichloroethane	2	1	9

Assigned Value = 15

Hazardous Waste Quantity

Total quantity of hazardous substances at the facility, excluding those with a containment score of 0 (Give a reasonable estimate even if quantity is above maximum):

Minimum of 100 drums (represents quantity known to have been present).
(Ref. 4, pg. R33; 10, pg. R70; and 13, pg. R87)

Basis of estimating and/or computing waste quantity:

Approximately 50 to 60 drums of wastes were reported at the site by the ECDEP in 1981 and subsequently removed. A total of 17 additional drums of waste material and 13 drums of soil were reportedly removed from the site in November 1986. An additional 10 drums (full or partially full) were observed at this time, and remain on-site. (Approximately 100 additional crushed and empty drums were observed in swamp area - former contents, if any, are unknown; therefore, these drums were not computed in waste quantity).
(Ref. 4, pg. R33; 10, pg. R70; and 13, pg. R87)

Assigned Value = 2

5 TARGETS

Ground Water Use

Use(s) of aquifer(s) of concern within a 3-mile radius of the facility:

Drinking water (private wells) with no municipal water presently available
(Ref. 14, pg. R89-R92; 15, pg. R93-R94; 16, pg. R96; 17, pg. R99; 18, pg. R101; and 19, pg. R103)

Assigned Value = 3

Distance to Nearest Well

Location of nearest well drawing from aquifer of concern or occupied building not served by a public water supply:

The nearest well serves a residence located just east of the site on Siehl Road. Depth of well is unknown. (There are also private wells located on-site; however, their use is seasonal).
(Ref. 15, pg. R94; 20, pg. R105; and 21, pg. R106-R110)

Distance to above well or building:

Approximately 500 feet to the southeast
(Ref. 20, pg. R105)

(value = 4)

Population Served by Ground Water Wells Within a 3-Mile Radius

Identified water-supply well(s) drawing from aquifer(s) of concern within a 3-mile radius and populations served by each:

Private wells provide a sole source of potable water to the entire population within a 3-mile radius of the site, with the following exceptions:

- o Town of Newstead - 23 units x 3.8 persons/unit = 87 persons
- o Town of Pembroke - 30 units x 3.8 persons/unit = 114 persons
- o Village of Corfu - 9 units x 3.8 persons/unit = 34 persons

Remaining population of Towns of Newstead, Pembroke, Darien and Alden served by private wells within specified distance - 289 units x 3.8 persons/unit = 1,098 persons (Village of Corfu municipal well lies outside 3-mile radius)

(Ref. 14, pg, R89-R92; 15, pg. R93-R94; 16, pg. R96; 17, pg. R99; 18, pg. R101; 19, pg. R103; and 20, pg. R105)

Computation of land area irrigated by supply well(s) drawing from aquifer(s) of concern within a 3-mile radius, and conversion to population (1.5 people per acre):

No known irrigation from wells within specified distance.
(Ref. 22, pg. R111; and 23, pg. R113)

Total population served by ground water within a 3-mile radius:

1,098 persons

(value = 3)
Assigned Value = 30

* * *

SURFACE WATER ROUTE

1 OBSERVED RELEASE

Contaminants detected in surface water at the facility or downhill from it (5 maximum):

Methylene chloride, trichloroethylene, tetrachloroethylene, chlorobenzene and toluene.
(Ref. 8, R53; and 11, pg. R74-R79)

Rationale for attributing the contaminants to the facility:

No surface water sampling conducted at the site; however, wastes (from leaking drums) were observed in swamp area located at north end of Sleepy Hollow Lake. Analytical results from waste sampling conducted in May 1985 confirm presence of above-cited contaminants.
(Ref. 4, pg. R33; 8, pg. R53; 11, pg. R74-R79; and 13, pg. 87)

Assigned Value = 45

2 ROUTE CHARACTERISTICS

Facility Slope and Intervening Terrain

Average slope of facility in percent:

Approximately 0.5% slope to the northwest.
(Ref. 20, pg. R105)

Name/description of nearest downslope surface water:

Sleepy Hollow Lake is located on-site. The lake drains into wetlands to the north and unnamed tributaries of Ellicott Creek.
(Ref. 20, pg. R105; and 21, pg. R106-R110)

Average slope of terrain between facility and above-cited surface water body in percent:

Surface water body is located on-site; facility slope is approximately 0.5% to the northwest.
(Ref. 20, pg. R105; and 21, pg. R106-R110)

Is the facility located either totally or partially in surface water?

Yes; Sleepy Hollow Lake is located on-site.
Ref. 20, pg. R105; and 21, pg. R106-R110)

Is the facility completely surrounded by areas of higher elevation?

No, the surrounding area is relatively flat-lying
(Ref. 20, pg. R105; and 21, pg. R106-R110)

Assigned Value = 3

1-Year 24-Hour Rainfall in Inches

2.1 inches
(Ref. 5, pg. R35; and 6, pg. R36)

Assigned Value = 2

Distance to Nearest Downslope Surface Water

Sleepy Hollow Lake is located on-site. Unnamed tributaries of Ellicott Creek lie adjacent to the site. Ellicott Creek lies approximately 6+ stream miles from the site
(Ref. 20, pg. R105; and 21, pg. R106-R110)

Assigned Value = 3

Physical State of Waste

Liquid and sludges
(Ref. 8, pg. R53; and 9, pg. R57)

Assigned Value = 3

* * *

3 CONTAINMENT

Containment

Method(s) of waste or leachate containment evaluated:

Drums are rusted and in unsound condition, some reportedly leaking their contents into on-site surface water. No diversion or containment structures present
(Ref. 4, pg. R33; 10, pg. R70; 13, pg. R87; and 21, pg. R106-R110)

Method with highest score:

Containers - leaking, no diversion or containment structures present.

Assigned Value = 3

4 WASTE CHARACTERISTICS

Toxicity and Persistence

Compound(s) evaluated

Methylene chloride, trichloroethylene, tetrachloroethylene, chlorobenzene, toluene, ethyl benzene, xylene (o, m and p), and 1,2-dichloroethane.
(Ref. 8, pg. R53; and 11, pg. R74-R79)

Compound with highest score:

Methylene chloride and trichloroethylene
(Ref. 5, pg. R35; and 11, pg. R74-R79)

	Toxicity	Persistence	Matrix Value
methylene chloride	3	2	15
trichloroethylene	3	2	15
tetrachlorethylene	3	1	12
chlorobenzene	2	2	12
toluene	2	1	9
ethyl benzene	2	1	9
xylene	2	1	9
1,2-dichloroethane	2	1	9

Assigned Value = 15

Hazardous Waste Quantity

Total quantity of hazardous substances at the facility, excluding those with a containment score of 0 (Give a reasonable estimate even if quantity is above maximum):

Minimum of 100 drums (represents quantity known to have been present).
(Ref. 4, pg. R33; 10, pg. R70; and 13, pg. R87)

Basis of estimating and/or computing waste quantity:

Approximately 50 to 60 drums of wastes were reported at the site by the ECDEP in 1981 and subsequently removed. A total of 17 additional drums of waste material and 13 drums of soil were reportedly removed from the site in November 1986. An additional 10 drums (full or partially full) were observed at this time, and remain on-site. (Approximately 100 additional crushed and empty drums were observed in swamp area - former contents, if any, are unknown; therefore, these drums were not computed in waste quantity.)
(Ref. 4, pg. R33; 10, pg. R70; and 13, pg. R87)

Assigned Value = 2

5 TARGETS

Surface Water Use

Use(s) of surface water within 3 miles downstream of the hazardous substance:

Surface water in the vicinity of the site is NYSDEC-designated Class "C" waters, which includes waters suitable for primary and secondard contact recreation, including fishing (in terms of water quality standards).
(Ref. 24, pg. R114; and 25, pg. R119)

Assigned Value = 2

Is there tidal influence?

No tidal influence on the site
(Ref. 20, pg. R105)

Distance to a Sensitive Environment

Distance to 5-acre (minimum) coastal wetland, if 2 miles or less:

No coastal wetlands within 2 miles.
(Ref. 20, pg. R105; 24, pg. R114; and 26, pg. 120)

(value = 0)

Distance to 5-acre (minimum) fresh-water wetland, if 1 mile or less:

Approximately 1,000 feet to the south to NYSDEC-regulated Class II wetland CR-16.
(Ref. 24, pg. R114; and 26, pg. R120)

(value = 2)

Distance to critical habitat of an endangered species or national wildlife refuge, if 1 mile or less:

None within one mile.
(Ref. 24, pg. R114; and 26, pg. R120

(value = 0)

Assigned Value = 2

Population Served by Surface Water

Location(s) of water-supply intake(s) within 3 miles (free-flowing bodies) or 1 mile (static water bodies) downstream of the hazardous substance and population served by each intake:

No surface water intakes within the specified distance downstream from the site
(Ref. 14, pg. R89-R92; and 24, pg. R114)

Computation of land area irrigated by above-cited intake(s) and conversion to population (1.5 people per acre):

No known irrigation of land by surface water intakes within the specified distance.
(Ref. 22, pg. R111; 23, pg. R113; and 24, pg. R114)

Total population served:

0 (zero)

Name/description of nearest of above water bodies:

N/A

Distance to above-cited intakes, measured in stream miles.

N/A

Assigned Value = 0

AIR ROUTE

1 OBSERVED RELEASE

Contaminants detected:

As part of this investigation, preliminary air monitoring was conducted using a Century OVA-128 GC instrument. No organic vapors exceeding background were detected.
(Ref. 21, pg. R106-R110)

Date and location of detection of contaminants:

N/A

Methods used to detect the contaminants:

N/A

Rationale for attributing the contaminants to the site:

N/A

Assigned Value = 0

* * *

2 WASTE CHARACTERISTICS

Reactivity and Incompatibility

Most reactive compound:

methylene chloride
(Ref. 5, pg. R35; 11, pg. R74-R79; 12, pg. R81-R86)

(value = 1)

Most incompatible pair of compounds:

None known to be present
(Ref. 5, pg. R35; 11, pg. R74-R79; and 12, pg. R81-R86)

(value = 0)

Assigned Value = 1

Toxicity

Most toxic compound:

methylene chloride, trichloroethylene and tetrachloroethylene
(Ref. 5, pg. R35; 11, pg. R74-R79; and 12, pg. R81-R86)

Assigned Value = 3

Hazardous Waste Quantity

Total quantity of hazardous waste:

Minimum of 100 drums (represents quantity known to have been present).
(Ref. 4, pg. R33; 10, pg. R70; and 13, pg. R87)

Basis of estimating and/or computing waste quantity:

Approximately 50 to 60 drums of wastes were reported at the site by the ECDEP is 1981 and subsequently removed. A total of 17 additional drums of waste material and 13 drums of soil were reportedly removed from the site in November 1986. An additional 10 drums (full or partially full) were observed at this time, and remain on-site. (Approximately 100 additional crushed and empty drums were observed in swamp area - former contents, if any, are unknown; therefore, these drums were not computed in waste quantity.)

3 TARGETS

Population Within 4-Mile Radius

Circle radius used, give population, and indicate how determined:

0 to 4 mi 0 to 1 mi 0 to 1/2 mi 0 to 1/4 mi

Sleepy Hollow Campground -- 200 sites x 3.8 people/site = 760
Homes within 1/4 mile radius -- 4 homes x 3.8 people/home = 15
Target population 775

(Ref. 20, pg. R105)

Assigned Value = 21

Distance to a Sensitive Environment

Distance to 5-acre (minimum) coastal wetland, if 2 miles or less:

No coastal wetlands within 2 miles.
(Ref. 20, pg. R105; 24, pg. R114; and 26, pg. R120)
(value = 0)

Distance to 5-acre (minimum) fresh-water wetland, if 1 mile or less:

Approximately 1,000 feet to the south to NYSDEC-regulated Class II wetland CR-16.
(Ref. 20, pg. R105; 24, pg. R114; and 26, pg. R120)

(value = 2)

Distance to critical habitat of an endangered species, if 1 mile or less:

None within one mile
(Ref. 20, pg. R105; 24, pg. R114; and 26, pg. R120)

(value = 0)

Assigned Value = 2

Land Use

Distance to commercial/industrial area, if 1 mile or less:

Approximately 900 feet to the north.
(Ref. 20, pg. R105)

(Value = 3)

Distance to national or state park, forest, or wildlife reserve, if 2 miles or less:

None within 2 miles
(Ref. 20, pg. 105; and 26, pg. R120)

(value = 0)

Distance to residential area, if 2 miles or less:

Residences located along Siehl Road, just south of site; nearest residence is at a distance of approximately 500 feet
(Ref. 20, pg. R105)

(value = 3)

Distance to agricultural land in production within past 5 years, if 1 mile or less:

Located immediately adjacent to the site, along the eastern site boundary.
(Ref. 22, pg. R111; and 23, pg. R113)

(value = 3)

Distance to prime agricultural land in production within past 5 years, if 2 miles or less:

Located immediately adjacent to the site, along the eastern site boundary.
(Ref. 20, pg. R105; and 22, pg. R111)

(value = 3)

Is a historic or landmark site (National Register or Historic Places and National Natural Landmarks) within the view of the site?

None known to be within view.
(Ref. 21, pg. R106-R110)

(value = 0)

Assigned Value = 3 (based on distances to commercial area, residential area, agricultural land and prime agricultural land).

FIRE AND EXPLOSION

1 CONTAINMENT

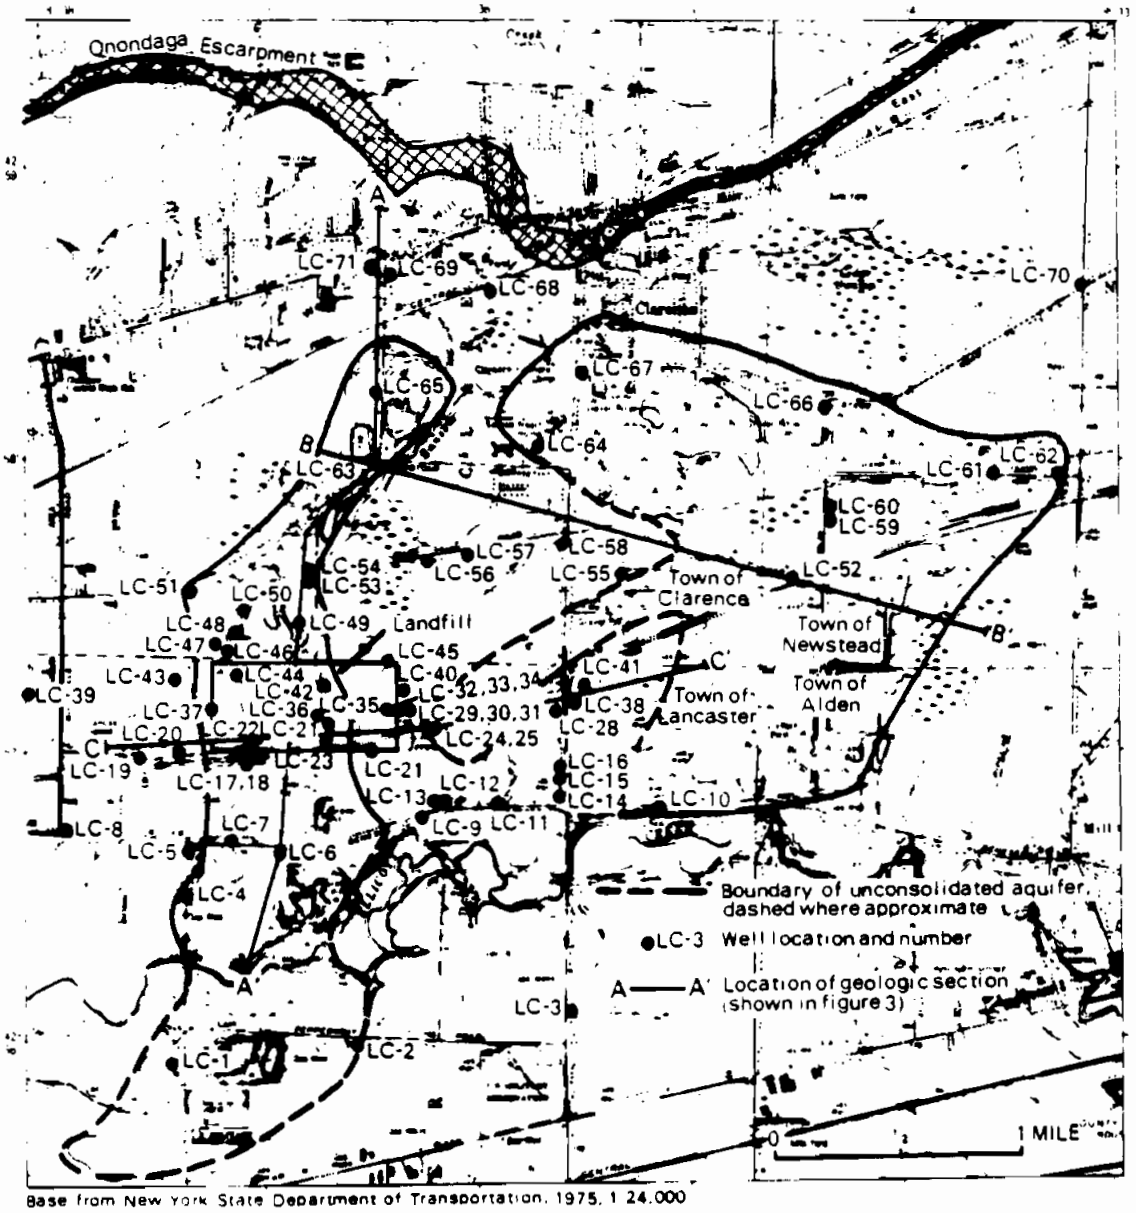
R2

Onondaga Limestone or the sand and gravel deposits as their primary or secondary source. For example, a nursing home in Clarence uses ground water for air conditioning, and many residents use ground water to water lawns. Ground water is the sole source of water for the Town of Newstead.

Ground-water use is not quantified because the number of residences in Clarence and Lancaster that use ground water is unknown, because withdrawals at several commercial facilities and institutions are unmetered, and because use of wells installed in sand and gravel and the underlying bedrock to supplement the public water-supply system is sometimes unreported.



Base from New York State Department of Transportation, 1975, 1:24,000

Figure 2.--Location of wells, landfill, Onondaga Escarpment, and geologic sections in Clarence-Lancaster-Newstead area. (Geologic sections are shown in fig. 3.)

R3

Hydrogeologic Framework

The unconsolidated surficial sand and gravel aquifer underlies parts of the gently westward sloping plain that overlies the Onondaga Limestone, as shown in figure 2. The part of the Onondaga Limestone that was investigated in this study is the part that directly underlies the unconsolidated aquifer.

Unconsolidated Aquifer

Glaciation of the area resulted in the deposition of a variety of sediments on the Onondaga Limestone. In the southwestern and central parts of the area (Muller, 1977), till overlies a poorly defined end moraine (poorly sorted silt, sand, gravel, and boulders that were deposited in front of the glacier) and subglacial or subaqueous outwash (sorted and stratified sand, or sand and gravel deposited by glacial meltwaters at the bottom of grounded ice). Logs of borings along the western side of the aquifer (section A-A', fig. 3) indicate 30 to 45 ft of sand with some gravel between a basal lodgment till 3 to 15 ft thick and an overlying surficial till. Well logs reveal that glacial sediments are thickest (30 to 45 ft) where they fill a buried north-south-trending preglacial valley incised into the Onondaga Limestone. (See section B-B' in fig. 3 and C-C' and the structure-contour map in fig. 4). The extent of the moraine in the center of the area is poorly defined because relatively few borings have been made and because its subdued, low to flat relief makes its extent difficult to trace.

Several borings in the southeastern part of the area reveal 20 to 30 ft of well-sorted stratified outwash sand and gravel underlain by 10 to 15 ft of lacustrine silt and sandy silt that is in turn underlain by 2 to 12 ft of

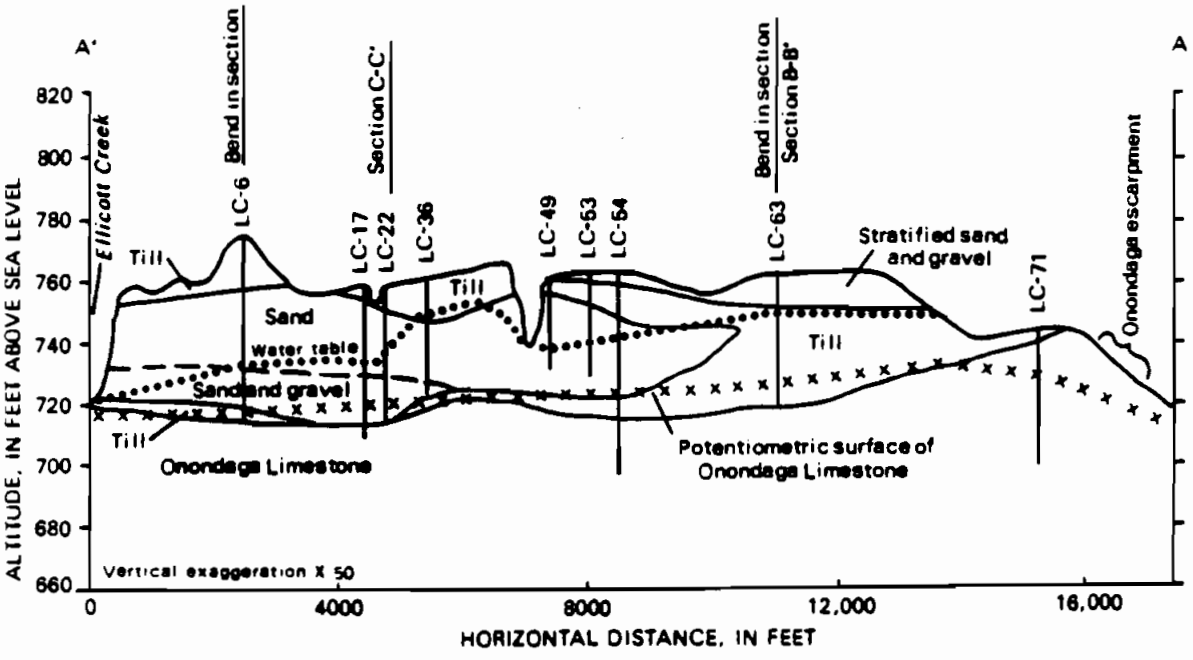


Figure 3A.--Geologic section A-A' north-south through Clarence-Lancaster-Newstead area. (Location is shown in fig. 2.)

