1. Introduction

This Work Plan has been developed on behalf of the National Fuel Gas Distribution Corporation (National Fuel) to describe the planned approach for conducting a Remedial Investigation (RI) and Feasibility Study (FS) in the Lower Scajaquada Creek area in Buffalo, New York, identified as the Lower Scajaquada Creek Operable Unit (Scajaquada Creek OU) (Figure 1). The RI focuses primarily on the areas south of the West Avenue bridge and includes upland areas bordering the Lower Scajaquada Creek and the Scajaquada Creek Slip area (also known as the Inlet (Figure 2)).

The New York State Department of Environmental Conservation (NYSDEC) issued an Order on Consent on June 23, 2021, requiring National Fuel to complete a Site Characterization (SC) in response to the discovery of dense non-aqueous phase liquid (DNAPL) believed to originate from historic manufactured gas plant (MGP) operations known as the Iroquois Gas/Westwood Pharmaceutical Terrestrial/Riparian Site that produced water-gas tar (Figure 3). The MGP source area was remediated over two decades ago, and engineering controls were installed to contain and remove mobile DNAPL in areas north of the West Avenue bridge.

The SC investigation (GEI, October 2022) identified DNAPL downstream from the West Avenue bridge in soils above an area-wide, red-brown clay layer, and in shallow creek sediment in the Inlet near the discharge from a City of Buffalo Pumphouse. The RI will determine if the presence of DNAPL above the clay layer in downgradient areas is associated with historic releases (pre-2000) prior to implementation of engineering controls at the Iroquois Gas/Westwood Pharmaceutical Terrestrial/Riparian Sites. Additionally, the SC investigation revealed comingled contamination in groundwater, soils, and sediments from non-MGP sources, including urban runoff, Combined Sewer Overflow (CSO) discharges, and releases from historic industries that operated in the area since the late 1800s, some of which are in the NYSDEC Brownfield Cleanup Program (BCP).

The SC Report recommended a remedial investigation to assess the extent of DNAPL and an evaluation of remedial alternatives through a Feasibility Study. The NYSDEC agreed with this conclusion and supported National Fuel's participation as a partner in an existing Project Agreement (PA) between the NYSDEC and the US Environmental Protection Agency (USEPA) under the Great Lakes Legacy Act (GLLA) program to address contamination in the Black Rock Canal and Scajaquada Creek.

1.1. GLLA Program and Niagara River Area of Concern

The GLLA program is a vital initiative aimed at addressing contaminated sediment in Areas of Concern (AOCs) within the Great Lakes Basin. Scajaquada Creek is a tributary of the Niagara River and discharges to the Black Rock Canal. Scajaquada Creek and the Black Rock Canal are located in the Niagara River AOC. On October 23rd, 2020 EPA entered into a GLLA Project agreement to address sediment contamination in Scajaquada Creek and the Black Rock Canal. The 2020 Project Agreement between USEPA and NYSDEC (NYSDEC Contract No. C011665) was amended in 2024 to add National Fuel as a non-federal sponsor and incorporate work previously completed by National Fuel from 2021 to 2023 related to the Site Characterization (SC, October 2022), Interim Remedial Measures (IRMs, March 2023) completed to mitigate contamination discharge from a City of Buffalo Pumphouse on Niagara Street, and the

completion of the Scajaquada Creek Remedial Investigation (RI) and Feasibility Study (FS). The Project Agreement was fully executed on January 6, 2025.

National Fuel is the Lead Partner for the Scajaquada Creek Operable Unit (OU) SC, IRMs, RI and FS, while the USEPA is the Lead Partner responsible for completing a Feasibility Study for the Black Rock Canal OU. The RI described in this workplan details work that will be performed by National Fuel in the Scajaquada Creek OU. NYSDEC will also conduct separate investigations during a Site Characterization Study in the Lower Scajaquada Creek OU to determine if there are existing sources affecting creek sediments from historic activities unrelated to former MGP operations. Findings from NYSDEC's SC are anticipated to be considered in the RI/FS report to be completed by National Fuel.

1.2. Scajaquada Creek OU RI/FS Objectives and Scope of Work Summary

The remediation of contaminated sediments in the Black Rock Canal and Scajaquada Creek is expected to contribute to the removal of the following Beneficial Use Impairments (BUIs) in the Niagara River Area of Concern:

- *Restrictions On Fish and Wildlife Consumption*,
- *Degradation Of Benthos*,
- *Bird or Animal Deformities or Reproductive Problems*, *and*
- *Degradation of Fish And Wildlife Populations*.

Additionally, these remedial efforts will promote recreational opportunities in Scajaquada Creek and Black Rock Canal.

Remedial investigation and evaluation of remedial alternatives through a feasibility study are necessary to support the design and completion of remedial actions for the Scajaquada Creek Operable Unit (OU). During scoping discussions, National Fuel and NYSDEC agreed on a framework (dated May 5, 2022) to implement a phased investigation and interim remedial measures (IRM) approach under a Project Agreement with the USEPA through the GLLA Program. This included completing the Site Characterization (SC), implementing an IRM to mitigate DNAPL entry into the storm sewer and Pumphouse and minimize re-suspension of contaminated sediments during discharge, and completing an RI and FS for the Lower Scajaquada Creek area.

As described in the May 2022 Framework for the Phased Scope of Work and the Scope of Work (SOW) for the GLLA Project Agreement, the following work is required to complete the RI and FS for the Lower Scajaquada Creek OU:

- Develop RI/FS Work Plan
- Delineate the vertical/horizontal extent of NAPL/DNAPL and associated dissolved phase contamination
- Assess the effectiveness of containment remedies previously installed upstream of West Avenue
- Assess the fate and transport of dissolved and non-aqueous phases of contamination

- Evaluate potential utility/infrastructure migration pathways to the extent feasible, without causing damage or risking worker safety during investigation
- Evaluate potential exposure pathways
- Evaluate existing sediment chemistry and sediment depth data to define the lateral and vertical extent of contamination to support volume estimates for the FS.
- Identify data gaps necessary to successfully complete the feasibility study
- Identify and evaluate potential structural and hydraulic limitations and any other physical factors affecting the remedial decision-making process. For the Inlet, the evaluation should include, at a minimum, the eastern wall adjacent to 1660 Niagara Street and the I-190 expressway piers
- Obtain additional data on the area-wide clay layer below the Inlet
- Prepare a data usability report
- Summarize RI findings with tables and figures
- Evaluate bioavailability of contaminants, as appropriate
- Develop remedial action objectives (RAOs) based on New York State sediment guidance values and other applicable sediment screening values that are consistent with AOC Beneficial Use Impairments (BUIs) and other appropriate considerations including planned future uses of adjacent areas
- Identify options for remedial actions that have the potential to fulfill the RAOs
- Identify the necessary technologies and general process options for implementing each of the general remedial actions
- Estimate costs associated with each remedial action option
- Based on comparative analysis of the remedial action options, and consultation with project stakeholders, select a preferred remedial action
- Evaluate historical sources of contamination to sediments, as well as ongoing sources of contamination that have the potential to re-contaminate the sediments after remediation
- Meet with NYSDEC/USEPA to discuss progress and management of agreement/contract activities
- Prepare Draft and Final Reports that summarize the findings of RI/FS
- Conduct a public meeting to present FS findings and incorporate comments received by the public into final FS.

As described in Section 1.1, the NYSDEC will be undertaking separate Site Characterization investigation in the Lower Scajaquada Creek OU as part of its cost-sharing responsibilities under the GLLA Project Agreement. This investigation is intended to delineate the nature and extent of Chlorinated Volatile Organic Compounds (CVOCs) on the property at 1660 Niagara Street and ascertain whether CVOC contamination from the site is a source of sediment contamination.

1.3. Work Plan Organization

This RI/FS Work Plan outlines the project objectives, provides background information on historical Site use and current conditions, identifies areas of environmental concern at the Site and adjacent areas, and describes the strategies and methodologies to be implemented during the RI and FS. The remainder of this RI/FS Work Plan includes the following:

- Section 2 – Site Description: Summarizes relevant background information including site location and surrounding land use, topography, geology/hydrogeology, surface water hydrology, wetlands, and waterways.
- Section 3 – Site Investigation Summary and Known Extent of DNAPL: Summarizes the SC investigation findings and known extent of DNAPL that supports the scope of the RI and FS activities.
- Section 4 – Interim Remedial Measures (IRMs): Describes IRMs completed at the Pumphouse to date and contamination that may remain.
- Section 5 – Initial Conceptual Site Model (CSM) and Data Gaps: Introduces the initial CSM, which identifies potential sources of contamination, release mechanisms, exposure media, and exposure routes based on current and potential future site use. The CSM presented in this section is preliminary and will be refined based on data from the RI. This section also identifies data gaps to be addressed in the RI and FS based on available prior studies and data needs.
- Section 6 – Remedial Investigation Scope of Work: Describes work to be performed during the RI for the Scajaquada Creek OU, including management of investigation derived waste (IDW). Additionally, this section references relevant documents including the Field Sampling Plan (FSP) describing field methods, the Quality Assurance Project Plan (QAPP) with data management and submission requirements, and the project Health and Safety Plan (HASP).
- Section 7 – RI Data Summary Report: Provides an outline of the Data Summary Report.
- Section 8 – Qualitative Human Health Exposure Assessment – Describes the performance of risk evaluation for human health.
- Section 9 – Fish and Wildlife Resource Impact Analysis – Describes the performance of the ecological resource characterization and ecological impact assessment per NYSDEC guidance.
- Section 10 – Feasibility Study: Describes the tasks associated with preparing the FS that will develop and assess various potential remedial action alternatives.
- Section 11 – Schedule: Outlines the proposed sequence and timing of RI/FS tasks through preparation and submittal of the FS Report.
- Section 12 – References

Various tables, figures, and appendices are also attached to this document and referenced throughout the text where appropriate.

2. Scajaquada Creek OU Description

A comprehensive overview of the Scajaquada Creek OU was prepared as part of the Site Characterization Report (GEI, October 2022). This report is provided in Appendix A and describes:

- historical and current land uses,
- contamination identified at several nearby properties in NYSDEC's Brownfield Cleanup Program (BCP) and other historic industrial properties with documented environmental impacts,
- geologic and hydrogeologic conditions,
- contaminant impacts to various media (soil, groundwater, creek sediments), and hydrologic conditions in Scajaquada Creek.

This information is summarized below and described in Section 3.

2.1. Area Description and Land Use

The Scajaquada Creek OU encompasses the lands adjacent to Scajaquada Creek, extending from south of the West Avenue Bridge to the creek's mouth where it discharges into the Black Rock Canal. The Scajaquada Creek Slip Area (Inlet Area), which was historically the creek's discharge location before being blocked during the construction of the I-190 New York State Thruway in the 1950s, is also part of the OU.

Upland areas include properties owned by the former Penn Central Railroad (now CSX Transportation), New York State, and City of Buffalo that are used for transportation and infrastructure corridors including a railroad passenger and freight train corridor, the NYS Thruway I-190, the Route 198 Scajaquada Expressway, and City of Buffalo roadways (West Avenue, Tonawanda Street, and Niagara Street). The upland areas also include privately owned properties, many of which were former industrial properties with environmental concerns. Some of those properties have been investigated, remediated, and/or developed for reuse under the NYSDEC Brownfield Cleanup Program (BCP) or the former Voluntary Cleanup Program (VCP) (Figure 3). Most properties in this area are zoned for commercial/industrial use.

2.2. Topography

The ground surface in the Lower Scajaquada Creek area has low topographic relief and gently slopes toward the Creek and Inlet. As shown in Figure 2, the highest elevations in the area are approximately 600 feet (NAVD 88) in the upland areas east of West Avenue. The elevation decreases to about 580 feet (NAVD 88) near the tops of the banks adjacent to the Creek. The creek bank then slopes steeply to the water's edge in most locations, reaching an elevation of 570 to 572 feet (NAVD 88), which corresponds to the typical surface water elevation of the creek.

2.3. Geology and Hydrogeology

2.3.1. Geology

The geology of the Lower Scajaquada Creek area has been characterized through logging of soil and sediment borings. During the 2021/2022 Site Characterization and 2022 City of Buffalo Pumphouse pre-design for the IRM, nine soil and nine sediment borings were completed. Additional data from over a dozen soil borings performed by other parties supported the geologic interpretation.

The geology consists of a layer of fill overlying native soils of alluvial and lacustrine origin. The fill thickness in borings closest to the creek and Inlet ranged from 10 to 19.5 feet and decreased with distance from the creek's edge. The fill materials varied in composition, including reworked red-brown clay soils, black silty sand, and anthropogenic materials like foundry sands, concrete, cinders, and wood debris.

Below the fill, alluvial deposits were identified, becoming coarser with depth. These deposits typically consisted of dark gray to black silt or sand with occasionally decayed woody materials. Deeper alluvium transitioned to black silty sand and fine gravel with wood pieces and shells (gastropods). The alluvium, associated with historic creek sediment deposition, was generally free of anthropogenic materials and ranged from 1 to 22.5 feet in thickness. The thickest alluvium layers were found near the Pumphouse and properties at 1660, 1654, and 1626 Niagara Street, where the historic creek channel had scoured the area-wide red-brown clay layer before depositing the alluvium. The alluvium thickness decreased with distance from the current creek channel.

The bottom of the alluvium was marked by a sharp contact with an area-wide red-brown clay layer which was encountered in all borings completed in the Lower Scajaquada Creek area. The red-brown clay's composition was consistent across borings, and its surface elevation sloped toward the creek in most areas. However, near Niagara Street, the surface elevation of the clay surface is deeper on the north of the Inlet suggesting that the ancestral channel of Scajaquada Creek was situated farther north than its current location. Also, as shown in Figure 4, the width of the alluvial sediments indicates the creek channel was historically broader near the intersection of Niagara and Tonawanda Streets.

Two soil borings advanced to bedrock during the 1995 Remedial Investigation (RI) at the Westwood Former MGP Terrestrial Site and 1956 NYSDOT borings completed for design of the route NY-198 Scajaquada Expressway and I-190 Thruway encountered bedrock at elevations of approximately 500 and 520 feet msl indicating that the area-wide red-brown clay is at least 50 feet thick throughout the Lower Scajaquada Creek area. The boring logs indicate the presence of a sandy till layer above the bedrock. Boring logs are included with the Site Investigation Report (Appendix A).

Within the creek, sediment borings identified a layer of recent fluvial deposits overlying red-brown clay or historic alluvial deposits. These recent deposits were described as black, soft silt mixed with sand and gravel, containing anthropogenic materials such as glass, foundry sand, wood, and occasional zebra mussels. Historic alluvial deposits, similar in composition to those described in soil borings, were identified in several sediment borings below the fluvial deposits.

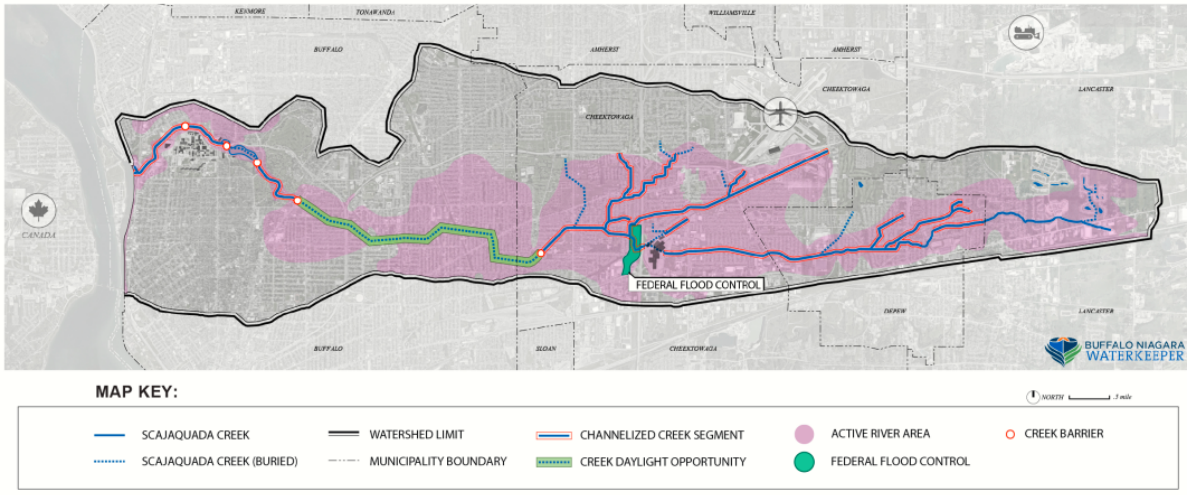
2.3.2. Hydrogeology

Groundwater in the area occurs under unconfined conditions in saturated fill and alluvium. Groundwater and surface water elevation data were recorded in monitoring wells, showing a correlation between creek surface elevations and groundwater levels. Groundwater typically occurs within 10 feet of the ground surface. The groundwater contour maps presented in the Site Characterization Report (Appendix A) indicate a convergent flow pattern toward the creek, with a depressed area of groundwater elevations near Niagara Street and the City of Buffalo Pump Station. The bedrock groundwater encountered during geotechnical NYSDOT drilling, sampling, and rock coring in 1956 for NY-198 Scajaquada Expressway design (see logs in Appendix A) identified artesian groundwater conditions in the bedrock with estimated flow rates up to 15 gpm at the top of the drill stem.

As described in Section 2.3.1, historical changes in the creek channel's positioning have impacted shallow groundwater flow in the creek area. Historical maps of the Black Rock area (see Section 3.2) show that the creek was wider than its current widths. Soil boring data confirm that alluvium soils are thicker beneath the parcels at 31 Tonawanda Street and 1660 Niagara Street. Hydraulic conductivity estimates obtained from well MW-PS-1 and MW-PS-2, located near the City of Buffalo Pumphouse reported values of 3.8 $X10^{-4}$ cm/s and 5.3$X10^{-5}$ cm/s, respectively for the alluvial soils (Appendix A).

2.4. Waterways and Surface Water Hydrology

The Scajaquada Creek watershed covers an urban area of 29 square miles. The source of Scajaquada Creek is in the Town of Lancaster, approximately 18 miles east of the Black Rock Canal at its mouth. A map of the Scajaquada Creek Watershed is shown in the figure below.



The course of the creek has been highly modified and channelized over its length. East (upstream) of the Lower Scajaquada Creek area, a portion of the creek is contained below urbanized areas of Buffalo in a three-mile-long tunnel. Upstream of the tunnel, the creek runs through developed commercial and residential areas of the Towns of Cheektowaga and Lancaster. Downstream of the tunnel, the creek passes through Delaware Park and then enters the former Black Rock industrial area. Only the lowermost portion of the creek (lower ½-mile) has been historically navigable for small boats that serviced former industries along the creek. The mouth of the creek was historically used as a small port

and supported naval vessels during the War of 1812 including the rehabilitation of watercraft. Prior to industrial development of the Black Rock area, the creek was wide, shallow, and meandering, surrounded by extensive marshes and meadows. Over the past two centuries, the Scajaquada Creek channel has been altered as urban and industrial development progressed in the City of Buffalo. Boat and barge traffic historically transported materials to and from the various industries located along the Lower Scajaquada Creek during the late 1800s and early 1900s. During that time, the creek was channelized and the wetland areas surrounding the creek were filled to accommodate industrial development. Boat slips lined the northern side of the creek adjacent to the 1660 Niagara Street parcel. The historic outlet of the creek was closed during the mid-1950s by backfilling during the construction of the NYS Thruway I-190 and the Scajaquada Creek Expressway (NY Route 198), when a new outlet to Black Rock Canal was constructed approximately 450 feet upstream. The modified creek outlet location created the more stagnant "Slip" or "Inlet" segment, which in-filled with depositional material over time.

Scajaquada Creek flows toward the Black Rock Channel under normal weather conditions. However, storm and wind events can cause flow in the Lower Scajaquada Creek area to temporarily reverse direction as lake levels at the eastern end of Lake Erie rise producing higher water levels in the Niagara River. More importantly, the surface water elevation in the Lower Scajaquada Creek is strongly influenced by the surface water elevation of the Black Rock Canal which is controlled by a lock at the north end of the canal. Creek elevation monitoring by GEI shows daily surface water elevations changes of one to two feet and often as much as four feet depending on wind speeds and direction. During high intensity wind and storm events, canal and creek level changes can become extreme. During a seiche event on December 23, 2022, a six to seven-foot rise in surface water elevation was recorded by the Black Rock USGS station and GEI pressure transducers monitoring the creek level and near-shore groundwater elevations. The event produced localized flooding on Niagara Street as surface water in the Inlet overtopped its banks on 1660 Niagara Street at an elevation of approximately 577 msl. These lake seiche conditions are temporary, typically lasting less than 48 hours, and occur more frequently during the late fall and early winter seasons in Western New York.

There are no active stream gauges on Scajaquada Creek. Stream flow at the entrance to the upstream tunnel located approximately 8 miles upstream from the mouth was historically recorded by USGS (gauge 04216200) from March 1, 1957, to September 30, 1994. The measured flow rates during this monitoring period ranged between 3 cubic feet per second (ft/s) (1992) and 292 cubic ft/s (1994).

Scajaquada Creek is navigable from the Black Rock Canal into the Slip Area and the downstream side of the CSX railroad bridge. Between the railroad bridge and the West Avenue bridge, multiple low clearance bridges associated with NY Route 198 (Scajaquada Expressway) make the creek passible by only small boats, kayaks, and canoes.

2.5. Wetlands

State-regulated wetlands were not identified in the Lower Scajaquada Creek area. The portion of Scajaquada Creek downstream from the West Avenue Bridge to the mouth, including the Inlet, as well as the Black Rock Canal is identified as a Riverine Wetland environment on US National Wetlands Inventory mapping.

2.6. Description of Fish and Wildlife Resources

Fish and wildlife resources have been identified in the Lower Scajaquada Creek area through desktop study and site reconnaissance. An onsite habitat assessment was conducted on October 23, 2024 in Lower Scajaquada Creek, focusing on the area primarily south of the West Avenue Bridge and the Scajaquada Creek Slip area. The Lower Scajaquada Creek area is characterized as a highly urbanized, degraded aquatic habitat within a heavily developed watershed, primarily consisting of a channelized creek with limited natural vegetation, and bank cover type dominated by staghorn sumac (*Rhus typhina*), tall goldenrod (*Solidago altissima*), box elder (*Acer negundo*) and various dogwood species (*Cornus* sp.). Dense stands of invasive species including Japanese knotweed (*Reynoutria japonica*) were also observed covering large sections of the banks.

Water at the time of the assessment was clear and the creek substrate was easily observable. The substrate of Lower Scajaquada Creek within the assessment area was observed to have limited areas of depositional sediment, although a few areas of sporadic depositional material were observed adjacent to the banks. The majority of the channel bottom, excluding the Inlet, is instead dominated by pebbles, cobbles, and sporadic boulders. Due to the nature of the observed substrate, submerged aquatic vegetation was limited to the shallower depositional areas of sediment along the creek banks thus significantly reducing fish cover. Observed fish species included rock bass (*Ambloplites rupestris*), smallmouth bass (*Micropterus dolomieu*) and striped shiner (*Luxilus chrysocephalus*). The banks of Lower Scajaquada Creek ranged from gently sloping areas dominated with terrestrial herbaceous vegetation and sporadic tree cover to engineered shorelines.

A US Fish and Wildlife Service Information for Planning and Consultation (IPaC) desktop review was conducted on October 21, 2024. The IPaC report was prepared for Lower Scajaquada Creek west of the West Avenue Bridge to its confluence with the Black Rock Canal. The IPaC report identified no known listed Federally threatened or endangered species within the specified reach of Lower Scajaquada Creek. One Federally proposed species, the salamander mussel (*Simpsonaias ambigua*) was identified in the IPaC report.

A review of the New York State Environmental Resource Mapper identified one state-listed threatened species, the lake sturgeon (*Acipenser fulvescens*) as a potential receptor within the reach of Lower Scajaquada Creek west of the West Avenue Bridge to its confluence with the Niagara River. The portion of Lower Scajaquada Creek in the OU is a Class B designated stream.

Further information regarding potential fish and wildlife receptors is discussed in Section 9.

3. Investigation History, Known Extent of DNAPL, And Historic Industrial Properties

Properties mentioned in this section are situated within the Lower Scajaquada Creek OU and are shown on Figure 3.

3.1. Investigation History

The Lower Scajaquada Creek area has been investigated by GEI and others over the past several decades. GEI completed a Site Characterization of the Lower Scajaquada Creek area and documented the findings in the Site Characterization Report (GEI, October 2022) which supports the basis for additional investigation to fill data gaps.

The 2022 Site Characterization (SC) Report, including text, figures, tables, and boring logs, is provided in Appendix A. The objective of the site characterization was to identify the source area(s) of coal-tar-related DNAPL in the Lower Scajaquada Creek. The NYSDEC suspected that the area of a former MGP gas holder, located on property owned by the New York State Thruway Authority near the current creek outlet (referred to as the P-Site), was a source of coal-tar-related DNAPL. However, the investigations did not identify this property as a DNAPL source area. Investigations did identified coal tar-related DNAPL contamination in deeper soils above the area wide clay layer adjacent to the creek near the Iroquois Gas/Westwood Pharmaceutical Riparian site (NYSDEC well on the bike path), in the subsurface soil below properties adjacent to the creek and below the creek between the West Avenue Bridge and the Inlet Area, and in shallow creek sediments near the discharge from a City of Buffalo Pumphouse. This pumphouse operates to remove groundwater and stormwater from Niagara Street below the CSX railroad bridge, including the storm sewer system and pumphouse wet well.

Additionally, dissolved-phase chemical constituents were detected in the groundwater, and commingled contamination, unrelated to coal tar, was also identified. The SC Report incorporated information from other investigations, detailed in publicly available reports for several nearby BCP Sites. These findings necessitated the development of this RI/FS Work Plan.

Key findings of prior investigations are summarized below.

3.2. DNAPL Observations and Extent

DNAPL, related to coal tar, was identified in coarser-grain alluvial soil and sediment samples, and in eight monitoring wells near the creek installed during NYSDEC site investigations and three wells installed during the GEI 2021/2022 Site Characterization. The DNAPL with a coal tar-like odor was found in deeper coarser-grain alluvial soils above the area-wide red-brown clay layer which is a barrier to downward migration of DNAPL. The area of borings where DNAPL was encountered is shown on Figure 4. Some existing wells, particularly those installed during earlier BCP site investigations, were not deep enough to intersect the top of the red-brown clay layer and are of limited use in establishing the extent of DNAPL presence.

DNAPL has been primarily observed in the deeper alluvial soils above the area-wide clay layer. A forensic evaluation of MAH (Monoaromatic Hydrocarbons) and PAH (Polycyclic Aromatic Hydrocarbons) chemical patterns in soil and sediment samples containing DNAPL identified similarities to those from historic gas manufacturing at the Iroquois Gas/Westwood Pharmaceutical sites (see Appendix A).

DNAPL was identified in three soil borings/wells located near the creek and in four shallow sediment borings downstream of the Niagara Street bridge. DNAPL was present in two sediment borings completed to the top of clay in the creek between West Avenue and Niagara Street. DNAPL was also observed in two Niagara Street manholes that convey stormwater/groundwater to the City of Buffalo Pumphouse and in a wet well (vault) in the Pumphouse where DNAPL accumulated in sediment and debris within the concrete vault. The DNAPL impacts identified in land-based borings/wells were limited to the deeper alluvial soil above the red-brown clay. The geometry of the clay surface and hydraulic gradients influence the distribution of DNAPL in the Lower Scajaquada Creek area. Figure 4 shows sediment and soil borings where DNAPL was observed in the Lower Scajaquada Creek area.

The Site Characterization also included a preliminary DNAPL mobility assessment, concluding that DNAPL migration in the Lower Scajaquada Creek area is primarily driven by hydraulic gradients, gravity, and the surface elevations of the area-wide red-brown clay layer (clay surface geometry). Figure 4 shows the contoured surface of this clay layer, which was historically scoured by the past flow of Scajaquada Creek.

The contoured surface of the clay layer plays a significant role in the location of DNAPL. Because DNAPL is heavier than water, it tends to sink until encountering a confining layer and then migrates via gravity-driven forces along the top of the confining layer. Therefore, the historic flow path of Scajaquada Creek, which scoured the surface of the area-wide clay layer, serves as a sink for DNAPL because it limits further downward migration and limits lateral movement away from the deepest portions of the historic creek channel.

In more recent times (post-1850s industrial development of the lower creek), the water's edge was much wider farther upstream as shown on the figure below.

Figure Above: *Recent aerial photography overlain on an 1856 map of the Black Rock Area to illustrate historic extents of Scajaquada Creek relative to its current channel (source: Georeferenced map provided by NYSDEC, 2024). The star identifies the upstream extent of the Lower Scajaquada Creek OU at the West Avenue bridge.*

Based on known geology, the limits of DNAPL presence would not be expected to extend much beyond the aerial geometry of the creek.

In the Lower Scajaquada Creek area, the DNAPL accumulates on top of the area-wide clay layer. However, due to its specific gravity being only marginally above that of water, DNAPL can become buoyant where vertical hydraulic gradients are sufficiently upward. This was evidenced by the finding of DNAPL in the infrastructure associated with the City of Buffalo Pumphouse. Near the City of Buffalo Pumping Station, groundwater underdrains and deeper storm sewers artificially depress the water table, creating an upward hydraulic gradient. This gradient can potentially cause DNAPL to migrate upward into storm sewers, particularly where the integrity of sewer manholes is compromised. The Site Investigation identified DNAPL in two Niagara Street storm sewer manholes and in the connected City of Buffalo Pumphouse wet well, which discharges into Scajaquada Creek.

DNAPL was removed from the manholes and wet well, and repairs were made to the manholes and piping during the IRMs completed in 2022 (manhole repairs) and 2024 (pipe sleeving) to eliminate this migration pathway. Additional details regarding these interim remedial measures are provided in Section 4.

Groundwater Contamination with DNAPL Presence:

Benzene, toluene, ethylbenzene, and xylenes (BTEX) and polycyclic aromatic hydrocarbon (PAH) compounds were detected above New York State's Ambient Water Quality Standards (AWQSs) in groundwater samples near the creek where DNAPL was present. PCBs and metals were either not detected or elevated above AWQS in groundwater. At several well locations, groundwater also contained chlorinated VOCs, 1,4-dioxane, and per- and polyfluoroalkyl substances (PFAS) above screening criteria. A stormwater/groundwater discharge sample collected from the City of Buffalo Pumphouse during the Pumphouse PDI/IRM (described in Section 4) also contained concentrations of BTEX compounds, PAHs, chlorinated VOCs and 1,4-dioxane above AWQS.

Sediment Contamination with DNAPL Presence:

DNAPL was identified in shallow sediments near the discharge location of the City of Buffalo Pumphouse in the Inlet. DNAPL was not identified in shallow sediments between the West Avenue Bridge and the current creek outlet. The PAH concentrations were highest in shallow sediment borings nearest the discharge point from the City of Buffalo Pumphouse, with one sample (SED-LSC-3 (0-0.5')) showing nearly 500 times the levels of other samples. Elevated levels of volatile and extractable petroleum hydrocarbons, PCBs, and metals (mercury, copper, lead, nickel, zinc) were detected at this location. Where sheens on Inlet surface water were observed prior to the Pumphouse IRM, chemical constituents associated with the sheen were deposited on surface soil along the creek bank along the water line.

The GEI 2021/2022 Site Characterization described the presence of DNAPL downstream of the West Avenue bridge as a result of DNAPL migration from historic MGP operations. These operations began in the late 1800s and continued until approximately 2000, when engineering controls were installed to mitigate migration from the source area (Iroquois Gas/Westwood Pharmaceuticals Terrestrial/Riparian Site). The RI scope of work (Section 6) will assess the effectiveness of source controls installed and operated from this site (see Section 3.3 for remedial actions).

3.3. Historic Industrial Properties in the Scajaquada Creek OU

Several historic industrial properties lie within the boundary of the Lower Scajaquada Creek OU (Figure 3). Both National Fuel and NYSDEC will be conducting RI work to determine if there are existing sources of contamination that are impacting sediment quality.

As described in Section 3.2 and Section 6, National Fuel will be assessing the adequacy of upstream engineering controls to contain coal tar-related DNAPL at the Iroquois Gas/Westwood Pharmaceuticals Site. That property was used for manufacturing gas from a carbureted water gas process using coke, oil, and coal feedstocks from about 1897 until the mid-1950s. A Remedial Investigation/Feasibility Study (RI/FS) was conducted in the mid-1990s by GeoTrans to determine the nature and extent of impacts. In a NYSDEC Consent Order, the site was divided into two portions: the Terrestrial Site (Site #915141) where gas manufacturing occurred, and the Riparian Site (Site #915141B) along the creek. The Terrestrial Site Remedy included:

- Capping of impacted soil
- In-situ biotreatment of soils
- On-site hydraulic control of NAPL and groundwater using vertical pumping wells and treatment
- Placement of a sheet pile barrier along the creek bank
- Site operation and monitoring

In 2017, vertical wells were replaced by a horizontal groundwater collection trench upgradient of the sheet pile barrier to improve hydraulic control.

The Riparian Site Remedy included:

- Excavation and removal of contaminated sediments from historic operations at the Terrestrial Site
- Capping of the creek bottom from approximately 50 feet east of the West Avenue Bridge to 1,600 feet upstream to the abandoned New York Central Railroad bridge

- Placement of a vertical sheet pile barrier near the West Avenue Bridge Long-term collection of DNAPL from coarse-grained deposits below the cap and creek sediments upgradient from the vertical barrier
- Long-term monitoring of the sediment cap

The Riparian remedy also included the installation of a subsurface sheet pile barrier perpendicular to the creek alignment upstream of the West Avenue Bridge, a sediment cap, and two angled collection wells into deeper creek sediments to collect mobile DNAPL (RETEC Engineering, P.C., August 2000).

While National Fuel's work will focus primarily assessing the extent of DNAPL and potential migration pathways, samples collected during the RI will also include a suite of analytes to assess COCs previously observed on adjacent properties and in sediment.

NYSDEC will be assessing potential source areas from other historic industrial properties namely the 1660 Niagara Street BCP site and property on the north side of Niagara Street near Tonawanda Street. Properties with known CVOC contamination are described below.

1660 Niagara Street: Historical use of this property since the 1940s included gasoline sales, underground petroleum storage, vehicle repair and collision shop, and boat sales. Soil and groundwater testing during a Phase II environmental site assessment (ESA) identified contamination from historic property use and detected the following Constituents of Concern (COCs): petroleum VOCs and chlorinated VOCs (i.e., tetrachloroethylene [PCE] and degradation products), PAHs, arsenic, and lead. Groundwater samples analyzed from monitoring wells located at the southern end of the property reported concentrations of chlorinated VOCs approaching 1% of the solubility limit of their parent compounds (tetrachloroethene and trichloroethene) indicating a potential source of non-coal-tar-related DNAPL.

31 Tonawanda Street: The Fedders Corporation constructed a large manufacturing facility on the property and historically used various chemicals, oils, solvents, and other materials in their manufacturing process. The processes at the property included metal stamping, soldering, brazing, welding, painting, acid washing and degreasing. Industrial waste was reported to include solder dross, degreasing still bottoms including TCE and PCE, petroleum-based lubricating fluids and other products and wastes. Percent level concentrations of chlorinated VOCs (PCE and breakdown products) were identified in groundwater at the 31 Tonawanda Street property and property west of the site at 1660 Niagara Street near the CSX railroad tracks.

Other historic industrial properties shown on Figure 3 that contained contamination but not considered an ongoing source include:

- 1675 Niagara Street
- 1626 Niagara Street
- 57-71 Tonawanda Street
- 68 Tonawanda Street
- 75 Tonawanda Street
- 189-205 Tonawanda Street
- 1451 West Avenue
- 166 Dart Street

Each of these sites are described in Appendix A.

4. City of Buffalo Pumphouse IRMs

In December 2021, the NYSDEC requested that National Fuel investigate and implement IRMs to address a petroleum-like sheen on Scajaquada Creek during discharge cycles of the City of Buffalo Pumphouse. Sheens had been observed in 2014 and 2019, and during site investigations by GEI in 2021 and 2022. Inspections identified DNAPL and contaminants including BTEX, CVOCs, 1,4-dioxane, and PAHs in the storm sewer system and Pumphouse wet well. National Fuel agreed to develop a scope of work to investigate tar entry mechanisms and implement IRMs collaboratively with NYSDEC. Emergency response actions included replacing booms, piezometer installations and groundwater sampling, sealing stormwater infrastructure, inspecting subsurface infrastructure, and managing contaminated media.

A pre-design investigation (PDI) performed by GEI identified several critical findings and recommendations for the design and construction IRM. Consistent with the Site Characterization Report (October 2022), it was observed that groundwater elevations are notably depressed in the area surrounding Niagara Street and the storm sewer piping leading to the pumphouse. Additionally, vertical hydraulic gradients in the water-bearing zone above the area-wide, red-brown clay layer near the Pumphouse and storm sewer were found to be upward. The investigation identified that the manhole bottoms within the stormwater conveyance system were poorly constructed or deteriorated, allowing contaminated groundwater and DNAPL to enter. Seepage of grossly contaminated materials was particularly noted in areas with these construction defects. Furthermore, it was determined that contaminated groundwater with elevated concentrations of chlorinated solvents from nearby sites also contributes to the contamination of the storm sewer system.

To effectively mitigate the sheen observed on Scajaquada Creek, it was essential to eliminate the entry of grossly contaminated materials into the storm sewer system and minimize the disturbance of near-shore sediment in the creek during discharge cycles. Epoxy and grout sealants were used to minimize the entry of contaminated groundwater and DNAPL into the manholes below Niagara Street and the Pumphouse wet well also cleaned and sealed. Water quality testing of the manholes and Pumphouse discharge identified seepage of contaminated groundwater (primarily CVOCs and BTEX) through a short section of the conveyance piping from manholes between the wet well and Niagara Street. Slip lining of certain stormwater piping was performed by a NYSDEC contractor to mitigate the infiltration of groundwater along this segment. The NYSDEC also installed a harbor boom across the southern end of Inlet to contain sheens from entering the main channel of Scajaquada Creek.

On behalf of National Fuel, GEI developed and implemented an IRM to address the sheen on Scajaquada Creek. This sheen occurrence was determined to be largely caused by the disturbance of heavily contaminated shallow creek sediments during Pumphouse discharges. The Pumphouse discharges at a rate of approximately 2,250 gallons per minute, causing re-suspension of contaminated sediments and hydrocarbon-like sheen on the surface water near the point of discharge. The selected IRM approach involved constructing a permeable wall of gabion baskets around the outfall, supported by a concrete slab on helical piles, and additional rip-rap armoring and a sheen mitigation barrier to dissipate flow velocity and protect the structure. IRM construction was completed on January 17, 2023. Details of investigations and IRMs completed at the City of Buffalo Pumphouse are documented in a report entitled "*Design Investigation and Interim Remedial Measures (IRM) Report - Lower Scajaquada Creek City of*

Buffalo Pumphouse - NYSDEC Spill #1406307" (GEI, March 2023). The figure below is from the GEI IRM Report and shows the layout of the storm sewer system below Niagara Street, manhole locations and IDs, the Pumphouse, and gabion wall constructed to dissipate turbulent flow from Pumphouse discharge cycles to minimize disturbance to near-shore shallow creek sediments.

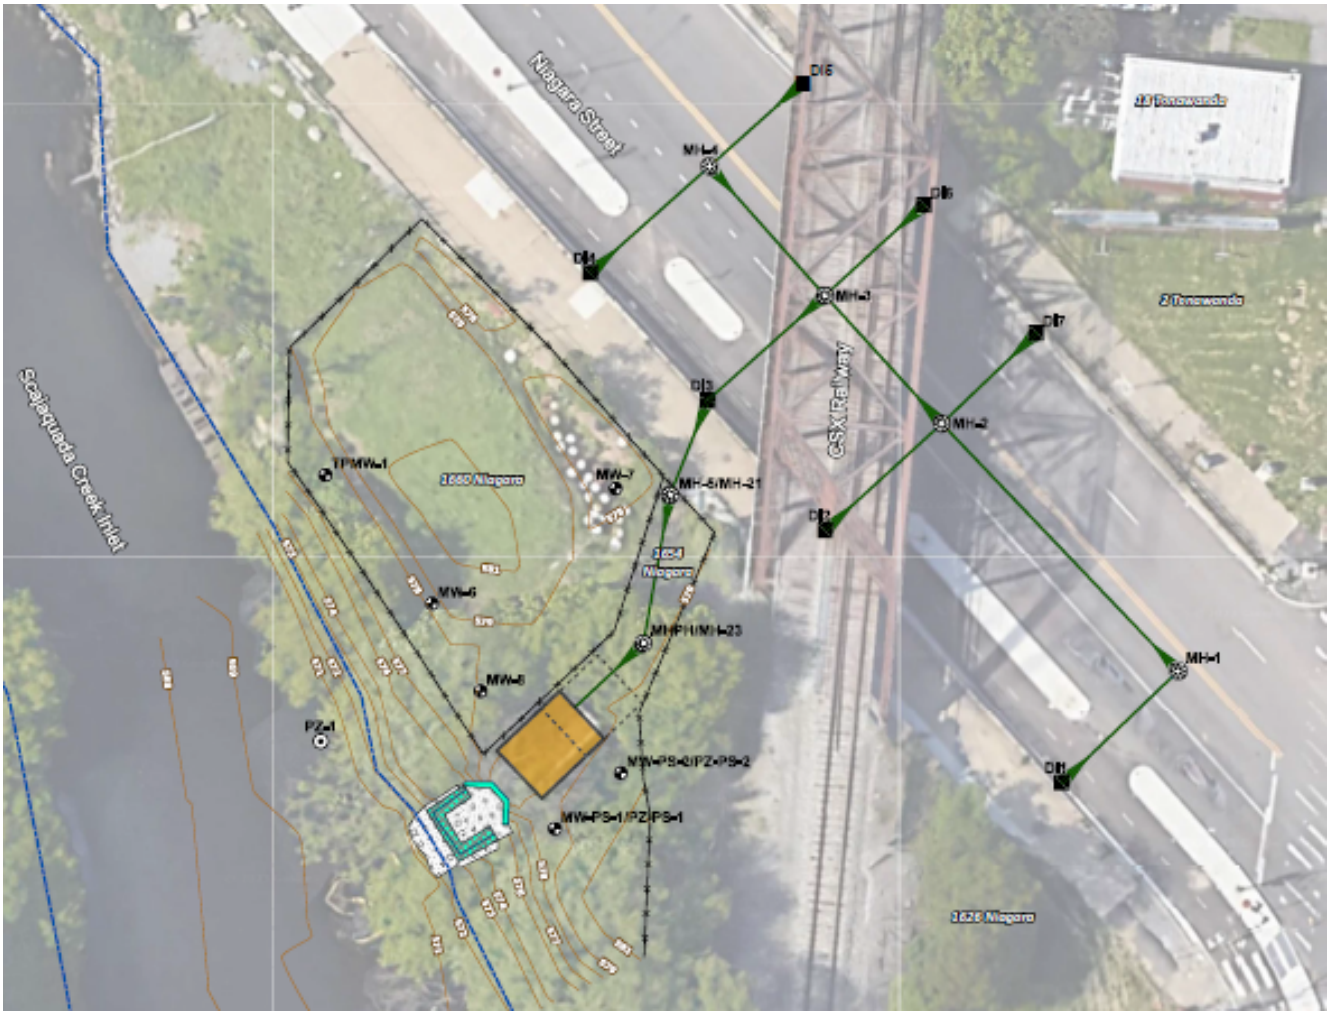


***Figure above**: an excerpt from the IRM Report (GEI, 2023).*

5. Preliminary Conceptual Site Model and Data Gaps

5.1. Preliminary Conceptual Site Model

The 2021/2022 Site Characterization (SC) of the Lower Scajaquada Creek area identified contamination in soils, groundwater, creek sediments, and City of Buffalo infrastructure. This contamination is linked to historic DNAPL transport from former MGP operations. Additionally, investigations by other parties and the NYSDEC at BCP sites revealed contamination of soil, groundwater, and sediments due to past industrial property use, described by the NYSDEC as commingled contamination.

Information from these investigations was used to develop a preliminary CSM for the Lower Scajaquada Creek OU. The CSM outlines potential sources of contamination, release mechanisms, exposure media, and exposure routes based on current and potential future land use. The CSM will be refined based on data collected in the RI.

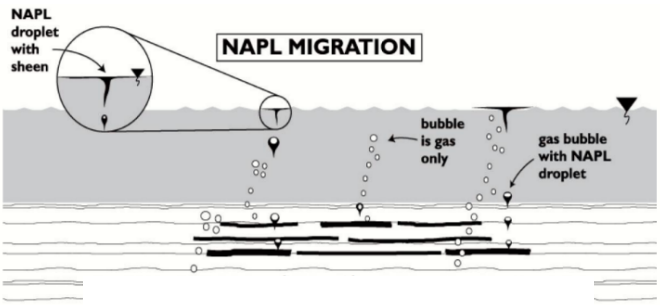
Previous investigations identified various chemical constituents in lower alluvial soil, groundwater, sediment, and City of Buffalo Pumphouse discharge in the Lower Scajaquada Creek OU. These environmental media could potentially serve as exposure media. The CSM provides a qualitative assessment of potential exposure via each medium for various types of receptors.

Data and findings from prior investigations indicate that sources of contamination affecting the Lower Scajaquada Creek originate from the former MGP operation, historic industrial use of nearby properties, and discharge to the creek from CSOs and the City of Buffalo Pumphouse. Contributions from upstream point and non-point sources are also likely given the highly urbanized status of the watershed.

Contamination release mechanisms refer to the processes by which contamination could be transferred from sources to environmental media. Contamination release mechanisms considered as part of the CSM are described below.

- Volatilization: VOCs from NAPL, contaminated soils, and/or groundwater that are released into air, including soil gas (i.e., the air entrained between soil particles in the vadose zone).
- DNAPL Migration: Gravity driven transport of DNAPL occurred as a result of product with specific gravity greater than 1.0 migrating vertically downward until encountering a low-permeability zone (i.e., clay) that precluded further vertical migration. When sufficient source existed, the DNAPL also spread laterally along the top of the clay confining layer, affecting a zone of coarser soil above the clay confining layer.
- Solubilization: Groundwater quality is affected through solubilization of contaminants from pooled or residual DNAPL. Once solubilized into groundwater, constituents are also transported with groundwater flow and may discharge into surface water.
- Discharges to the Creek: Surface water and groundwater collected in the City of Buffalo Pumphouse wet well was discharged to surface water as part of normal pumphouse operations (Pumphouse IRMs mitigated DNAPL entry into the system).

- Ebullition transport: NAPL migration from shallow DNAPL in creek sediments near the Pumphouse to the creek surface driven by gas bubbles caused by changes in hydraulic pressures (e.g., as created by Black Rock Canal lock operation). This contaminant release mechanism produces observed sheen on the surface water in the creek. Ebullition is conceptually shown graphically in the adjacent schematic.



Source: USEPA, 2015

Potential exposure describes the mechanism (exposure route) by which human receptors can be exposed to contamination during current or potentially foreseeable uses of the Lower Scajaquada Creek area. Such receptors include commercial workers, utility workers, construction workers, and passive recreational users of the creek and land adjacent to the waterway. Direct contact, ingestion, inhalation, and vapor intrusion/exposure are all exposure routes that could potentially impact receptors, depending on the nature of their specific activities and exposure areas.