R4

lodgment till. (See section C-C' in fig. 3 and map in fig. 4.) A gravel pit in the central area near Jones and Stage Roads exposes morainal deposits of sand and gravel with large boulders of Onondaga Limestone (sec. B-B' in fig. 3). The morainal sand and gravel disappears near Stage Road south of Clarence. A large amount of the outwash and morainal deposits have been extracted by sand and gravel mining.

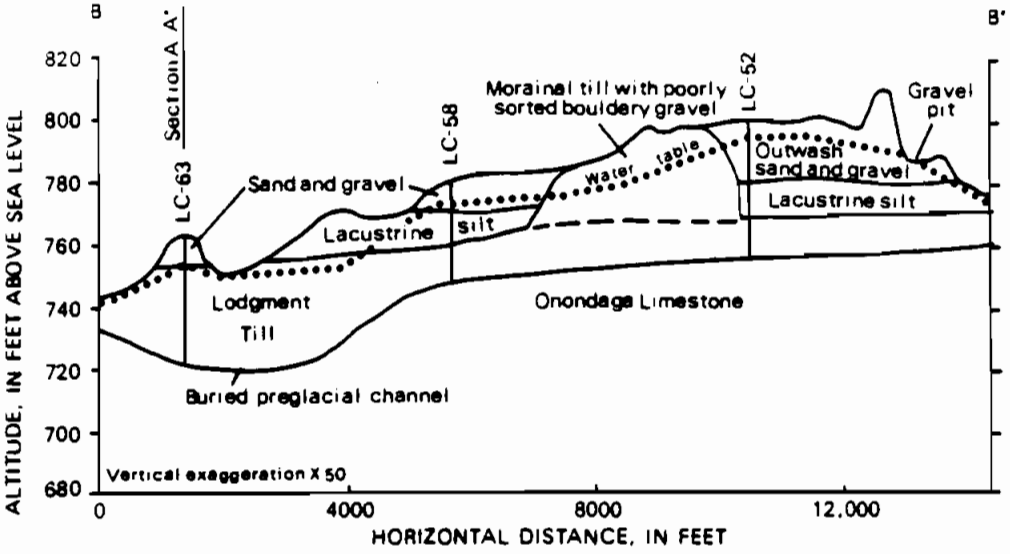

Figure 3B.--Geologic section B-B' through northern part of Clarence-Lancaster-Newstead area. (Location is shown in fig. 2.)

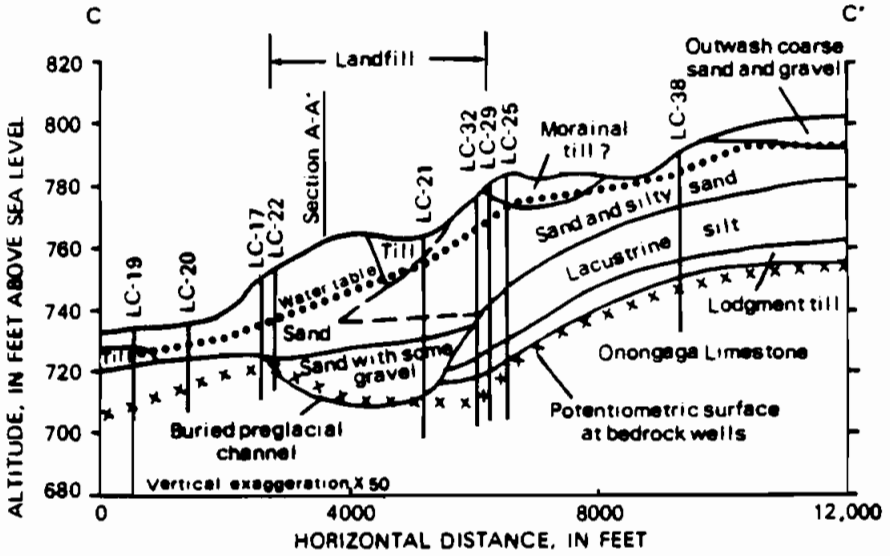

Figure 3C.--Geologic section C-C' through southern part of Clarence-Lancaster-Newstead area. (Location is shown in fig. 2.)

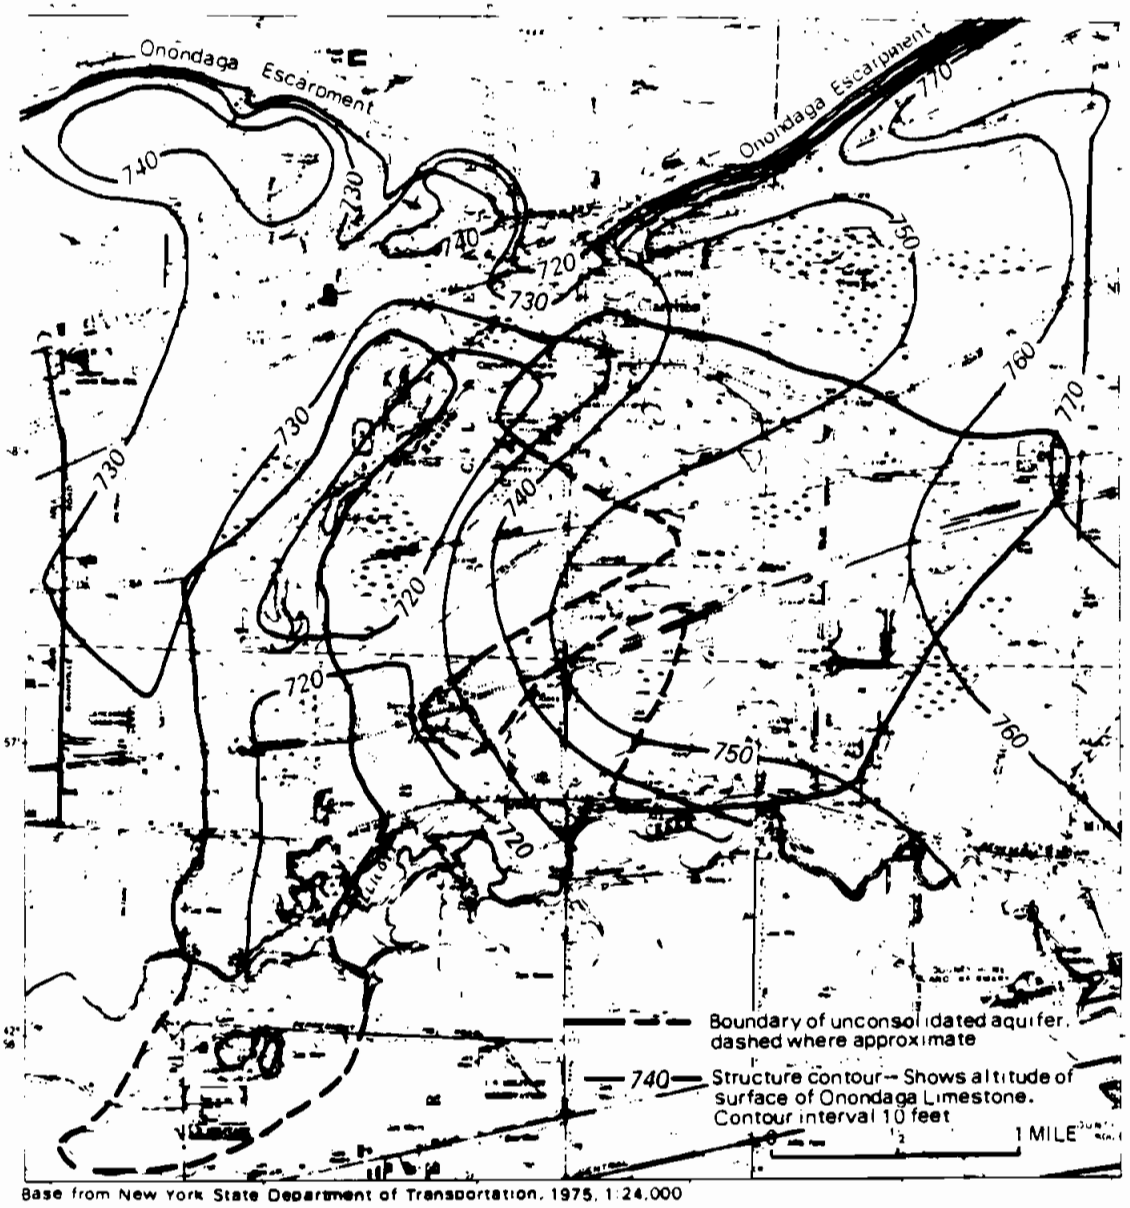
R5



Base from New York State Department of Transportation, 1975, 1:24,000

Figure 4.--Altitude of top of Onondaga Limestone and boundary of unconsolidated aquifer in Clarence-Lancaster-Newstead area.

Onondaga Limestone

The Onondaga Limestone is a productive aquifer that extends from Buffalo to Albany as an east-west belt several miles wide. It is a massive cherty and argillaceous limestone approximately 140 ft thick (Buehler, 1966) where it has not been subjected to erosion. Along the escarpment in the Clarence area, it has been eroded to several tens of feet thick.

The Onondaga Limestone contains little primary porosity but does contain significant secondary openings in the form of joints and fractures, widened by solutioning. Where the widening of joints and fractures is significant, the

RG

overlying rock and sediments may collapse, forming sinkholes. Sinkholes were observed both east and west of the landfill area. Wells installed in the limestone typically yield 10 to 300 gal/min (La Sala, 1968). Most wells do not fully penetrate to the bottom of the Onondaga Limestone, so the thickness of this unit could not be determined.

Saturated Thickness

The unconsolidated aquifers lie within relatively thin outwash and morainal deposits that range in thickness from 5 to 55 ft; the saturated thickness is between 10 and 25 ft in most places (fig. 5). The thickest saturated deposits are in the buried preglacial valley. In the eastern part

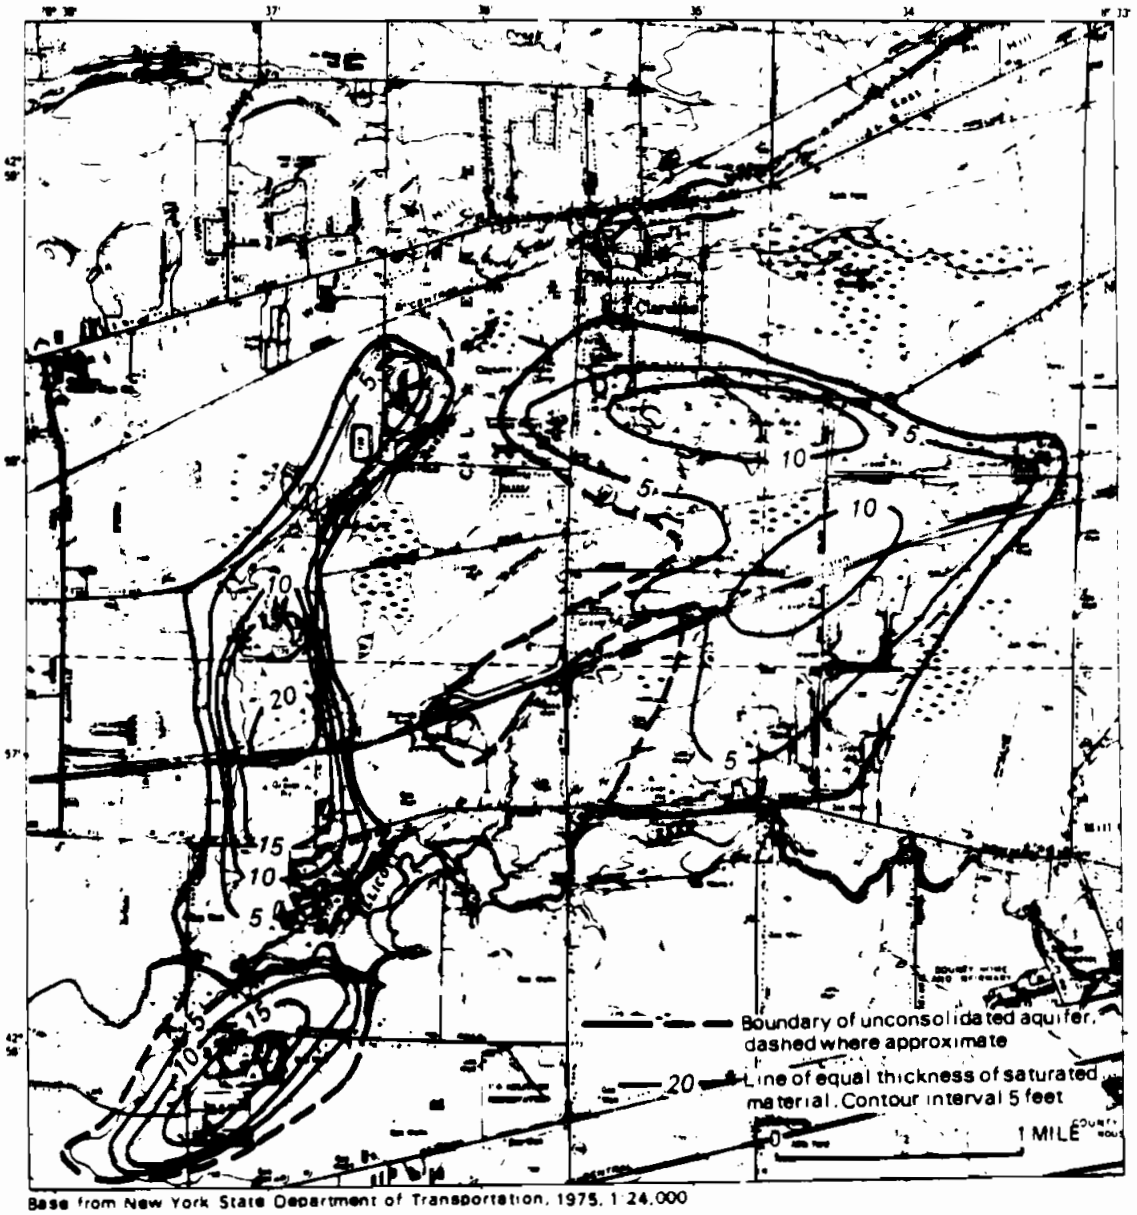


Figure 5.--Saturated thickness of unconsolidated aquifer in the Clarence-Lancaster-Newstead area.

R7

of the aquifer, where much of the sand and gravel has been mined away, 5 to 14 ft of saturated sand and gravel overlies thin lake and till deposits (fig. 3, section B-B'). In the western part of the aquifer, 5 to 23 ft of saturated sand with some sand and gravel in the deeper zones overlies the buried bedrock valley (fig. 3, section A-A'). Saturated thickness is greatest (25 ft) in the area under the landfill. South of Ellicott Creek, a gravel pit and a log from well LC-2 indicate 5 to 15 ft of saturated morainal sand and sand and gravel.

Ground-Water Movement

Recharge

Unconsolidated aquifer.-Recharge to the unconsolidated aquifer, which contains the water table, is solely from precipitation that infiltrates downward to the water table. Because the unconsolidated aquifer is on a level area on a topographic high, it is not bounded by valley walls that could provide recharge, nor does it have streams to provide seepage from higher areas. Estimated average annual recharge ranges from 0.2 to 0.4 (Mgal/d)/mi^2 La Sala, 1968).

The water table rises and falls in response to changes in the rate of recharge and discharge of ground water. Water-level measurements were used to construct hydrographs (fig. 6), which indicate that most recharge occurs from October or November through April, when evapotranspiration is at a minimum,

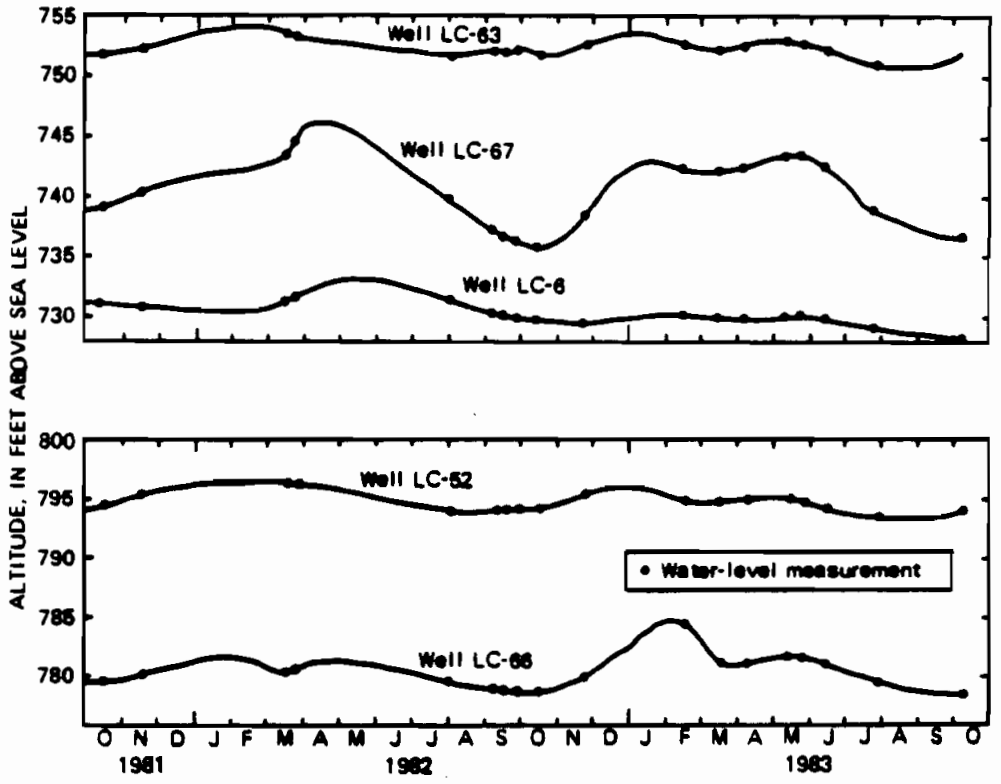

Figure 6.--1981-83 hydrographs of wells that tap the unconsolidated aquifer in Clarence-Lancaster-Newstead area. (Well locations are shown in fig. 2.)

R8

and that water levels were highest in February. A second peak in May 1983 was due to an unseasonably wet spring. Annual water-level fluctuations ranged from 2 to 8 ft and averaged 4 ft. Water levels at wells LC-52, LC-63, and LC-6, which are near ground-water discharge areas such as ponds, wetlands, and streams, fluctuated less because relatively large amounts of ground water move from the edges of the aquifer toward these discharge areas. Water levels in wells LC-66 and LC-67, which are nearer the ground-water divide and further from discharge areas, fluctuated more because they have smaller catchment areas and receive less ground-water flow.

Onondaga Limestone aquifer.--Recharge to the limestone aquifer occurs (1) by infiltration of precipitation into the joints, fractures, and solution openings where the formation crops out at or near land surface, (2) by downward seepage of water from the overlying unconsolidated deposits and wetlands, (3) by seepage from storm runoff and streams flowing into sinks or swallets on top of the limestone, and (4) possibly by water that has been pumped out of a quarry 6 mi east of the study area and then discharged as surface flow, some of which may infiltrate back into the limestone.

Discharge

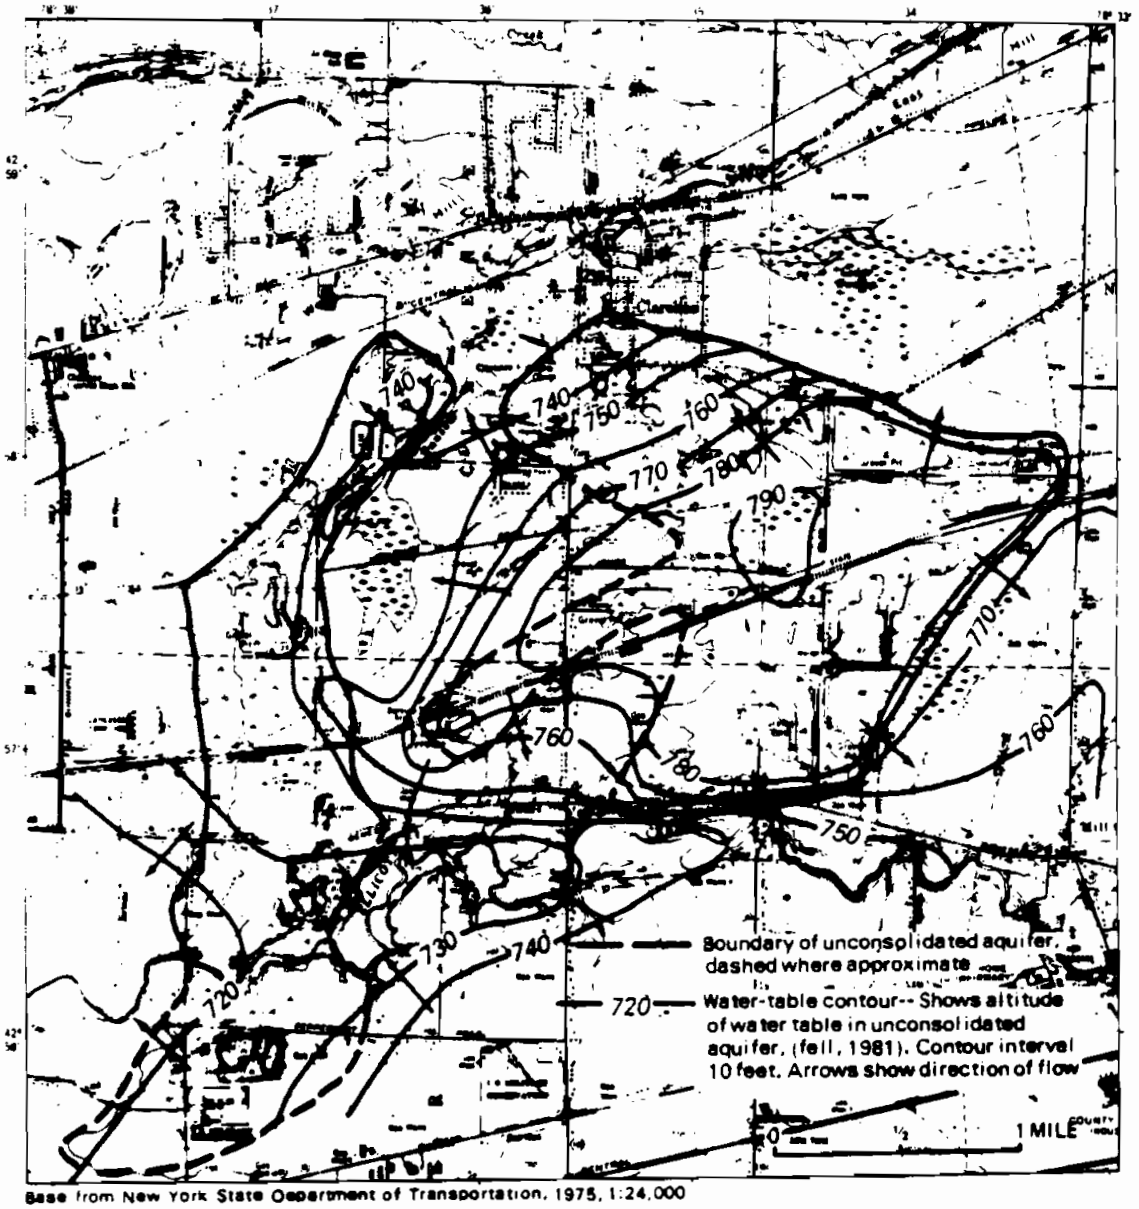
Unconsolidated aquifer.--During the late spring, summer, and early fall, when most precipitation is lost through evapotranspiration, the ground-water discharge to springs, streams, wetlands, and underlying bedrock exceeds the recharge, and the water table declines. A map of the water-table altitude with directions of ground-water flow is given in figure 7. The contours are based on water levels measured by the U.S. Geological Survey and the Erie County Department of Environment and Planning on October 15, 1981, in shallow wells and where water was first encountered during the drilling of deeper wells. A ground-water divide trends roughly east-west through the unconsolidated deposits. Ground-water flow south of the divide moves predominantly south and southwestward and discharges into Ellicott Creek, and ground water south of Ellicott Creek moves northwestward into Ellicott Creek. Ground water north of the divide moves northward and discharges to surface-water bodies such as Tillman and Cedar Swamps, and ultimately into Ransom Creek, which flows north over the Onondaga Escarpment.