Primary and secondary contact recreation and fishing exposure (i.e., consumption of fish caught from the creek) are pathways that could potentially impact human receptors. DNAPL-impacted soils are typically deeper than 15 feet below the ground surface, so human exposure to DNAPL in soil would be limited to construction workers involved in deep excavation work such as major utility infrastructure development or building construction with deep foundations. Under these scenarios, human exposure routes for chemicals include:

- inhalation of VOCs volatized from groundwater (particularly CVOCs in the area of Niagara Street);
- dermal contact, inhalation, and incidental ingestion of soil/sediment particulates; and
- dermal contact and incidental ingestion of groundwater/surface water.

Groundwater in the area is not a source of drinking water. Scajaquada Creek surface water is also not a drinking water source.

Ecological exposure mechanisms in the Lower Scajaquada Creek are direct exposure to impacted sediments and pore water in the observed depositional areas and assimilation by a species (e.g., prey/food item) at one trophic level and transferred to a higher trophic level species through consumption. For certain types of chemicals, bioaccumulation can exacerbate this pathway at certain levels in the food chain. Based on the evaluation of exposure pathways, the key receptors of concern are benthic invertebrates, fish and semi-aquatic piscivorous mammals and avian species.

The key findings from the Site Characterization are summarized below and establish the preliminary CSM for the investigation of the Lower Scajaquada Creek OU.

5.1.1. Soil Contamination

Soil Quality and DNAPL Presence: Pesticides, PCBs, herbicides, and cyanide were not detected in Site Characterization soil samples above NYSDEC's soil guidance values, regardless of the presence of DNAPL

impacts. However, VOCs and SVOCs (primarily PAHs) were found in soils affected by DNAPL. Certain metals, including arsenic, copper, lead, mercury, nickel, and zinc, were detected in some soil samples above soil guidance values. The presence of chemical impacts associated with DNAPL contamination did not correlate with elevated metal concentrations. Grossly contaminated soil and DNAPL were primarily found in deeper alluvial soils directly above the red-brown clay layer. DNAPL accumulation was observed in the sumps of several monitoring wells near Scajaquada Creek, with well screens monitoring the bottom of the alluvial soils above the clay layer.

The uniformity, thickness, and low permeability of the area-wide red-brown clay layer indicate that this layer acts as a confining layer, preventing the downward vertical migration of DNAPL. DNAPL impacts extending into the red-brown clay layer were not identified during the Site Characterization. The extent to which the clay layer serves as a competent and contiguous vertical migration barrier will be further evaluated as part of the RI.

Source Analysis: Forensic analysis of DNAPL and grossly contaminated soil samples indicate a water gas tar source of pyrogenic origin. DNAPL impacts are confined to deeper alluvial soil due to the surface geometry of the red-brown clay and hydraulic gradients. DNAPL was not identified in shallow soil, suggesting lateral migration of DNAPL from an upgradient source on top of the red-brown clay layer. The DNAPL source is presumed to be historic migration from the Iroquois Gas/Westwood Pharmaceutical Terrestrial/Riparian Site, prior to the installation of engineering controls that contain and remove DNAPL from areas upstream of the West Avenue Bridge.

Chemical fingerprinting of the DNAPL found in borings and wells downstream from the Terrestrial/ Riparian Site engineering controls is similar to that recovered at the Iroquois Gas/Westwood Pharmaceutical Sites. DNAPL has not been detected in shallower soils or sediments near the West Avenue Bridge, suggesting no ongoing releases are occurring. However, this will be further investigated as part of the RI.

There is a possibility of CVOC DNAPL associated with historic industrial usage at BCP sites located at 31 Tonawanda St. and 1660 Niagara St. This is based on dissolved phase concentrations in groundwater of several chlorinated volatile organic compounds approaching 1% of their individual solubility limits. NYSDEC is investigating CVOC contamination in Lower Scajaquada Creek OU.

5.1.2. Groundwater Contamination

MGP Constituent Detection: Site Characterization groundwater samples collected from the Lower Scajaquada Creek area contained BTEX and PAH compounds of pyrogenic origin above New York State ambient water quality standards (AWQS). These constituents were detected in wells with wells screens intercepting the area-wide red-brown clay and where DNAPL was identified to accumulate in the bottom of the well.

Additional Contaminants: Petroleum-related (petrogenic) VOCs, CVOCs, 1,4-dioxane, and PFAS were also detected above AWQS in some wells located on and near BCP properties and near the Inlet. Where present with pyrogenic VOCs and PAHs, their presence is identified as comingled contamination. CVOCs and 1,4-dioxane were also present in the City of Buffalo Pumphouse discharge water at concentrations

above AWQS. As described in Section 4, an IRM was completed in 2022 to mitigate entry of DNAPL and comingled contamination into the manholes and conveyance piping.

Pesticides and herbicides were not detected in groundwater samples analyzed during the Site Characterization. RCRA metals were not detected above AWQS in most wells and none containing DNAPL.

5.1.3. Sediment Contamination

Shallow Sediments: DNAPL impacted recent fluvial deposits were observed in shallow sediments (0-6" depth) in the creek Inlet near the City of Buffalo Pumphouse discharge outlet. PAH concentrations in some shallow sediment samples were elevated, with the sample collected directly adjacent to the Pumphouse discharge outlet (SED-LSC-3; total PAH-16 concentration of 5,649 mg/kg). DNAPL was not identified in shallow sediments elsewhere in the creek during the Site Characterization.

Contaminant Levels: Shallow sediments exhibited elevated levels of volatile and extractable petroleum hydrocarbons, PCBs, and metals (copper, lead, nickel, zinc) when compared to sediment guidance values. Deeper sediments also showed significant contamination, particularly in the creek Inlet area, with high concentrations of BTEX, PAHs, PCBs, and metals (copper, lead nickel, mercury, zinc). DNAPL or sheens/ staining associated with suspected water gas tar residual was identified in deeper alluvial-derived soils below the recent fluvial deposits above the area-wide clay in five of nine sediment borings.

5.2. Data Gaps

Additional data are required to assess the nature and extent of impacts more fully in soil, groundwater, and sediments to evaluate remedial alternatives for the Lower Scajaquada Creek OU. Data gaps with RI objectives are summarized in the following subsections.

5.2.1. Adequacy of DNAPL Source Control

Data Gap: The adequacy of engineering controls upstream of the West Avenue Bridge to contain mobile DNAPL requires demonstration to support the assumption of source control.

RI Objective: Assess the presence and mobility of DNAPL in the vicinity of the West Avenue Bridge to evaluate the effectiveness of upstream physical barriers and DNAPL containment and/or collection and removal systems in preventing DNAPL transport to the south. While residual DNAPL is expected, it will be important to assess mobility and its potential to be a continuing source.

Data Gap: The longer-term performance of Pumphouse IRMs has not been monitored.

RI Objective: Inspect IRM work completed to seal the manholes and conveyance piping for DNAPL entry and groundwater infiltration, as feasible. Water quality will be evaluated by collecting samples from the stormwater conveyance manholes and water discharged at the Pumphouse outfall.

5.2.2. Extent of DNAPL in Soil

Data Gap: The horizontal limits of DNAPL in the subsurface have not been fully characterized below the creek sediments and adjacent upland area above the area wide red-brown clay layer. Construction of Expressway piers may have acted as a temporary migration pathway for vertical transport below the area-wide clay layer.

RI Objective: Establish the horizontal and vertical extent of DNAPL in the OU in consideration of potential migration pathways in natural geologic materials and manmade pathways associated with buried urban infrastructure. This would include evaluating the lateral extents adjacent to the creek, the northern extent of DNAPL in soils beyond the 1660 Niagara Street BCP site, and the soil located near the former outlet of Scajaquada Creek to the Black Rock Canal below the I-190 Thruway. Additional characterization of the surface of the area-wide red-brown clay layer in the lower Scajaquada Creek Area is important as it plays a major role in the fate and transport of DNAPL. Investigation of the sand unit below the area-wide clay layer is warranted.

5.2.3. Identification of Utilities and Infrastructure as DNAPL Migration Pathways

Data Gap: The lower Scajaquada Creek area contains many underground utilities and it is not known whether any of these, other than the Niagara Street storm sewer and City of Buffalo Pumphouse, represent potential preferential pathways for migration away from the creek.

RI Objective: Identify subsurface utilities that occur at or below depths where DNAPL has been identified and assess their potential as a pathway for migration.

5.2.4. Extent of DNAPL in Shallow Creek Sediments

Data Gap: The extent of DNAPL presence in shallow sediments in the Inlet area of the Creek near the Pumphouse discharge outfall.

RI Objective: Use probing and borings to map the distribution DNAPL presence in shallow sediments. While DNAPL presence in shallow sediments was primarily observed in the creek Inlet, a comprehensive probing survey of the shallow creek sediments is needed for verification between the West Avenue Bridge and the Black Rock Channel, including other areas of the Inlet.

Data Gap: Ebullition transport and re-suspension of shallow sediments containing DNAPL near the Pumphouse outfall were observed, producing a sheen that was deposited on creek bank soils. This phenomenon was identified as a migration pathway. The extent of this impact requires further characterization.

RI Objective: Characterize the composition of shallow sediments, including total organic carbon content and the lateral and vertical extents of DNAPL. Additionally, assess the hydraulic influences from daily water level fluctuations in the Black Rock Canal and the impact on surface soils along the creek bank in the Inlet area.

5.2.5. Sediment Quality and Ecological Risks

Data Gap: The quality of creek sediment, the risk posed to benthic organisms, fish, and wildlife, and the data needed to evaluate FS remedial alternatives is required to develop a remedy that could allow removal of Beneficial Use Impairments (BUIs) in the creek.

RI Objective: Assess sediment quality in the Lower Scajaquada Creek and Inlet with a detailed emphasis on known COCs including volatile and extractable petroleum hydrocarbons (EPH), PAHs, PCBs, and metals (mercury, copper, lead, nickel, zinc) to evaluate the risks to benthos, fish, and wildlife. Identify the information needed to evaluate remedial alternatives aimed at removing BUIs in the creek.

5.2.6. Shallow Groundwater Quality

Data Gap: The impact of subsurface DNAPL on shallow groundwater quality.

RI Objective: Wells installed during the 2021/2022 SC were equipped with well screens extending through the deeper alluvial soils into the top of the clay layer. Assess whether the presence of deeper DNAPL affects the groundwater quality near the water table, which is significantly shallower than the area-wide clay layer.

5.2.7. Information to Support the FS

Data Gap: Existing data requires supplementation from the filling of RI data gaps described above. Structural and hydraulic limitations exist that could affect the decision-making process to address contaminated soils and sediments. To inform the development, evaluation, and selection of remedial actions for the Lower Scajaquada Creek OU, each of the data gaps identified above needs to be addressed. In addition, other site-specific data collection and observations will be performed as part of the RI to support the FS and subsequent remedial design phases.

RI Objective: Data should be collected in and near the Inlet to evaluate the eastern wall adjacent to 1660 Niagara Street, the sheet pile wall adjacent to the I-190 Thruway, and piers adjacent to the creek. Data will also be collected to characterize potential treatment and disposal options for media that may be considered for soil/sediment removal under FS alternatives.

5.2.8. CVOCs in Soil and Groundwater

Data Gap: Chlorinated Volatile Organic Compounds (CVOCs) were identified in the upland areas adjacent to the Lower Scajaquada Creek during Brownfield Cleanup Program (BCP) site investigations and the 2021/2022 Site Characterization (SC). These CVOCs are not associated with coal tar-derived DNAPL contamination. The source and extent of CVOCs in the media of Lower Scajaquada Creek remain incompletely understood.

RI Objective: The NYSDEC is leading a Site Characterization on property located at 1660 Niagara Steet including properties located on the northern side of Niagara Street to delineate the nature and extent of CVOCs in soil and groundwater and to determine whether CVOC contamination is a source of sediment contamination in Lower Scajaquada Creek OU. Their findings will be incorporated into the RI/FS.

6. Remedial Investigation Work Scope

The RI will be conducted consistent with EPA and NYSDEC DER-10 guidance and the following supporting project plans:

- Field Sampling (FSP) - provides field sampling methods and procedures to be used during the investigation (Appendix B).
- Quality Assurance Project Plan (QAPP) specifies data quality objectives, and criteria, data acquisition, data management and data submission requirements, laboratory analytical procedures, quality control measures, data validation, and assessment and oversight details (Appendix C).
- Site-Specific Health and Safety Plan (HASP) - Outline procedures that will be undertaken to protect site workers, visitors, and the public in the areas adjacent to the site from potential hazards that may exist as a result of the field work performed during the RI (Appendix D)
- The HASP also includes a Community Air Monitoring Plan (CAMP) to describe methods to monitor and, if necessary, control the potential release of airborne constituents at the downwind perimeters of the investigation work areas. Additionally, an odor control plan is included with the CAMP if intrusive activities produce noticeable odors outside the work area.

As discussed in previous sections, DNAPL associated with former MGP operations is present in the subsurface and locally in shallow sediments. Although significant data have been collected, data gaps identified in Section 5 need to be addressed. The scope of the RI is designed to fill the identified data gaps and support the preparation of the Feasibility Study to evaluate remedial alternatives. The RI scope includes:

- Source Control Assessment
- Subsurface Soil Investigation
- Groundwater Investigation
- Creek Sediment Investigation
- DNAPL Mobility Assessment
- Evaluation of DNAPL Migration Pathways Associated with Infrastructure
- Groundwater/Surface Water Elevation Monitoring

Prior to initiating field work, administrative functions such as obtaining property access agreements and applying for required environmental permits will be necessary. These will be completed prior to initiating drilling and other field work.

Environmental samples collected during the RI will be analyzed by Pace Analytical Laboratory, an ELAP-approved laboratory certified by New York to perform the specified analyses. The laboratory will provide a New York Analytical Services Protocols (ASP) - Level IV laboratory deliverable package for the applicable results. The data will be reviewed by a data validator for conformance to laboratory contract

requirements and provided to General Dynamics Information Technology, Inc. (GDIT) for data validation as described in the QAPP (Appendix C). Data will be provided in electronic data deliverables (EDDs) in SEDD2 format and EQuIS format that are compatible with EPA and NYSDEC requirements.

6.1. Source Control Assessment

The RI will assess the performance of Engineered Source Controls (ESCs) to verify the effectiveness of the Iroquois Gas/Westwood Pharmaceutical Terrestrial/Riparian Site Remedies (described in Section 3) in containing DNAPL in the upstream adjacent area of the Lower Scajaquada Creek OU. This evaluation will include a review of DNAPL collection records from the Southern DNAPL collection system at the Riparian Site, subsurface soil explorations, and assessments of DNAPL mobility where identified. DNAPL is expected to be present on the downgradient/stream side of the engineering controls. This expectation arises because the ESCs were installed during the late 1990s/early 2000s, whereas the release and migration of DNAPL likely began soon after the MGP startup in 1898 and continued until the mid to late 1990s, when the Iroquois Gas/Westwood Pharmaceutical Terrestrial and Riparian remedies were implemented. Therefore, subsurface soil investigations will be completed on land (Sections 6.2 and 6.3) and in the creek and Inlet (Section 6.4) to assess the lateral and vertical extent of DNAPL impacted soils. Borings and wells to be installed to investigate ESCs are summarized in Table 1 and are shown on Figure 7.

In addition to the source control assessment of ESCs upstream of the Scajaquada Creek OU, the performance of interim remedial measures completed at the City of Pumphouse adjacent to the Inlet creek area described in Section 4 will be evaluated. The scope is described in Section 6.6 with the assessment of infrastructure in the Scajaquada Creek OU.

6.2. Subsurface Soil Investigation

Soil borings will be completed at locations shown in Figures 5 through 7 and summarized in Table 1 to evaluate the lateral and vertical extent of DNAPL presence in the subsurface soil. A total of 28 borings are identified as either Primary or Contingency borings. Primary borings will be completed to refine the extent of known DNAPL presence and address other objectives identified in Table 1. If DNAPL is identified at the primary boring location, a contingency boring will be completed at a “stepped out location” to satisfy the objective of mapping the extent of DNAPL. At select locations, soil borings will be completed as groundwater monitoring wells to evaluate groundwater quality and for the assessment of DNAPL mobility. The NYSDEC oversight team will be consulted during the investigation. The borings and monitoring wells to be completed are described below.

6.2.1. Primary and Contingency Soil Borings

Including primary borings to be converted to monitoring wells, 22 primary borings (inclusive of 2 creek borings T26A and T26B to evaluate Source Control) will be completed during the investigation. As shown on Figures 5 through 7, groundwater monitoring wells will be installed in seven of the soil borings. Monitoring well installation methods are summarized in Section 6.3 and described in detail in the FSP (Appendix B). As many as seven Contingency soil borings may be added at step-out locations if needed to satisfy investigation objectives in the Lower Scajaquada Creek OU. If DNAPL is identified in a

Contingency boring, another boring will be completed at a step-out location with agreement from the NYSDEC. Boring termination depths for Primary and Secondary soil borings are summarized in Table 1.

At each location, the boring will be advanced by either a direct-push (Geoprobe™) drilling rig equipped with 2-inch diameter Macro-Core™ samplers, or by a conventional hollow-stem auger (HSA) drill rig equipped with 2-inch diameter split-spoon samplers as described in the FSP (Appendix B). Each boring will be completed through fill and native soil and then a minimum of four feet into the red-brown clay unit. If DNAPL is observed within the top four feet of the native red-brown clay unit, the soil boring will be advanced until no visual evidence of impact is observed. At soil boring locations SB-RI-9 and SB-RI-11, the boring will be advanced through the native red-brown clay unit into the underlying sand unit which directly overlies bedrock. These two borings are anticipated to be drilled to a depth of approximately 70 feet below ground surface. The objective of the deeper soil borings is to evaluate the potential for DNAPL impacts below the native red-brown clay unit. Soil drilling and logging methods including screening (with a PID) are described in the FSP (Appendix B).

6.2.2. Soil Boring Sampling and Analytical

A minimum of two soil samples will be collected from each boring and submitted for laboratory analysis. A sample will be collected from the most apparently impacted interval based on PID screening and field observations. If impacts are not observed, a sample will be collected from the 1-foot interval immediately below the water table, and a second sample will be collected from the bottom of the boring presumed to be from the upper red-brown clay unit. At deeper soil boring locations SB-RI-9 and SB-RI-11, an additional soil sample will be collected from the sand unit directly underlying the red-brown clay unit. Soil sample collection methods including screening (with a PID) are described in the Field Sampling Plan (Appendix B). The laboratory sample analytical program for soil samples is as follows (Table 2).

- TCL VOCs (EPA SW8260D/5035)
- PAH-17 (EPA SW8270E)
- COC Metals (arsenic, copper, lead, mercury, nickel, and zinc) (EPA 6020B/7471B)
- PCBs (EPA 8082A) (granular soils only – not clay)
- Grain Size analysis (ASTM D422), Standard Penetration Testing (SPT) (ASTM D1586), TOC (EPA Method 9060A/Lloyd Kahn)

If light NAPL (LNAPL) or DNAPL is encountered in any soil boring exhibiting properties inconsistent with prior findings of NAPL (characteristic of coal-tar-like gross contamination), a sample will be collected and submitted for laboratory forensic analysis by method EPA SW8270M/8015M as summarized in Table 2.

6.3. Groundwater Investigation

6.3.1. Monitoring Well Installation

The goal of the groundwater investigation is to assess groundwater quality in the unconfined water-bearing zone where DNAPL is known to exist. In areas where DNAPL presence is to be investigated, well

screens will be positioned to monitor the bottom of the alluvial soils directly above the area-wide clay layer that forms a barrier to vertical downward migration of DNAPL. These will also support DNAPL mobility testing (Section 6.5) if DNAPL is present. To achieve this objective, five new monitoring wells (MW-RI-1 through MW-RI-5) will be installed at the proposed locations shown on Figures 5, 6, and 7 to supplement the existing network of monitoring wells in the Lower Scajaquada OU. Each well will be constructed using 2-inch diameter Schedule 40 polyvinyl chloride (PVC) with a screened section consisting of 0.02-inch sized slot openings. The bottom of the well will terminate in the area-wide red-brown clay layer between approximately elevations 550 to 558 feet (NAVD88). Wells monitoring the top of the clay layer will be equipped with a 2-foot DNAPL collection sump extending into the area-wide clay layer below the well screen. As described in the FSP (Appendix B), the annular space surrounding the sump with be sealed with bentonite prior to installation of the sand pack.

In areas where DNAPL-impacted soils were identified and shallow wells are not present, proposed monitoring wells MW-LSC-2S-RI and MW-LSC-4S-RI will be installed with well screens positioned to monitor the upper 5 feet of the saturated zone at an approximate elevation of 565 feet (NAVD88), or 5 feet below the top of the water table as observed during drilling. These wells will have 5-foot screen lengths to assess groundwater quality in shallow groundwater near the water table.

The objective and rationale for each monitoring well installation is provided in Table 1. Monitoring well installation construction details are provided in the FSP (Appendix B).

6.3.2. Monitoring Well Development

Prior to development, the wells will be checked for NAPL presence (LNAPL and DNAPL). If NAPL is encountered, the field observations (i.e., thickness and description) will be documented on the well development forms. New wells will be developed no sooner than 48 hours after completion to remove fine-grained sediments that may have accumulated in the well during construction and to promote the hydraulic communication between the well and surrounding soil formation. For wells that do not contain NAPL, wells will be developed by surging and pumping techniques. Monitoring well development methods are described in the FSP (Appendix B). If NAPL is present, well development will utilize the methods described in the FSP that minimize the movement of NAPL to prevent contact with the riser and screened portion of the well not already in contact with DNAPL.

Following well development, an assessment of NAPL presence and mobility will be conducted at each new monitoring well location as discussed further in Section 6.5.

6.3.3. Groundwater Quality Sampling and Analysis

Following well development, new monitoring wells will be allowed to stabilize for at least two weeks and then sampled using low flow sampling methods. Prior to sampling, wells will be checked for the presence of NAPL (both LNAPL and DNAPL).

The groundwater samples collected will be analyzed for the following parameters:

- TCL VOCs by EPA Method 8260D

- TCL SVOCs by EPA Method 8270E including 1,4-Dioxane by EPA Method 8270E SIM with isotope dilution
- PFAS by EPA Method 1633
- PCBs by EPA Method 8082A
- TAL Metals by EPA Method 6020B/7470A
- Total Cyanide by EPA Method 9012B

If NAPL is encountered in new monitoring wells, and if observations based on olfactory and visual evidence, along with groundwater analytical testing results, indicate that the NAPL is inconsistent with previous findings (e.g., coal-tar-like odor with elevated BTEX and naphthalene concentrations in the aqueous phase), a sample of the NAPL will be collected and submitted for forensic analysis using EPA Methods 8270E-SIM/8015D(M).

Additional information regarding the collection methods and analysis to be used during groundwater sampling is included in the FSP (Appendix B). The analytical summary for groundwater sampling is provided in Table 2.

6.3.4. Hydraulic Conductivity Testing (New and Existing Wells)

Estimates of saturated soil hydraulic conductivity will be obtained from RI monitoring wells and monitoring wells installed during the 2021/22 Site Characterization by performing slug tests. Slug testing will be performed using rising head methods. A known volume of water will be displaced to effect head change by removing a volume of water with a hand bailer. Water level recovery will be measured automatically via instrumentation temporarily installed in the well, such as a down-hole pressure transducer. Hand measurements will also be periodically recorded to demonstrate at least 80% recovery during the test. Slug test displacement and recovery data will be analyzed using AQTESOLV (or similar) software by the Bouwer and Rice Method (1976) to yield estimates of hydraulic conductivity in each well.

6.4. Creek and Inlet Area Sediment Investigation

6.4.1. Inlet Creek Bank Surface Soil

Surface water sheens have historically (prior to IRMs) been observed on the creek bank due to daily fluctuations in surface water levels in the Inlet. When sheen was present on the surface water in the Inlet Area near the City of Buffalo Pumphouse, the sheen residue was observed to be deposited on the shoreline at the water/bank interface. Surface soil samples will be collected from the creek bank at 10 locations identified on Figure 8. The surface soil samples will be analyzed for the following parameters:

- TCL VOCs by EPA Method 8260D/5035
- PAH-17 by EPA Method 8270E
- PCBs by EPA Method 8082A
- COC Metals (arsenic, copper, lead, mercury, nickel, and zinc) by EPA Method 6020B/7471B

The creek bank surface soil sample collection involves probing surface soils in proposed sampling locations at an elevation of approximately 574 to 575 feet as described in the FSP (Appendix B). Table 2 provides an analytical summary.