Deep piezometers in sets of nested piezometers near the landfill had lower potentiometric surfaces than shallow piezometers at the same location (Wehran Engineering and Recra Research, 1980), which indicates a significant downward gradient. Therefore, ground water in the unconsolidated aquifer moves not only laterally but also downward to the underlying limestone.

Onondaga Limestone aquifer.--Ground water leaves the limestone aquifer as pumpage from wells at quarries, private residences, institutions, and commercial facilities; as seepage to the underlying rock formations and to Ellicott Creek, and to streams and springs along the lower part of the face of the escarpment. Water levels measured during late summer and early fall of 1981 were used to compile a potentiometric-surface map of the Onondaga Limestone (fig. 8); the contours indicate a ground-water divide trending east-west approximately 1 mi south of the escarpment. Ground water south of the divide moves west-southwest and discharges into Ellicott Creek and quarries; ground water north of the divide flows north and discharges as springs and headwaters of streams at the base of the escarpment.

R9

Several wetlands in the Clarence-Newstead area and many wells in the Newstead area went dry and had to be deepened during the summers of 1982 and 1983 because of severely declining water levels in the limestone aquifer. The cause of the decline is not known at this time. Water levels in the overlying unconsolidated deposits declined considerably less, probably because of the relatively impermeable lacustrine silt and lodgment till between the two layers, which retards vertical movement of ground water. If the confining unit were absent, ground water would have moved downward to recharge the limestone aquifer, and the water level in the sand and gravel would have declined more.



Base from New York State Department of Transportation, 1975, 1:24,000

Geology and Hydrology of the Onondaga Aquifer in Eastern Erie County, New York, with Emphasis on Ground-Water-Level Declines Since 1982

By Ward W. Staubitz and Todd S. Miller

ABSTRACT

The Onondaga aquifer is a nearly flat-lying, 25- to 110-foot-thick, cherty limestone with moderately developed karst features such as sinkholes, disappearing streams, and solution-widened joints. Most ground water moves through solution-widened bedding planes, and some moves through vertical joints. Yield of water to 42 wells ranges from 3 to 100 gallons per minute and averages 20 gallons per minute.

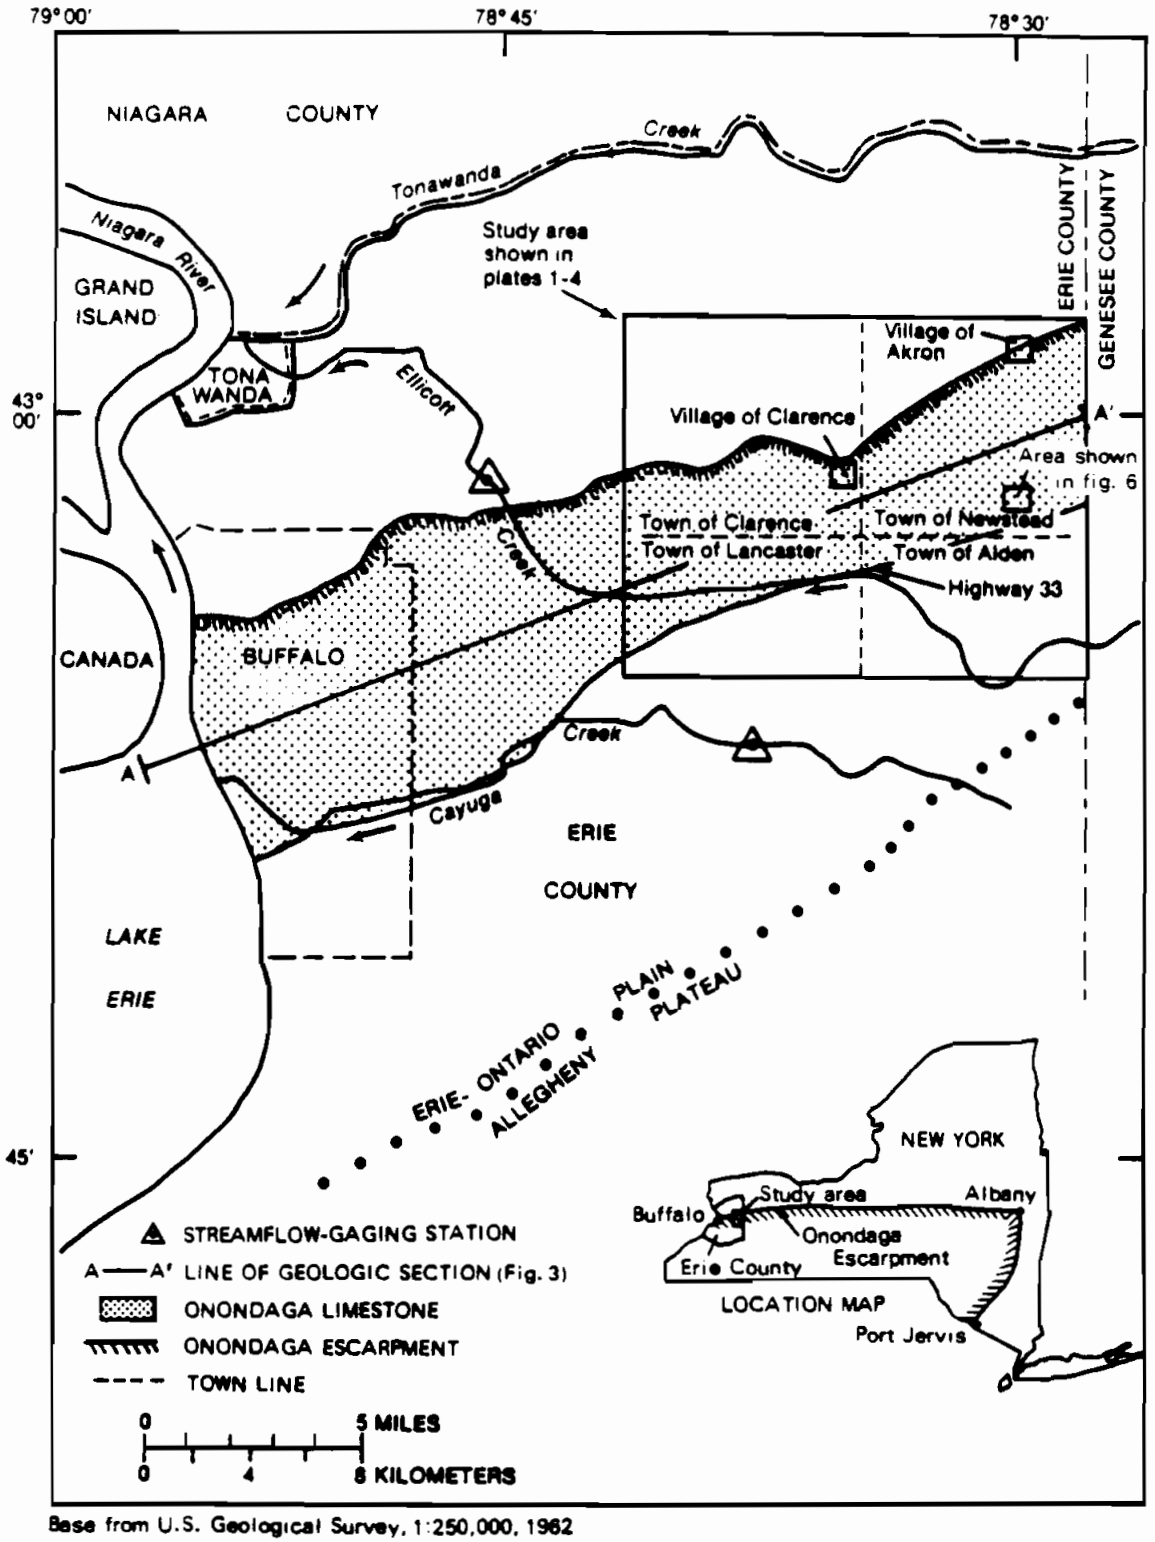
Ground-water levels in the Onondaga aquifer declined during the fall of 1981 and summer and fall of 1982-85 near a 2.2-mile-long and 800-foot-wide land-surface depression in the eastern part of Erie County. More than 60 wells and several wetlands went dry, and at least three sinkholes developed. Ground-water levels were measured in 150 wells during a high-water-level period in April 1984 and a low-water period in October 1984. Water levels fluctuated 20 to 50 feet near the depression and near quarries but fluctuated only 5 to 10 feet elsewhere. The water-level decline is caused by the combined effect of ground-water removal by pumpage from a quarry (the water is then discharged to Dorsch Creek) and by the diversion of some water of Dorsch Creek since 1981 away from swallets in the 2.2-mile-long depression area, which are recharge points for the aquifer. In 1982, sinkholes formed in a surface-depression area in Harris Hill. The enlargement of sinkholes in the Harris Hill area seems unrelated to the water-level decline in the eastern part of the county and is probably caused by local drainage alterations.

INTRODUCTION

Ground-water levels in some parts of the Towns of Newstead and Clarence in eastern Erie County (fig. 1) declined greatly during the fall of 1981 and each summer and fall during 1982-85. More than 60 wells went dry during this period, most of which were then drilled deeper. Some of the redrilled wells went dry in subsequent years, and others have nearly gone dry. Several wetlands in the central part of the Towns of Newstead and Clarence reportedly dried up during the summer of 1982, and at least three sinkholes developed or enlarged in the Harris Hill area in the Town of Clarence (pl. 1).

The area where water levels declined is underlain by the Onondaga Limestone--an important aquifer that, in eastern Erie County, supplies water to approximately 750 households, 20 commercial and industrial facilities, and many farms. The Onondaga aquifer is a major source of water supply elsewhere in New York State (fig. 1) and is particularly important because it provides water of suitable quality for most uses. Water in the underlying Akron and Bertie Dolomites and Camillus Shale is less desirable for most uses because it contains elevated levels of hydrogen sulfide and dissolved iron and manganese.

R13



Base from U.S. Geological Survey, 1:250,000, 1962

Figure 1.--Location and major geographic features of Newstead-Clarence area, Erie County, N.Y.

R14

Discharge measurements also were made at several locations along Dorsch Creek downstream from the gaging station and along several small streams that flow over the escarpment to locate sites of ground-water discharge to the streams and where the streams lose water to the aquifer.

Survey of Springs

The locations of springs were plotted on a map, and discharge, pH, water temperature, and specific conductance of most springs were measured to identify ground-water discharge areas. Specific conductance and pH indicate whether the water is from the Onondaga aquifer or the underlying Camillus Shale. (The latter has higher specific conductance and lower pH.) The discharge indicates whether the source of the spring is a diffuse flow system through small joints (discharge less than 0.5 ft^3/s) or from a cave-conduit or solution-widened joint system (discharge greater than 0.5 ft^3/s).

Dye-Tracer Study

Two dye-tracer studies were conducted at a swallet (sinkhole into which a stream disappears) in the Harris Hill area in the western part of the Town of Clarence in April 1984 and October 1985 in an attempt to determine the velocity and direction of ground-water flow. In April 1984, fluoroscene dye was mixed with stream water that flowed into the swallet, and activated-charcoal packets that adsorb the dye were placed in 14 springs considered likely discharge areas at the base of the Onondaga Escarpment. The charcoal packets were replaced periodically and analyzed in the laboratory by fluorometer to detect the dye (Aley and Fletcher, 1976). In October 1985, dye was again mixed with stream water that flowed into the swallet, but this time, charcoal packets were placed along seepage faces in a quarry 0.9 mi south of the swallet and in a drainage ditch that receives pumpage from the quarry.

Precipitation and Evapotranspiration Measurements

Monthly, annual, and long-term average precipitation values in the study area were tabulated from data from the U.S. Weather Service station at the Buffalo International Airport (2 mi southwest of the study area, pl. 1) and from a local observer in Clarence. Potential evapotranspiration in the study area was calculated through Hamon's method (1961) and long-term average monthly temperature data from the airport.

GEOLOGY

The study area is underlain by Devonian and Silurian sedimentary rocks that trend east-west and dip slightly to the south-southwest at about 40 ft/mi. The bedrock in most of the area is overlain by unconsolidated deposits. The western and eastern ends of the study area are mantled by a thin cover of till and (or) lacustrine silt and clay, generally 3 to 15 ft thick, and the central part by sand and gravel, sand, and till deposits 25 to 50 ft thick that fill a north-south-trending buried valley (Miller and Staubitz, 1985) shown on plate 1. The uppermost formation in the study area is the Onondaga Limestone, which is underlain by the Bois Blanc Limestone (locally absent) and the Akron and Bertie Dolomites, which overlie the Camillus shale (table 1).

R15

Table 1.--Summary of geologic units in Newstead-Clarence area, Erie County, N.Y. (Modified from Oliver, 1956.)

Period	Formation	Member	Thickness (feet)	Description
Devonian	Onondaga Limestone	Seneca	40	Olive-gray, massive bedded limestone, contains sparse tabulate and rugose corals and abundant dark nodular chert (5 to 25 percent). Exposures are few because the upper part of the Onondaga Limestone is eroded.
		Moorehouse	55	Olive-gray and light olive-gray, fine-grained, massive bedded limestone, contains brachiopods, sparse tabulate and rugose corals, and abundant nodular chert (5 to 50 percent).
		Clarence	40	Olive-gray, fine-grained, massive bedded limestone, contains few fossils and extremely abundant chert (25 to 75 percent).
		Edgecliff	5	Light-gray, coarsely crystalline, massive bedded limestone, numerous corals, and some nodular chert (5 to 25 percent).
	Bois Blanc Limestone		0-4	Gray, fine-grained, discontinuous limestone.
Silurian	Akron Dolomite		8	Greenish-gray to light buff, mottled and banded fine-grained dolomite.
	Bertie Dolomite		55	Gray to dark gray, thin to medium-bedded, fine-grained dolomite, dolomitic limestone, and shaly dolomite.
	Camillus Shale		400	Gray to brownish gray, thin to massive-bedded, shale with some interbedded limestone and dolomite, contains abundant gypsum with beds up to 5 ft thick. No fossils. Gypsum is mined near Akron.

R16

The study area is characterized by minor development of karst features such as sinkholes, solution-widened joints, and swallets. Sinkholes are surface depressions, typically several feet to several tens of feet in diameter, that form when surficial unconsolidated sediments subside into enlarged subsurface openings produced by solution of carbonate rocks such as limestones and dolomites, or when the roof of a subsurface cave in the rock collapses. Solution-widened joints are secondary openings in the rock, such as horizontal bedding joints or vertical fractures, that have been enlarged by the dissolution of the carbonate rock by circulating ground water. Swallets are sinkholes into which a stream flows; thus, the streamflow recharges the groundwater reservoir. Swallets generally form over solution-widened joints in the limestone.

Onondaga Limestone

In New York, the Onondaga Limestone outcrop extends east-west from Lake Erie to just south of Albany, then south to Port Jervis. (See inset in fig. 1). It is a nearly flat-lying complex of massive, cherty, and argillaceous limestones deposited in a marine environment during Middle Devonian time. In Erie County, the outcrop area is 4 mi wide and 23 mi long and extends east-west from Lake Erie to the Erie-Genesee County border (fig. 1). The gentle south-southwestward dip of the Onondaga Limestone gives rise to a 20- to 50-ft-high escarpment that trends roughly east-west and marks the northern extent of the Onondaga. South of the escarpment, the land surface parallels the gently dipping surface of the Onondaga. The escarpment separates a low-lying plain to the north from a higher plain to the south.

The formation is 140 ft thick (Oliver, 1966) south of the study area, where it is buried and protected from erosion by more recent overlying formations. Where it crops out within the study area, however, it ranges from only 25 to 110 ft in thickness because erosion has removed its upper levels.

In western New York, the Onondaga is divided into four members, which are, in descending order, the Seneca, Moorehouse, Clarence, and Edgecliff. The northward-facing cliff of the Onondaga Escarpment consists chiefly of the Edgecliff and Clarence. The stratigraphy of the Onondaga and deeper formations is depicted in table 1.

The Onondaga Limestone is an important source of crushed stone in Erie County. Currently, three quarries operate in the study area (pl. 1).

Bois Blanc Limestone

Underlying the Onondaga Limestone is the Bois Blanc Limestone, a gray, fine-grained limestone that was deposited in a marine environment during Devonian time. It ranges in thickness from a few inches to 4 ft but is discontinuous within the study area and may be absent in many places.

Akron and Bertie Dolomites

Underlying the Bois Blanc Limestone and, in places, the Onondaga Limestone, are the Akron and Bertie Dolomites, which are fine-grained dolomites, shaly

[2] OLS = Onondaga Limestone, BDL = Akron and Bertie Dolomites, CMS = Camillus Shale

Ground Water in the Onondaga Limestone

Ground water occurs in bedding planes and vertical joints and fractures in the Onondaga Limestone, some of which have been widened by dissolution. The upper 5 to 15 ft of the limestone contains the most joints, all of which are widened by the more intense weathering that occurs near land surface.

Bedding planes.--Bedding planes, which transmit most of the water in the Onondaga Limestone, are planar openings parallel to the nearly horizontal bedding in the rock. They were formed by the expansion of the rock during removal of weight by erosion of overlying rock units and by the retreat of

R18

wells and springs in the Newstead-Clarence area and with respect to selected minerals.

[3] Saturation index (SI) <0 indicates the water is undersaturated with respect to the mineral,
SI = 0 indicates the water is in theoretical equilibrium with the mineral.
SI >0 = indicates the water is oversaturated with respect to the mineral.

glaciers from the area. Major bedding planes extend at least several miles, which makes them effective conduits for ground water. Although the separation along bedding planes is generally small (less than 1/4 inch), dissolution has widened them to several inches in some places. Bedding planes widened by dissolution were observed in quarries and along the escarpment at the bottom of the Onondaga and at the top of the Clarence Member of the Onondaga. These planes undergo a greater rate of dissolution than smaller joints because they form a preferential path for horizontal ground-water flow. The downward migration of water is inhibited by the relatively impermeable underlying Akron and Bertie Dolomites and some massive beds within the Onondaga, especially the Clarence Member of the Onondaga, 50 to 75 percent of which is highly insoluble chert.

R19

The walls of quarries show where prominent joints occur in the Onondaga Limestone. A quarry in the southwestern part of the study area (pl. 1) has large seeps of water from two prominent bedding planes; one was observed on top of the cherty Clarence Member (altitude about 625 ft), and the other was reported by the quarry operator to be at the base of the Onondaga (altitude 565 ft), where water cascades into a sump pit.

Vertical joints.--Vertical joints are planar openings roughly perpendicular to bedding planes but are generally less extensive and therefore form less significant water-bearing openings except where dissolution has widened them. Vertical joints in the study area are typically 5 to 18 ft apart, penetrate 10 to 25 ft, and are preferentially oriented N75°E, N40°W, and N5°E (Goldberg-Zoino Associates, 1984). Most vertical joints extend several tens of feet laterally, but some extend for several miles. A quarry that previously occupied the site of Spaulding Lake, north of Main Street in the Town of Clarence (pl. 1), was abandoned when mining intercepted a major vertical joint from which large volumes of water flooded the quarry. The joint's trend is N43°W and is traceable on air photos from the escarpment at County Route 216 (Old Goodrich Road) to Tillman Swamp.

The separation along vertical joints ranges from less than 1/16 inch to 0.5 ft. The wider separations are in the upper 5 to 15 ft of the Onondaga Limestone, where dissolution is most rapid, and at the escarpment, where tension-release stresses from the absence of supporting rock mass has caused the rock to expand away from the cliff. Vertical joints become narrower, less numerous, and less continuous with depth.

Well yields.--The reported yield of 42 wells with open-hole construction that tap the Onondaga aquifer indicated that the yields of wells range from 3 to 100 gal/min and average 20 gal/min. The yield of water to a well depends on how many saturated bedding planes and vertical joints with significant openings are penetrated. The highest reported well yields in the study area are near the channellike depression in the central part of Newstead (pl. 1), which indicates the presence of numerous, continuous, solution-widened joints beneath the depression area.

Recharge.--The ultimate source of recharge is precipitation, which reaches the saturated zone in the Onondaga aquifer by (1) direct areal infiltration of rain and snow-melt through the overlying unconsolidated deposits (lake deposits and till), (2) flow of stream water into swallets and into vertical joints that intersect stream channels, and (3) seepage of water from wetlands through the underlying organic debris and glacial deposits into the Onondaga aquifer. Recharge occurs over most of the study area except at the base of the escarpment, in quarries where water is pumped, in the upgradient parts of wetlands during periods of high water levels, and in the channellike depression during periods of low water levels. The rate of recharge to the aquifer depends on the amount of precipitation and streamflow available for recharge, the amount of water lost through evapotranspiration, and the permeability of the Onondaga Limestone and overlying unconsolidated deposits. Each of these factors is described below.

Infiltration of precipitation. If the amount of water available for recharge either exceeds the rate at which water can move to the water table, or the

R20

rate at which water can flow through the aquifer, recharge either becomes ponded at land surface or is lost as runoff. This occurs in many places in the spring, when large amounts of snowmelt and rain exceed the infiltration capacity of the area. During this period, intermittent streams flow from a few weeks to several months, and water accumulates in low areas, such as wetlands and the channellike depression areas in Newstead and Harris Hill.

Conversely, when the amount of water available for recharge is less than the discharge from the aquifer, ground-water levels decline. Comparison of the long-term average monthly precipitation with the corresponding estimated potential evapotranspiration (table 4) reveals that the 19.6 inches of potential evapotranspiration exceeds the 16.1 inches of precipitation from May through September, which means that little of the precipitation during this period is available for ground-water recharge, so that ground-water levels decline. Intermittent streams flow and water ponds in low areas only during heavy rains and snowmelt. After periods of significant precipitation, ground-water levels rise for a time (from several hours to 3 days). Hydrographs of water levels in wells measured during 1983-85 (pl. 4) show that water levels declined from May through October and rose from November through April.

Infiltration from streams. Streamflow that seeps into swallets provides a significant amount of recharge to the Onondaga aquifer. At least 14 swallets were identified in the study area, the majority of which are clustered within the channellike depression near South Newstead Road, Steiner Road, and Ayers Road in the Town of Newstead (pl. 1). Individual swallets were observed to accept streamflow at rates of 0.1 to 1.5 ft^3/s without overflowing; a cluster of swallets, such as those within the channellike depression in the Newstead area, could probably accept several times that amount before ponding would occur. Immediately after snowmelt or particularly heavy rains, however, the swallets may not accept all of the incoming streamflow if the carrying capacity of the aquifer is exceeded and ground-water levels rise. During these periods, the swallet may overflow and produce runoff to tributaries that drain outside the study area. During the summer and fall, intermittent streams that flow into swallets dry up.

At the top of the escarpment, some streamflow seeps downward through vertical joints exposed in the stream channels. These joints have been enlarged by tension-release stresses, ice wedging, and dissolution; they range in width from 0.25 to 8 inches. Most of the water that seeps into the Onondaga aquifer at the top of the escarpment discharges to springs and streams at the base of the escarpment, where more impermeable bedrock units (Akron and Bertie Dolomites) that underlie the Onondaga Limestone retard further vertical seepage.

Regional flow and discharge.--Ground water in the Onondaga aquifer moves from areas of higher head (recharge areas) to areas of lower head (discharge areas) through a network of joints and bedding planes. The direction of ground-water movement in the Onondaga aquifer during a period of high ground-water levels (April 1984) and low ground-water levels (October 1984) is shown by arrows on the potentiometric-surface maps in plates 2 and 3, respectively. Water levels in approximately 150 wells were measured once during each of

R21

these two months to document the seasonal fluctuation of ground-water levels and the changes in direction of ground-water flow. Ground water discharges to wells, springs, wetlands, the channellike depressions, and quarries.

Ground-water movement in the Onondaga aquifer generally follows the east-to-west slope of the Erie-Niagara basin--that is, it moves from the higher parts of the basin in eastern Erie County to lower areas further west and eventually discharges to Lake Erie or the Niagara River (fig. 3). In the central part of the study area, flow paths in the underlying Akron and Bertie Dolomites and Camillus Shale are similar to those of the Onondaga aquifer (Goldberg-Zoino and Associates, 1984), except that the Akron and Bertie Dolomites have a larger downward component of flow than the Onondaga aquifer (fig. 3).

The differences in hydraulic conductivity (permeability) of the four formations have a significant effect on the regional flow system. Hydraulic conductivity values for the Onondaga Limestone, Akron Dolomite, Bertie Dolomite, and Camillus Shale are summarized in table 9. The Camillus Shale is the most permeable aquifer. As a result of dissolution of gypsum, the shale is 2 to 3 times more permeable than the Onondaga Limestone, which is, in turn, 4 to 10 times more permeable than the Akron and Bertie Dolomites.

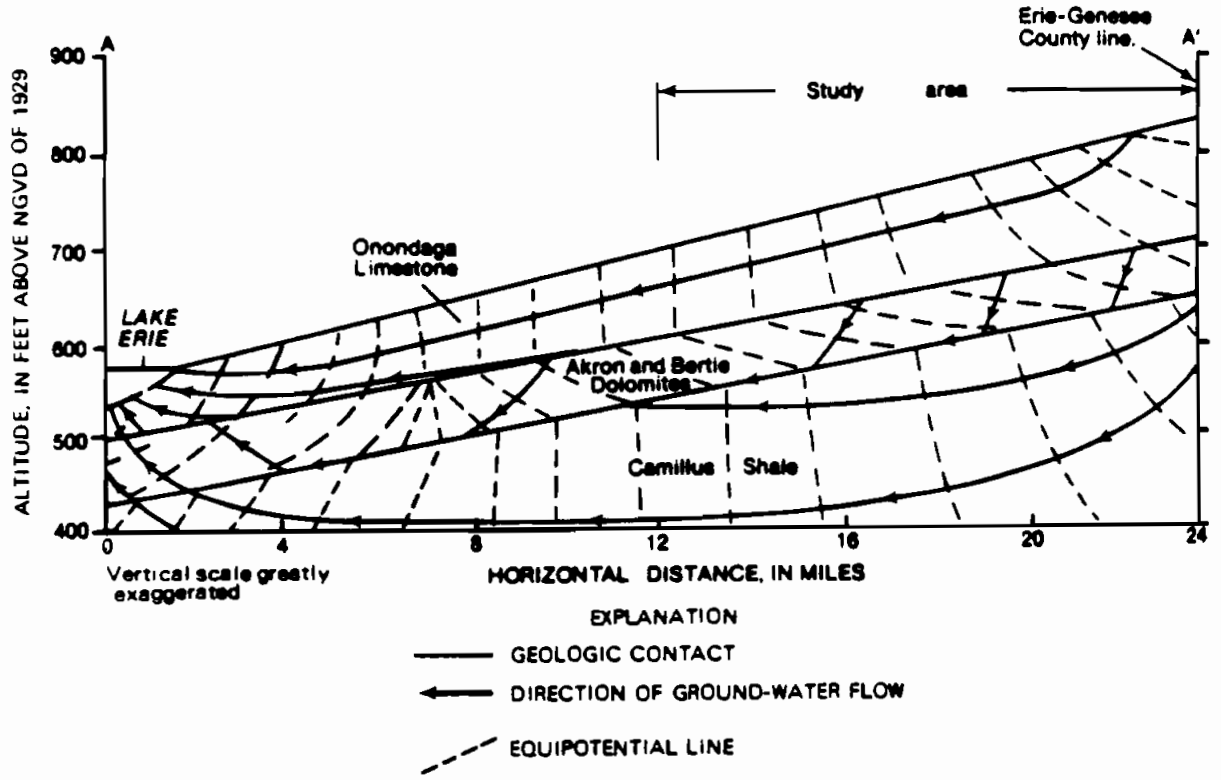

Figure 3.--Generalized regional ground-water movement from study area to Lake Erie.

R22

SUMMARY

The Onondaga aquifer is a nearly flat-lying, 25- to 110-ft-thick, cherty limestone with moderately developed karst features such as sinkholes, swallets, and solution-widened joints. Most ground water moves through solution-widened bedding planes, although some moves through vertical joints. Yield of water to 42 wells in the study area ranged from 3 to 100 gal/min and averaged 20 gal/min.

Ground-water levels declined sharply during the fall of 1981 and each summer and fall from 1982 through 1985 in some parts of the Onondaga aquifer in the Towns of Newstead and Clarence. Several wetlands and more than 60 wells went dry, and at least three sinkholes formed. The area contains two large, channellike surface depressions--one in Harris Hill and one in the Town of Newstead. Sinkholes formed in the depression in Harris Hill in 1982, and wells went dry near the depression in Newstead.

Water-level measurements during periods of high and low water levels indicate that greater annual fluctuations (20 to 50 ft) occur near the depressions than in the surrounding area (5 to 10 ft). During periods of low water levels in summer and fall, ground water drains toward the depression in the Newstead area and then flows westward. Water-level fluctuations in the vicinity of the channellike depression are greater than in other areas because the depression has a high density of solution-widened joints that can quickly drain the area. Water-level fluctuations decrease with distance from the depression. The area of severe water-level declines is within 2,500 ft of the center line of the depression in the Newstead area.

An average of 5.3 Mgal/d of water is pumped into Dorsch Creek from a quarry 1.5 mi east of the channellike depression. Before 1981, some of this water reentered the ground when part of the discharge of Dorsch Creek flowed into swallets within the depression. The water entering the swallet was a major source of ground-water recharge during the summer and fall. When the channel of Dorsch Creek was improved and its flow diverted from the swallets, a significant part of the summer and fall recharge was lost, and ground-water levels declined within the aquifer.

The formation of sinkholes in the Harris Hill area is caused by slumping of unconsolidated deposits into solution-widened openings in the bedrock. The sinkholes are in a surface-depression area and are underlain by a relatively thick (up to 16 ft) deposit of cohesive silty clay; sinkholes are less likely to form where the surficial deposits are thin or absent. The enlargement of sinkholes in the Harris Hill area seems unrelated to the water-level decline in the eastern part of the study area and is likely the result of local drainage alteration in the Harris Hill area.

Water in the Onondaga aquifer is generally of good quality and is suitable for most domestic and agricultural purposes. Water in the underlying Akron and Bertie Dolomites and Camillus Shale tends to be of poorer quality, especially in the Camillus Shale, where the water contains appreciable concentrations of dissolved iron and manganese and has a strong hydrogen sulfide odor. Water from wells close to the depression in Newstead had elevated sulfate concentrations during a low-water period. This indicates that water

R23

Table 12.--Records of Selected Wells in Eastern Erie County, N.Y.

NUMBERING AND ARRANGEMENT OF WELLS

All wells and borings are identified by latitude and longitude to the nearest second, as measured from 7 1/2-minute topographic maps, scale 1:24,000. The location of each well or boring record was plotted on these maps by U.S. Geological Survey staff during a visit to the site or from large-scale engineering drawings.

The location of each well and boring is shown on plate 4 and on additional maps within the text. The four numbers used to identify each well on these illustrations are the seconds of latitude and longitude. For example, a well located at 42°45'38" latitude and 78°34'31" longitude is identified in illustrations as well 38-31. Data are arranged in 1-minute strips of latitude and longitude, and well numbers are placed near the well symbols. The first well in this listing is in the southernmost strip and is followed by other strips successively farther north.

Observed Release

The release and the background well must be in the same aquifer at comparable elevations.

Knowledge of flow gradients helps in determining where to look for background versus contamination...but beware of local or seasonal variation. The purpose is to find a nearby well in the aquifer of concern that is not under the influence of the site.

Background well(s) must discriminate out any alternative sources of the contamination.

The attribution of the release to the facility is strengthened if the substances found in the release are documented to have been deposited at the facility.

Depth of the Aquifer of Concern (Page 12)

- Distance between the deepest point of known contamination and the top of the aquifer of concern.

  - Deepest level at which contamination is documented.
  - Highest seasonal level of the saturated zone of the aquifer.

- If depth of deposit is unknown, 6 feet may be assumed.

MEMORANDUM

TO: Sleepy Hollow Lake Campground File
FROM: Dennis Farrar
SUBJECT: Inspection and Sampling Event
DATE: 5/28/85

On 5/24/85 I met Investigator Don Becker for the purpose of inspecting and sampling the Sleepy Hollow Lake Campground in the Town of Newstead. We arrived at the site at 10:00 a.m. and were given permission to proceed. We drove back to a dumpsite in the rear of the campground which contained cleared brush, some rubbish and 2 - 3 drums which had been cut open at one or both ends and were empty. On the right side of the road was a wetland, to which the lake drained. There were many drums in this area, all approximately 5 - 20 feet from the road. After a count was taken, it was determined that 18 drums were present. It appeared that the drums had been in place for some time, as they had sunk into the swamp and were quite rusty. No labels were evident on any drums and all were very difficult to open, if at all possible. An inventory is attached. At 1:20 p.m. we completed the sampling. Three samples were taken, #5, #9 and #10. As we were leaving the site, we met Tony, who is the current owner of the site. He indicated that the former owner of the site is responsible for the dumping and he (Tony) would be unwilling to pay for a cleanup again. Investigator Becker told him that HE, as the property holder would probably be responsible. We left the site at about 1:30 p.m.

DRUM INVENTORY

DRUM #		DESCRIPTION
1 - 4	-	Unable to open; #1 was determined to be empty; #2 - #4 had some material in them.
5	-	25 gallons of a thick, hardened light brown sludge. Some liquid was evident in the sludge. A solvent odor was noticed.
6	-	Empty, crushed drum.
7		Open bung, drum contained 25 gallons of swamp water.
8	-	30 gallons of a hardened green sludge, solvent odor was noticed.
9	-	40 gallons of a clear, non-viscous liquid, with a very strong solvent odor. Material appeared to be pure solvent.
10	-	Vented upon opening, contained a pink-orange material mixed with a brown sludge. This material quickly hardened to form a plastic glue-like substance. A solvent odor was again noticed.
11	-	Upside down - appeared to be empty.
12	-	Upside down - had some material in it.
13	-	Drum was quite heavy, but I was unable to open it.
14	-	Drum was quite heavy, but I was unable to open it.
15	-	Holes in bottom of drum, appeared to be full of swamp water.
16	-	25 gallons of what appeared to be a motor oil and water mixture.
17	-	25 gallons of what appeared to be a motor oil and water mixture.
18	-	Holes in drum top - leaking a very viscous white glue-like substance.

R40

Depth to bedrock is 5 feet or more. The surface layer and subsoil are very strongly acid to medium acid.

This soil is well suited to farming, and most of the acreage is farmed. It has few limitations for most urban uses.

This Allard soil is well suited to most cultivated crops. Potatoes do exceptionally well. Corn, potatoes, and beans are the main crops. Crops respond well to liberal application of lime and fertilizer. The use of mechanical harvesters is not restricted by gravel or cobblestones. This soil dries out quickly early in the spring and after heavy rains. Keeping tillage to a minimum, using cover crops, incorporating crop residues into the soil, and rotating crops help maintain the organic matter content and good tilth. Irrigation systems are easy to manage on this nearly level soil.

This soil is suited to pasture and hay. Proper stocking, rotational grazing, yearly mowing, and deferment of grazing when the soil is wet are the chief management needs for maintaining high quality pasture.

The potential of this soil for wood crops is good, but only a small acreage is wooded. There are few limitations for the use of equipment, and there is little hazard of erosion or of trees uprooting during windstorms. Seedling mortality is usually low because of the high available water capacity of the soil.

This Allard soil is well suited to most urban and recreational uses. Septic tank absorption fields function well, but care must be taken to avoid possible contamination of the water table because the substratum is rapidly permeable. Frequent fertilization, liming, and irrigation help maintain grass and shrubs. This soil is a good source of topsoil, and when the silty overburden is removed, it is a good source of sand and gravel. Some areas provide excellent sites for athletic fields or for other uses that require a nearly level, stone-free site.

This Allard soil is in capability class I.

AlB—Allard silt loam, 3 to 8 percent slopes. This gently sloping soil is deep and well drained. It is on stream terraces of silt-mantled glacial outwash. Areas of this soil are roughly rectangular or oblong and range from 5 to 20 acres.

Typically, this soil has a surface layer of dark brown silt loam about 9 inches thick. The subsoil extends to a depth of 27 inches. It is strong brown silt loam in the upper part and yellowish brown light silt loam in the lower part. The substratum to a depth of 60 inches is brown and light grayish brown very gravelly loamy sand.

Included with this soil in mapping are small intermingled areas of moderately well drained Scio soils in slight depressions where a thick silt mantle is underlain by gravel deposits. Also included is a soil that has a silt mantle less than 18 inches thick. Areas of the included soils are 1/4 acre to 3 acres.

The permeability of this Allard soil is moderate in the subsoil and rapid or very rapid in the substratum. The available water capacity is high, and runoff is medium. There is generally no gravel in the surface layer and subsoil. Depth to bedrock is 5 feet or more. The surface layer and subsoil are very strongly acid to medium acid.

This soil is well suited to farming, and most of the acreage is farmed. It has few limitations for most urban uses.

This Allard soil is suited to most cultivated crops. Corn, potatoes, and beans are the main crops. Because the soil is acid and low in natural fertility, crops respond well to liberal application of both lime and fertilizer. The use of mechanical harvesters is not restricted by gravel or cobblestones. This soil dries out quickly in the spring and after heavy rains. Erosion is a hazard, particularly where slopes are long. Keeping tillage to a minimum, tilling across slope, using cover crops, incorporating crop residues into the soil, and including sod crops in the cropping system help reduce the erosion hazard, maintain the organic matter content, and preserve tilth. This soil is suited to irrigation, but irrigation systems are more difficult to manage than on the nearly level Allard soils.

This soil is suited to pasture and hay. Proper stocking, rotational grazing, yearly mowing, and deferment of grazing when the soil is wet help prevent seedling loss and promote good forage growth. Fertilizer and lime should be applied for best pasture growth.

The potential of this soil for wood crops is good, but only a small acreage is wooded. There are few limitations for the use of equipment, and the uprooting of trees during windstorms is usually not a hazard. Erosion along logging trails can be a problem on long slopes. Seedling mortality is normally low because of the high available water capacity of the soil.

This Allard soil is suitable for many urban and recreational uses. It is suitable for septic tank absorption fields, but care must be taken to avoid possible contamination of the underlying water table because the substratum is rapidly permeable. Frequent fertilization, liming, and irrigation help maintain grass and shrubs. This soil is a good source of topsoil, and the substratum is a suitable source of sand and gravel.

This Allard soil is in capability subclass IIe.

AmA—Alton fine gravelly loam, 0 to 3 percent slopes. This nearly level soil is deep and well drained and somewhat excessively drained. It formed in beach and deltaic deposits that are dominantly sand and gravel. This soil is on ridgetops, terraces, and remnant deltas. Areas of this soil range from 5 to 100 acres or more and are generally oblong.

Typically, this soil has a surface layer of very friable, dark grayish brown fine gravelly loam about 9 inches thick. The subsoil extends to a depth of about 30 inches. It is yellowish brown fine gravelly loam in the upper part and dark yellowish brown fine very gravelly sandy loam in the lower part. The substratum is loose, dark brown

R41

fine very gravelly loamy sand to a depth of 60 inches or more.

Included with this soil in mapping are areas of slightly wetter Phelps soils in small depressions. Also included are small areas of the sandy Colonie soils, the gravelly Palmyra soils, and the shaly Blasdell soils. A few included areas are gently sloping. Included wet spots and sand spots are indicated by special symbols on the soil map. Areas of included soils range from 1/4 acre to 2 acres.

The permeability of this Alton soil is moderately rapid in the subsoil and rapid to very rapid in the substratum. The available water capacity in the root zone is low to moderate, and runoff is slow. Gravel makes up 20 to 35 percent of the surface layer and consists mostly of pebbles less than one-half inch in diameter. Unless this soil is limed, reaction is strongly acid or very strongly acid in the surface layer and strongly acid to neutral in the subsoil.

This soil is suitable for farming. Most of the acreage is cultivated and used for vegetables.

This Alton soil is well suited to cultivated crops and is especially productive for selected vegetable crops. Fine gravel, summer droughtiness, and rapid leaching of nutrients are the main limitations. This nearly level soil responds well to irrigation during extended dry periods and is somewhat easier to irrigate than the gently sloping Alton soils. Management should include additions of large quantities of organic matter and fertilizer during the growing season. Keeping tillage to a minimum, using cover crops, incorporating crop residues into the soil, and rotating crops help maintain good tilth and increase the organic matter content. Increasing the organic matter content improves the available water capacity of the soil.

This soil is also suited to hay and pasture. Overgrazing when the soil is dry can cause the loss of the forage plants.

Timber production on this soil is good. There are generally no limitations to the use of equipment on this soil. Seedling mortality is generally not a problem, but seedlings should be planted in the spring when the soil is moist. Removing brush, careful planting, and fertilizing improve seedling survival.

This soil is suited to many urban uses. The pollution of the water table is a hazard if the soil is used for septic tank absorption fields because the substratum is rapidly to very rapidly permeable. Although small, gravel can be bothersome in landscaping and seeding lawns. Frequent fertilization and irrigation help maintain grass and shrubs. Some areas of this soil are suitable for athletic fields and other uses that require a nearly level site, although fine gravel and a slight tendency to droughtiness are minor limitations.

This Alton soil is in capability subclass IIs.

AmB—Alton fine gravelly loam, 3 to 8 percent slopes. This gently sloping soil is deep and well drained and somewhat excessively drained. It formed in beach and deltaic deposits. This soil is on ridges, undulating terraces, and remnant deltas. Areas of this soil range from 5 to 100 acres or more and are generally oblong.

Typically, this soil has a surface layer of very friable, dark grayish brown fine gravelly loam about 9 inches thick. The subsoil extends to a depth of about 30 inches. It is yellowish brown fine gravelly loam in the upper part and dark yellowish brown fine very gravelly sandy loam in the lower part. The substratum is loose, dark brown fine very gravelly loamy sand to a depth of 60 inches or more.

Included with this soil in mapping are areas of slightly wetter Phelps soils in small depressions. Also included are small areas of the sandy Colonie soils, the gravelly Palmyra soils, and the shaly Blasdell soils. Included wet spots and sand spots are indicated by special symbols on the soil map. Areas of included soils range from 1/4 acre to 2 acres.

The permeability of this Alton soil is moderately rapid in the subsoil and rapid to very rapid in the substratum. The available water capacity in the root zone is low to moderate, and runoff is slow. Gravel makes up 20 to 35 percent of the surface layer and consists mostly of pebbles less than one-half inch in diameter. Unless this soil is limed, reaction is strongly acid or very strongly acid in the surface layer and strongly acid to neutral in the subsoil.

This soil is suited to farming. Most of the acreage is cultivated and used for vegetables.

This Alton soil is suited to cultivated crops and is especially productive for selected vegetable crops. The slight erosion hazard, droughtiness in midsummer, gravel, and the rapid leaching of nutrients are the main limitations. Tillage of row crops or clean-cultivated crops should be on the contour as much as possible to control erosion. The soil responds well to irrigation during extended dry periods but is somewhat more difficult to irrigate than the nearly level Alton soils. Fertilizer should be applied at intervals during the growing season. Keeping tillage to a minimum, using cover crops, incorporating crop residues into the soil, and rotating crops help maintain tilth and increase organic matter content. Increasing the organic matter content improves the available water capacity of the soil.

Hay and pasture crops do well on this soil, especially deep-rooted forage plants, such as alfalfa. Overgrazing when the soil is dry can cause the loss of the pasture plants.

Timber production on this soil is good. Although the erosion hazard is slight, logging roads and skid trails should be on the contour or across the slope wherever possible. There are generally no limitations to the use of equipment on this soil. Seedling mortality is generally not a problem, but seedlings should be planted in the spring when the soil is moist. Removing brush, careful planting, and fertilizing improve seedling survival.

suitable for many crops grown in the county, except for early-market and long-season varieties.