6.4.2. Bathymetric Survey

Mapping and surveying work will be performed by a combination of standard Geographical Information Service (GIS) mapping combined with survey-grade GPS methods and bathymetric surveying.

A bathymetric survey of the investigation area will be performed using a single-beam bathymetric survey methodology with GPS location. Sufficient points along the shore will also be obtained so that the bathymetric survey can be tied to the upland topographic survey and a unified map of land and creek-bottom elevations prepared. The survey results will be used to create a contour figure of the creek-bottom, and the data will be provided in digital GIS-compatible format.

Mapping from the bathymetric survey will be obtained before probing and coring, so that the results of the survey can be used to modify the sampling plan, as appropriate, to consider current field conditions at the time of the work.

6.4.3. Sediment Probing Transects

Systematic sediment probing will be performed to assess the thickness and quality of sediment within the investigation area and observe for sheen generation. Probing will be conducted along 26 transects, spaced approximately 50 to 100 feet apart, as shown on Figures 8, 9, and 10. The endpoints of each transect, each probing location along the transect, and the water surface elevation will be established using survey-grade GPS. The depth of water at each location will be measured by a tape or probe with a flat plate to prevent the end from sinking into the sediment. Once the endpoints of each transect have been located, a rope will be strung across the creek between the endpoints to help the probing crew stay on the transect as they probe and sample across the length of the transect. Probes will be attempted at approximately 10-foot intervals along transect lines. Sediment probing is described in the FSP (Appendix B).

6.4.4. Sediment Sampling

Sediment borings will be completed in the Scajaquada Creek main channel and Inlet along 26 transects to evaluate sediment quality. Target sediment sampling locations are provided on Figures 8 through 10. The final location of each sediment boring may be adjusted in the field based on the presence of utilities buried beneath the Creek channel, accessibility with the sampling barge, obstructions (rip-rap, large debris), or if poor sample recovery occurs. Sediment sample locations will generally be collected at the nearest (relative to target locations on Figures 8-10) 10-foot probing locations along each transect, and the sediment sampling effort will replace the physical probing (Section 6.4.3 above) at those locations.

Sediment borings will be advanced using 3-inch diameter flush-jointed casing or 2.75-inch diameter hollow stem augers. Samples will be collected using a 4-foot Macrocore sampler or 2-inch diameter split spoon samplers. If sample recovery in sediment borings is below 70%, sampling methods will be modified in order to achieve a minimum 70% recovery goal. These modifications may include increasing

the sampler diameter, adjusting the cutting shoe on the sampler, varying core-catcher type, or modifying the Macrocore liner type or configuration. The rate of sampler advancement may also be modified to maximize sediment sample recovery. Sediment boring and sampling procedures are provided in the FSP (Appendix B). At all sediment boring locations, the full length of recovered sediment and underlying clay will be visually characterized. At certain locations, sediment will be collected from selected intervals for laboratory analyses, as indicated on Table 4. The target intervals for sampling are generally the upper two feet of sediment and the most impacted interval observed in the core. In the event the 0- to 2-ft depth interval is also the most visibly impacted, or if no depth interval appears more impacted than others, the second sample will be collected from the 2-foot interval overlying the red-brown clay. Each sediment boring will be advanced a minimum of 4 feet into the area-wide red-brown clay layer which occurs more than 15 feet below the soft sediment surface.

Each sediment boring location will be surveyed at the time of completion using a hand-held GPS capable of sub-meter accuracy. GPS coordinates will be recorded on sediment boring logs and reported in NAVD88 format.

6.4.5. Sediment Analysis

Sediments collected from Scajaquada Creek will be analyzed for chemical, biological, waste profiling, and geotechnical purposes; specific analyte lists will vary based on specific locations and objectives. The analyses to be performed on the samples from the specific sampling locations shown on Figures 8 through 10 are identified in Table 4. The various sampling activities, rationale, and analytes are summarized in the following subsections.

6.4.5.1. COC Delineation Samples

As indicated on Figures 8 through 10, there are 29 locations where analyses target a list of COCs potentially affecting the lower Scajaquada Creek area based on the findings of prior investigations in and near the creek. The primary purpose of these samples is to delineate the nature and extent of impacts. At each of those locations, two sample intervals are proposed for analysis, totaling 58 samples (excluding QA/QC samples). Of those, 47 are proposed for analysis of the focused COC Parameters analyte list and 11 are proposed for analysis of an expanded Full Suite COC analyte list. The analytes associated with each list are indicated on Table 4 and summarized below:

List	Analytes Included
COC Parameters (focused list)	TCL VOCs, PAH17, Selected metals (arsenic, copper, lead, mercury, nickel, and zinc), TOC
Full Suite COCs (expanded list)	TCL VOCs, TCL SVOCs, EPH, expanded NOAA PAH34 list, PCBs, TAL metals, total cyanide, and TOC

Where Table 4 indicates a location where samples are subject to both COC Parameters and Full Suite COCs analyses, the shallow (0- to 6-inch depth) will be subject to the Full Suite analytical list and the second sample (collected from a deeper interval) will be analyzed for the more focused COC Parameters list.

6.4.5.2. Benthic Toxicity Analysis

Sediment samples will be collected from the uppermost six inches of sediment (i.e., the most biologically active zone) at a subset of 26 of the 29 locations where COC-related sampling is planned. In addition to collecting COC-related information at these locations, additional parameters will also be analyzed to better assess other factors that may affect benthic toxicity apart from identified COCs. The additional analytical parameters at these locations are indicated on Table 4 and summarized below:

List	Analytes Included
Ecological Risk Assessment Parameters	Ammonia, TOC (if not already part of the Full Suite analyses at that location), sulfide, Acid Volatile Sulfide / Simultaneously Extracted Metals (AVS/SEM), and grain size

In addition, sediment will be collected from the upper six inches of sediment at three locations for the purpose of laboratory toxicity testing. The three target locations include T9B, T15B, and T26B (Figures 8, 9, and 10), although adjustments may be made based on the results of the Ecological Risk Assessment Parameters analysis indicated above. Standard toxicity testing will include conducting chronic, 28-day whole-sediment toxicity test with the amphipod, *Hyalella azteca*. Endpoints measured in this chronic test will include effects on survival, growth, and reproduction from 28-day exposure to site sediments per "Methods for Measuring the Toxicity and Bioaccumulation of Sediment-associated Contaminants with Freshwater Invertebrates" (USEPA 2000) and "A Guidance Manual to Support the Assessment of Contaminated Sediments in Freshwater Ecosystems" (USEPA 2002). Sediment toxicity tests will include collection of bulk sediment from three pre-determined locations and will also incorporate laboratory provided control samples and a reference site/background sample for statistical comparison.

6.4.5.3. Waste Characterization

The evaluation of waste management costs in the FS requires evaluation of chemistry and characteristics for sediment that may be dredged from the creek and subject to offsite disposal. Three sediment boring locations are proposed for collection of waste characterization samples. These locations (T2B, T6B, and T23A; Figures 8 and 10) focus on the Inlet area where the greatest volume of deposition sediment is anticipated and where prior data suggests the majority of chemical impacts are present. These analyses, combined with the suite of area-wide chemical tests listed above, will allow for evaluation of both landfill and thermal treatment disposal options. Analyses for waste characterization will be performed on composite samples created from the uppermost 4 feet or full thickness of depositional material retrieved at each location, whichever is less. One composite sample will be collected at each of the three locations; three samples in total will be analyzed for waste characterization parameters. The waste characterization analytes, which are listed on Table 4, reflect typical waste profiling requirements at nearby commercial disposal facilities. The analytical parameters are summarized below:

List	Analytes Included
Waste Characterization	TCL VOCs, TCL SVOCs, TAL Metals, Pesticides/herbicides, PCBs, hazardous characteristics (pH, ignitability, reactivity, and corrosivity), total cyanide, TPH, sulfur content, and BTU content

As indicated in Table 4, both total and TCLP analyses will be performed for certain of these parameters (VOCs, SVOCs, and metals).

6.4.5.4. Geotechnical

The evaluation of certain remedial technologies for the creek as part of the planned FS may require an assessment of the effects of each technology on the stability of roads and structures along the creek. Knowledge of geotechnical properties may also be pertinent to designing support facilities, sediment dewatering, excavation support, and other ancillary activities that may be needed to implement certain remedial technologies. To support this assessment, limited geotechnical testing is proposed at six locations as part of the sediment investigation scope. The six locations were selected to be adjacent to structures that may be most susceptible to being destabilized by certain remedial activities, and focus on the following areas:

- Along the bulkhead supporting highway I-190 and closing the former creek outlet (T2A, T3A, and T5A)
- Between the State Route 198 on-ramp and Niagara Street bridge (T16B)
- Adjacent to the West Avenue Bridge (T26A and T26B)

At each of these locations, samples will be collected from the clay at the bottom of the sediment core and analyzed for the following:

List	Analytes Included
Geotechnical Parameters	Grain size, TOC, Atterberg Limits, and permeability (if intact Shelby tube samples can be recovered)

6.5. DNAPL Mobility Assessments

DNAPL mobility assessments will be conducted at:

- Wells installed during the RI containing DNAPL
- Temporary wells installed at creek borings T26A and T26B (if DNAPL is observed)
- Six existing wells monitored during 2021/2022 SC that contained DNAPL (DEC-MW-100, MW-LSC-2, MW-LSC-4, MW-LSC-5, 1660-MW-7, 1660-MW-8)

The mobility assessment will be conducted after the completion of monitoring well development, sampling, and hydraulic conductivity testing. The procedure involves removing accumulated DNAPL from the 2-foot sump in each well and measuring the rate of DNAPL recovery over time until the sump is completely refilled (approximately 1/3 of a gallon). Details are described in the FSP (Appendix B).

The frequency of testing will be well-specific:

- Daily DNAPL removal will occur in wells for approximate one week if the gravity recovery of DNAPL in the well is sufficiently rapid to re-fill the entire sump and additional DNAPL removal is necessary to allow continued gravity drainage of DNAPL.
- The testing will be reduced if DNAPL recovery rates are slower.

The duration of DNAPL mobility testing will extend for a maximum of 6 months after RI monitoring wells are sampling and hydraulic conductivity testing is complete.

Planned Mobility Assessment Schedule:

Initial Phase: Daily assessments for the first week to establish recovery rates.

Intermediate Phase: Adjust frequency based on initial findings; wells with rapid recovery may continue daily checks (for a maximum of one week), while others may shift to weekly.

Final Phase: Monthly assessments for all wells for the last three months, focusing on wells with slower recovery rates and DNAPL recovery in more rapidly re-filling wells.

6.6. Evaluation of DNAPL Migration Pathways Associated with Infrastructure

The 2022 Site Characterization identified numerous utilities and below-grade infrastructure in the Lower Scajaquada Creek area. This included the evaluation of the Niagara Street stormwater sewers below the CSX Railroad Bridge and the conveyance piping to the City of Buffalo Pumphouse. As described in Section 4, an IRM was implemented to minimize contaminated groundwater from infiltrating the storm sewer system and to mitigate the entry of DNAPL, including accumulated DNAPL in the Pumphouse Wet Well (vault). Although sampling was conducted shortly after the IRM's completion, including NYSDEC pipe slip-lining, the performance of the IRM has not been quantified through analytical testing.

The following will be conducted to assess DNAPL/contaminated groundwater entry into the Niagara St. storm sewer servicing the City of Buffalo Pumphouse (see Figure in Section 4):

- Manholes #1 through #4 in Niagara Street, Manholes 21 and 23, and the Pumphouse vault will be inspected and probed with a white, PVC rod for DNAPL presence.
- Water samples will be collected from Manholes 21 and 23 and the Pumphouse discharge and analyzed for parameters specified in Table 2 (full suite of compounds).

During RI/FS work plan preparation, design drawings provided by the Buffalo Sewer Authority (BSA) showing infrastructure (e.g., sewer and utility lines), as well as drawings provided by others, were reviewed with the objective of identifying potential migration pathways for the transport of DNAPL away from the Lower Scajaquada Creek area. These included:

- The Buffalo Sewer Authority (BSA) interceptor sewer that parallels the NYS Thruway I-190 and passes beneath the former and current creek outlet,
- Buried high-voltage electric transmission lines beneath Niagara Street, and

- BSA Stormwater and sanitary sewers along Niagara Street and Tonawanda Street.

The presence of these utilities and features and the ability to act as preferential pathways for DNAPL migration away from the Scajaquada Creek area will be evaluated following completion of investigations described in Section 6.1 through 6.5. For example, if DNAPL is identified in boring SB-RI-14, then manholes located along Wayne Street and Niagara Street will be probed for DNAPL presence. Decisions to investigate infrastructure outside the Scajaquada Creek OU will be made after consultation with the representatives from the Project Coordination Team.

6.7. Groundwater and Surface Water Elevation Monitoring

Groundwater elevation measurements (synoptic rounds) will be collected monthly for a duration of six months and quarterly for one year afterward. The measurements will be collected from the following monitoring wells:

RI Monitoring Wells:		
Well ID	**Top of Riser Elevation (EL.)[1]**	**Location**
MW-RI-1	To be surveyed upon Completion	Under 198 expressway, west of southern DNAPL recovery vault
MW-RI-2		Northeastern corner of 31 Tonawanda Street parcel, near West Avenue Bridge
MW-RI-3		Former location of 31-MW-4R.
MW-RI-4		1660 Niagara Street
MW-RI-5		Next to 190, on Jesse Kregal pathway
MW-LCS-2S-RI		Next to MW-LCS-2
MW-LCS-4S-RI		Next to MW-LCS-4
Existing Monitoring Wells:		
Well ID	**Top of Riser Elevation (EL.)[1]**	**Location**
1660-TPMW-1	582.20	1660 Niagara Street
1660-MW-1	578.79	1660 Niagara Street
1660-MW-2	577.65	1660 Niagara Street
1660-MW-3R	578.63	1660 Niagara Street
1660-MW-5R	577.61	1660 Niagara Street
1660-MW-6	577.20	1660 Niagara Street
1660-MW-7	578.34	1660 Niagara Street
1660-MW-8	580.80	1660 Niagara Street
1675-MW-1	577.51	1675 Niagara Street
1675-MW-2	580.29	1675 Niagara Street
MW-100	578.56	Bike Path
MW-103	578.37	Bike Path
MW-106	579.84	Bike Path
68-MW-2	585.55	68 Tonawanda Street
68-MW-3	584.26	68 Tonawanda Street
68-MW-4	579.22	68 Tonawanda Street
31-MW-2	581.59	31 Tonawanda Street
31-MW-3R	578.93	31 Tonawanda Street
57-MW-1	577.70	57-71 Tonawanda Street
57-MW-3	579.15	57-71 Tonawanda Street
57-MW-4	582.75	57-71 Tonawanda Street
57-MW-5	584.00	57-71 Tonawanda Street
MW-BGL-1	581.74	On Bike Path, under Route 198 ramp and I-190 Expressway
MW-BG1-3	579.82	Off Bike Path, under I-190 Expressway
MW-LCS-1	585.69	Between Route 198 ramp and West Avenue
MW-LCS-2	585.35	Under Route 198 ramp

MW-LSC-3	586.95	Under Route 198 ramp
MW-LSC-4	582.13	Between the on and off Route 198 ramps
MW-LSC-5	582.48	Corner of Niagara Street and Tonawanda Street
MW-PS-1	578.34	East of pumphouse
PZ-PS-1	578.33	East of pumphouse
MW-PS-2	579.42	East of pumphouse
PZ-PS-2	579.42	East of pumphouse

Notes: 1. Elevations reported in NAVD88 datum.

Monitoring well locations are shown on Figures 5, 6, and 7.

Two surface water elevation monitoring stations will be temporarily installed at an upstream location (US-Surface-1) and a downstream location (DS-Surface-2) along Scajaquada Creek. The stations will be constructed using a PVC standpipe fastened to post. A transducer/data logger will be installed at each surface water monitoring location. Exact locations will be field determined considering safe access and physical protection of the station. Surface water elevations will be manually measured and documented daily during drilling activities.

The groundwater and surface water elevation measurements will be analyzed to determine a direct correlation between the two.

6.8. Survey

A survey of the RI sampling points and important site features will be performed by a NYS licensed surveyor. All horizontal locations will be reported in the applicable NYS horizontal coordinates (North American Horizontal Datum 1983 (NAD83, NYS West Zone) and latitude and longitude coordinates. All vertical measurements will be reported in NAVD88.

6.9. Management of Investigation Derived Waste

Waste materials generated from field investigation activities including drill cuttings, sediments and plastic used for surface containment of spoils and fluids, purge water, drill cuttings, personal protective equipment, and disposable sampling equipment will be containerized in separate 55-gallon drums. Management of IDW is described in the FSP (Appendix B).

6.10. Community Air Monitoring

Community air monitoring will be performed to provide real-time measurements of total VOCs and particulate (airborne dust) concentrations in air at the downwind perimeter of each designated work area when intrusive investigation activities (i.e., drilling activities) are in progress. The monitoring provides protection for the downwind community, including residences and businesses and on-site passersby not directly involved with the RI work activities. The procedures follow methods described in the CAMP, which is included with the HASP (Appendix D), and are consistent with NYSDOH guidance.

6.11. CVOC Source Characterization

The NYSDEC is leading a SC to delineate the nature and extent CVOCs on the property at 1660 Niagara Street (the site) in the City of Buffalo and to determine whether CVOC contamination from the site is a

source of sediment contamination in lower Scajaquada Creek. The planned investigation will include surface soil sampling, soil borings and the installation and sampling of groundwater monitoring wells. The SC will include:

- Surface Sampling – Collection of five surface soil samples from the mound area on the southwestern end of the 1660 Niagara St. property.
- Soil Borings - Install 12 soil borings to the depth of the area-wide brown clay to determine the vertical extent of CVOC contamination in the overburden soils on site and collect two samples from each boring for laboratory analysis.

Soil samples collected during the SC will be analyzed for: TAL Metals, PCBs, 8260 VOCs, 8270 SVOCs, 1,4-dioxane and PFOA/PFAS.

- Groundwater Investigation – Install five overburden monitoring wells to the depth of the area-wide brown clay.

Samples collected during the SC will be analyzed for: TAL Metals, PCBs, 8260 VOCs, 8270 SVOCs, 1,4-dioxane and PFOA/PFAS.

Site Characterization findings will be summarized by the NYSDEC and incorporated into RI Data Summary Report (see Section 7).

7. RI Data Summary Report

The RI Data Summary Report will be prepared to support the Feasibility Study. National Fuel will coordinate with NYSDEC to incorporate findings from their Site Characterization activities into an appendix of the RI Data Summary Report. A preliminary outline is provided below:

1. Executive Summary - Brief overview of the site, objectives, key findings, and recommendations.
2. Introduction - Background information on the site, purpose and scope of the investigation, regulatory framework, and project objectives.
3. Site Description and History - Location and physical setting, historical site use and previous investigations.
4. Sampling and Analysis Summary - Description of sampling locations and rationale, types of samples collected, work plan deviations, analytical methods and laboratory procedure, quality assurance/quality control (QA/QC) discussion, data validation and usability assessment.
5. Data Summary, Findings, and Interpretation - Presentation of data in tables, graphical summaries, and maps, interpretation of analytical results, comparison with regulatory standards and guidelines.
6. Updated Conceptual Site Model – The preliminary CSM will be updated with information obtained from investigations completed in the Lower Scajaquada Creek OU.
7. Conclusions and Recommendations.
8. References.

The RI Data Summary Report will also include tables, figures, and attachments to document the completed work and summarize the results and findings.

8. Qualitative Human Health Exposure Assessment

The Qualitative Human Health Exposure Assessment (or the exposure assessment) for the Lower Scajaquada Creek OU will focus on potential human exposure to DNAPL constituents under current land use conditions of the Lower Scajaquada Creek area. The exposure assessment will be completed after the RI Summary Report and will be incorporated into the Feasibility Study (see Section 10) and will include:

- A description of the constituent source;
- An explanation of the release and transport mechanisms;
- Identification of all potential exposure point(s) where actual or potential human contact with an impacted medium may occur;
- Description(s) of the route(s) of exposure (i.e., ingestion, inhalation, dermal absorption); and
- A characterization of the receptor populations who may be exposed to DNAPL constituents at a point of exposure.

These items represent the five elements of an exposure pathway. An exposure pathway is complete when all five elements of an exposure pathway are documented; a potential exposure pathway exists when any one or more of the five elements comprising an exposure pathway are unknown. An exposure pathway may be eliminated from further evaluation when any one of the five elements comprising an exposure pathway has not existed in the past, does not exist in the present, and can reasonably be anticipated to never exist in the future.

The NYSDEC and NYSDOH will integrate the exposure assessment findings related to coal tar-derived DNAPL and associated constituents of potential concern (COPCs) into their overall exposure assessment of the upland areas in the Lower Scajaquada Creek OU. This comprehensive assessment will include non-coal tar-related COPCs identified during their investigation. The findings will be summarized in the Feasibility Study Report described in Section 10.

9. Fish and Wildlife Resource Impact Analysis

A Fish and Wildlife Resource Impact Analysis (FWRIA) will be performed as part of the RI by qualified personnel as defined within the NYSDEC Fish and Wildlife Impact Analysis for Inactive Hazardous Waste Sites guidance document (NYSDEC, 1994). An initial habitat assessment conducted as a component of FWRIA Part 1 - Resource Characterization, was completed during the preparation of this workplan. The remaining components of the Part 1 - Resource Characterization and Part 2- Ecological Impact Assessment will be completed using information collected from the sediment investigation and information in this work plan and incorporated into the FS Report (see Section 10).

In accordance with the FWRIA guidance, a qualitative evaluation of actual or potential impacts to fish and wildlife resources from site-related constituents will be performed. Available information and the resource descriptions developed from the evaluation will be used to characterize the exposure setting, identify migration pathways, and evaluate contaminant fate and transport and potential effects to fish and wildlife resources. This information will also be used to identify contaminants of potential ecological concern (COPECs) via comparison of the existing site media data to ecologically based screening values and/or criteria.

An onsite habitat assessment was conducted on October 23, 2024 in Lower Scajaquada Creek, focusing on the area primarily south of the West Avenue Bridge and the Scajaquada Creek Slip area. The Lower Scajaquada Creek area is characterized as a highly urbanized, degraded aquatic habitat within a heavily developed watershed, primarily consisting of a channelized creek with limited natural vegetation, and bank cover type dominated by staghorn sumac (*Rhus typhina*), tall goldenrod (*Solidago altissima*), box elder (*Acer negundo*) and various dogwood species (*Cornus* sp.). Due to the nature of the observed substrate, submerged aquatic vegetation was limited to the shallower depositional areas of sediment along the creek banks thus significantly reducing fish cover. Observed fish species included rock bass (*Ambloplites rupestris*), small mouth bass (*Micropterus dolomieu*) and striped shiner (*Luxilus chrysocephalus*). The banks of Lower Scajaquada Creek ranged from gently sloping areas dominated with terrestrial herbaceous vegetation and sporadic tree cover to engineered shores lines.

Scajaquada Creek in the Lower Scajaquada Creek OU transitions from a Class C to a Class B stream and flows into the Niagara River, (Class A-Special stream). Sensitive species potentially present in this segment of Lower Scajaquada Creek include the salamander mussel (Simpsonaias ambigua) and the lake sturgeon (Acipenser fulvescens). The Niagara River, to which Lower Scajaquada Creek discharge, is listed as a NYS freshwater mussel screening stream.

9.1. Initial Sediment Characterization

As part of the FWRIA, sediment data collected during the RI/FS will initially be evaluated through a comparison to NYSDEC screening benchmarks, including the NYSDEC (2014c) Class A and Class C freshwater Sediment Guidance Values (SGV). SGV are not available for all contaminants; therefore, for contaminants where SGV are not available, the SGV will be supplemented with benchmarks from additional sources. The research for alternate screening benchmarks will include a general literature search and query of multiple databases, including the following:

- National Oceanic and Atmospheric Administration (NOAA) Screening Quick Reference Tables (SQuiRT) (Buchman, 2008)
- USEPA Region 4 Ecological Risk Assessment Supplemental Guidance (March 2018 update)
- USEPA Region 3 sediment screening benchmarks (2006); and
- USEPA Region 5 Resource Conservation Recovery Act (RCRA) Corrective Action – Ecological Screening Benchmarks (2003)

The screening approach initially identifies a preliminary list of COPEC that includes constituents detected above conservative benchmarks, specifically the Class A SGV, which will be retained for further evaluation as detailed in the following sections.

9.2. COPEC Refinement

An ecological CSM will be developed following the RI sediment characterization. The ecological CSM will describe the predicted relationships between ecological receptors and stressors to which they may be exposed. The CSM will also describe the primary, secondary, and tertiary exposure pathways or co-occurrences among exposure pathways, ecological effects, and ecological receptors (USEPA, 1998). The CSM will summarize how COPECs may be transported through potentially impacted sediments and result in exposure to ecological receptors. Based on the observations made during the October 2024 habitat assessment, the primary mechanisms of exposure to COPECs in the Lower Scajaquada Creek are direct exposure to impacted sediments in the observed depositional areas and assimilation by a species (e.g., prey/food item) at one trophic level, bioaccumulated by that trophic level, and transferred to a higher trophic level species through consumption. Bioavailability considerations, including total organic carbon and AVS/SEM modeling, will be incorporated into the exposure assessment process. Based on the proposed exposure pathways, the key receptors of concern are benthic invertebrates, fish and semi-aquatic piscivorous mammals and avian species.

In order to assess the potential for impacted sediments to pose ecological harm to receptors within Lower Scajaquada Creek, surrogate species, including American mink (*Neogale vison*) and belted kingfisher (*Megaceryle alcyon*) have been identified as representative species to evaluate exposure to mammalian and avian receptors based on feeding guild. Surrogate species for benthic invertebrates and fish were not selected as these receptors were evaluated on a community rather than individual level. The following sections discuss the identification of endpoints that will be utilized to evaluate the ecological effects associated with the potential exposure of ecological receptors to COPECs.

9.2.1. Assessment and Measurement Endpoints

Assessment endpoints are statements of the characteristics or attributes of the environment that are to be protected. The following assessment endpoints were developed based on the selection criteria described in the USEPA Environmental Risk Assessment Guidance for Superfund (USEPA, 1997).

- Assessment Endpoint #1: Evaluate the potential for adverse changes in the survival, reproduction, and growth of benthic invertebrate and fish populations on a community level resulting from potential exposure to COPECs in depositional sediments.

- Assessment Endpoint #2: Evaluate the potential for adverse changes in the survival, reproduction, and growth of populations of semi-aquatic mammal species potentially utilizing the Site resulting from exposures to COPECs in sediments and prey (fish and benthic invertebrates).
- Assessment Endpoint #3: Evaluate the potential for adverse changes in the survival, reproduction, and growth of populations of semi-aquatic avian species potentially utilizing the Site resulting from exposures to COPECs in sediments and prey (fish and benthic invertebrates).

Because the above assessment endpoints generally cannot be measured directly, measurement endpoints have been identified. There are three types of measurement endpoints, or lines of evidence, that are used to assess the status and potential changes in the attributes of the environment. The lines of evidence will include:

- Determination of the potential for ecological effects by the comparison of COPEC concentrations to media-specific ecotoxicological benchmarks derived from the literature, when available;
- Estimation of the potential for ecological effects on higher trophic level organisms (American mink and belted kingfisher) from COPECs based on dietary exposure; and
- Toxicity studies to directly measure the effects of contaminants on local biota.

9.2.2. Risk Characterization

The analytical results for sediment COPECs observed to exceed the initial sediment characterization (Section 9.1) will be utilized to calculate Exposure Point Concentrations (EPCs) that will be used to further refine the potential for COPEC exposure to ecological receptors. The EPCs for ecological receptors in sediment will be developed based on calculation of the 95% Upper Confidence Limit (UCL) of each COPEC.

The direct contact exposure evaluation includes the comparison of EPC of detected COPECs to direct contact ecological criteria for the analysis of risks to benthic macroinvertebrate and fish communities will be conducted, as will estimations of potential exposures to the surrogate wildlife receptor (American mink and belted kingfisher). The exposure to COPECs in sediment and prey will be calculated through the development of an average daily dose (ADD), which is the amount of COPEC that an individual organism may be exposed to daily through direct or indirect exposure pathways within the Site area.

The calculated ADDs will then be compared to industry recognized Toxicity Reference Values (TRVs). TRVs will be selected for each COPEC to develop Hazard Quotients to assess the potential presence of risk to ecological receptors from sediments with Lower Scajaquada Creek.

10. Feasibility Study

The FS for the Scajaquada Creek OU will evaluate potential remedial actions to address DNAPL and other COC contamination in creek sediments, soils, and groundwater as necessary to meet remedial objectives. The FS will include the following:

- Summarize RI Findings: Provide a summary of site investigation information describing the extent of DNAPL and other COCs, the fate and transport of contamination, and identification of complete exposure pathways that could impact human health, and ecological risk findings.
- The RI Summary Findings will be coordinated with NYSDEC to incorporate findings from RI work conducted by National Fuel and by NYSDEC.
- Identify Remedial Action Objectives (RAOs): Establish specific goals for the protection of human health and the environment, considering the nature and extent contamination. This will include consideration of New York State sediment guidance values and other applicable screening values that are consistent with Niagara River AOC BUIs and other appropriate considerations including planned future uses.
- Identify Response Actions and Development of Remedial Alternatives: A range of potential remedial actions will be formulated to address the RAOs. This will include but not limited to, removal and containment strategies, practical treatment technologies, and institutional controls.
- Screen and Evaluate Alternatives: Conduct a detailed analysis of each remedial alternative based on criteria such as effectiveness, implementability, and regulatory compliance. Each alternative will include a cost estimate.
- Conduct a Comparative Analysis: Compare the shortlisted alternatives against each other to determine the most suitable remedial action. This analysis will consider long-term effectiveness, reduction of toxicity, mobility, or volume of contaminants, short-term effectiveness, and overall protection of human health and the environment.
- Recommend the Preferred Alternative: Recommend the most appropriate remedial action based on the comparative analysis, stakeholder input, and regulatory requirements. This will include involvement of community members, regulatory agencies, and other stakeholders in the decision-making process to ensure transparency.

The FS findings will be incorporated in a Draft RI/FS Report. The draft report will summarize the RI findings and FS activities identified above. The RI/FS findings will be presented at a public meeting. Comments received from the public will be incorporated into the Final Remedial Investigation/Feasibility Study Report for the Scajaquada Creek OU.

1. Introduction

This Site Characterization (SC) Report has been prepared for National Fuel Gas Distribution Corporation (National Fuel) by GEI Consultants, Inc., P.C. (GEI) for property in the Black Rock area of Buffalo, New York adjacent to Scajaquada Creek. The SC Report describes investigation activities and findings for land formerly owned by a National Fuel predecessor company (Iroquois Gas Corporation), as well as the City of Buffalo, the United States of America, and the State of New York. The land was later developed for construction of the Niagara Section of the New York State (NYS) Thruway I-190 with on-ramp/off-ramp access to Route 198 (Scajaquada Expressway). The New York State Department of Conservation (NYSDEC) assigned the property a "Class P" (Potential listing) classification with Site Number 915351 and is referred to as the "P-Site" or "Site" in this report. In addition to the P-Site, investigation activities also included the lower portion of Scajaquada Creek and lands bordering the creek not owned by National Fuel. This area extends from the West Avenue bridge downstream to the creek outlet and is referred to as the Lower Scajaquada Creek Area.

The scope of SC activities was presented in the Site Characterization Work Plan (Work Plan) (GEI, August 2021). One objective of the investigation was to assess the potential for historical releases at the P-Site and whether or not the Site poses a potential threat to public health or the environment such that further investigation pursuant to NYSDEC DER-10 guidelines may be warranted. A second objective of the investigation was to characterize observations of suspected coal tar previously identified in the Lower Scajaquada Creek Area derived from historic manufactured gas plant (MGP) operations at the Iroquois Gas/Westwood Pharmaceutical Terrestrial Site. The requirement to investigate the P-Site and the Lower Scajaquada Creek Area is specified in an Order on Consent (Order or OC) between National Fuel and the NYSDEC that was signed by the NYSDEC Director of Environmental Remediation on June 23, 2021.

This SC Report summarizes the scope and preliminarily evaluates the resulting data associated with the completed SC activities, which were performed between October 2021 and April 2022. This report is organized as follows:

- Section 2 – Site Description and History – Presents a description of the P-Site and the Lower Scajaquada Creek Area (Figures 1 and 2), Site historical information, current Site use, sites bordering the Lower Scajaquada Creek Area and the creek itself having Recognized Environmental Conditions (RECs) as reported by others for these areas are also identified.
- Section 3 – Summary of Site Characterization Activities – Describes the scope of work, investigation methods, and deviations from the SC Work Plan.

- Section 4 – Site Characterization Findings and Assessment – Describes the investigation findings, preliminary site conceptual model, and the associated potential threat to public health and the environment.

- Section 5 – Conclusions and Recommendation – Summarizes SC conclusions and recommendations.

- Section – References – Provides references to documents cited in this report.

Various tables, figures, and appendices are also included and referenced within the text where appropriate.

2. Site Description and History

This section describes the P-Site and the Lower Scajaquada Creek Area, provides historical information and current property use, and identifies and summarizes properties in the Lower Scajaquada Creek Area with Recognized Environmental Conditions (RECs). Figures 1, 2, and 3 show various site locations and features referenced in the following text.

2.1 Site Description and Use

The P-Site property is a 2.6-acre area located between the Black Rock Channel and the Scajaquada Creek in the Black Rock section of the City of Buffalo, Erie County, New York (Figure 1). The Site does not have a street address, but the location of the former gas holder was located central to the following coordinates: latitude 42 deg 55'45.30" North and longitude 78 deg 53'56.12" West. Figure 2 is an expanded view of the area designated in this report as the Lower Scajaquada Creek Area.

The P-Site property has been developed for vehicular traffic on the Niagara Section of the NYS Thruway I-190, along with elevated on- and off- ramps for the NYS Route 198 Scajaquada Expressway, a City of Buffalo walking/biking trail, and contains an underground wastewater sewer conveyance system operated by the Buffalo Sewer Authority (BSA) known as the BSA interceptor sewer. During construction of the I-190, the property was substantially modified where the natural Scajaquada Creek outlet was filled (creating the Scajaquada Creek Inlet shown on Figure 2), and the creek outlet was relocated by excavating a channel through the property at its current location. Perimeter fencing extends along both sides of the NYS Thruway corridor.

No definitive plans for change of property use by the Niagara Section of the NYS Thruway or the Scajaquada Expressway near the Site or the Lower Scajaquada Creek area have been publicized by the NYS Department of Transportation (NYSDOT). In 2017, the NYSDOT completed a Final Design Report / Final Environmental Impact Statement / Final 4(f) Evaluation for a 2.2-mile segment of the Scajaquada Expressway corridor between the Grant Street interchange to the intersection with Parkside Avenue in the City of Buffalo (NYSDOT, November 2017), herein referred to as the NYSDOT Scajaquada Expressway 2017 Corridor Design/FEIS or NYSDOT Scajaquada project report. While outside the NYSDOT's project development area, the FEIS included a summary of environmental information along the full length of the Scajaquada Expressway corridor from the NYS Thruway I-190/Scajaquada Express exchange (area of the P-Site) to the Grant Street exchange. This summary presents pertinent information including RECs at the P-Site as well as at nearby properties. Following report completion and stakeholder review, NYSDOT Region 5 Director Frank Cirillo issued a brief (January 8, 2018) that stated *"... a consensus could not be reached with the many stakeholders involved. More than two-thirds of the most recent public comments received by*

NYSDOT were not in favor of the proposed Scajaquada Corridor project moving forward. As a result, NYSDOT will rescind work on the Environmental Impact Statement and not move forward with the project in its current form." Since that time, the Greater Buffalo Niagara Regional Transportation Council (GBNRTC) has resumed interest in modifications to the expressway corridor in the Olmsted Park area of expressway near Delaware Park approximately 1.5 miles northeast from the West Avenue bridge (Figure 1).

2.2 Site Ownership, Zoning, and Current Property Use

The City of Buffalo GIS property viewer (https://www.buffalony.gov/543/GIS-Maps) identifies the entire P-Site without a property identifier code indicating the property is currently owned by the State of New York. The NYSDEC provided National Fuel with historic plans (Drawing 301.0-8 Sheet 27 dated 3-21-1955 by the New York State Thruway Authority) that included record plans for constructing a portion of the Niagara Section of the NYS Thruway - Porter Avenue to Ontario Street Part 1. The plans identify the transfer of lands from various owners of the historic P-Site property including Iroquois Gas Corporation, the US Government, and the City of Buffalo to the State of New York. The 1955 drawings designed a new creek channel line as proposed by the US Army Corps of Engineers to re-route the Scajaquada Creek outlet by cutting an approximate 20-foot-deep channel directly across the area of the former gasholder on the NYS-acquired property. The historic natural Scajaquada Creek outlet was shown as being backfilled.

The P-Site property is currently utilized by the New York State Thruway Authority as a traffic corridor for the NYS Thruway System. A portion of the property includes a walking and biking trail used for recreational activity. The property is not zoned.

Properties adjacent to the creek in the Lower Scajaquada Creek Area are not owned by National Fuel but are owned by various public and private entities. Many of these properties have documented Recognize Environmental Conditions (RECs) including sites listed in the NYS Brownfields Cleanup Program (BCP), spill sites, and historic industrial properties. These sites are shown on Figure 3.

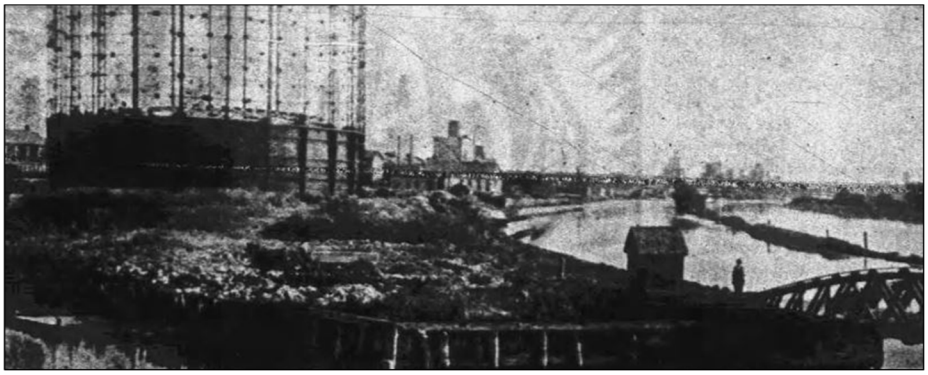
2.3 Historic Industrial Sites, BCP Sites, and Spill Sites

The P-Site property and nearby properties in the Black Rock Area near Scajaquada Creek have a long history of industrial use in the City of Buffalo from the mid-1800s though the mid to late 1900s. As shown in the 1927 aerial photograph below and information found in various environmental database searches and mapping records, industrial use of properties in the Lower Scajaquada/Black Rock area included: metal foundries, coal yards, rail lines, factories and manufacturing plants (i.e., paint and lacquer), gas manufacture and storage, steel works, and other industrial operations.

Photograph - *1927 aerial photograph showing the highly industrialized development of the Black Rock area (note original location of the Scajaquada Creek outlet to the Black Rock Channel and concrete foundation of gasholder at the P-Site property).*

2.3.1 P-Site History

The property was occupied by Shepard Hardware Company around 1883. The Shepard Hardware Company was a foundry that manufactured iron and brass household items, including ice cream freezers, iron piggybanks and other household goods. In May 1893, the foundry was destroyed by an intense fire that leveled the buildings on the property. Buffalo Gas Light Company purchased the property that comprised the Site in February 1896. In April 1896, Buffalo Gaslight Company began the construction of an above ground gasholder (see historic photo below).

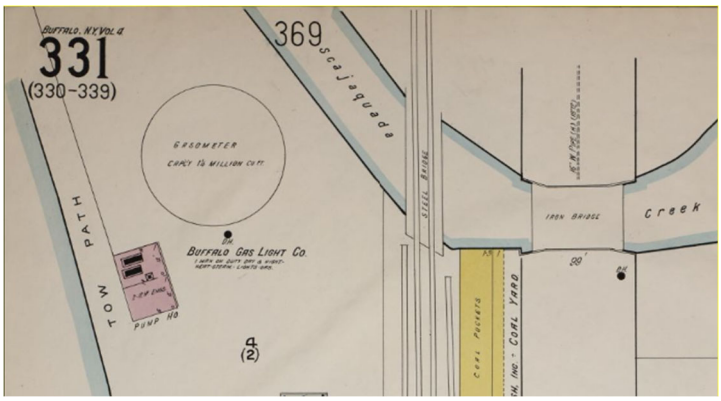


An article in the Buffalo Evening News (April 16, 1896) stated that,

> "*The tank will be situated between the Scajaquada Creek and the Erie Canal on the ground once occupied by the Shepard Hardware foundry. The gasometer will be the largest in the State outside of New York. The interior diameter of the great steel tank will be 132 feet, six*

> *inches and when full will rise to a height of 150 feet. The foundation will be of concrete and will be three feet below the surface. It will be constructed in three sections, which will telescope so that when empty it will be 50 feet high. The capacity of the tank will be 2,500,000 cubic feet of gas which is not under pressure. The gas will be manufactured at the present works and piped to Black Rock."*

As stated in the article above and supported by a review of aerial photographs, historical maps, and Sanborn Maps, gas was not manufactured on the property. Sanborn maps for 1900 and 1916 show a structure containing a pumphouse and boiler near the gasholder. A structure is present south of the P-Site and is not related to operations at the property.



From: Sanborn Map 1916

The gasholder remained on the property until no later than 1928 based on aerial photo review.

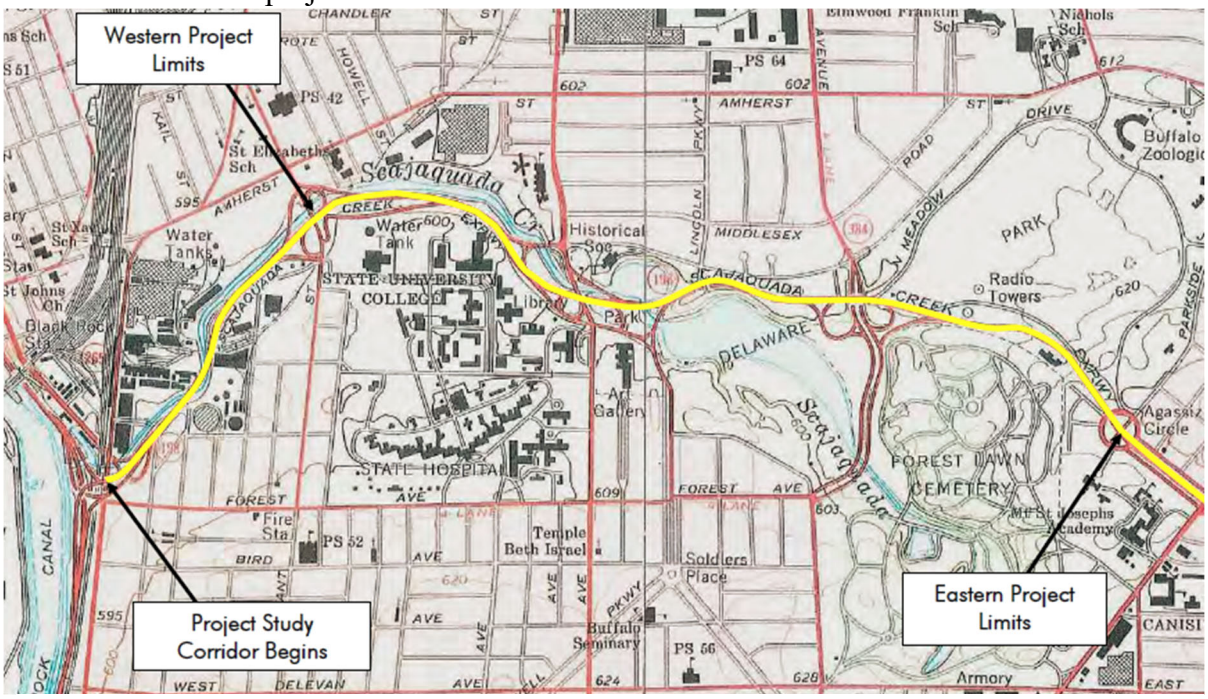
Subsequently, the property became unused until development for the Niagara Section of the NYS Thruway I-90 in the mid-1950s. NYS Thruway Authority design drawings were obtained and reviewed. The as-build drawings show complete excavation and removal of the concrete pad of the former gas holder as well as soil to a depth of 21 feet for relocation of the Scajaquada Creek outlet. Information related to backfilling the natural outlet of Scajaquada Creek has not been identified in the drawing packages reviewed.

Potential related Areas of Concern (AOCs) at the Site include its use as a holder for manufactured gas from an off-site source. Also, the location of the structure containing the pumphouse and boiler is considered an AOC for the property.

2.3.2 Industrial Sites, BCP Sites, and Spill Sites

As mentioned in Section 2.1, a redesign development project was contemplated for the Scajaquada Expressway. The scope of the project necessitated completion of a preliminary design and completion of environmental impact study. The NYSDOT Scajaquada Expressway 2017 Corridor Design/FEIS included the identification of properties with

potential environmental concern in the expressway corridor in the Lower Scajaquada Creek area. The map below identifies the corridor project study limits and Western and Eastern limit of the corridor project.



Map from NYSDOT, November 2017 Scajaquada Expressway 2017 Corridor Design/FEIS or NYSDOT Scajaquada project report NYSDOT Volume 8

Their report identified 25 properties posing an environmental concern along the Scajaquada Expressway corridor between the I-190 and the expressway's Grant Street exchange. The NYSDOT report included the property associated with the P-Site which was identified in the report as, "Site F – I-190 Section" and concluded the following, "Despite redevelopment, the use of this property as a foundry and a gas company with a large gas tank [*sic.* gasometer] indicates the potential for encountering soil contamination from petroleum products and the potential for abandoned USTs in the existing ROW."

During the past several decades, investigations and some remedial activities have occurred on properties in the area of the Lower Scajaquada Creek. Sites are shown on Figure 3 and are listed below with a brief description.

- Property at 1600 (also identified as 1654) Niagara Street (Spill number 1901060) – NYSDEC spill reported on April 30, 2019, at City of Buffalo Pump Station which pumps collected storm water from Niagara Street beneath the depressed section of the roadway beneath the CSX railroad bridge. A petroleum-type sheen was reported on surface water near the outfall discharge from the pump house to Scajaquada Creek. The NYSDEC spill inspector stated that he did not observe a sheen in the water being pumped from the pump house basement which collects stormwater from depressed

roadway below the railroad bridge. The spill report stated that, the rocks near the discharge "had distinct strong creosote odor and coated the rocks." The report also stated, "the coated rocks appear to be releasing petroleum sheen whenever water flows over them." The spill number was closed on May 8, 2019, and according to the Department, was referred to the NYSDEC's remedial section for follow-up work.

- Property at 1660 Niagara Street (BCP Site number C915311) – Historical use of the Site since the 1940s as gasoline sales and underground petroleum storage, vehicle repair and collision shop, and boat sales. Soil and groundwater testing during a Phase II environmental site assessment (ESA) identified contamination from historic property use and detected the following Constituents of Concern (COCs): petroleum VOCs and chlorinated VOCs (i.e., tetrachloroethylene [PCE] and degradation products), PAHs, arsenic, and lead.