Without adequate drainage this soil is better suited to hay or pasture. Overgrazing and grazing when the soil is wet are major concerns of pasture management. They cause soil compaction and trampling of forage plants, which lead to reduced plant growth and the eventual loss of the pasture seeding. Proper stocking, rotation of pastures, yearly mowing, and deferment of grazing during wet periods are the chief management needs.

The potential of this soil for wood crops is fair to good. Erosion is usually not a hazard, but seasonal wetness causes moderate seedling mortality and limits the use of equipment. The seasonal high water table also limits rooting depth, which can result in uprooting of trees during windstorms. Trees that can withstand high lime conditions are best suited to this soil.

The seasonal high water table, slow permeability in the substratum, and danger of frost heave are serious limitations for many urban uses of this Ovid soil. Drains around foundations are needed to minimize wetness. Some areas are suitable sites for recreation, such as picnic areas and hiking trails. Many areas are good sites for dugout ponds.

This Ovid soil is in capability subclass IIIw.

OvB—Ovid silt loam, 3 to 8 percent slopes. This gently sloping soil is somewhat poorly drained. It is in low, undulating, slightly concave areas on lower sideslopes, along field drainageways, and in shallow depressions. This soil formed in red glacial till or lacustrine sediments that were reglaciated and mixed with till. Areas of this soil are oblong or irregular in shape and range from 3 to 50 acres or more.

Typically, this soil has a surface layer of very dark grayish brown silt loam 10 inches thick. The subsoil extends to a depth of 20 inches. The upper 2 inches is mottled, brown light silty clay loam, and the lower part is mottled, dark brown clay loam. The substratum is mottled, reddish brown gravelly loam to a depth of 60 inches.

Included with this soil in mapping are small areas of the Cazenovia, Kendaia, Appleton, Churchville, and Ilion soils. The well drained and moderately well drained Cazenovia soils are on a few small convex knolls. The Kendaia and Appleton soils have a lower clay content in the subsoil than this Ovid soil. The Churchville soils have a moderately deep layer of clayey sediments. The poorly drained Ilion soils are in wet spots and the bottom of drainageways. Areas of included soils range from 1/2 acre to 3 acres.

From January through May this Ovid soil has a perched seasonal high water table in the upper part of the subsoil. Permeability is moderately slow in the subsoil and slow in the substratum. The available water capacity is moderate to high, and runoff is slow to medium. Gravel makes up 0 to 15 percent of the surface layer. Bedrock is generally many feet deep, but may be as little as 5 feet deep. Unless limed, the surface layer is medium acid or slightly acid and the subsoil is medium acid to neutral.

Because of seasonal wetness and slow permeability, this soil is only moderately suited to farming and is poorly suited to many urban uses. Most of the acreage is farmed, in woodland, or idle. A few areas are urbanized.

This Ovid soil is moderately suited to cultivated crops, unless drained. Subsurface drains generally require close spacing to be effective. Interceptor drains divert runoff and seepage. Erosion is a moderate hazard, and puddling and soil compaction are problems if the soil is tilled when wet. Keeping tillage to a minimum, using cover crops, plowing at the proper soil moisture level, tilling across slopes, and including grasses and legumes in the cropping system improve tilth, increase crop yields, and control erosion. This gently sloping soil is often easier to drain than the nearly level Ovid soil because suitable outlets are available. With adequate drainage and maintenance of tilth and fertility, this soil is suitable for many crops grown in the county, except for early-market and long-season varieties.

Without adequate drainage, this soil is often better suited to hay crops or pasture. Overgrazing and grazing when the soil is wet are major concerns of pasture management. Overgrazing can cause the loss of the pasture seeding. Grazing when the soil is wet can cause soil compaction and trampling of forage plants. Proper stocking, rotation of pastures, yearly mowing, and deferment of grazing during wet periods are the chief management needs.

The potential of this soil for wood crops is fair to good. Erosion is usually not a hazard, but seasonal wetness causes moderate seeding mortality and limits the use of equipment on this soil. The seasonal high water table also limits rooting depth, which can result in the uprooting of trees during windstorms.

The seasonal high water table, slow permeability in the substratum, and danger of frost heave are serious limitations for many urban uses of this Ovid soil. Drains around foundations and interceptor drains placed upslope from buildings minimize the wetness. Many areas are good sites for diked ponds.

This Ovid soil is in capability subclass IIIw.

Pa—Palms muck. This nearly level organic soil is deep and very poorly drained. It is in basinlike areas on the lowland lake plain and in depressions on the upland plateau. The organic material is well decomposed and 16 to 50 inches thick. It is underlain by loamy mineral soil. Areas of this soil are roughly oval or irregular in shape and range from 3 to 50 acres, but areas of 5 to 20 acres are most common.

Typically, this soil has a black, well decomposed, organic (muck) surface layer about 12 inches thick. The subsurfce layer extends to a depth of about 38 inches. It

R43

is friable, black to dark grayish brown well decomposed muck. The mineral substratum below a depth of about 38 inches is dark gray to gray loam.

Included with this soil in mapping are small intermingled areas of the Canandaigua, Lamson, and Lyons soils that have a mucky surface layer. These soils formed in organic deposits that are less than 16 inches deep. The Canandaigua soils have a silty subsoil, the Lamson soils have a high sand content in the subsoil, and the Lyons soils have gravel and stones mixed with the mineral material. These mineral soils generally are narrow bands around the edge of this map unit or on slight rises within the unit. Also included in mapping are small areas of muck deposits deeper than 50 inches, usually near the center of the mapped area. Areas of included soils range up to 3 acres.

This Palms soil is subject to frequent flooding or ponding. It has a high water table at or near the soil surface from November through May. Permeability is moderately slow to moderately rapid in the organic layers and moderate or moderately slow in the loamy mineral substratum. The available water capacity is high, and runoff and internal drainage are very slow. Bedrock is at a depth of more than 6 feet. The organic layers range from strongly acid to moderately alkaline.

Palms muck, where drained, is well suited to special crops and many field crops. It has very serious limitations for urban and recreational uses, mainly because of excessive wetness, flooding, and instability. Most of the acreage is in cattails and other water-tolerant grasses, sedges, brush, and trees. A few areas are drained and farmed.

This Palms soil is well suited to many cultivated crops, particularly vegetable crops, if it is properly drained. Drainage usually requires a system of open ditches and subsurface drains. Drainage is extremely difficult to install in many areas because the soil is low on the landscape and suitable outlets are not available. If the soil is drained, keeping tillage to a minimum, using cover crops, plowing at proper soil moisture level, and rotating crops help maintain good tilth and reduce the loss of organic matter. If this organic soil is drained and left idle it is subject to wind erosion, but by maintaining windbreaks and cover crops or sod crops on the soil this hazard is reduced. Using equipment that minimizes soil compaction helps maintain tilth and a good rate of water percolation through the soil. Lettuce, onions, and potatoes do very well in drained areas of this muck soil.

Undrained areas are usually poorly suited to pasture or hay crops. Soil compaction and trampling of desirable grasses are serious problems in pastured areas.

The potential of this soil for wood crops is poor because of prolonged wetness. Use of equipment, seedling mortality, and uprooting of trees during windstorms are very serious problems on this soil. Only seedlings that can withstand excessive wetness can be grown.

Prolonged wetness, seepage, excess humus, frequent flooding or ponding, compressibility, and high risk of frost damage are severe limitations for most urban and recreational uses of this soil. Many areas are suited to wetland wildlife habitat.

This Palms muck soil is in capability subclass Vw.

PbA—Palmyra gravelly loam, 0 to 3 percent slopes. This nearly level soil is deep and well drained. It is on flat terraces and plains in the northern part of the county. This loamy soil is derived from outwash deposits that have a relatively high content of sand and limestone gravel. Areas of this soil are large and oblong or irregular in shape, and range from 3 to 200 acres, but areas of 5 to 20 acres are most common.

Typically, this soil has a surface layer of very dark grayish brown gravelly loam 9 inches thick. The subsoil extends to a depth of 28 inches. It is brown gravelly loam in the upper part, brown gravelly heavy loam in the middle part, and brown gravelly light clay loam in the lower part. The grayish brown substratum is very gravelly loamy sand in the upper part and very gravelly sand in the lower part.

Included with this soil in mapping are small areas of the Phelps, Halsey, Arkport, and Minoa soils. The Phelps soils are not as well drained as this Palmyra soil and are on slightly lower terraces. The Halsey soils are in wet depressions and in other low areas. The well drained Arkport soils and the somewhat poorly drained Minoa soils are free of gravel and cobblestones. Also included are a few areas of a gently sloping soil. Areas of included soils range from 1/4 acre to 3 acres.

The permeability of this Palmyra soil is moderate in the surface layer and subsoil and very rapid in the substratum. The available water capacity is moderate, and runoff is slow. Depth to bedrock is 5 feet or more. Gravel makes up 15 to 30 percent of the surface layer. In unlimed areas, the surface layer is medium acid to neutral, and the subsoil is slightly acid to mildly alkaline.

This soil is well suited to farming and to many urban uses. Most of the acreage is urbanized or is farmed. A few small areas of this soil are idle.

This Palmyra soil is well suited to cultivated crops. Gravel in the surface layer interferes with the planting and harvesting of some specialized crops and causes more rapid wear of equipment. Keeping tillage to a minimum, using cover crops, incorporating crop residues into the soil, and occasionally including sod crops in the cropping system help maintain tilth and improve the organic matter content. This soil is suited to irrigated vegetable crops, and irrigation systems are easier to manage than on the more sloping Palmyra soil.

Pasture and hay crops also do well on this soil. Overgrazing restricts plant growth and can cause the loss of the pasture plants. Proper stocking, rotation of pastures, yearly mowing, and deferment of grazing when

R44

investigations are essential, and each site must be considered individually.

Pits, borrow, have not been assigned a capability subclass.

Pu—Pits, gravel. This unit consists of excavated areas from which gravel has been removed for construction purposes. They are usually 5 to about 50 feet deep. The soils in these areas have a high sand and gravel content. Pit sides are mostly steep, and the floor is relatively level. Piles of stones and boulders and sloughed materials are commonly scattered over the floor. Small pools of water are common in low parts of some of the pits, particularly in the spring. These excavated areas are commonly irregular in shape, depending on the nature of the soil deposits and ownership boundaries, and they range from 3 to 200 acres or more.

Pits are usually devoid of vegetation; however in some of the older ones there are scattered bushes and grass. Pits are droughty because of the very low available water capacity of the soil. Permeability varies, but usually it is moderately rapid to very rapid.

These miscellaneous areas are generally not suited to farming and woodland because the topsoil has been removed and the subsoil material is not suitable for root development. The potential of these areas is usually poor for wildlife habitat, although some animals and birds may find shelter or refuge in these areas.

The suitability of these areas for urban and recreational uses ranges from good to poor. Onsite investigations are essential and each site must be considered individually.

Pits, gravel, have not been assigned a capability subclass.

Qu—Quarries. These are open pits created by removing limestone rock for agricultural, industrial, and construction purposes. They are mainly in the northern part of the county, and the surrounding soils are usually shallow over bedrock. The excavated areas are usually 20 to 100 feet deep. They are irregular in shape, depending on the nature of the bedrock strata and ownership boundaries. They range from 3 to 125 acres or more.

Quarries are generally devoid of vegetation; however, in some of the older quarries, scattered plants and grass have become established in cracks where the bedrock has weathered and some soil has accumulated. Piles of stones and boulders are commonly scattered over the quarry floor. Included in mapping are small pools of water on many of the quarry floors. The entire floor of some abandoned quarries is covered with water up to several feet deep.

The suitability of abandoned areas for some urban and recreational uses ranges from poor to fair. Onsite investigation is necessary, and each site is considered individually for any proposed use.

Some areas are well suited to educational uses, such as outdoor classrooms for studying the bedrock geology of the region. Onsite investigation is needed to determine the feasibility of using Quarries for such purposes.

Abandoned Quarries are usually poorly suited to farming and woodland becuase of the lack of soil material. Some areas provide habitat for certain kinds of wildlife and birds, and a few areas that are ponded contain fish and other aquatic animals. Boating is also possible in some of the pits that are ponded. Where trash and other wastes are dumped in abandoned quarries there is a hazard of pollution of the water table by seepage through the cavernous and fractured limestone bedrock.

Quarries are not assigned a capability subclass.

RaA—Raynham silt loam, 0 to 3 percent slopes. This level or nearly level, silty soil is deep and somewhat poorly drained. It is mainly on broad plains in the lowlands in the northern part of the county and in small pockets on the upland plateau. Areas of this soil are irregular in shape or roughly elongated where they parallel streams. Most areas range from 50 to 200 acres or more, but in the uplands, areas range from 3 to 50 acres in size.

Typically, this soil has a surface layer of dark grayish brown silt loam about 8 inches thick. The subsoil is about 18 inches thick. It is mottled, yellowish brown silt loam. The substratum extends to a depth of 60 inches. The upper part is mottled, yellowish brown silt loam, and the lower part is grayish brown fine sand.

Included with this soil in mapping are small areas of the Minoa and the Niagara soils. The Minoa soils are more sandy and the Niagara soils are more clayey than this Raynham soil. Also included are soils that are similar to this Raynham soil but have a dense fragipan in the subsoil. In some areas, particularly in the uplands, the subsoil is more acid than is typical for this Raynham soil. Areas of included soils range from 1/2 acre to 3 acres.

From November through June this Raynham soil has a seasonal high water table in the upper part of the subsoil. Permeability is moderate or moderately slow in the subsoil and slow in the substratum. The available water capacity is high, and internal drainage and runoff are slow. There is usually no gravel in this soil, and bedrock is more than 5 feet deep. The surface layer and subsoil are strongly acid to neutral.

This soil is moderately suited to farming but poorly suited to many urban uses. Most of the acreage is in hay, pasture, woodland, or it is idle. Some areas of this soil are in residential development.

The suitability of this Raynham soil for cultivated crops can be improved with drainage. In undrained areas, seasonal wetness delays planting until late spring.

MEMORANDUM

TO: Sleepy Hollow Lake Campground File
FROM: Robert N. Leary RNL
SUBJECT: Sampling Results
DATE: 7/30/85

The results of the analyses of our samples were received by this office on July 26, 1985. Three samples, representing 120 gallons of liquid and sludge, were analyzed with the following results:

Volatiles found: Methylene chloride, trichloroethylene, Tetrachloroethylene, chlorobenzene. toluene, ethyl benzene, xylene (o,m, and p), and 1,2,-dichloroethane

As shown in the attached table, extremely high concentrations in percent levels were found for toluene in all three drums and ethyl benzene, m, p - xylene, and o - xylene in drum #5. A primary use of these five chemicals is as a solvent for paint, varnish, lacquer, resins, fats, oils, etc. Methylene chloride, 1,2-dichloroethane, trichloroethylene, and tetrachloroethylene are also primarily used as solvents. Chlorobenzene can be used as a solvent but is primarily a chemical intermediate.

All the chemicals except 1,2-dichloroethane are listed Generic Hazardous Wastes. All the chemicals except 1,2-dichloroethane, chlorobenzene, and ethyl benzene are listed Toxic Wastes.

RNL:jb

Encl.

cc: Don Becker

R53

SLEEPY HOLLOW LAKE
SUMMARY OF SAMPLING RESULTS

Contaminant ppm \ Sample #	05 DRUM	09 DRUM	10 DRUM
Methylene Chloride	110	75	60
1,2- dichloroethane			6.9
Trichloroethylene	110		800
Tetrachloroethylene	39		4.9
Chlorobenzene	110		1300
Toluene	650,000	460,000	210 000
Ethyl Benzene	28.000		
Xylene (m,p)	110.000		
Xylene (o)	45.000

STATE OF NEW YORK : DEPARTMENT OF ENVIRONMENTAL CONSERVATION

In the Matter of a Remedial Program pursuant to Article 27 of the Environmental Conservation Law, to Eliminate any Threat to the Environment Caused by the Storage or Disposal of Hazardous Wastes,

ORDER ON CONSENT

BY:

F. N. BURT COMPANY, INC.

FEITZHANS AND MAUER TRUCKING, INC.

ANTHONY LATELLO

MARIO LATELLO

RESPONDENTS

B9-0100-85-07

WHEREAS:

1. The New York State Department of Environmental Conservation (the "Department") is responsible for the enforcement of Article 27, Title 13, of the Environmental Conservation Law of the State of New York (the "ECL"), entitled "Inactive Hazardous Waste Disposal Sites".

2. Respondent F. N. Burt Company, Inc. is a corporation organized and existing under the laws of the State of Delaware authorized to do business and doing business in the State of New York.

3. Respondent Feitzhans & Mauer Trucking, Inc. is a corporation organized and existing under the laws of the State of New York and is doing business in the State of New York.

R56

4. Respondent, F. N. Burt Company, Inc. in or around the year 1971, was the generator of approximately eighteen 55-gallon drums of oils, solvents and other liquids and sludges which were excess materials and constituted wastes as defined by statutes and regulations, which were turned over to Respondent Feitzhans and Mauer Trucking, Inc. for disposition.

5. Respondent Feitzhans and Mauer Trucking, Inc., in or around the year 1971, transported a number of 55-gallon drums of waste materials from F. N. Burt Company and placed the drums on property then owned by Respondent, Feitzhans and Mauer Trucking, Inc., and left them there.

6. The real property on which the wastes had been placed was sold in 1976 to Respondents Anthony Latello and Mario Latello, the current owners of this real property (the "Site"), known as "Sleepy Hollow Campsite" located on Siehl Road in the Town of Newstead, County of Erie, State of New York.

7. During the spring of 1985, the presence of these drums was brought to the attention of the Department. Inspection of the Site by Department personnel revealed that there are approximately 18 55-gallon drums of waste materials, some of the drums being full and some partially full, while others may contain waste residue.

8. On or about May 24, 1985, the Department collected some samples of the contents of drums for laboratory analysis. Laboratory analysis of the samples indicates the presence of Methylene chloride, Trichloroethylene, Tetrachloroethylene, Toluene, Xylene and other substances among the waste within said drums.

9. Each of these spent solvents is a hazardous waste as that term is defined at 27-0903(3) of the ECL and is included in the listing of hazardous wastes under 6 NYCRR Part 371.4(d)(6) as a toxic substance.

10. The Site is an inactive hazardous waste disposal site as that term is defined in of ECL §27-1301(2).

11. Pursuant to ECL Section 27-1313(3)(a), whenever the Commissioner of Environmental Conservation (the "Commissioner") "finds that hazardous wastes at an inactive hazardous waste disposal site constitute a significant threat to the environment, he may order the owner of such site and/or any person responsible for the disposal of hazardous wastes at such site (i) to develop an inactive hazardous waste disposal site remedial program, subject to the approval of the Department, at such site, and (ii) to implement such program within reasonable time limits specified in the order".

12. Respondents have submitted to the Department, a consultant's estimate for a drum and waste disposal program which has been reviewed by the Department and tentatively approved, subject to oversight and approval by Department representatives of all procedures undertaken at the time of implementation. Such proposal is attached hereto and incorporated herein as Appendix "A".

13. Respondents, having waived their rights to a hearing herein as provided by law, and having consented to the issuance and entry of this Order, agree to be bound by the provisions, terms and conditions hereof.

14. The Department and Respondents acknowledge that the goals of this Order shall be that Respondents shall develop and implement a remedial program to remove and properly dispose of all drums present at the Site, as well as adjacent soils contaminated thereby.

NOW THEREFORE, having considered this matter and being duly advised, it is ORDERED that:

I. Respondents shall undertake and complete at the Site, the proposed drum and waste disposal program described in Appendix "A", subject to the oversight and approval by the Department, of any specific protocols and procedures which are not delineated in Appendix "A", and shall complete the implementation of the program not later than 45 days after

the effective date of this Order. The program shall include, but need not be limited to, the following:

A) All drums present at the Site shall be properly packaged in accordance with applicable State and Federal laws and regulations.

B) Lawful removal of the drums and their contents to an authorized treatment or disposal facility via a properly permitted waste transporter.

C) All visibly stained or otherwise contaminated surficial soils in the general vicinity of the drum disposal areas shall be excavated, removed from the Site, and transported and disposed of as hazardous wastes in accordance with applicable provisions of Federal and State laws and regulations.

II. Respondents shall provide notice to the Department of all excavating, sampling or other field activities to be conducted pursuant to the terms of this Order at least five (5) working days in advance of such activities.

III. The failure of Respondent to comply with any provision of this Order shall constitute a default and a failure to perform an obligation under this Order and under the ECL.

RGO

IV. The effective date of this Order shall be the date upon which the Order, signed by the Commissioner or his designated representative, is delivered to the Respondents.

V. The provisions of this Order shall be deemed to bind the consenting Respondents, successors and assigns, individually and jointly with the other signatories hereto, regardless of whether all Respondents herein named consent to the issuing and entering of this Order.

VI. This Order shall remain in effect until Respondents receive written notification from the Department that Respondents have satisfactorily complied with the terms of this Order and the approved removal program.

VII. Copies of all laboratory analytical results, all permits, manifests and other administrative documents prepared during the preparation and implementation of this removal program shall be submitted to the Department at the following address:

RC1

New York State Department of
Environmental Conservation
Division of Solid and Hazardous Waste
600 Delaware Avenue
Buffalo New York 14202-1073

This paragraph shall be in addition to any other submissions required by law, regulation or procedure.

ADVISORY NOTE

The information contained in this document is presented to show environmental conditions, comparisons to ambient environmental standards and criteria and compliance status relative to applicable environmental regulations.

Any use of this information to assess the risks to personal or public health, identify potential personal or public liability or to estimate the costs of remedial activity should only be done after consultation with appropriate government agencies or private consultants.

R68

General Information

Feitshans, Siehl Road, Town of Newstead, Erie County 14001. The site is known as the Sleepy Hollow Campgrounds. The present owners are Mario and Anthony Latello, 146 Sheldon Avenue, Lancaster, New York. Phone number 716-685-3031.

Disposition of Assigned Site Number

Based on the inspection findings, and on going actions by the New York State Department of Environmental Conservation it is recommended on the site be added to this Registry.

Background

Sleepy Hollow Campground which covers an area of about 100 acres, was developed into a camping area in the early 1960's. Aerial photography showed the site to be wooded and agricultural in 1950. The 1960 photo showed development into a campground had started. By 1972 aerial photos showed a long narrow lake along the eastern boundry and campsites in both wooded and cleared areas throughout. Numerous permanent buildings and shelters were evident in the cleared areas. Site inspections on 10/21/85 and 11/1/85 show little or no changes since 1972. The campsite was owned and operated by the Feitshans family until 1976 when the property was purchased by the Latello's.

June 4th, 1981 - the ECDEP received a complaint stating numerous drums on site at Sleepy Hollow Campgrounds. An ECDEP investigator found about "50 to 60 unlabled drums full of waste material", adjacent to the lake and near Siehl Road. "Most drums are leaking, and large quantities of waste material is on the ground. Vegetation in the area is discolored. Waste appears to be glue or adhesive and waste oil". Another 100 empty drums were also found on site.

Mr. Anthony Latello, current owner of the campground, informed the investigator that the drums were on site when he purchased the property in 1976. Mr. Latello was advised not to move or disturb the drums until proper disposal was arranged through the NYSDEC.

Sometime in June or early July of 1981 Mr. Latello moved the drums to the property of Elmer Case at 13970 Genesee Street, Alden, NY. On 9/9/82 NYSDEC charged Mr. Latello with storage and transportation of waste material without a permit. Mr. Case was charged with storage without a permit.

During the DEC investigation in was learned that the waste material had originated at the F.N. Burt Co. of Buffalo. DEC negotiated to have Mr. Latello pay for loading and transportion of drums and F.N. Burt Co. pay for disposal of drums at Frontier Chamical Services in Niagara Falls. Mr. Case was fined $100.00 and all other charges were dismissed upon removal and disposal of drums.

April 25, 1985 - Don Folger, Town of Newstead Building Inspector, discovered some drums in a swampy area north of the lake. Mr. Donald Becker investigator for NYSDEC and Mr. Dennis Farrar also of DEC conducted a site inspection on 5/24/85.

Mr. Becker and Mr. Farrar found 18 drums in a swampy area toward the north end of the property. The drums were numbered and samples were taken from drums #5, 9 and 10. Analysis found all three drums to have high Toluene concentrations. Almost all the contaminants detected by the analysis are listed as toxic wastes. Mr. Farrar's drum inventory list and a table with analytical results are included in this report. Mr. Becker has been designated to coordinate the removal of the drums.

Inspection Findings

The site was inspected by Erie County Department of Environment and Planning on November 1st, 1985.

A) Raw Material

1. The site is not a processor or manufacturer. No raw material was observed on site.

R70

B) Waste Handling and Disposal

1. The drums originally located by D.E.C. were observed in the swamp located at the rear of the campgrounds. No evidence of removal or relocation of the drums was noted. Several other drums containing an unknown substance were observed on site next to buildings located near Siehl Road. Approximately 50 empty drums were also noted in this same area.

Conclusions and Reccommendations

Based on the fact that the drums of concern are located directly in the swamp and that analysis shows they contain solvents which are listed hazardous waste, it is recommended that immediate action is undertaken to satisfactorly remove and properly dispose of this material. It is understood that D.E.C. is handling this matter. The drummed material containing an unknown substance should be analyzed and properly disposed. Further follow up by D.E.C. is recommended.

Dangerous Properties of Industrial Materials

Sixth Edition

N. IRVING SAX

Assisted by:

Benjamin Feiner/Joseph J. Fitzgerald/Thomas J. Haley/Elizabeth K. Weisburger

VNR VAN NOSTRAND REINHOLD COMPANY

New York

its low volatility, narcosis is less severe and much less common in industrial poisoning than in the case of other chlorinated HC. The toxic action of this material is chiefly on the liver, where it produces acute yellow atrophy and cirrhosis. Fatty degeneration of the kidneys and heart, hemorrhage into the lungs and serous membranes, and edema of the brain have also been found in fatal cases. Some reports indicate a toxic action on the CNS, with changes in the brain and in the peripheral nerves. The effect on the blood is one of hemolysis, with appearance of young cells in the circulation and a monocytosis. Due to its solvent action on the natural skin oils, dermatitis is not uncommon.

The initial symptoms resulting from exposure to the vapor are lacrimation, salivation and irritation of the nose and throat. Continued exposure to high concentrations results in restlessness, dizziness, nausea and vomiting and narcosis. The latter, however, is rare in industry. More commonly, exposure is less severe, and most complaints are vague and related to the digestive and nervous systems. The patient's symptoms gradually progress to a more serious illness, with development of toxic jaundice, liver tenderness, etc., and possibly albuminuria and edema. With serious liver damage the jaundice increases and tox symptoms appear, with somnolence, delirium, convulsions and coma usually preceding death. An exper CARC, ETA. MUT data.

This material is considered to be a very severe industrial hazard and its use has been restricted or even forbidden in certain countries.

Explosion Hazard: Reacts violently with N_2O_4, 2,4-dinitrophenyl disulfide and contact with sodium or potassium. When heated in contact with solid potassium hydroxide, a spontaneous flammable gas is evolved. Any water can cause appreciable hydrolysis even at room temp. and both hydrolysis and oxidation become comparatively rapid above 110°.

Disaster Hazard: Dangerous; when heated it emits highly tox decomp products.

NCI Carcinogenesis Bioassay Completed; Results positive: Mouse (NCITR* NCI-CG-TR-2,76). NCI Carcinogenesis Bioassay Completed; Results negative: Rat (NCITR* NCI-CG-TR-2,76). Currently Tested by NTP for Carcinogenesis by Standard Bioassay Protocol as of December 1980. "NIOSH Manual of Analytical Methods" VOL 1 127, VOL 3 S336. NIOSH Current Intelligence Bulletin 2, 1975. Reported in EPA TSCA Inventory, 1980. EPA TSCA 8E No. 05780146—Followup sent as of April, 1979.

THR: HIGH via ivn; MOD via ipr, inhal, orl. An exper CARC, ETA. MUT data. Inhal of high conc causes narcosis and anesthesia. A form of addiction has been observed in exposed workers. Prolonged inhal of mod conc causes headache and drowsiness. Fatalities follow-

R81

ing severe, acute exposure have been attributed to ventricular fibrillation resulting in cardiac failure. There is damage to liver and other organs from chronic exposure. Cases have been reported but are of questionable validity. Determination of the metabolites trichloracetic acid and trichloroethanol in urine reflects the absorption of trichloroethylene. A food additive permitted in food for human consumption. A common air contaminant. SEV eye irr in rbt.

Fire Hazard: Low, when exposed to heat or flame. High conc of trichloroethylene vapor in high-temp. air can be made to burn mildly if plied with a strong flame. Though such a condition is difficult to produce, flames or arcs should not be used in closed equipment which contains any solvent residue or vapor. Can react violently with Al, Ba, N_2O_4, Li, Mg, liquid O_2, O_2, KOH, KNO_3, Na, NaOH, Ti.

Spontaneous Heating: No.

Disaster Hazard: Dangerous; see chlorides.

Aquatic Toxicity Rating: TLm96:1000-100 ppm WQCHM* 3,-,74. Carcinogenic Determination: Indefinite IARC** 20,449,79.

TLV: Air: 100 ppm DTLVS* 4,275,80. *Toxicology Review:* FAZMAE 18,365,74; 27ZTAP 3,94,69. OSHA Standard: Air: TWA 500 ppm; CL 1000; Pk 2000/5M/2H (SCP-J) FEREAC 39,23540,74. DOT-ORM-A, Label: None FEREAC 41,57018,76. Occupational Exposure to Methylene Chloride recm std: Air: TWA 75 ppm; Pk 500 ppm/15M NTIS**. Currently tested by NTP for Carcinogenesis by Standard Bioassay Protocol as of December 1980. "NIOSH Manual of Analytical Methods" Vol 1 127, Vol 3 S329. Reported in EPA TSCA Inventory, 1980. EPA TSCA 8(a) Preliminary Assessment Information Proposed Rule FERREAC 45,13646,80.

THR: MUT data. A skn, eye irr. An exper ETA, ± CARC. A hmn CNS, BLD. HIGH orl, ivn; MOD ipr, orl, scu, ihl; LOW ihl, scu. See also chlorinated aliphatic hydrocarbons. Very dangerous to the eyes. Except for its property of inducing narcosis, it has very few other acute toxicity effects. Its narcotic powers are quite strong, and in view of its great volatility, care should be taken in its use. It will not form explosive mixtures with air at ordinary temp. However, it can be decomp by contact with hot surfaces and open flame, and it can then yield toxic fumes, which are irr and will thus give warning of their presence. It has been used as an anesthetic in Europe and is still used there for local anesthesia. Exper have shown that 25,000 ppm conc for 2 hr exposures were not lethal. Conc of 7,200 ppm after 8 min caused paresthesia of the extremities; after 16 min, acceleration of the pulse to 100; during the first 20 min, congestion in the head, a sense of heat and slight irr of the eyes. At a level of 2,300 ppm, there was no feeling of dizziness during 1-hr exposures, but nausea did occur after 30 min of exposure. The limit of perception by smell is set at 25-50 ppm conc. Can cause a dermatitis upon prolonged skin contact. A respirator for organic vapors and fumes should be worn to avoid excessive inhal. Used as a food additive permitted in food for human consumption.

Fire Hazard: Reacts violently with Li, NaK, potassium-*tert*-butoxide, (KOH + *n*-methyl-*n*-nitrosourea).

Explosion Hazard: None under ordinary conditions, but will form explosive mixtures in atmosphere having high oxygen content, in liquid O_2, N_2O_4, K, Na, NaK.

Disaster Hazard: Dangerous; when heated to decomp, emits highly tox fumes of phosgene.

METHANESULFONIC ACID

NCI Carcinogenesis Bioassay Completed; Results Positive: Mouse (NCITR* NCI-CG-TR-13,77). NCI Carcinogenesis Bioassay Completed; Results Negative: Rat (NCITR* NCI-CG-TR-13,77). Currently Tested by NTP for Carcinogenesis by Standard Bioassay Protocol as of December 1980."NIOSH Manual of Analytical Methods" VOL 1 127, VOL 3 S335. NIOSH Current Intelligence Bulletin 20, 1978. Reported in EPA TSCA Inventory, 1980. EPA TSCA 8E No: 05780146-Followup Sent as of April, 1979.

THR: MOD via inhal, oral, scu, ipr and dermal routes. HIGH via ivn route. Not corrosive or dangerously acutely reactive, but toxic by inhal, by prolonged or repeated contact with the skin or mu mem, or when ingested by mouth. The liquid can cause injuries to the eyes; however, with proper precautions it can be handled safely. The symptoms of acute intoxication from this material are the result of its effects upon the nervous system.

Exposures to higher conc than 200 ppm cause irr, lachrymation and burning of the eyes and irr of the nose and throat. There may be vomiting, nausea, drowsiness, an attitude of irresponsibility, and even an appearance resembling alcoholic intoxication. This material also acts as an anesthetic, through the inhalation of excessive amounts within a short time. The symptoms of fatal intoxication are irritation of the eyes, nose and throat, then fullness in the head, mental confusion; there may be headache stupefaction, nausea and vomiting, personnel suffering from subacute poisoning

R85

may suffer from such symptoms as headache, fatigue, nausea, vomiting, mental confusion and temporary blurring of the vision. This can occur when inadequate ventilation results in concentrations higher than 200 ppm, or where the vapor conc are intermittently high due to faulty handling of the material, or when an individual fails to take adequate precautionary measures.

This material can cause dermatitis, particularly after repeated or prolonged contact with the skin. The dermatitis is preceded by a reddening and burning and more rarely, a blistering of the skin. In any event, the skin becomes rough and dry, due largely to the removal of skin oils by material. The skin then cracks easily and is readily susceptible to infection. Upon ingestion it causes irr of the gastrointestinal tract, which, in turn, causes nausea, vomiting, diarrhea and bloody stools. However, such effects are usually less severe than the effects of swallowing similar amounts of other chlorinated hydrocarbons. An exper CARC. MUT data.

It may be handled in the presence or absence of air, water, and light with any of the common construction materials at temp. up to 140°C. This material is extremely stable and resists hydrolysis. A common air contaminant. Reacts violently with Ba, Be, Li; N_2O_4; metals; NaOH.

Disaster Hazard: Dangerous; when heated to decomp it emits high tox fumes of chlorides.

For further information see Perchloroethylene Vol. 1, No. 2 of *DPIM Report.*

New York State Department of Environmental Conservation

MEMORANDUM

TO: Ms. JoAnn Gould
FROM: Mr. Robert Wozniak RW
SUBJECT: DRUM REMOVAL SLEEPY HOLLOW CAMPGROUND

DATE: November 21, 1986

On 11/17/86, Ms. Nancy Overfield witnessed the removal of ten drums and four drums full of soil from the swamp located at the north end of Sleepy Hollow Lake. This removal was performed by two technicians working for Envirosure Management Corporation, cleanup contractor for F. N. Burt Company, Inc. All work was performed to the C.E.S. work plan submitted to this office.

On Tuesday, 11/18/86, the writer witnessed the removal of seven additional drums and nine drums of soil from the same swamp area. The work was performed by the same Envirosure people; Mr. Eugene Manning, Supervisor and Mr. Kent Brong, Technician. Another technician, no name obtained, arrived at approximately 1:00 PM to obtain samples from the drums and soil.

Mr. Fred Connine represented F. N. Burt, and he stated Mr. Mario Latello had called a lady across the street from the campground and asked her to tell Mr. Connine there was four additional drums at the maintenance building that should be removed. Mr. Connine questioned removing those drums since he was not sure they originated from F. N. Burt, and the original DEC survey indicated there was only a total of 18 drums. He also stated their contact with Envirosure was for a total of 18 drums.

The writer searched the area around the maintenance building and found ten additional drums full or partially full of unknown material. This was shown to Mr. Connine, and he elected not to have Envirosure remove the drums from the maintenance area until he gets assurance that the material originated from F. N. Burt and he gets approval from F. N. Burt's owners that they agree to pay the additional handling and disposal cost.

You may have to review the original order on consent to see if these ten additional drums are covered and if they are not, you may have to contact Mr. Mark Spitler or Mr. Fred Connine and renegotiate. I am sure Mr. Tom Johnson or the writer or both could QC the remaining ten drums. Since these drums are staged at the maintenance building, there is the possibility they could have originated from the operation of the campground or Mr. Fitzhans Trucking concern.

Besides the full drums on site, it should be noted that there are 100 plus drums that are empty. Many of these drums are crushed and used as fill material in the wetlands. Mr. Latello stated these drums were brought out to the campground by the Fitzhans to be used as burn barrels. No doubt the contents were also emptied into the same swamp area as the full drums.

RCW:sz

Dear Ms. Borcht:

As I mentioned during our telephone conversations on March 9, 1989 and March 13, 1989, Recra Environmental, Inc. is currently conducting a Phase I investigation of the Sleepy Hollow Campground Site located on Shiehl Rd., Town of Newstead, NY and the Lancaster Sanitary Landfill Site located on Gunnville Rd., Town of Lancaster, NY.

We are performing this investigation for the New York State Department of Environmental Conservation pursuant to the requirements of the New York State Superfund Law (Chapter 857 of the Laws of 1982).

This is to confirm our telephone conservation wherein you provided the following information:

- Within a 3-mile radius of both sites, the population of the Town of Newstead, NY uses private wells as a sole source of water and no municipal water system readily available. (Please see maps enclosed.)

We would appreciate if you would review this information, note any necessary corrections and return a signed and dated copy to indicate your concurrence. Your prompt attention to this would be appreciated, as the information is necessary to complete our evaluation of the site.

Thank you for your assistance.

Sincerely,

Linda J. Clark

Dear Ms. Clark:

The following information is in response to your written request concerning irrigation and agricultural production activity in the vicinity of Sleepy Hollow Campgrounds. I am not aware of any irrigation from wells or surface water within a three-mile radius of the campground in Genesee Linda Clark

I have enclosed an 1985 aerial photo showing cropland fields outlined in blue which were in crop production during the past five years. Field number one on Tract 1540 was in barley and corn during 1988. Field three on Tract 1973 was in corn in 1986. These fields are within 2000 feet of the camp.

Also, enclosed is a map showing prime farmland and additional farmland of statewide importance in Genesee Co. The above fields occupy prime farmland soils and farmland of statewide importance.

Hopefully, I have answered all your questions. If you need any further assistance, please feel free to call or write.

Sincerely,

Art Hanson

Subject: Phase I Investigation of Two (2) Hazardous Waste Disposal Sites in Erie County, New York

In response to your letter dated March 9, 1989 the following is information is provided:

Lancaster Sanitary Landfill, Town of Lancaster, New York

-no known or indicated use of groundwater from wells for agricultural irrigation within a three mile radius of the center of the site at present
-no known or indicated use of surface water for agricultural irrigation within three miles downstream from the site at present
-closest agricultural land in production within the past 5 years is immediately south of the site separated from the site by the NYS Thruway and its right-of-way (approx. 250 ft.)
-closest prime agricultural land in production within the past 5 years is immediately south of the site separated from the site by the NYS Thruway and its right-of-way (approx. 250 ft.)

Sleep Hollow Campgrounds, Town of Newstead, New York

-no known or indicated use of groundwater from wells for agricultural irrigation within a three mile radius of the center of the site at present (in Erie County)
-no known or indicated use of surface water for agricultural irrigation within three miles downstream from the site at present (in Erie County)
-closest agricultural land in production within the past 5 years is immediately adjacent to the site along the eastern edge of the site
-closest prime agricultural land in production with the past 5 years is immediately adjacent to the site along the eastern edge of the site

This information is true and complete to the best of my knowledge. The potential for agricultural irrigation exists within a three mile radius of both sites. Your evaluation should consider this factor as well. Small scale irrigation of gardens, lawns, etc. is possible and likely though we have no data regarding this usage of either groundwater or surface water within a three mile radius of either site.

Sincerely,

John R. Whitney
District Conservationist

December 27, 1988

Mr. Kenneth A. Shisler, Jr.
Recra Environmental, Inc.
Audubon Business Centre
10 Hazelwood Drive
Suite No. 106
Amherst, NY 14150

Dear Mr. Shisler:

Your letter of December 5 to James R. Snider in regard to three sites in Region 9 under Phase I investigations has been referred to me for an overall response.

I have enclosed maps of DEC regulated wetlands and stream classification maps for each of the sites. A few comments about each site are appropriate.

Lancaster Sanitary Landfill - ID #915068

Segments of streams classified "C(T)" are shown in red; those that are "B" are purple. All other classified waters may be assumed to be "D" at the present time with probable elevation to a "C" status once the Erie-Niagara Basin goes through the next round of reclassification hearings. Mr. Gordon Batchellor Region 9 Wildlife Biologist reports that there are no "critical habitats" for any wildlife species in the area. The landfill is, however, very close to the DEC owned Tillman Road Wildlife Management Area (see special map). My review of material excerpted from the Natural Heritage Program Operations Manual suggests that no endangered plant or animal species have been documented near the landfill site.

Sleepy Hollow Lake Campground - ID #915136

Essentially all surface waters near this site are or will be classified "C". I believe this is also true of the nearby area within Genesee County which is under the jurisdiction of the Region 8 DEC office at Avon, New York. We do not have maps of DEC regulated wetlands in Genesee County so it will be necessary for you to consult with the Region 8 office if you have not already done so. Comments on "critical habitats" and endangered plant and animal species are the same as those for the preceding site; again this pertains only to Region 9.

R114

Day's Farm - ID #902013

Waters classified "C(T)" are outlined in red; all other streams or segments thereof may be assumed to be "C". Mr. Michael Ermer, Region 9 Wildlife Biologist reports that there are no closely "critical habitats" for wildlife. Review of material excerpted from the Natural Heritage Program Operations Manual indicates that there is concern for several species of fish, primarily darters, in Oswayo Creek and the Allegheny River System into which the Little Genesee Creek drains. Some of these species are on the rare and endangered species list. I suggest that you contact Ms. Rachel Pleuthner at 518-439-7488 for further information as well as for confirmation of any other statements I have made based upon the Natural Heritage Program Operations Manual.

Sincerely,

James K. Pomeroy
Habitat Protection Biologist

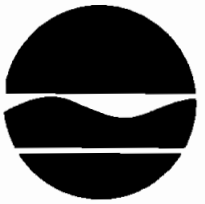
WATER QUALITY REGULATIONS

SURFACE WATER AND GROUNDWATER CLASSIFICATIONS AND STANDARDS

New York State
Codes, Rules and Regulations
Title 6, Chapter X
Parts 700-705



New York State Department of Environmental Conservation

R118

CLASS "B"

Best usage of waters. Primary contact recreation and any other uses except as a source of water supply for drinking, culinary or food processing purposes.

Quality Standards for Class "B" Waters

Items	*Specifications*
1. Coliform.	The monthly median coliform value for 100 ml of sample shall not exceed 2,400 from a minimum of five examinations, and provided that not more than 20 percent of the samples shall exceed a coliform value of 5,000 for 100 ml of sample and the monthly geometric mean fecal coliform value for 100 ml of sample shall not exceed 200 from a minimum of five examinations. This standard shall be met during all periods when disinfection is practiced.
2. pH	Shall be between 6.5 and 8.5.
3. Total dissolved solids.	None at concentrations which will be detrimental to the growth and propagation of aquatic life. Waters having present levels less than 500 milligrams per liter shall be kept below this limit.
4. Dissolved oxygen.	For cold waters suitable for trout spawning, the DO concentration shall not be less than 7.0 mg/l from other than natural conditions. For trout waters, the minimum daily average shall not be less than 6.0 mg/l. At no time shall the DO concentration be less than 5.0 mg/l. For non-trout waters, the minimum daily average shall not be less than 5.0 mg/l. At no time shall the DO concentration be less than 4.0 mg/l.

CLASS "C"

Best usage of waters. The waters are suitable for fishing and fish propagation. The water quality shall be suitable for primary and secondary contact recreation even though other factors may limit the use for that purpose.

Quality Standards for Class "C" Waters

Items	*Specifications*
1. Coliform.	The monthly median coliform value for 100 ml of sample shall not exceed 2,400 from a minimum of five examinations, and provided that not more than 20 percent of the samples shall exceed a coliform value of 5,000 for 100 ml of sample and the monthly geometric mean fecal coliform value for 100 ml of sample shall not exceed 200 from a minimum of five examinations. This standard shall be met during all periods when disinfection is practiced.
2. pH	Shall be between 6.5 and 8.5.
3. Total dissolved solids.	None at concentrations which will be detrimental to the growth and propagation of aquatic life. Waters having present levels less than 500 milligrams per liter shall be kept below this limit.
4. Dissolved oxygen.	For cold waters suitable for trout spawning, the DO concentration shall not be less than 7.0 mg/l from other than natural conditions. For trout waters, the minimum daily average shall not be less than 6.0 mg/l. At no time shall the DO concentration be less than 5.0 mg/l. For non-trout waters, the minimum daily average shall not be less than 5.0 mg/l. At no time shall the DO concentration be less than 4.0 mg/l.