- Property at 1626 Niagara Street (no NYSDEC Site No.) – The 2017 NYSDOT Scajaquada Corridor Study identified 1626 Niagara Street as a historic property used as a power station (circa 1912) and an area of concern for redevelopment. Two spills were identified in the EDR search and confirmed by review of NYSDEC spill database. The former on-site building (later used as a substation) was decommissioned during the 1990s.

- Former Pratt & Letchworth malleable iron and steel works, 189-205 Tonawanda St. (Site number 915045) – Operated as an iron steel works plant from the late 1890s through the mid-1900s and utilized "Fletcher Furnaces" for heating steel. Historic aerial photographs, Sanborn Maps, and the NYSDOT Scajaquada project report identified substantial petroleum bulk storage including a 500,000-gallon fuel oil tank installed in 1941; a 2,000-gallon gasoline underground storage tank installed in 1955; and a 30,000-gallon propane aboveground storage tank installed in 1977. A concrete oil tank house was constructed at this site in 1916. Four 20,000-gallon #6 fuel oil aboveground storage tanks (installation date unknown, removed 1995) were listed for this site. An investigation documented subsurface soil, surface soil, and surface water contamination on this site. Contaminants included PAHs, PCBs, phenolics, VOCs, and heavy metals. A petition to delist a portion of the site for the construction of a store and parking lot was submitted and approved. Some PCB contaminated soils have been removed from the site. Following site cleanup, the NYSDEC issued a "No Further Action" Record of Decision in 1995.

- Former Pratt & Lambert Paint and Varnish Plant, 75 Tonawanda St. (no site number) – The past use of the property as a paint and solvent manufacturer, as well as the past presence of over 100 petroleum and chemical storage tanks on the property, indicate the potential for soil and groundwater contamination from petroleum, chemicals,

solvents, and paint products to have been released from the site. Recorded spills and limited soil cleanup have been documented at the site.

- Former Pratt & Lambert Paint and Varnish Plant, 1451 West Avenue (no site number) – The past use of the property for lacquer manufacturing, as well as the past presence of bulk solvent and petroleum storage in above-ground and below-ground tanks on the property, represent potential sources of impact to Scajaquada Creek. Recorded spills and soil cleanups have been documented at the site.

- Property at 68 Tonawanda Street (NYSDEC Site No. C915316) – The property houses the historic New York Central Freight House and Office constructed in the early 1900s. The property is situated adjacent to railroad tracks operated by the New York Central railroad (currently CSX railroad). Railroads are RECs as they typically are associated with environmental impacts from operations which include use of creosote and diesel fuel. The results of a Phase II ESA (Panamerican Environmental, Inc./BE3, February 2017) indicate that semi-volatile organic compounds (SVOCs) (primarily PAHs) and metal compounds were detected throughout the Site at levels above residential and restricted residential soil cleanup objectives (SCOs). VOCs and PCB/Pesticides were detected but at concentrations below SCOs.

- Property at 57-71 Tonawanda Street (NYSDEC Site No. C915024) – The property was a lateral expansion of the Fedders Corporation situated at 31 Tonawanda Street. A portion of the site was listed as a Class 3 site on the NYSDEC's Registry of Inactive Hazardous Waste Disposal Sites in New York State. Soil and groundwater testing on the property identified the following COCs: chlorinated VOCs (TCE and degradation products), petroleum-related VOCs (BTEX), PAHs, PCBs, and heavy metals. The property is currently undergoing cleanup and redevelopment under the BCP.

- Property at 31 Tonawanda Street (NYSDEC Site No. C915299) – The original use of this property included brick making and sewer pipe making during the mid to late 1800s. In the early 1900s, the Fedders Corporation constructed a large manufacturing facility on the property. The Fedders complex historically used various chemicals, oils, solvents, and other materials in their manufacturing process. The processes at the property included metal stamping, soldering, brazing, welding, painting, acid washing and degreasing. Industrial wastes were reported to include solder dross, degreasing still bottoms including TCE and PCE, petroleum-based lubricating fluids and other products and wastes. Percent level concentrations of chlorinated VOCs (PCE and breakdown products) were identified in groundwater at the 31 Tonawanda Street property and property west of the site at 1660 Niagara Street.

- Property at 166 Dart Street (No site number) – Historical property involved in producing structural steel. According to a book by J. N. Larned (1911), Buffalo Structural Steel operated a steel forming facility with a capacity for producing about 8,000 tons of structural steel per year. Little else was found concerning history of the facility other than an expansion of the operation to the north. The property was acquired by the City of Buffalo after plant closure around 2010 and used as a salvage/impound lot. The past use of this property as a steel company and an automobile storage area indicates the potential for soil contamination from petroleum, chemicals, and solvents to exist on site. In addition, a portion of Scajaquada Creek was filled in on this site.

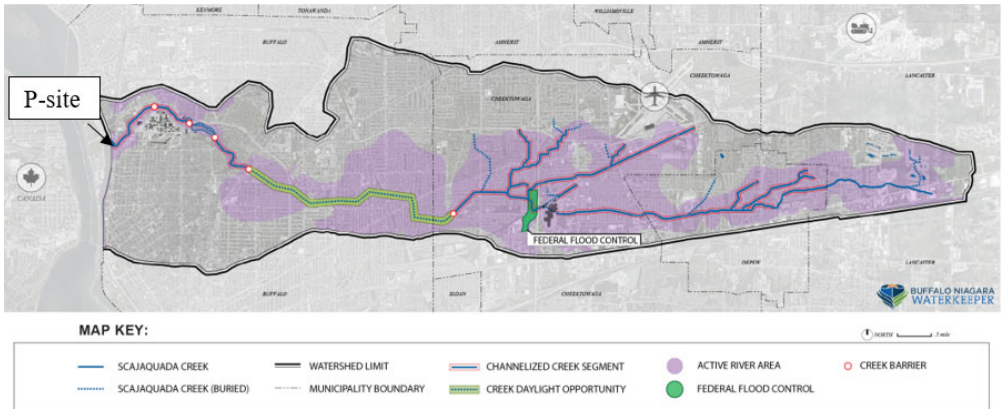
- Property at 120 Dart and 40 Bradley Street (NYSDEC Site No. #915141) – Property located at Dart and Bradley Street was formerly utilized as a manufactured gas plant and identified as the Iroquois Gas/Westwood Pharmaceutical Site. The property was development for manufactured gas generation about 1897 by the People's Gast Light and Coke Company. Feed stocks used in the gas manufacturing process were coke, oil, and coal. MGP operations reportedly ceased in 1955. Iroquois Gas continued to store natural gas at the site until 1972. In 1994, GeoTrans, Inc. completed a Remedial Investigation at the property. The RI characterized geology and distribution of COCs identified in soil, groundwater, and creek sediment. The RI identified benzene, toluene, ethylbenzene, and xylenes (BTEX) and PAHs in site media including the presence of non-aqueous phase liquid (NAPL) classified as coal tar. The remedies for the land side and creek side portions of the property were separated under NYSDEC consent decrees and identified as the Iroquois Gas/Westwood Pharmaceutical Terrestrial Site - #915141 and the Iroquois Gas/Westwood Pharmaceutical Riparian Site - #915141B. The Terrestrial Site remedy included in-situ containment with a sheet pile barrier wall placed between the land side and the creek and hydraulic control with groundwater extraction and treatment, and groundwater quality monitoring. In 2017, vertical groundwater collection wells were replaced by a horizontal groundwater collection trench placed upgradient of the sheet pile barrier to improve hydraulic control. The Riparian Site remedy included excavation and removal of contaminated sediments impacted by historic operations at the Terrestrial Site, capping of the creek bottom beginning approximately 50 feet east from the West Avenue Bridge and extending approximately 1,600 feet upstream to the abandoned New York Central Railroad bridge, placement of a vertical sheet pile barrier near the West Avenue bridge, long-term collection of DNAPL from coarse-grained deposits below the cap and creek sediments upgradient from the vertical barrier, and long-term monitoring of the sediment cap. The remedial measures were in place by 2000.

Documents with site information for many of the sites listed above are available on-line through the NYSDEC DECInfoLocator and https://www.dec.ny.gov/data/DecDocs/ by searching the NYSDEC Site Number. Boring logs/monitoring well construction details

from these investigations relevant to this study (as prepared by others) are included in Appendix B.1.

2.4 Description of Scajaquada Creek and Historic Sampling

The Scajaquada Creek watershed covers an urban area of 29 square miles. The source of Scajaquada Creek is located in the Town of Lancaster, approximately 18 miles east of the Black Rock Channel at its mouth. A map of the Scajaquada Creek Watershed is shown in the figure below.



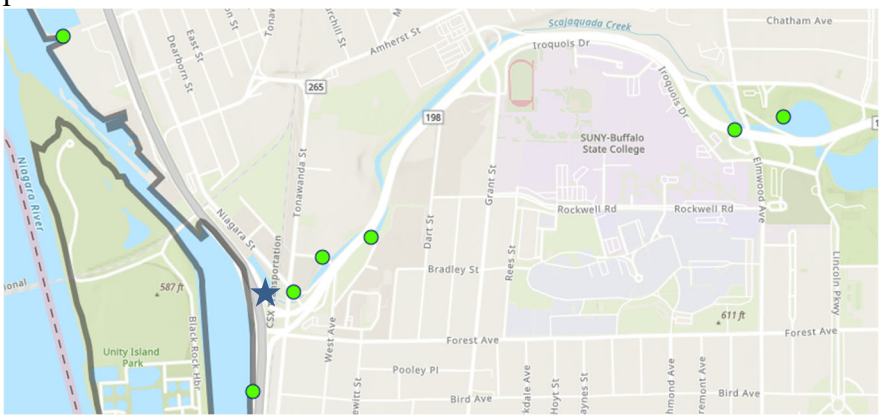
From: Buffalo Niagara Waterkeeper, https://bnwaterkeeper.org/scajaquada-creek/ and annotated by GEI with P-Site location

The course of the creek has been highly modified and channelized over its length. East of the Lower Scajaquada Creek Area, a portion of the creek is contained below urbanized areas of Buffalo in a three-mile-long tunnel, upstream of Forest Lawn Cemetery. Above the upstream entrance to the tunnel the creek runs through highly developed residential areas of the Towns of Cheektowaga and Lancaster. Downstream of the tunnel, the creek passes through Delaware Park, and then enters the former industrial area of Black Rock. The lower portion of the creek has historically been navigable for small boats which serviced industries along the creek. The mouth of the creek historically was used as a small port and supported naval vessels during the War of 1812 including the rehabilitation of watercraft. Prior to industrial development of the Black Rock area, the creek was wide, shallow, and meandering, surrounded by extensive marshes and meadows. Over the past two centuries, the Scajaquada Creek channel has been altered as urban and industrial development progressed in the City of Buffalo. Boat and barge traffic historically transported materials to and from the various industries located along the Lower Scajaquada Creek during the late 1800s and early 1900s. During that time, the creek was channelized and the wetland areas surrounding the creek were filled to accommodate industrial development. Boat slips lined the northern side of the creek prior to closure of the original creek mouth during re-routing of the creek to accommodate the development of the NYS Thruway Authority I-190 highway.

Scajaquada Creek flows toward the Black Rock Channel under normal weather conditions. However, storm and wind events can cause flow in the lower Scajaquada Creek area to

temporarily reverse direction as lake levels at the eastern end of Lake Erie rise producing higher water levels in the Niagara River resulting in a flow reversal in the lower portion of Scajaquada Creek. These lake seiche conditions are temporary and short duration, typically less than 48-hours, and occur more frequently during the late fall and early winter seasons in Western New York.

The NYSDEC stream classification for Scajaquada Creek is Class B-Fresh Surface Waters, Standards B, pursuant to 6 NYCRR Part 701. The best usages for Class B waters are for primary and secondary contact recreation and fishing. The water quality must be suitable for fish propagation and survival. Scajaquada Creek is on the Final New York State 2014 Section 303(d) List of Impaired Waters Requiring a Total Maximum Daily Load (TMDL). These are waters with verified impairments that are expected to be addressed by a segment/pollutant specific TMDL. Pollutants listed include floatables, dissolved oxygen/oxygen demand, phosphorus, PCBs, pesticides, heavy metals, and pathogens. The sources for these pollutants are listed as Combined Sewer Overflows (CSOs) and Urban Runoff. The map below from the Buffalo Sewer Authority (BSA) website (https://buffalosewer.org) shows permitted CSO discharge locations in the Lower Scajaquada Creek Area, areas upstream of the Westwood Riparian Site and the Black Rock Channel within the mapped limits shown below.



- Combined Sewer Overflow discharge locations near the P-Site
- P-Site location

In addition to the direct discharge of pollutants at CSOs, historic activities at industrial properties situated along the creek have impaired sediment quality with debris such as foundry sands and household trash, as well as COCs such as VOCs, PAHs, PCBs, pesticides, and heavy metals (see Section 2.3).

The USEPA designated the Niagara River as a binational Area of Concern (AOC) in 1987 because past industrial discharges and hazardous waste sites caused extensive degradation of aquatic habitats, particularly the degradation of the benthic macroinvertebrate community. In an unrelated study in 1993, the NYSDEC collected sediment samples at eight transect locations in the Lower Scajaquada Creek area to preliminarily assess the impact to sediments near historic industrial properties between Grant Street and the Black Rock Channel (NYSDEC, 1993). The sediment sample collected and analyzed farthest upstream (east of

Grant NS- No sample, ND – None Street) detected a total base neutral acid extractable concentration (BNA) of 191.4 mg/kg. BNA concentrations in sediments downstream opposite industrial properties (shown on Figure 3 and discussed in Section 2.5.3) ranged between 2.76 mg/kg and 580.4 mg/kg with the highest concentration occurrence near the Dart and Bradley site (pre-remediation). BNA concentrations in samples farther downstream (upstream side of the CSX steel railroad bridge) ranged from 14.2 mg/kg to 169.3 mg/kg. At all sample locations, PAHs had the highest BNA constituent concentrations. Pesticides and PCBs were detected at nearly all sample locations with no clear pattern of distribution. PCB concentrations ranged from non-detect to 4.2 mg/kg with the highest concentration detected upstream of the Dart and Bradley property. Arsenic, cadmium, lead, and mercury were elevated at most sample locations.

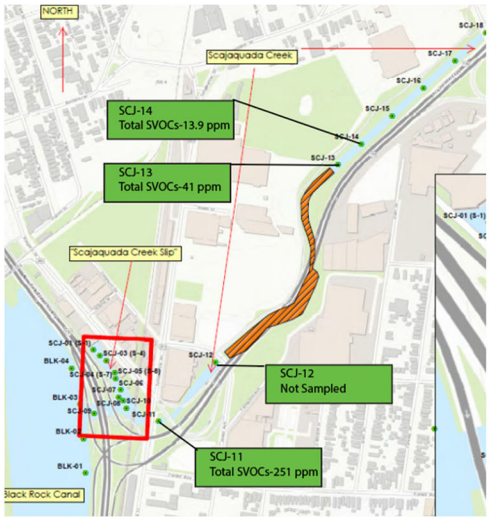
Preliminary studies conducted by the USEPA/USACE in 2014 and 2015 assessed sediment quality in tributaries to the Niagara River. Sediment testing in the Lower Scajaquada Creek Inlet (near the former boat slip area) east of the P-Site indicated sediment toxicity associated with contaminated bed sediments (USGS, 2016). Subsequently, contractors to the NYSDEC conducted additional sediment sampling in Scajaquada Creek primarily in the closed, dead-end portion of the former outlet of Scajaquada Creek (NYSDEC/Empire GEO Services, February 2015). The adjacent aerial photograph shows these sediment sampling locations. Sample results for the 2015 NYSDEC Scajaquada Creek Slip Area (Inlet area) sediment sampling are summarized below.

SAMPLE ID	Total SVOCs (ppm)	TOTAL PAHS (ppm)	Total VOCs (ppm)	Total CVOCs (ppm)	Total PCBs (ppm)	Petroleum Hydrocarbon Fingerprint (ppm)
S-1	959	610.5	27.4	ND	2.17	Fuel Oil #6- 10,000 / Motor Oil- 6,800
S-2	23,284	11,157	3,737	ND	NS	NS
S-3	199.7	109.7	0.16	ND	NS	NS
S-4	216.3	216.3	2.28	ND	NS	NS
S-5	555.7	500.6	0.64	ND	NS	NS
S-6	76.4	76.4	2.32	1.4	NS	NS
S-7	172.3	166.6	49.7	ND	9.01	Fuel Oil #6- 4,600 / Motor Oil- 3,900
S-8	156.7	156.7	75.5	ND	NS	NS
S-9	73.6	73.6	3.06	ND	NS	NS
S-10	137.3	137.3	1.18	ND	3	Fuel Oil #6- 5,300 / Motor Oil- 4,800

ND – Not detected; NS – No sample

Testing indicated the presence of PAHs, petroleum and chlorinated VOCs, and PCBs in shallow creek sediments. The TPH method fingerprints suggested low- to mid-distillate petroleum source material.

In 2017, additional sediment sampling was conducted in Scajaquada Creek by the USACE and the NYSDEC. These studies included sample collection and analysis of sediments from the eastern side of the Black Rock Channel near the P-Site and areas upstream from the mouth to Elmwood Avenue (NYSDEC/Empire GEO Services, June 2017). A portion of the data are summarized below.



Scajaquada Creek 2017 Sediment Sample Summary

SAMPLE ID	Total SVOCs (ppm)	TOTAL PAHS (ppm)	Total VOCs (ppm)	Total CVOCs (ppm)	Total PCBs (ppm)
SCJ-11	251	130	NS	NS	0.003
SCJ-13	41	41	NS	NS	0.99
SCJ-14	13.9	13.5	NS	NS	0.176

NS-Not Sampled

Data excerpt from NYSDEC/Empire GEO Services, 2017 and annotated by GEI.

Sediment sample data collected in 2017 from Scajaquada Creek identified PAHs, pesticides/PCBs, and heavy metals in Scajaquada Creek extending from the mouth of the creek upstream to sample location east of Grant Street (upstream from the mapped area shown in the figure above). The highest concentrations of COCs detected during the study were found in the slip area of the creek which is consistent with 2015 NYSDEC/Empire GEO Services. The elevated COC concentrations in the slip are most likely the result of stagnated flow conditions caused by the closure of the creek's natural outlet and re-routing of the creek channel to accommodate the 1950s construction of the Niagara Section of the NYS Thruway, thus allowing for the accumulation of sediments in this portion of the creek.

2.5 Previous Testing and Observations

Known site conditions prior to implementing the SC Work Plan included the detection of COCs in Scajaquada Creek sediments derived from:

- historic and current activities at properties in the Lower Scajaquada Creek (see Section 2.3);
- historic and active discharges from combined sewer overflows (CSOs); and

- point source and nonpoint source discharges from properties farther upstream within the Scajaquada Creek watershed including other outfalls discharging to the creek not described in this report.

In 2020, the NYSDEC investigated deeper soil adjacent to Scajaquada Creek. The investigation included the completion of soil borings and monitoring wells on properties located at 1660 and 1675 Niagara Street and later along the walking/biking trail on the west side of the Iroquois Gas/Westwood Pharmaceutical Site Riparian Site (see Figures 2 and 3). The NYSDEC investigation occurred after the NYSDEC's finding of "coated rocks with a distinct strong creosote odor" associated with Spill number 1901060 at 1654 Niagara Street associated with the discharge from the vault of the City of Buffalo Pump Station adjacent to the CSX Railroad bridge.

The NYSDEC provided NFG with documents and field records indicating the presence of COCs in soil and groundwater, as well as NAPL suggestive of coal tar. Suspected coal tar-like DNAPL was reported at wells MW-5R, MW-7, and MW-8R installed at 1660 Niagara Street. In addition to elevated PAH concentrations, analytical data provided by the NYSDEC for well MW-7 identified percent levels of chlorinated VOCs (TCE and PCE) suggestive of a mixture of product sources. Petroleum odors were reported at MW-3R installed at 1660 Niagara Street.

Where DNAPL was identified, the NYSDEC installed wells to depths greater than 25 feet below grade having well screens that extended deep enough to fully penetrate coarser grain materials and encounter the underlying aerially extensive red-brown clay layer. Monitoring wells installed at 1660 Niagara Street parcel during a 2016 BCP Phase II investigation (Labella, 2016) reported the detection of petroleum and chlorinated solvent-related contamination. Wells installed during the BCP Phase II investigation were completed to depths less than 20 feet below grade. DNAPL was not detected in the two wells installed at 1675 Niagara Street located northeast of the 1660 Niagara Street property. DNAPL having high PAH content was identified in well MW-100. This well is situated upgradient from the vertical barrier placed on the downstream end of the Riparian Site remedy that includes NAPL collection at the South Vault and is considered to be within the area of remediation of the Iroquois Gas/Westwood Pharmaceutical Riparian Site. NAPL accumulation was not identified farther upgradient in wells MW-103 and MW106 located along the bicycle path (see Figure 8 and discussion in Section 4.2.2). Based on these findings, an AOC was identified in both shallow and deeper soils adjacent to Scajaquada Creek at 1660 Niagara Street parcel.

3. Summary of Site Characterization Activities

This section describes the activities performed during the SC. Each field activity performed during the investigation, grouped by field task or environmental media, is described in the following sections. The SC sample locations and monitoring well locations on nearby properties installed by others are shown on Figure 2.

Representatives of the NYSDEC were present to observe the majority of the field activities, including the boring/monitoring well installation, sediment boring completion and sample collection, monitoring well sampling, and the City of Buffalo Niagara Street Pump Station sampling. A photographic log documenting SC field investigations is included following the text of this report.

3.1 SC Work Plan Documents

The SC was performed according to the methods and procedures described in the Site Characterization Work Plan (August 2021), which was approved by the Department on October 5, 2021. Four companion documents were included as appendices to the Site Characterization Work Plan:

- **Field Sampling and Analytical Plan (FSAP)** – The Site Characterization sampling, unless otherwise noted in the sections below, were conducted in accordance with the methods described in the site-specific FSAP.
- **Quality Assurance Project Plan (QAPP)** – The QAPP identified the quality assurance objectives for the measurement data, the QA/QC procedures to be used in the field, the sample chain-of-custody methods to be used, and the analytical procedures to be followed.
- **Community Air Monitoring Plan (CAMP)** – A CAMP was prepared which was followed during all invasive fieldwork including soil borings and the well installations.
- **Site-Specific Health and Safety Plan (HASP)** – A site-specific HASP was prepared to describe health and safety risks and procedures for the site sampling personnel.

3.2 Property Access and Underground Utility Clearance Activities

The SC field activities were performed beginning in November 2021 and continued through April 2022. As National Fuel is not a current property owner for any of the investigation locations, property access agreements were required to gain entry to complete field work. The following property owners or State/Federal governmental agencies were contacted to obtain access agreements and/or work permits to complete the work:

Property	Current Owner
P-Site Parcel	NYSDOT/ NYS Thruway Authority
1660 Niagara Street	Buffalo Niagara Riverkeeper
Scajaquada Creek	U.S. Army Corp. of Engineers, City of Buffalo, NYS Office of General Services, NYS Dept. of State.
Parcel Underlying State Route 198 and I-190 interchange, southeast of Scajaquada Creek.	NYSDOT/ NYS Thruway Authority
1626 Niagara Street	Niagara Mohawk Power Corporation (National Grid)
Bicycle Path adjacent to the Riparian Site	City of Buffalo

An on-Site meeting was requested by GEI to all utility entities identified during the initial DigSafe call-in. GEI met on-Site with representatives from National Grid and City of Buffalo to review the locations of buried infrastructure ahead of intrusive activities. Other utilities were either clearly identified on the ground surface during the mark-out process or were identified as "clear" from respondents during the Dig Safely New York process.