CLASS "D"

Best usage of waters. The waters are suitable for fishing. The water quality shall be suitable for primary and secondary contact recreation even though other factors may limit the use for that purpose. Due to such natural conditions as intermittency of flow, water conditions not conducive to propagation of game fishery or stream bed conditions, the waters will not support fish propagation.

Conditions related to best usage of waters. The waters must be suitable for fish survival.

Quality Standards for Class "D" Waters

Items	*Specifications*
1. pH	Shall be between 6.0 and 9.5.
2. Dissolved oxygen.	Shall not be less than 3 milligrams per liter at any time.
3. Coliform.	The monthly median coliform value for 100 ml of sample shall not exceed 2,400 from a minimum of five examinations and provided that not more than 20 percent of the samples shall exceed a coliform value of 5,000 for 100 ml of sample and the monthly geometric mean fecal coliform value for 100 ml of sample shall not exceed 200 from a minimum of five examinations. This standard shall be met during all periods when disinfection is practiced.

Historical Note

Sec. added by renum. and amd. 701.4, filed July 3, 1985; amd. filed Sept. 20, 1985 eff. 30 days after filing.

701.20 Classes and standards for saline surface waters. The following items and specifications shall be the standards applicable to all New York saline surface waters which are assigned the classification of SA, SB, SC or SD, in addition to the specific standards which are found in this section under the heading of each such classification.

RECEIVED March 9, 1989

MAR 1[illegible]

REGION #8
Regional Supervisor

Ms. Kathy Kirsch
Fish and Wildlife Technician
NYSDEC - Fish and Wildlife Division
6274 East Avon - Lima Road
Avon, New York 14414

Dear Ms. Kirsch:

As discussed during our telephone conversation on March 8, 1989, Recra Envionmental, Inc. is currently conducting a Phase I investigation of the following site:

Sleepy Hollow Campgrounds (Feitshans) (#915136)
Siehl Road
Town of Newstead, Erie County, New York

Although the site is located in Erie County (NYSDEC Region 9), a portion of the area of concern extends into Genesee County (Region 8).

In order to complete a Hazard Ranking System (HRS) evaluation, we request the following information on the above site, for the Genesee County portion only:

- ✓o Location of 5-acre (minimum) coastal wetland, if 2 miles or less. none
- ✓o Location of 5-acre (minimum) fresh-water wetland, if 1 mile or less. wetland map attached
- ✓o Distance to critical habitat of an endangered species or national wildlife refuge, if 1 mile or less. none within 1 mile
- ✓o Distance to national or state park, forest, or wildlife reserve, if 2 miles or less. none within 2 miles

R120

Each site has been located on a road map and the appropriate USGS 7½ minute quadrangle, portions of which are enclosed. If you have any questions, please contact me. We would appreciate your prompt attention to this, as the information is necessary to complete our evaluation of the site. Thank you for your assistance.

Sincerely,

Town of Newstead
Town Hall
P.O. Box 227
Akron, New York 14001

Dear Mr. Folger:

As I mentioned during our telephone conversation on March 21, 1989, Recra Environmental is currently conducting a Phase I investigation of the Sleepy Hollow Campgrounds site located on Siehl Road, Town of Newstead, New York.

We are performing this investigation for the New York State Department of Environmental Conservation pursuant to the requirements of the New York State Superfund Law (Chapter 857 of the Laws of 1982).

This is to confirm our telephone conversation wherein you provided the following information:

- o The facility does not present a <u>significant</u> threat of fire or explosion (no certified threat exists).

We would appreciate if you would review this information, note any necessary corrections, and return a signed and dated copy to indicate your

concurrence. Your prompt attention to this would be appreciated, as the information is necessary to complete our evaluation of the site. Thank you for your assistance.

Sincerely,

Linda J. Clark

14 DESCRIPTION OF SITE IN RELATION TO SURROUNDING TOPOGRAPHY

The site and surrounding area is relatively flat lying, sloping gently to the northwest. The site is largely covered with vegetation, including grasses, weeds & trees. A long and narrow lake (Sleepy Hollow Lake) is located along the eastern boundary. A swampy area (into which the lake drains) lies in the northern portion of the site.

6.0 ASSESSMENT OF DATE ADEQUACY AND RECOMMENDATIONS

6.1 Assessment of Data Adequacy

Data collected during the Phase I Investigation of the Sleepy Hollow Campgrounds site, which were used to develop the Hazard Ranking System (HRS) scores for the site, are considered inadequate in the following areas:

- o Observed Release:
  - No groundwater sampling and analysis have been performed at, or in the vicinity of, the site. Therefore, additional information is necessary to determine groundwater flow patterns and the extent, if any, of contaminant migration from the site.
  - No surface water sampling and analysis have been conducted at the site; therefore, no information is presently available to conclusively assess the impact of the site on this route.
  - As part of this investigation, a preliminary survey was performed using a Century OVA-128GC instrument. Although no organic vapors exceeding background were detected, a complete program is necessary to further assess the impact of the site on this particular route.
- o Waste Characteristics:
  - Limited waste sampling and analytical data have confirmed the presence of some contaminants at the site. However, additional information is necessary to identify all hazardous substances, the outcome of which could increase the final toxicity/ per-

sistence scores. (At present the toxicity/persistence score is 15; maximum score possible is 18). This could effect both the groundwater and surface water route scores, as well as the composite migration route score.

- Additional information is necessary in order to provide an accurate assessment of waste quantity. Scoring was based on the number of drums of waste and contaminated soil reportedly removed from the site and/or observed to be present at the site. These figures do not include any drums which may have contained hazardous materials at the time of disposal (quantity unknown) and have since leaked their contents. (An estimated 100 or more empty drums were reported at the site.)

o Direct Contact:

- Wastes were observed leaking onto the ground surface in both the swampy area to the north, and near Siehl Road in the southern portion of the site. Although soils were removed in the northern area (in 1986), soil sampling and analyses are necessary to further assess the potential impact of the site on the direct contact hazard mode.

6.2 Recommendations

Several data inadequacies exist, as delineated in Section 6.1, which prohibit the computation and support of a final, defensible HRS score. The following activities have been identified for the Phase II Investigation:

o Air Monitoring

- o Geophysical Investigation
- o Subsurface Investigation
- o Monitoring Well Installation
- o Sampling and Analysis

6.2.1 Air Monitoring

Air monitoring conducted during the Phase I site visit did not result in measureable (ie., OVA) air contaminants being identified. However, a further in-depth air monitoring program should be conducted to determine if contaminants are actually migrating from the site via the air route and to assist in the development of a future Health and Safety Plan for field activities.

An initial site perimeter screening should be conducted using an Organic Vapor Analyzer (OVA) and/or an HNu photoionizer.

6.2.2 Geophysical Investigation

After initial assessment of the ambient air quality at the site, a geophysical terrain conductivity investigation should be performed to determine possible presence of buried drums, to characterize the electrical conductivity of the site, and to determine the possible presence of conductive groundwater contaminant plumes. The geophysical information obtained should be used to minimize the number of drill sites, assist in determining the location of monitoring wells, and reduce the risk associated with drilling into unknown terrain and waste.

6.2.3 Subsurface Investigation

In order to obtain additional information concerning possible groundwater contamination originating from the Sleepy Hollow site, a subsurface investigation consisting of drilling 5 test borings should be conducted (Figure 6-1). The borings should be terminated at the upper water bearing zone (approx. 30 feet). Drilling identification and decontamination operations should be conducted in accordance with NYSDEC protocol for Phase II investigations.

6.2.4 Monitoring Well Installation

It is proposed that 5 monitoring wells be installed within the original test boring holes. A field determination should be made as to the placement of the well screens. This determination will be based on the information obtained from soil samples and water level measurements. Well construction and development should be conducted according to NYSDEC protocol for Phase I Investigations.

6.2.5 Sampling and Analysis

As identified in Figure 6-1, it is proposed that several environmental samples be secured to determine the possible existance of contamination. Sampling and analysis should be conducted according to NYSDEC protocol for Phase II investigations. Table 6-1 identifies the proposed analytical parameters for each sample type.

NEW YORK STATE DEPARTMENT OF ENVIRONMENTAL CONSERVATION
DIVISION OF SOLID AND HAZARDOUS WASTE
INACTIVE HAZARDOUS WASTE DISPOSAL SITE REPORT

CLASSIFICATION CODE: _____ REGION: 9 SITE CODE: 915136

NAME OF SITE: Sleepy Hollow Campgrounds (Feitshans)
STREET ADDRESS: Siehl Road
TOWN/CITY: Town of Newstead COUNTY: Erie ZIP: 14001

SITE TYPE: Open Dump X Structure _ Lagoon _ Landfill _ Treatment Pond _
ESTIMATED SIZE: 109 Acres

SITE OWNER/OPERATOR INFORMATION:
CURRENT OWNER NAME: Anthony Latello and Mario Latello
CURRENT OWNER ADDRESS: 146 Sheldon Avenue, Lancaster, NY 14086
OWNER(S) DURING USE: Feitshans and Mauer Trucking, Inc.
OPERATOR DURING USE: Feitshans and Mauer Trucking, Inc.
OPERATOR ADDRESS unknown
PERIOD ASSOCIATED WITH HAZARDOUS WASTE: From 1971 To present

SITE DESCRIPTION:

The site is an active campground located on the north side of Siehl Road in the Town of Newstead, New York. Sleepy Hollow Lake, which is located along the eastern site boundary, drains into a swampy area in the northern portion of the site. In the early 1970s, Feitshans disposed of numerous drums of waste solvents, adhesives and oils generated by F. N. Burt, Inc. of Buffalo, New York. Approximately 50 to 60 drums of wastes were removed in 1981. An additional 17 drums of wastes were observed during an inspection by the NYSDEC in May 1985. Waste sampling conducted by NYSDEC in 1985 detected methylene chloride, trichloroethylene, toluene, chlorobenzene and other volatile organic compounds at relatively high concentrations. In November 1986, 17 drums of wastes and 13 drums of contaminated soil were removed from the site. Ten drums of wastes currently remain on-site. A Phase I Investigation was conducted at this site in 1988-89.

HAZARDOUS WASTE DISPOSED: Confirmed X Suspected _

TYPE	QUANTITY (units)
Waste solvents, adhesives, oils, and other liquids and sludges	77 drums of waste material (+13 drums of contaminated soil removed from site).

SITE CODE: 915136

ANALYTICAL DATA AVAILABLE:

Air _ Surface Water _ Groundwater _ Soil _ Sediment _ None _
*Waste sampling conducted

CONTRAVENTION OF STANDARDS:

Groundwater _ Drinking Water _ Surface Water _ Air _

LEGAL ACTION:

TYPE: Order on Consent in 1986 State X Federal _
STATUS: In Progress _ Completed X

REMEDIAL ACTION:

Proposed _ Under Design _ In Progress _ Completed X
NATURE OF ACTION: Drums containing wastes & contaminated soil were removed under Consent Order.

GEOTECHNICAL INFORMATION:
SOIL TYPE: Pa (Palms Muck); Pu (gravel); AmA & AmB, & others (silty loam to fine gravelly loam)
GROUNDWATER DEPTH: approx. 5 feet.

ASSESSMENT OF ENVIRONMENTAL PROBLEMS:

Site has potential to impact groundwater and surface water (including Sleepy Hollow Lake and unnamed tributaries of Ellicott Creek).

ASSESSMENT OF HEALTH PROBLEMS:

Medium	Contaminants Available	Migration Potential	Potentially Exposed Population	Need For Investigation
Air				
Surface Soil				
Groundwater				
Surface Water				

Health Department Site Inspection Date: _____

Municipal Waste ID: _____

ICS ID: _____

SPEDES ID: _____

Part (§§ 663.1-663.11) filed May 20, 1980; for effective date see § 663.11.

Section 663.1 Purposes. (a) It is the public policy of the State, as set forth in the Freshwater Wetlands Act, to preserve, protect and conserve freshwater wetlands and the benefits derived therefrom, to prevent the despoliation and destruction of freshwater wetlands, and to regulate use and development of such wetlands to secure the natural benefits of wetlands, consistent with the general welfare and beneficial economic, social and agricultural development of the State. It is the purpose of this Part to implement that policy by establishing regulations that:

(1) define the procedural requirements to be followed in undertaking different activities in wetlands and in areas adjacent to wetlands;

(2) establish standards governing the issuance of permits by the department pursuant to the act; and

(3) govern the department's implementation of the act.

(b) The system of wetlands classification upon which this Part is based is presented in Part 664 of this Title. That Part, which is administered by the department, describes the benefits of wetlands cited in the act and the characteristics associated with them.

(c) The statewide minimum land-use regulations for freshwater wetlands are contained in section 665.7(g) of this Title. They are set forth in section 663.4(d) of this Part for the convenience of permit applicants, and will be referenced in this Part where appropriate.

Historical Note

Sec. filed May 20, 1980; amd. filed Sept. 9, 1985 eff. Sept. 9, 1985. Added (c).

663.2 Definitions. (a) *Act* means the Freshwater Wetlands Act (article 24 and title 23 of article 71 of the Environmental Conservation Law).

(b) *Adjacent area* means those areas of land or water that are outside a wetland and within 100 feet (approximately 30 meters), measured horizontally, of the boundary of the wetland. However, the department may establish an adjacent area broader than 100 feet (approximately 30 meters) where necessary to protect and preserve a wetland, as set forth in subdivision 24-0701.2 of the Act and pursuant to Part 664 of this Title.

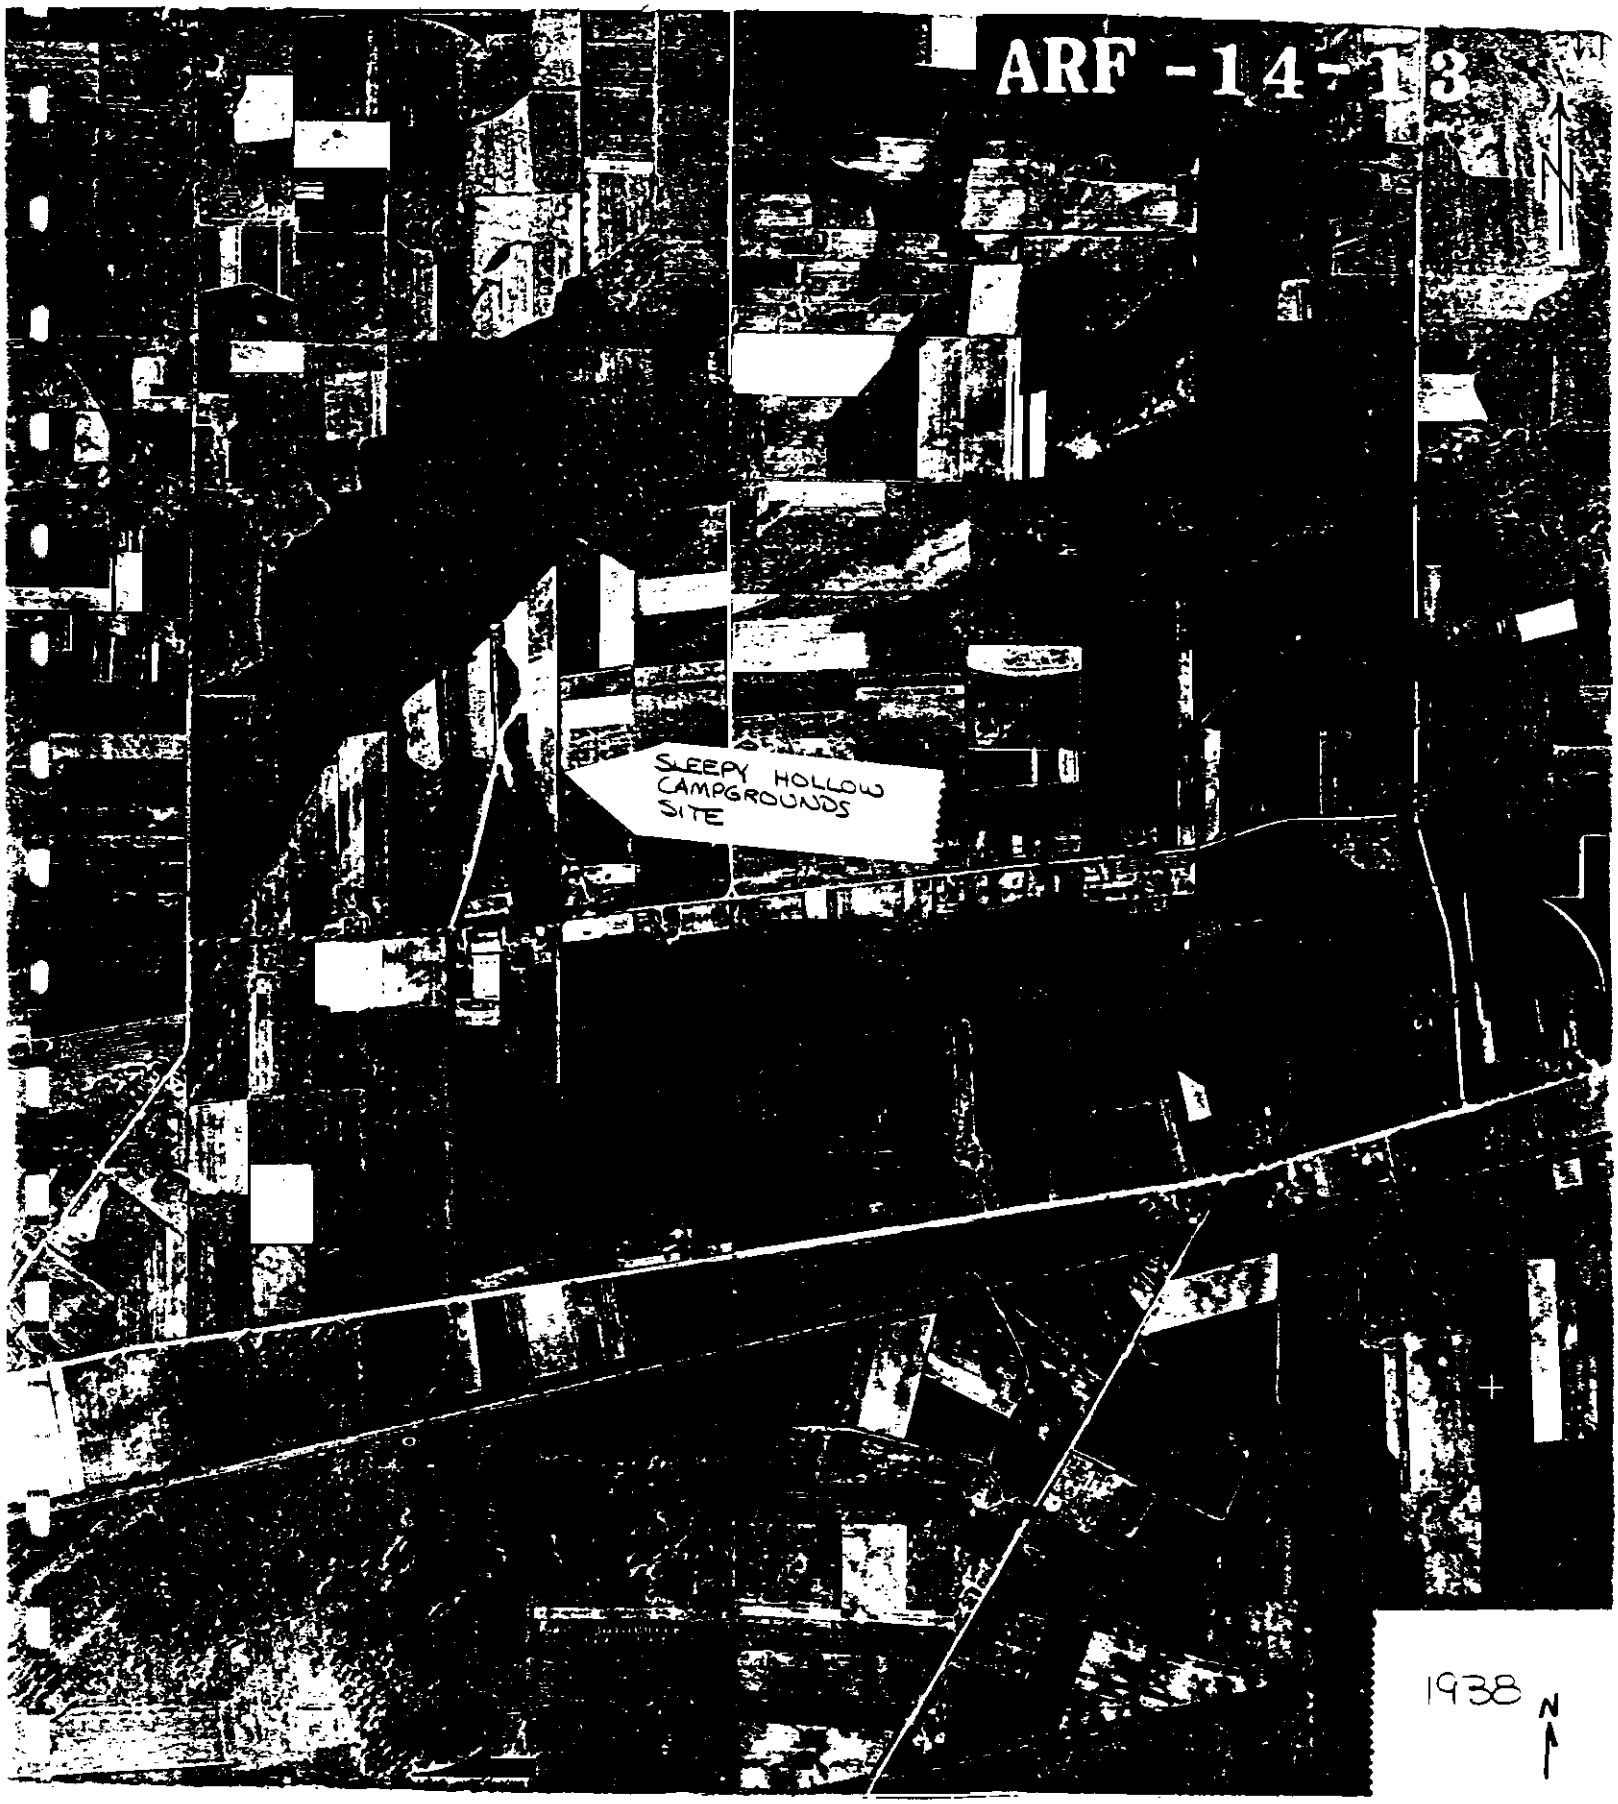
(c) *Agricultural activity* means:

(1) the activity of an individual farmer or other landowner in:

(i) grazing and watering livestock;

(ii) making reasonable use of water resources for agricultural purposes;

R139



R131

mits and letters of permission. (a) A person re ires a permit or letter of permission, as , ist meet the standards for permit issuance ission prior to commencing that activity. The vity will comply with the policies and provisions he pplicant.

ed nly if the commissioner has determined that lly alter or impair the functions or benefits of a as "LP" in section 665.7(g) of this Title, the ns or freshwater wetlands, and as "L" in the ar g a letter of permission, the commissioner ity complies with the limits of the activities as e regulations contained in Part 665 of this Title.

ig permit, the commissioner shall apply the i l subdivision (e) of this section in conjunction /etland as indicated on the official freshwater and as established in Part 664 of this Title. In dic r will consider the effects of the proposed s.

on (e) of this section, a determination of compati- enefits lost are the criteria for decisionmaking. be sed for all activities listed in the minimum o is Part that carry a compatibility category this Title and in section 663.4(d). Activities and d use regulations or in the procedures table in st the three-part compatibility test. Activities /e en determined under the minimum land use their compatibility or weighing analysis need be permission as defined in section 663.2(r). Activi- o not require either a permit or letter of permis- ction 663.4(d) to assist the department and oc ures.

lbility given in the chart in subdivision (e) of this ar rds need apply, regardless of the wetland's itl it conditions, may be issued for the proposed e part test, the statewide minimum land use hem that has been duly adopted according to the he basis for determinations of compatibility.

r et all three tests of compatibility or if it is for a permit to be issued, the activity must meet in the chart in subdivision (e) of this section for ou be affected by the proposed activity.

n quest for a letter of permission exceeds the ed in sections 665.7(g) and 663.4(d), a letter of the proposed action must be tested for compati- v on (e) of this section and a permit application a l this Part. If there is question or doubt as to re iewed for compatibility with the three-part three parts of the test, the action must be treated ighed according to the standards identified in

(e) *Standards for Permit Issuance*

(1) *Compatibility.* These three tests are to be used to determine the compatibility of all activities identified as P(C) or P(N) in section 663.4(d) of this Part or for any actions not listed in section 663.4(d). If all three of the following tests of compatibility are met, no other weighing standards need be met, regardless of the wetland class. A permit, with or without conditions, may be issued for a proposed activity on a wetland of any class or in a wetland's adjacent area if it is determined that the activity (i) would be compatible with preservation, protection and conservation of the wetland and its benefits, and (ii) would result in no more than insubstantial degradation to, or loss of, any part of the wetland, and (iii) would be compatible with the public health and welfare.