Additionally, personnel from the Buffalo Sewer Authority (BSA) field-identified the location of a tunnel interceptor sanitary sewer system which traverses the P-Site in a general north-south direction at a depth of approximately 24 feet below the average surface water elevation of Scajaquada Creek. BSA outlined a "no dig zone" in the field such that any intrusive work on the P-Site would remain a safe distance from the sewer. The location of the no dig zone is identified on Figure 2. Soil borings and monitoring wells proposed to be completed in the no-dig zone as part of the SC investigation were omitted or relocated as described in Section 3.13.

Soil boring locations were cleared using a combination of hand excavation and air-knife methods to a depth of approximately 5 feet below ground surface (bgs) in areas where a high density of buried infrastructure was identified to ensure that shallow utilities were not damaged during drilling.

3.3 Geophysical Survey

A subsurface geophysical survey was performed on the P-Site on October 28, 2021, to evaluate the potential for buried relic structures (gas holder foundation, support buildings, piping, etc.) associated with historic site use. An electromagnetic survey was performed using a Geonics EM-61 unit along transects shown on Figure 2. The results of the electromagnetic survey did not

identify any subsurface anomalies suggestive of relic structures on the P-Site. Additionally, soil boring data from P-Site locations MW-BGL-1 and MW-BGL-3 indicated reworked native clay backfill at the surface across the P-Site. Because no buried anomalies were indicated during the initial EM survey, the ground penetrating radar survey was not performed, and test pits to identify underground structures were not necessary . Results of the geophysical survey are presented in Appendix A.

3.4 Subsurface Sampling

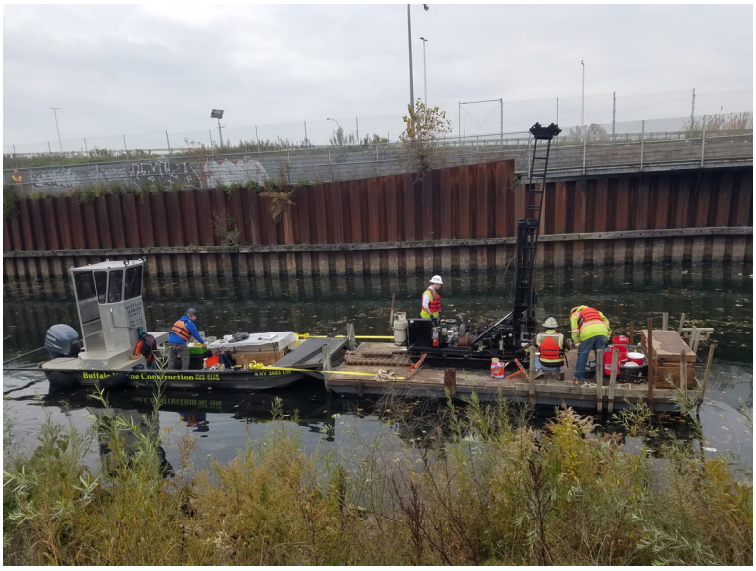
3.4.1 Soil Borings and Soil Sampling

As shown on Figure 2, a total of seven soil borings were completed and converted to monitoring wells during the Site Characterization. Soil samples from boring were submitted for laboratory analyses. Soil borings were completed between November 1 and November 11, 2021, and on January 4 and 5, 2022 (MW-LSC-5) following receipt of a property access agreement on the Niagara Mohawk property at 1626 Niagara Street. Two soil borings (MW-BGL-1 and MW-BGL-3) were completed on the P-Site Buffalo Gas Light (BGL) and five soil borings (MW-LSC-1, MW-LSC-2, MW-LSC-3, MW-LSC-4, and MW-LSC-5) were completed on parcels along the Lower Scajaquada Creek (LSC) corridor. Each boring was completed through fill and native soil into the native, low permeability red-brown (oxidized) clay exhibiting no impacts, consistent with methods outlined in the FSAP of the SC Work Plan. Soil boring logs are presented in Appendix B.2 which include sample collections depths from each boring. Sample collection methods were consistent with the FSAP of the SC Work Plan. A summary of soil samples and analytical methods is discussed in Section 3.12.

3.4.2 Sediment Sampling

Nine sediment borings (designated SED-BGL-1 and SED-LSC-1 through SED-LSC-8) were completed in Scajaquada Creek at locations shown on Figure 2 in accordance with methods described in the FSAP of the SC Work Plan. SJB Services, Inc. completed sediment borings SED-LSC-6, SED-LSC-7 and SED-LSC-8 during the week of November 1, 2021, using a pontoon barge and skid-mounted drill rig with support skiff that was manually launched immediately downstream of the West Ave. bridge. Manually launching the barge to directly access these boring locations was necessary due to height restrictions between the Creek surface and the Niagara Street Bridge and I-198 eastbound entrance ramp. Each of these borings was advanced using 2" diameter split spoon samplers driven by a 140 lb. hammer. Split-spoon sample depths were measured from the barge deck surface and the depth of water was recorded at each sampling location. Samples were

transferred from the pontoon barge to land for logging, sample collection and photo documentation.



The remaining sediment borings were completed west of the Niagara Street bridge by Nothnagle Drilling, Inc. with a support craft provided by Buffalo Marine Construction during the week of November 8, 2021. The barge was launched at a private marina on Niagara St. and shuttled down the Black Rock Canal to Scajaquada Creek. Each sediment boring was advanced using 4¼" hollow stem augers (Diedrich D25) and a dual-tube Macrocore® sampler advanced with an automatic hammer. Macrocore® sample depths were measured from the barge deck surface and the depth of water and deck height above water were recorded at each sampling location. Retrieved samples were transferred to the support craft for logging, sample collection and photo documentation.

At each location, the upper six inches of sediment was collected representing the modern transport and deposition system, and to perform laboratory chemical analyses to assess the sediment quality. Each sediment boring was advanced through historic alluvium and advanced several feet into the native red-brown clay unit. Sediment boring depths are summarized in Table 1B. Samples of deeper sediment/alluvium were collected from each boring to evaluate the quality of deeper deposits in the Creek channel. Samples collected for laboratory analysis were identified by the boring location and sample collection depth. Sample collection depths identified on deeper sediment sampling IDs were based on the barge deck surface measuring point (i.e., not depth below the top of sediment). Surface water elevations were measured throughout the sediment sampling process such that the elevation of each analytical sample could be calculated. Sediment sample analysis for shallow and deeper samples is identified in Section 3.12 and analytical results are discussed in Section 4. Sediment boring logs are provided in Appendix B.3. The location of each sediment boring was marked in the field and surveyed by Fisher Associates in March 2022.

3.5 Monitoring Well Installations and Development

A 2-inch diameter PVC monitoring well was constructed in each soil boring described in Section 3.4, consistent with procedures outlined in the FSAP of the SC Work Plan. Monitoring wells MW-LSC-1, MW-LSC-4, MW-LSC-5 and MW-BGL-1 were completed as flush-mount wells; MW-LSC-2, MW-LSC3 and MW-BGL-3 were completed with stick-up surface completions.

Table 1A summarizes monitoring well screen intervals and geologic material screened. Monitoring well construction logs are included as Appendix B.2. Each newly installed monitoring well was developed no sooner than 24 hours following installation, and consistent with procedures detailed in the FSAP of the SC Work Plan. Monitoring well development parameters are provided in Table 2. Monitoring well development water was collected and containerized as IDW and transported to the 1660 Niagara Street property for temporary storage. The location, ground surface elevation and top of casing elevation of each monitoring well was surveyed by Fisher Associates, Inc.

3.6 DNAPL Mobility Assessment and DNAPL Sampling

An assessment of DNAPL presence and mobility was performed on monitoring wells at the 1660 Niagara Street property (MW-5R, MW-7 and MW-8) and at MW-100 along the City of Buffalo Bike Path on October 26, 2021. At each location, DNAPL presence was evaluated using a weighted white PVC rod to measure NAPL thickness (DNAPL readily stains the surface of the white PVC clearly indicating DNAPL thickness). Where sufficient NAPL was present, accumulated DNAPL was removed using a peristaltic pump with down-hole tubing. NAPL was collected in a 5-gallon bucket and containerized as IDW and transported to 1660 Niagara Street for temporary storage. DNAPL recovery in each of the above wells was evaluated on November 12, 2021, again using a weighted PVC rod. At each location, DNAPL had recovered to pre-removal levels indicating a potentially high degree of mobility at each location. Table 3 identifies DNAPL presence in monitoring wells and measured thickness.

A representative DNAPL sample was collected from each monitoring well and submitted for forensic analysis by META Environmental (see Section 3.12). Additionally, DNAPL samples were collected from the North and South DNAPL collection vaults at the Scajaquada Riparian Site.

3.7 Groundwater Sampling and Water Level Gauging

Following well development, each newly installed SC monitoring well was sampled using low flow sampling methods (peristaltic pump and downhole tubing) in accordance with the FSAP contained in the SC Work Plan. Groundwater samples were collected for laboratory analyses as described in Section 3.12.

Groundwater measurements were collected from each newly installed monitoring well, existing wells on nearby properties, and at two Scajaquada Creek surface water measurement points during the investigation. Measurements were made jointly with Groundwater and Environmental Services, Inc. (GES), a contractor to the NYSDEC, who were previously collecting groundwater elevation measurements from existing wells in the Lower Scajaquada Creek area. Table 3 summarizes groundwater and surface water elevations collected prior to and during the investigation.

3.8 Creek Bank and Outfall Survey

Fisher Associates completed a survey of the creek bank from the northern end of the P-Site and the Inlet area of the creek to the West Avenue bridge (the Riparian Site). The survey was completed on March 15 and 16, 2022 and delineated accessible edges of the creek bank (edge of surface water), the presence of outfalls and headwalls, and structures associated with the City of Buffalo Pump Station. These features are indicated on Figure 2 and further discussed in Section 4.2.3. On March 15, 2022, only the City of Buffalo SPDES outfall near West Avenue was observed to be flowing. The outfall was flowing on all occasions when viewed, which included several dry weather conditions.

3.9 Pump Station and Vault

During field activities, sheens were observed on Scajaquada Creek during discharge from the City of Buffalo Pump Station located adjacent to the 1660 Niagara Street property. Subsequently, the NYSDEC spills group collected samples of water and sediment/debris from the subterranean vault below the Pump Station and a storm sewer manhole leading to the vault on November 17, 2021. Concurrent with NYSDEC sampling, GEI collected a sediment/debris sample from the Pump Station vault and a water sample from stormwater Manhole #23 directly upstream of the vault for laboratory analyses. Samples of debris containing tar-like material (TLM) were also collected from the Pump Station vault and Manhole #23 for forensic analysis by Meta Environmental. Analytical result for sediment/debris and water samples collected from the Pump Station are discussed in Section 4.4.

3.10 Investigation-Derived Waste Management

Investigation-Derived Waste (IDW) generated during the project included soil cuttings, sediment, groundwater, NAPL, decontamination water, decontamination materials and personal protective equipment. IDW was placed in 55-gallon DOT-approved drums and labeled with the contents (PPE, water, soil, etc.), quantity, date of generation, and generator name. An IDW staging area was established at the existing NYSDEC drum staging in the fenced portion of the property at 1660 Niagara Street following an agreement with the property owner.

3.11 Community Air Monitoring

Community air monitoring was performed using PIDs to provide real-time measurements of total VOCs and a Dust Track monitor to measure particulate (airborne dust) concentrations in air at the upwind (background) and downwind perimeter of each designated work area when intrusive investigation activities were performed. Action levels were not exceeded during intrusive investigation activities. CAMP data are provided in Appendix C.

3.12 Analytical Program

Samples of groundwater, shallow sediment, deeper sediment, soil, and debris from a manhole and pump house vault were collected during the investigation. Analyses of these media is described below.

3.12.1 SC Sample Collection

The laboratory samples collected, and the chemical analyses performed during the investigation are identified in Table 4. Constituents analyses were consistent with the work plan and DER-10 and included additional analyses for possible future assessment of toxicological impacts (i.e., NOAA 34 PAHs).

3.12.2 Laboratory Analysis and Data Usability Report

Investigation samples and associated QA/QC samples were collected and analyzed in accordance with the FSAP and QAPP of the SC Work Plan. Soil, sediment, groundwater, and debris samples were analyzed by Alpha Analytical. Forensic samples of suspected TLM-impacted soil and sediment and DNAPL in wells were analyzed by ESS Laboratories and the data were evaluated by META Environmental. The Alpha Analytical Category B ASP data package is provided in Appendix D.1 and the META Environmental/ESS Laboratories forensic report is provided in Appendix D.2. NOAA 34 PAHs results for shallow sediments and included in the Alpha Analytical data package are tabulated in Appendix D.3. A Data Usability Summary Report (DUSR) was prepared for soil, sediment, debris and groundwater samples in accordance with the QAPP of the SC Work Plan and is provided in Appendix E.

3.12.3 EIMS Data Submittal

Validated laboratory data were uploaded to a NYSDEC EQuIS EDD file and submitted through the EarthSoft NYSDEC EDP EDD Format Files Website.

3.13 Deviations from the Work Plan

Deviations from the work plan are summarized below:

- The EM geophysical survey performed on the P-Site did not identify any subsurface anomalies suggestive of relic structures or infrastructure (tanks, piping, etc.). As a result, the ground penetrating radar survey was not performed and subsequently no test pits were excavated.
- As discussed in Section 3.2, the staff from Buffalo Sewer Authority (BSA) identified the location of the BSA Interceptor Sanitary Sewer which in the subsurface, predominantly occupies the area between the I-190 northbound lane and the entrance ramp to the I-190 outbound entrance ramp from I-198 shown on Figure 2. Based on this information, proposed monitoring well MW-BGL-2 had to be omitted and proposed locations MW-

BGL-1 and SED-BGL-1 were modified to avoid this critical infrastructure. These revisions to the SC Work Plan field investigation were communicated in a letter to NYSDEC on November 10, 2021, and approved by NYSDEC in an e-mail that day. The revised locations of MW-BGL-1 and SED-BGL-1 were subsequently approved in the field by BSA personnel and cleared in the field by Dig Safely New York.

- The DNAPL presence and mobility assessment included gauging and removal of NAPL from monitoring wells on the 1660 Niagara Street property (MW-5R, MW-7 and MW-8) and at MW-100 along the City of Buffalo Bike Path. Following removal, NAPL levels in each well recovered to pre-removal levels following the initial two-week recovery period proposed in the SC Work Plan. DNAPL at upgradient and downgradient locations all exhibited similar high-mobility properties and were consistent with DNAPL observations in soil borings and monitoring wells installed during the SC. Subsequently, additional DNAPL mobility assessment was not performed on monitoring wells installed during the SC.
- The SC Work Plan proposed that two synoptic rounds of groundwater elevations would be collected following installation of the SC monitoring wells. A synoptic round of groundwater elevations in the Lower Scajaquada Creek well network was performed on November 23, 2021, by GES and GEI and is provided on Table 3. This included gauging accessible wells installed prior to the SC and wells installed-to-date as part of the SC which including MW-BGL-1, MW-BGL-3, MW-LSC-1, MW-LSC-2, MW-LSC-3 and MW-LSC-4. Well MW-LSC-5 was installed in January 2022 and was therefore not included in the November event. Subsequent gauging events by GES in January and March 2022 are considered substantially complete but some wells could not be accessed due to snow cover or locked access gates.
- The Work Plan called for analysis of shallow creek sediment samples for Extractable Petroleum Hydrocarbons (EPH) using Massachusetts-specified methods. The laboratory inadvertently utilized New Jersey EPH methods. Because the EPH analyses were for forensic purposes, are not associated with DER-10 or New York procedures, and the New Jersey method provides comparable data for the intended purposes, reanalysis by Massachusetts methods was not performed.
- All work activity associated with observations and sampling described in Section 3.9 related to the City of Buffalo Pump Station was outside the Work Plan scope.

4. Site Characterization Findings and Assessment

This section describes site characterization findings including geologic and hydrogeologic conditions and field observations during data collection. These field observations include discharges to Scajaquada Creek (one generating sheens), TLM in soil samples collected from borings, and DNAPL observed in wells. This section also describes constituents detected in media and provides a preliminary conceptual site model.

4.1 Geology and Hydrogeology

Intense development and industrialization of properties in the area of Scajaquada Creek has altered the natural setting of the P-Site and Lower Scajaquada Creek Area. As a result, the shallow geology has been highly disturbed. The ground surface elevation of the P-Site is approximately 573 feet North American Vertical Datum of 1988 (NAVD88) with higher elevations occurring closest to the northbound and southbound highways as engineered fill was placed during construction of the highway. The surrounding properties in the area of the Lower Scajaquada Creek are generally flat lying with ground surface elevations approximately 10 to 15 feet higher than the typical surface water elevation of Scajaquada Creek (typical elevations 570 to 573 ft NAVD88).

The general geology of the P-Site and the Lower Scajaquada Area consists of industrial fill material overlying an aerially extensive red-brown clay of lacustrine origin. Near Scajaquada Creek, alluvial deposits associated with historic or recently deposited sediments lie above the clay. Bedrock below the P-Site was identified in NYSDOT core logs as the Onondaga Limestone. A stratigraphic summary of soil and sediment encountered in soil and sediment borings is included in Table 1A and 1B, respectively. Geologic cross-sections showing strata encountered are provided on Figures 4A through 4F.

4.1.1 P-Site Geology

P-Site geology was characterized using five soil/rock boring logs completed by the NYSDOT in 1956 NYS Thruway I-190 on ramp/off ramp design for Route 198 (Scajaquada Expressway) (boring locations and logs are presented in Appendix B) as well as soil/sediment borings completed for the SC at MW-BGL-1, MW-BGL-3, and SED-BGL-1 (see Figure 2 and boring logs included in Appendix B). The boring logs indicate 8 to 20 feet of heterogenous fill material composed of either reworked red silty clay mixed with construction material (concrete and gravel) or black sand and gravel and mixed with fines and cinders and construction rubble. The fill at the P-Site directly overlies the lacustrine red-brown clay. The red-brown clay is greater than 50 feet thick below the P-Site. NYSDOT boring logs for Scajaquada Expressway design indicate limestone bedrock occurs at a depth of approximately 70 to 75 feet below the current Scajaquada Creek outlet. In some borings, a thin layer of sandy till (approximately 5 feet thick) was reportedly observed immediately above the bedrock (between the red-brown clay and

bedrock). Because the current Scajaquada Creek outlet was constructed during the mid-1950s by excavating through the fill into the upper lacustrine red-brown clay, and because this location likely has a higher scour velocity than the nearby Inlet area, less than 0.5 feet of recent fluvial fine-grain sediment was identified above the red-brown clay in sediment boring SED-BGL-1 in the creek channel at the P-Site.

4.1.2 Lower Scajaquada Creek Area Geology

The geology of Lower Scajaquada Creek area was characterized using five SC soil borings sampled for monitoring well installations (MW-LSC-1 through MW-LSC-5), and eight SC sediment borings (SED-LSC-1 through SED-LSC-8). Additionally, over a dozen soil borings/well installations completed by others to characterize the former industrial properties bordering Scajaquada Creek supported geologic interpretation (boring logs are included in Appendix B for boring/well locations shown on Figure 2). The SC boring logs identified a fill thickness ranging from 10 to 19.5 feet. The fill thickness was interpreted to decrease with distance from the current Scajaquada Creek channel as shown on cross-sections 4A-F based on soil boring data at nearby Brownfield sites. For example, wells completed at the former Fedders Corp Site at 57-71 Tonawanda Street report fill thickness of about 5 feet or less. Historic fill materials were variable in composition consisting of reworked red-brown clay soils and black silty sand with little gravel. The fill material contained anthropogenic materials including brown foundry sands, concrete, cinders, and wood debris.

At nearly all borings completed in the Lower Scajaquada Creek area, alluvial deposits were encountered below fill. The alluvial deposits became increasingly coarse grained with depth. These deposits were typically composed of dark gray to black silt or sand with occasional decayed woody materials. With depth, the alluvium transitioned to black silty sand and fine gravel with occasional wood pieces and shells from gastropods. The alluvium deposits are associated with historic deposition of creek sediments and are typically void of anthropogenic construction materials. The alluvium thickness ranged between 1 and 22.5 feet as encountered in borings. The thickest layer of alluvium was identified in borings completed at 1660, 1654, and 1626 Niagara Street as the historic creek channel scoured the red-brown clay during deposition of early alluvial sediments. The alluvium thickness diminishes with distance from the current creek channel as shown on geologic cross-sections (Figures 4A through 4F).

The bottom of the alluvium was observed as a sharp contact with the area-wide red-brown clay layer. With the exception of MW-LSC-1, all SC borings were advanced at least 5 feet into clay for verification. The composition of the red-brown clay was consistent at each of the borings. The surface elevation of the aerially extensive red-brown clay slopes toward the creek as shown in cross-sections and contour mapping shown on Figure 5. Figure 5 suggests the ancestral channel of Scajaquada Creek was situated farther north in comparison to its current channel (see additional discussion in 4.2.1).

Two soil borings were advanced to bedrock by GeoTrans during the RI at the Westwood Former MGP Terrestrial Site (1995) and encountered bedrock at elevations of 506 and 520 ft msl indicating the thickness of the red-brown clay is at least 50 feet thick throughout the Lower Scajaquada Creek Area.

Within the Scajaquada Creek channel, sediment borings identified a layer of recent fluvial deposits directly overlying red-brown clay or historic alluvial deposits. The recent fluvial deposits were described as black, soft silt with mixtures of sand and gravel containing anthropogenic materials such as glass, foundry sand, and wood with occasional zebra mussels. At sediment borings SED-LSC-1, -2,- 6, -7, and -8, historic alluvial deposits were identified having a similar composition to the alluvium described in SC soil borings below fill material when present. At sediment boring SED-BGL-1, less than six-inches of recent fluvial deposits were identified. The recent fluvial deposits occurred directly over the red-brown clay.

4.1.3 Area Hydrogeology

Groundwater in the area occurs under unconfined (water table) conditions in saturated fill and in alluvium. Groundwater and Scajaquada Creek surface water elevation data were recorded in monitoring wells by GES (contractor to the NYSDEC) prior to the SC and during the SC with GEI; gauging data are summarized in Table 3. Water level data indicate a direct correlation between surface elevations in the creek and groundwater elevations in monitoring wells as groundwater elevations respond to changes in surface water elevation. Figure 6 plots groundwater and creek surface water elevation data for the March 29, 2022, event which includes the SC monitoring wells and existing wells located on nearby Brownfield sites. The groundwater contour map on Figure 6 shows a convergent groundwater flow pattern toward the creek. A depressed area of groundwater elevations is observed in the area of Niagara Street with groundwater lows occurring near the City of Buffalo Pump Station. A possible cause of the depressed groundwater elevations is described in Section 4.4.2.

4.2 Field Observations

4.2.1 Scajaquada Creek Conditions, Bank Mapping, Historic Channel and Known Discharges

The outlet of the creek was modified during the mid-1950s during the construction of the NYS Thruway I-190 and the Scajaquada Creek Expressway (NY Route 198). The historic outlet of the creek was filled, and a new outlet created about 450 feet south by land excavation (directly across the P-Site). This created a shorter path for the creek to discharge to the Black Rock Channel and left a cut-off segment of the creek with no flow through it (currently identified as the Inlet).

There are no active stream gauges on Scajaquada Creek. Stream flow at the entrance to the tunnel was recorded by the USGS from March 1, 1957, to September 30, 1994 (gauging station

04216200). Flow rates ranges from a low of just under 0.2 cubic feet per second (cfs) to a high of nearly 900 cfs, with typical flows in the 2 to 70 cfs range. Data from 1958 to 1994 showed a maximum peak flow of about 2800 cfs.

A gauge that measures the water level is located in a storm sewer near the mouth of the creek, 50 feet east of Niagara Street and 115 feet south of the creek. The reported data show a relatively stable water level, with occasional brief rises of up to 2 feet, most likely due to minor seiche influences. Flow reversals in the lower portion of the creek occur due to seiches in Lake Erie, driven by sustained winds from the west that elevate the lake level at Buffalo and in the inlet to the Niagara River. Flow can also be slightly affected by the operations of the Black Rock Canal Lock, which is located 2,000 feet downstream of the mouth of the creek.