(2) *Weighing.* These weighing standards must be applied to all activities identified as P(X) in section 663.(d) of this Part, and to all those activities listed as P(C) of (N) in section 663.4(d) or not listed in section 663.4(d) that do not meet the three tests of compatibility listed in section 663.5(e)(1). If the proposed activity is listed as (X) or cannot meet the three tests for compatibility, then a permit may be issued only if the proposed activity meets each of the standards below for the class of wetland affected:

For wetland Classes I, II, III and IV, the proposed activity must be compatible with the public health and welfare, be the only practicable alternative that could accomplish the applicant's objectives and have no practicable alternative on a site that is not a freshwater wetland or adjacent area.

For wetland Classes I, II and III, the proposed activity must minimize degradation to, or loss of, any part of the wetland or is adjacent area and must minimize any adverse impacts on the functions and benefits that the wetland provides.

For wetland Class IV, the proposed activity must make a reasonable effort to minimize degradation to, or loss of, any part of the wetland or its adjacent area.

Class I wetlands

Class I wetlands provide the most critical of the State's wetland benefits, reduction of which is acceptable only in the most unusual circumstances. A permit shall be issued only if it is determined that the proposed activity satisfies a compelling economic or social need that clearly outweighs the loss of or detriment to the benefit(s) of the Class I wetland.

Class II wetlands

Class II wetlands provide important wetland benefits, the loss of which is acceptable only in very limited circumstances. A permit shall be issued only if it is determined that the proposed activity satisfies a pressing economic or social need that clearly outweighs the loss of or detriment to the benefit(s) of the Class II wetland.

Class III wetlands

Class III wetlands supply wetland benefits, the loss of which is acceptable only after the exercise of caution and discernment. A permit shall be issued only if it is determined that the proposed activity satisfies an economic or social need that outweighs the loss of or detriment to the benefit(s) of the Class III wetland.

Class IV Wetlands

Class IV wetlands provide some wildlife and open space benefits and may provide other benefits cited in the act. Therefore, wanton or uncontrolled degradation or loss of Class IV wetlands is unacceptable. A permit shall be issued for a proposed activity in a Class IV wetland only if it is determined that the activity would be the only practicable alternative which could accomplish the applicant's objectives.

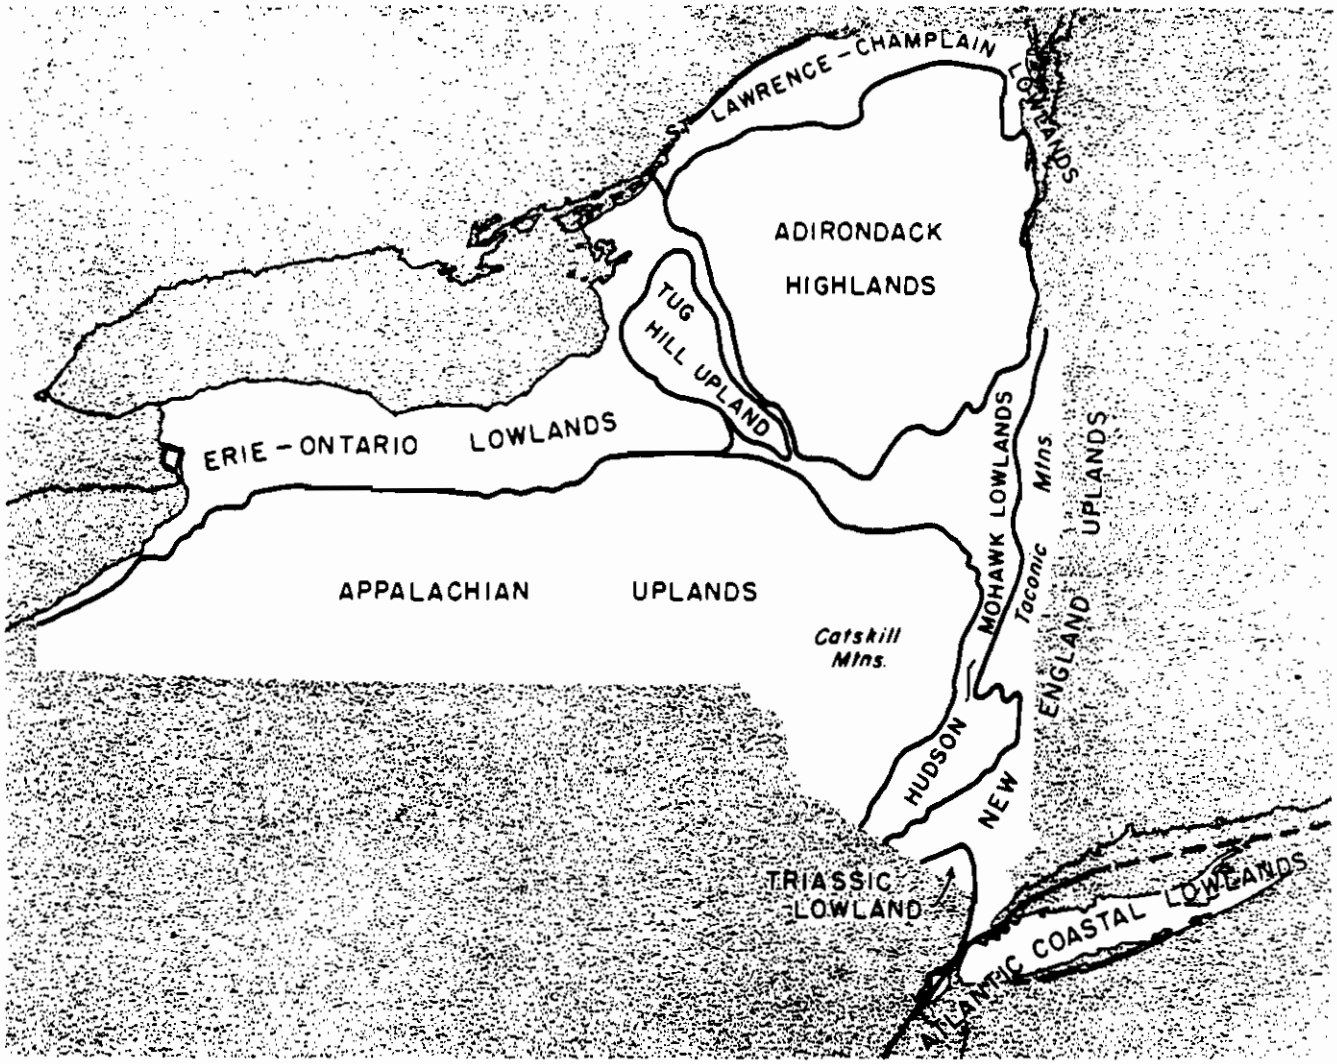

FIGURE 19. Physiographic provinces of New York, based on relief and geology (Modified after G. B. Cressey, 1952)

Cenozoic Era

PHYSIOGRAPHIC PROVINCES AND TERTIARY HISTORY

The physiographic provinces of New York are shown in figure 19. Modern landscapes of the State were shaped largely during the Cenozoic Era, the most recent 65 million years of geologic history. Although the overall features later would be modified and blurred by glaciation, the broad outlines of modern mountain, valley, and plain first were carved by the unrelenting rush of water to the earlier Cenozoic seas.

The long sequence of erosion presumably began with the arching of the Jurassic Fall Zone erosion surface in mid-Cretaceous time. As its eastern flank dipped beneath the encroaching Atlantic Ocean to receive Coastal Plain deposits, the axis domed sufficiently to initiate the sculpture of the Appalachians and Adirondacks. Few, if any of today's land forms can be traced so far back, however. Most researchers believe that all the exposed remnants of the dissected Fall Zone surface were obliterated by subsequent erosion.

South of New York, at least a partial record of Tertiary geology persists in the Coastal Plain deposits. In addition to a sedimentary record, datable igneous intrusions cut rocks of varying degrees of deformation in the western states. But in New York, no such tangible evidence of Cenozoic events exists. The Coastal Plains sediments derived from the long-continued degradation of New York and New England now rest on the Continental

R142

Shelf, beneath many fathoms of water. Because of a relatively recent tilting of the coastline about a northwest-southeast axis near New York City, the Coastal Plain has been raised south of New York; east and north of the city, all but the Long Island Cretaceous has been depressed below sea level.

Since exposed Tertiary sedimentary deposits are absent in New York, its geological history must be reconstructed from the only data available, the present physiographic features of the State. In an area as small as New York, where climate does not vary significantly, land forms have been determined primarily by geology. Characteristic differences between the physiographic provinces have resulted from the ways in which rocks of differing lithologies and structures have reacted to the erosional force of the Cenozoic. Thus, while many authorities have classified New York's physiographic provinces in various ways, all are more or less in agreement as to the outlines of the major provinces; they differ mainly in the names applied to the provinces. Those used here were proposed by George B. Cressey (1952, personal communication, J.G. B.). From north to south, the physiographic provinces of New York are:

St. Lawrence-Champlain Lowlands

New York's northernmost province includes the St. Lawrence River Valley (northeast of the Thousand Islands), the low hills south of the river valley, and the Lake Champlain Valley (figure 19). The underlying rocks —Cambrian and Ordovician sandstones, dolomites, and limestones—dip gently away from the Adirondacks. Relief is approximately 100 feet. Streams draining the northern and eastern slopes of the Adirondacks flow across the province. The shoreline of Lake Champlain is largely controlled by north-south and east-west faults which have chopped the Paleozoic sandstones and carbonates into large blocks.

Adirondack Highlands

The highest mountains in New York occur in the Adirondack Highlands, especially in the High Peaks region; the High Peaks, in the east-central part of the province, are underlain by anorthosite, which is highly resistant to erosion. Two peaks—Mt. Marcy and Mt. Algonquin—are over 5,000 feet in elevation, and many exceed 4,000 feet. Average relief in the Adirondack Highlands is 2,000 feet. North, west, and south of the High Peaks area, elevations decrease gradually; east to the Champlain Lowland, the slope is more abrupt.

The Adirondacks are transected by long, northeast-southwest lineaments, representing shear zones or major faults. The lineaments frequently control drainage and the shape of land forms. Many lakes follow geologic contacts, or are confined to valleys along weak metasedimentary rocks. Because glacial deposits have clogged the normal radial drainage, lower areas are dotted with lakes, ponds, and swamps.

Tug Hill Upland

The Tug Hill, an isolated upland in the eastern part of the Erie-Ontario Lowlands, is probably the most desolate area of the State. Elevation is 1,800 to 2,000 feet, and relief is very low. The Tug Hill results from a resistant cap rock of Oswego Sandstone (an Ordovician sedimentary quartzite), resting on a thick series of sandy shales. These, in turn, overlie Trenton and Black River limestones, which form a flight of rock terraces along the west side of the Black River Valley. The low slope of the cap rock and the thin cover of glacial deposits have caused poor drainage and many swamps.

Erie-Ontario Lowlands

This province encompasses the relatively low, flat areas lying south of Lake Erie and Lake Ontario and extending up the Black River Valley. From the lake levels of 570 feet and 244 feet, respectively, the land rises gently eastward and southward. The maximum elevation (1,000-1,500 feet) occurs along the Portage Escarpment, the boundary with the Appalachian Uplands to the south. Particularly in the Ontario Lowland, east-west escarpments are formed by the Onondaga Limestone and Lockport Dolomite. (The Lockport is the cap rock of Niagara Falls and the falls of the Genesee River at Rochester.) The simple erosional topography has been modified substantially by glacial deposition of drumlin fields, recessional moraines, and shoreline deposits.

Hudson-Mohawk Lowlands

The general topography of the Hudson-Mohawk Lowlands resulted from erosion along outcrop belts of weak rocks. In the Mohawk Lowlands, the outcrop belts lie between the Adirondacks and the Helderberg Escarpment; for the Hudson, they lie between the Catskills and the metamorphosed shale hills of the Taconics. Most of the province has low elevation and relief. It is underlain primarily by Ordovician shales which have been exposed by the southward and westward stripping off of Silurian and Devonian limestones.

EXPLANATION

al — Recent deposits
Generally confined to floodplains within a valley,
oxidized, non-calcareous, fine sand to gravel,
in larger valleys may be overlain by silt,
subject to frequent flooding, thickness 1-10 meters.

alf — Alluvial fan
Fan shaped accumulations,
poorly stratified silt, sand and boulders,
at the foot of steep slopes,
generally permeable.

co — Colluvium
Mixture of sediments,
deposited by mass wasting,
thickness generally 1-5 meters.

cof — Colluvial fan
Fan shaped accumulation,
mixture of sediments,
at mouths of gullies,
thickness generally 1-5 meters.

cd — Colluvial diamicton
Mixture of sediments,
unique to region beyond Wisconsinan glacial limit,
rebedded saprolite and glacial debris,
may be old (Illinoian) drift,
homogenized by varying degrees of colluviation,
bedrock may sporadically crop out or be within 1-3 meters of the surface.

pm — Swamp deposits
Peat-muck, organic silt and sand in poorly drained areas,
un-oxidized,
may overlay marl and lake silts,
potential land instability,
thickness generally 2-20 meters.

lb — Lacustrine beach
Generally well sorted sand and gravel,
stratified, permeable and well drained,
deposited at a lake shoreline,
generally non-calcareous,
may have wave-winnowed lag gravel,
thickness variable (1-5 meters).

ld — Lacustrine delta
Coarse to fine gravel and sand,
stratified, generally well sorted,
deposited at a lake shoreline,
thickness variable (3-15 meters).

lsc — Lacustrine silt and clay
Generally laminated silt and clay,
deposited in proglacial lakes,
generally calcareous,
potential land instability,
thickness variable (up to 100 meters);

R149

deposited at a lake shoreline,
thickness variable (3–15 meters).

lsc — Lacustrine silt and clay
Generally laminated silt and clay,
deposited in proglacial lakes,
generally calcareous,
potential land instability,
thickness variable (up to 100 meters);
stipple overprint where bedrock is within 1–3 meters of the surface.

ls — Lacustrine sand
Sand deposits associated with large bodies of water,
generally a near-shore deposit or near a sand source,
well sorted, stratified,
generally quartz sand,
thickness variable (2–20 meters).

og — Outwash sand and gravel
Coarse to fine gravel with sand,
proglacial fluvial deposition,
well rounded and stratified,
generally finer texture away from ice border,
may be calcreted beyond Wisconsinan glacial limit,
thickness variable (2–20 meters).

fg — Fluvial gravel
Same as outwash sand and gravel,
except deposition farther from glacier,
age uncertain.

k — Kame deposits
Includes kames, eskers, kame terraces, kame deltas,
coarse to fine gravel and/or sand,
deposition adjacent to ice (if at ice margin, relief is below elevation of associated outwa
lateral variability in sorting, coarseness and thickness,
may be calcreted beyond Wisconsinan glacial limit,
thickness variable (10–30 meters).

usda — Undifferentiated stratified drift assemblage
Dominantly clay, silt and sand,
limited gravel and diamicton,
stratification includes undisturbed and deformed laminations,
ice contact structures,
lenticular, discontinuous bodies of gravel and flow till,
may represent dead-ice, disintegration and local ice-contact lake deposits in ice-margin
environments,
thickness variable (3–30 meters).

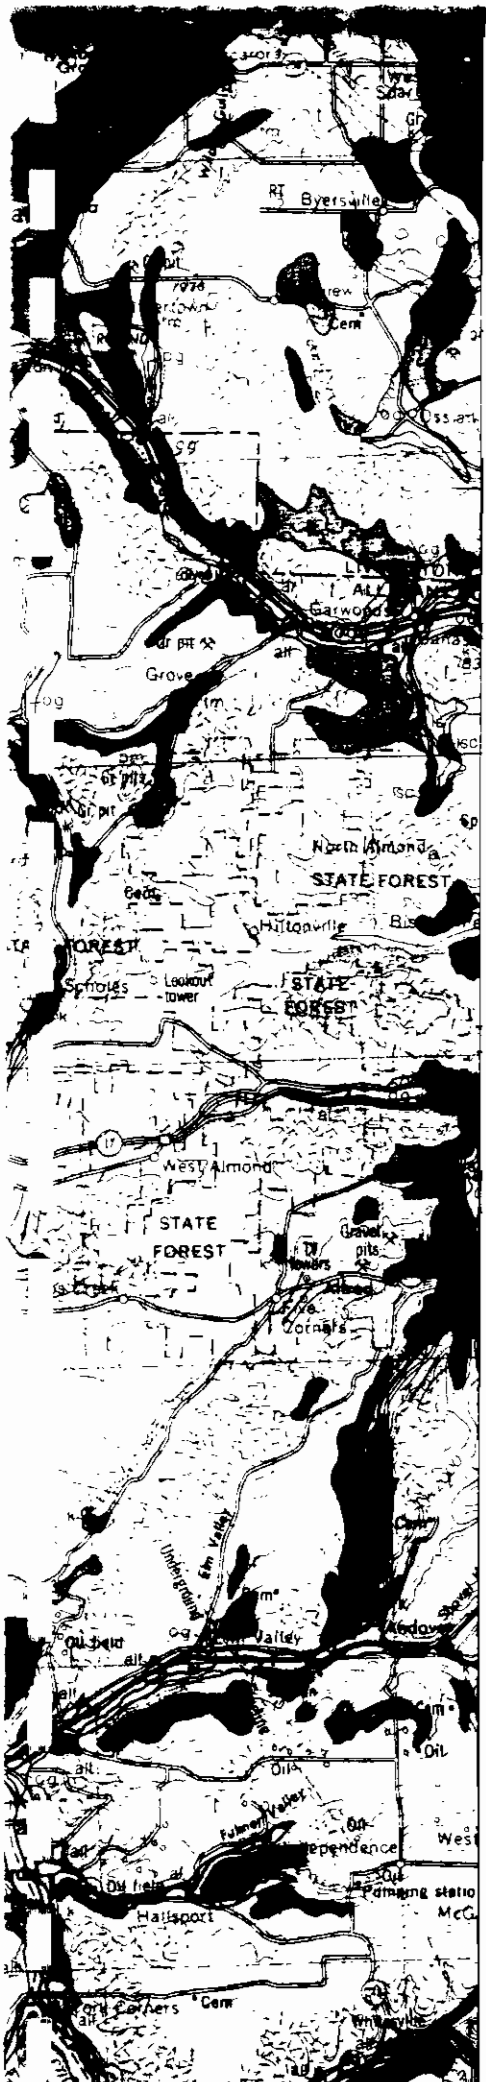
km — Kame moraine
Variable texture (size and sorting) from boulders to sand,
deposition at an ice margin during deglaciation,
relief is above elevation of associated outwash,
locally cemented with calcareous cement,
thickness variable (10–30 meters).

tm — Till moraine
More variably sorted than till,
generally more permeable than till,
deposition adjacent to ice,
more variably drained,
may include ablation till,
thickness variable (10–30 meters).

t — Till
Variable texture (e.g. clay, silt-clay, boulder clay),
usually poorly sorted diamict,
deposition beneath glacier ice,
relatively impermeable (loamy matrix),
variable clast content — ranging from abundant well-rounded diverse lithologies
relatively angular, more limited lithologies in upland tills, tends to be sandy in areas
or sandstone,
potential land instability on steep slopes,
thickness variable (1–50 meters).

r — Bedrock
Exposed or generally within 1 meter of the surface.

R150



above elevation of associated outwash,
locally cemented with calcareous cement,
thickness variable (10–30 meters).

tm — Till moraine
More variably sorted than till,
generally more permeable than till,
deposition adjacent to ice,
more variably drained,
may include ablation till,
thickness variable (10–30 meters).

t — Till
Variable texture (e.g. clay, silt-clay, boulder clay),
usually poorly sorted diamict,
deposition beneath glacier ice,
relatively impermeable (loamy matrix),
variable clast content — ranging from abundant well-rounded diverse lithologies in valley r
relatively angular, more limited lithologies in upland tills, tends to be sandy in areas underlain by
or sandstone,
potential land instability on steep slopes,
thickness variable (1–50 meters).

r — Bedrock
Exposed or generally within 1 meter of the surface.

Bedrock stipple overprint
Bedrock may be within 1–3 meters of the surface,
may sporadically crop out,
variable mantle of rock debris and glacial till.