The edge of the water was mapped during the SC survey on March 16 and 17, 2022 for comparison to historic mapping of the Scajaquada Creek channel and is shown on Figure 2. Historic mapping of the Black Rock area shows the creek wider than its current configuration, as shown in the 1901 USGS topographic map shown below. This is consistent with extensive observations of fill in the area.

Figure above from USGS Topographic Map dated 1901.

Figure 7 is a more detailed historic map G.M. Hopkins Atlas Map from 1894 that is an overlay on the current aerial of the Lower Scajaquada Creek Area. Similar to the 1901 USGS topographic map, the creek is wider to the east and appears to have a structure to control flow at the original creek outlet. As described in Section 4.1.2, boring data indicate thicker alluvium on the west side of Niagara Street near the rail tracks crossing the creek (see Figure 5) and property at 1660 Niagara Street. These data indicate the historic outlet area of the creek (currently identified as the Inlet after 1950s construction of the NYS I-190 Thruway) was closer to the present-day location of Niagara Street.

4.2.2 TLM and DNAPL Observation

TLM[1] was identified in some coarser grain alluvial soil and sediment samples and DNAPL[2] was observed in some monitoring wells installed during NYSDEC site investigations and three monitoring wells installed during the Site Characterization. The following wells contained DNAPL: MW-LSC-2, MW-LSC-4, MW-LSC-5, 1660-MW-3R, 1660-MW-5R, 1660-MW-7, 1660-MW-8, and MW-100. TLM was described in many soil and sediment samples collected from deeper coarser-grain alluvial soils. Wells containing DNAPL with borings completed in soil/sediment having TLM are shown on Figure 8. As shown in Figure 8, the occurrence of DNAPL in wells and observation of TLM is confined to an area below the creek and land in close proximity to the current creek channel. It is recognized that some wells, particularly those at the north end of property at 1660 Niagara Street, were installed to monitor water quality in saturated fill and are of limited use for DNAPL monitoring. TLM and/or DNAPL potentially present within the underlying alluvial soils at these locations would not accumulate in wells penetrating only the fill materials. DNAPL may have been identified if those well locations had well screens installed to the top of clay in the alluvial soils.

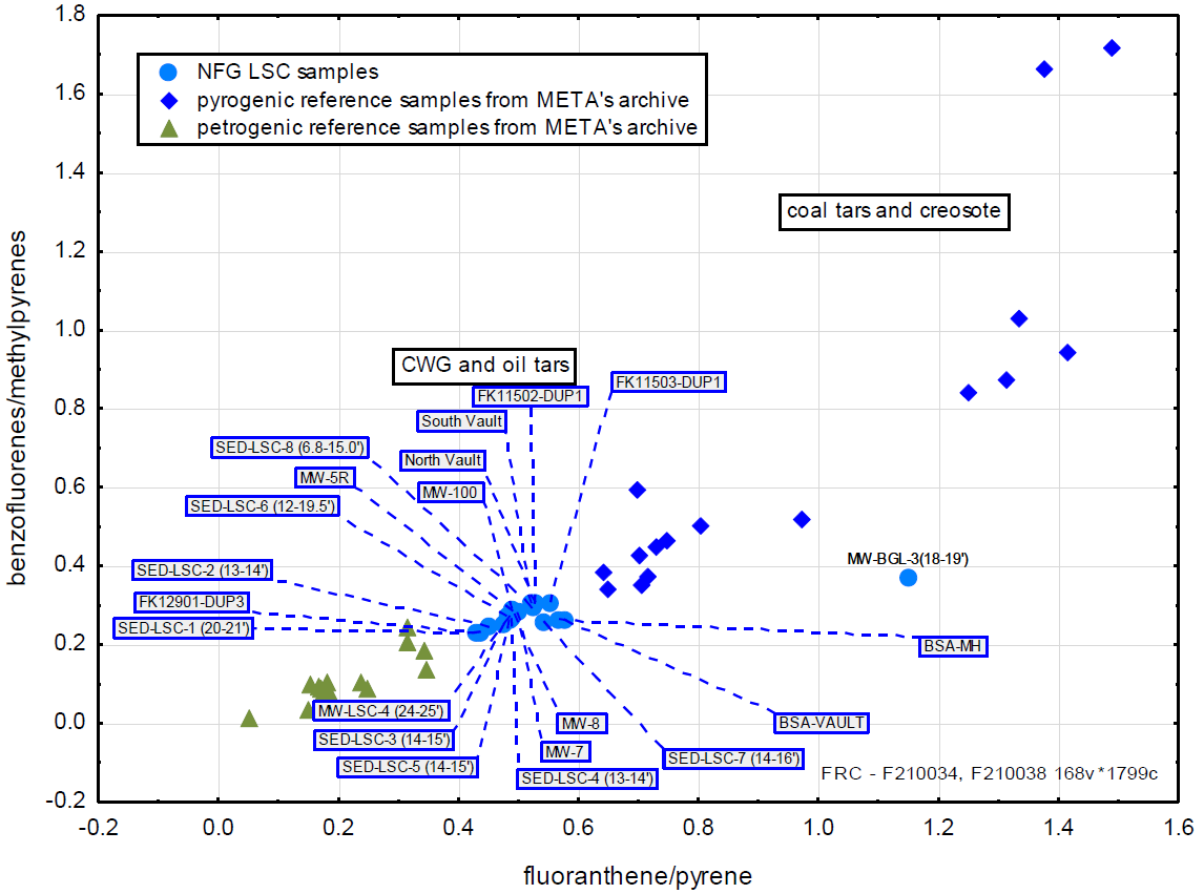
TLM and DNAPL, where present, were observed only in the deeper soils. Based on the absence of shallow TLM and DNAPL in any of the borings, it is apparent that TLM migrated laterally to areas where it was identified. The chemical composition of the TLM/DNAPL was evaluated and a preliminary assessment of potential mobility was performed.

4.2.2.1 Chemical Composition

As described in Section 3.12.2, sediment and soil samples that were visibly impacted with TLM were submitted for forensic analysis. In addition, samples of DNAPL in monitoring wells and the DNAPL recovery systems (South Vault and North Vault) at the Westwood Former MGP Riparian Site were also analyzed. Forensic analyses identified monocyclic aromatic hydrocarbons (MAHs), including benzene, toluene, ethylbenzene, and xylenes, polycyclic aromatic hydrocarbons (PAHs), and saturated hydrocarbons in each of the samples. The forensic report is included in Appendix D.2 and key findings are summarized below.

The graphic below from the forensic report is a double ratio plot that identifies META's pyrogenic reference samples for coal tars and creosote as well as carbureted water gas (CWG) and oil tars from known MGP source samples. The ratio plot also includes petrogenic (non-MGP related) reference samples for comparison of PAH ratios. Iroquois Gas/Westwood Pharmaceutical Former MGP source material samples collected are identified as North Vault and South Vault.

[1] TLM refers to tar-like material present in soil or sediment as observed in sample cores or excavation
[2] DNAPL refers to dense non-aqueous phase liquid that is observed on the bottom of a monitoring well that can accumulate if TLM is sufficiently mobile.



Forensic analysis of MAH and PAH chemical patterns of DNAPL samples analyzed from the North Vault and South Vault were reported to be similar in chemical composition and likely produced by a CWG or oil gas pyrogenic process. Similar chemical patterns were found in DNAPL samples collected from monitoring wells. TLM in soil and sediment samples contained mixtures of pyrogenic and petroleum-related compounds as shown by the wider range of Fl/Py ratios with SED-LSC-1 and BSA-MH as mixing end members (see plot above). This is evident by some sediment samples containing elevated concentrations of TPH and extractable petroleum hydrocarbons. Several soil samples analyzed from sediment borings were identified as being weathered and included SED-LSC-1, SED-LSC-7, and SED-LSC-8. Weathered tar refers to samples of DNAPL or soil/sediment containing TLM that shows evidence of environmental weathering (e.g., loss of compounds by evaporation, dissolution in water, or biodegradation). A "hump" on the chromatogram for sample SED-LSC-8 (see Appendix D.2 Forensic Report) suggests the presence of long chain and cyclic hydrocarbons associated with petroleum.

Soil sample MW-BGL-3 (18-19') in the plot above was characterized as being different and did not contain tar-like material from a pyrogenic-source of PAHs (i.e., sourced from combustion of coal or coal/oil mixture). That sample was collected from the P-Site and contained petrogenic PAHs derived from No. 2 fuel oil or diesel product (i.e., sourced from a petroleum distilled product).

4.2.2.2 Preliminary Mobility Assessment

TLM in soil can migrate via advective forces caused by hydraulic gradients and its own gravity if the specific gravity is greater than water. TLM migration in sediment can also occur by the same mechanisms as well as by ebullition and scour. Monitoring well bail tests showing full DNAPL recovery to pre-bail levels indicate TLM in soil at tested well locations has potential mobility (as DNAPL) via advection and gravity.

TLM encountered in some sediment boring locations in the historic alluvial deposits above the clay layer would have potential similar mobility as TLM encountered in soil borings. Ebullition-facilitated transport is a mechanism which occurs when gas bubbles (commonly methane but also CO2) form in sediments from degrading organic materials, pass through NAPL-impacted material and transport sheen and/or NAPL to the water column. Ebullition facilitated transport of sheen and NAPL was observed in the near-shore sediments in the creek near the City of Buffalo Pump Station. Scour is possible where surface water discharges to the creek and agitates areas where TLM occurs in shallow sediments. Based on the high MAH and PAH concentration in shallow sediments at sediment boring SED-LSC-3 with reported sheen, TLM is suspected in the area. During discharge from the City of Buffalo Pump Station, the high-volume of water discharging to the creek has the potential to scour the sediment surface and place TLM into suspension, thereby transporting MAHs and PAHs visible as a sheen on the surface water. This mechanism is discussed in Section 4.4.

4.2.3 Discharges to the Lower Scajaquada Creek and Sheen Observations

Section 2.4 identifies several combined sewer overflow discharges to the creek. As described in Section 3.8, outfalls to the creek in the Lower Scajaquada Creek Area were mapped during the investigation. Mapped concrete headwall and discharge pipes are shown on Figure 9A identified below:

16” RCP (reinforced concrete pipe) with gabion baskets for erosion control upstream from the West Avenue bridge with discharge to the surface water in the Riparian site.	Buffalo Sewer Authority (BSA) CSO SPDES Outfall #059
6” VCP (vitreous clay pipe)	BSA CSO SPDES Outfall #058 (unconfirmed continuously flowing VCP)
Headwall	Unknown concrete headwall south of City of Buffalo SPDES Outfall #58 (no pipe observed)
16” RCP	Unknown outfall along south bank of Creek, approx. 70’ south of West Ave.
30” RCP	BSA CSO SPDES Outfall #057 Stormwater outfall on south bank of Creek, east of Niagara St.
16” Steel outfall	Outfall associated with City of Buffalo Pump Station.

6" HDPE outfall/ 4" CPP (concrete)	Adjacent outfall along south bank of the Scajaquada Creek Outlet (presumed French drains/groundwater drainage for I-190 overpass berm)

Stormwater runoff from nearby streets and downspouts from the Scajaquada Expressway contribute to the mapped point source discharges to the creek in the Lower Scajaquada Creek. During the investigation, only the 6" VCP outfall was observed to be continuously flowing. This was true during longer periods of dry weather. Intermittent flow (cycled discharge) was observed at the 16-inch pipe associated with the City of Buffalo Pump Station. The flow rate during cycled pumping station discharge was visually estimated at more than 400 gpm. Since 2014, NYSDEC records reported petroleum-type sheens in the area of the pump house discharge on surface water in Scajaquada Creek. The City of Buffalo Pump Station, its function, and sheen generation is discussed in Section 4.4.

4.3 Soil, Groundwater, Sediment Quality

The SC Work Plan included collection and analysis of various soil, groundwater, and sediment samples to evaluate the P-Site and Lower Scajaquada Creek Area. Field sampling activities, laboratory analyses, and data usability assessments were discussed in Section 3. Laboratory analytical data included in Appendix D and Data Usability Summary Reports (DUSRs) are included in Appendix E. The resulting data are summarized in the following tables:

- Table 5A – Land Subsurface Soil Borings
- Table 5B – Groundwater
- Table 5C – Shallow Creek Sediment
- Table 5D – Deeper Creek Sediment

In addition to summarizing the data for each medium, Tables 5A through 5D identify various NYSDEC screening criteria and use color coding to indicate results that exceed the various screening criteria. The screening criteria are not intended to imply applicability to the site at this time, but only an indication of whether and to what extent the analytical results exceed various screening levels. The media-specific screening levels to which data are compared are summarized below:

Medium	Screening Criteria
Soil (land-based borings)	• Unrestricted Soil Cleanup Objectives (SCOs) from 6 NYCRR Part 375, Table 375-6.8(a) • Restricted Residential SCOs from 6 NYCRR Part 375, Table 375-6.8(b)* • Protection of Ecological Resources SCOs from 6 NYCRR Part 375, Table 375-6.8(b)* • Ecological Supplemental Soil Cleanup Objectives (SSCOs) from Table 1 of NYSDEC Policy CP-51 dated October 21, 2010*

Medium	Screening Criteria

Groundwater	• New York State Ambient Water Quality Standards (AWQSs) and Guidance Values (TOGS 1.1.1, June 1998)
	• NYSDEC interim guidance for 1,4-dioxane and PFAS as follows:
	  • For PFAS - Sampling, Analysis, and Assessment of PFAS under NYSDEC's Part 375 Remedial Programs (June 2021)
	  • For 1,4-Dioxane – Sampling for 1,4-Dioxane and PFAS under DEC's Part 375 Remedial Programs (February 2019)

Shallow Sediment	• The upper range of Class B Freshwater Sediment Guidance Values from Table 5 of NYSDEC's "Screening and Assessment of Contaminated Sediment" (June 14, 2014)
Deeper Creek Soil/ "Sediment"	• The upper range of Class B Freshwater Sediment Guidance Values from Table 5 of NYSDEC's "Screening and Assessment of Contaminated Sediment" (June 14, 2014) • Unrestricted Soil Cleanup Objectives (SCOs) from 6 NYCRR Part 375, Table 375-6.8(a) • Protection of Ecological Resources SCOs from 6 NYCRR Part 375, Table 375-6.8(b)* • Ecological Supplemental Soil Cleanup Objectives (SSCOs) from Table 1 of NYSDEC Policy CP-51 dated October 21, 2010*

* - Screening levels from Table 375-6.8(b) and CP-51 apply to a depth of 15 feet; soil samples collected entirely below 15 feet bgs were not considered when comparing to these values

It should be noted that deeper creek sediment samples were compared to both sediment screening values from NYSDEC's "Screening and Assessment of Contaminated Sediment" (June 14, 2014) and soil SCOs similar to land-based soil samples. This is based on the fact that – as indicated on the sediment core logs in Appendix B.3 – the deeper "sediment" samples were collected at various intervals including some within the fluvial deposits, some entirely below the fluvial deposits in the historical alluvial deposits, and some straddling the interface of the two materials. Material entirely within the depositional zone is consistent with the description of "sediment" in NYSDEC's guidance because this material "is comprised of all detrital, inorganic, or organic particles eventually settling on the bottom of a body of water." The deeper samples collected from historical alluvial and/or lacustrine silty clay deposits (see logs in Appendix B.3) are area-wide and geologically pre-date the formation of the Scajaquada Creek channel. Those materials are not representative of sediment that has deposited in Scajaquada Creek but are consistent with the land-based soil samples (Table 5A). Because the deeper sediment samples are comprised of both soil and sediment material, they are comparatively screened relative to both sediment- and soil-based standards in Table 5D. However, unlike the land-based soil samples, they are not screened relative to Restricted Residential SCOs because their in-water location precludes residential use at that specific location.

The following subsections discuss key media-specific observations based on the analytical results and screening comparisons provided in Table 5A through 5D. The first subsection discusses data for samples collected within the limits of the P-Site, as shown on Figure 2. The

second subsection discusses data for samples collected from other locations within the Lower Scajaquada Creek area. Note also that Section 4.4 discusses two additional media samples (water and debris) collected from a stormwater drainage vault that discharges to Lower Scajaquada Creek.

4.3.1 P-Site Area

As shown on Figure 2, two monitoring wells (MW-BGL-1 and MW-BGL-3) and one sediment boring (SED-BGL-1) were advanced within the limits of the P-Site. Media samples from these locations included two soil samples (plus a duplicate), two groundwater samples, one shallow sediment sample, and one deeper sediment sample. The primary objective of the sampling was to initially assess the potential presence and extent of contaminants within the P-Site and relative to the LSC Area. The following subsections summarize the key findings and observations relative to each medium.

4.3.1.1 P-Site Soil Samples

Two soil samples plus one blind duplicate were collected within the P-Site. One sample (plus the duplicate) was collected from a depth of 16-20 feet below grade (ftbg) at location MW-BGL-1. The other was collected from a depth of 17-19 ftbg at location MW-BGL-3. These samples were collected from lacustrine clay and fill material, respectively. As indicated on Table 5A:

- no VOCs, SVOCs, PCBs, herbicides, or cyanide were detected at concentrations exceeding any screening criteria.
- One pesticide (4-4'-DDT) was detected in the sample from location MW-BGL-3 at a concentration exceeding the Unrestricted SCO.
- Various metals were also detected, but only lead and zinc were detected above applicable screening levels. Both the lead and zinc exceedances were detected in the blind duplicate from location MW-BGL-1 but did not exceed in the corresponding parent sample.

As noted in Section 3.12 and discussed in Section 4.2.2, a forensic soil sample was analyzed from soil at a depth of 18-19 ftbg at MW-BGL-3. The sample was collected from the lower fill based on observation of sheen and petroleum-type odor. The Forensic Report (Appendix D.2) identified a non-pyrogenic source (diesel fuel) of PAH constituents detected in the sample.

4.3.1.2 P-Site Groundwater Samples

A monitoring well was constructed at each soil boring completed at the P-Site (MW-BGL-1 and MW-BGL-3). One groundwater sample was collected from each location and analyzed as discussed in Section 3.5. As indicated on Table 5B:

- no VOCs, pesticides, herbicides, PCBs, or PFAS were detected at concentrations exceeding any screening criteria.
- Selected SVOCs (and more specifically PAHs) were detected above AWQS screening levels in one or both samples, including benzo(a)anthracene, benzo(k)fluoranthene, benzo(a)pyrene, chrysene, indeno(1,2,3-cd)pyrene, and naphthalene.
- For metals, iron, magnesium, manganese, and sodium were detected at concentrations exceeding the AWQS screening criteria in one or both samples.

As noted in Section 4.3.1.1, the PAHs detected in the soil sample analyzed from the saturated zone at MW-BGL-3 are derived from a non-pyrogenic source indicating the PAHs detected in the groundwater sample from MW-BGL-3 are similarly sourced.

4.3.1.3 P-Site Sediment

One shallow and one deep sample were collected from the sediment boring location SED-BGL-1. The shallow sample was collected from the uppermost 6-inches of material at the bottom of the creek. The deeper sample was collected from a depth of approximately 1 to 3 feet below the sediment interface. As indicated on Table 5C, the shallow sediment sample did not exceed specified screening levels for any target analytes. As shown on Table 5D, the deeper sample did not exceed screening criteria for any analyte with the exception of calcium.

4.3.2 Lower Scajaquada Creek Area

As shown on Figure 2, five monitoring wells (MW-LSC-1 through -5) were installed and eight sediment borings (SED-LSC-1 through -8) were advanced to assess conditions within the Lower Scajaquada Creek area. Media samples from these locations included nine soil samples, five groundwater samples (plus two duplicates3), eight shallow sediment samples (plus one duplicate), and eight deeper sediment samples. The following subsections summarize the key findings and observations relative to each medium.

4.3.2.1 Lower Scajaquada Creek Area Soil Samples

Nine subsurface soil samples were collected during drilling of the five boreholes for monitoring well installation. This included two samples per boring with the exception of MW-LSC-2, where only one sample was collected for analysis. As indicated on Table 5A:

- Pesticides, PCBs, herbicides, and cyanide were not detected in any of the Lower Scajaquada Creek soil samples at concentrations exceeding specified screening levels.
- No VOCs were detected above screening levels in any of the samples collected from the MW-LSC-1 or MW-LSC-2 locations.

[3] One duplicate was analyzed for PFAS compounds, and the other was analyzed for other groundwater analytes

- Certain VOCs, including acetone, benzene, ethylbenzene, toluene, and xylenes were detected above Unrestricted SCOs in one or more samples from locations MW-LSC-3 through -5. Xylene concentrations are also noted in Table 5A to exceed the protection of ecological resources SCO due to the fact that the criterion is the same as the Unrestricted SCO. The acetone concentrations are generally low, and the exceedances are all estimated values below the laboratory Reporting Limit. The detections of benzene, ethylbenzene, toluene, and xylenes (BTEX) are likely related to the TLM observed in the soil at those locations.
- Only two of the nine samples (the 11-12' sample from MW-LSC-3 and the 24-28' sample from MW-LSC-4) indicated SVOC concentrations above screening levels. Several SVOCs exceed screening levels in each sample, with exceedances primarily PAH compounds associated with TLM observed in the lower alluvial soils above the red-brown clay. In most cases, the detected concentrations exceed only the most stringent Unrestricted SCO and exceedances of other screening levels are noted because those standards are equal to the Unrestricted SCO value. The two exceptions where a detected SVOC concentration exceeds a less stringent (i.e., numerically higher) screening level are benzo(a)pyrene and hexachlorobenzene; both occur in the 11-12' sample collected from fill having a suspected solvent-type odor from location MW-LSC-3. TLM was not observed at that location.
- Various metals were detected in all of the Lower Scajaquada Creek soil samples, but only three samples [MW-LSC-1(13-15), MW-LSC-3(11-12), and MW-LSC-4(22-24)] indicated exceedances of screening level values for one or more metals. The metals exceeding screening levels in one or more samples include arsenic (one sample), copper (two samples), lead (one sample), mercury (two samples), and zinc (one sample). The exceedances were all relative to the most stringent Unrestricted SCO. Table 5A also indicates exceedances of other screening levels, but in each case those values are equivalent to the Unrestricted SCO.

4.3.2.2 Lower Scajaquada Creek Area Groundwater Samples

Five monitoring wells were constructed within the Lower Scajaquada Creek area, and one sample was collected from each well as part of the site characterization. The groundwater samples were analyzed for the parameters indicated in Section 3.12 and the results are included in Table 5B. As indicated by the screening-level evaluations on that table:

- With the exception of metals (discussed below), no target analytes were detected in the groundwater sample collected from well MW-LSC-1.
- No pesticides, herbicides, or PCBs were detected in any of the groundwater samples
- Total cyanide concentrations, when detected, were well below AWQSs.
- BTEX compounds were detected in samples from four of the wells (excluding MW-LSC-1), in most cases at concentrations above AWQSs.

- Other VOCs detected above AWQSs in one or more samples included isopropylbenzene, styrene, and vinyl chloride.
- Several SVOCs, primarily PAHs, were detected above AWQSs in the samples collected from locations MW-LSC-2 through -5.
- 1,4-Dioxane was detected in four groundwater samples, with one (MW-LSC-5) exceeding the screening level of 0.35 ug/l.
- Other SVOCs detected above AWQSs included in at least one sample included biphenyl and 2-methylphenol.
- Various metals were detected in groundwater samples from each of the wells. Metals detected above AWQSs in one or more samples included iron, magnesium, manganese, and sodium.
- Various PFAS compounds were detected in all samples except the one from MW-LSC-1. Only the detected concentration of PFOS in MW-LSC-4 was above the screening level.

PAHs detected in groundwater samples in the LSC wells are primarily related to TLM observed in soils at these locations. 1,4-Dioxane detection in MW-LSC-5 is likely associated with the chlorinated VOC impacts detected in groundwater at 31 Tonawanda Street. PFAS detected in groundwater samples are likely related to storm water/CSO discharges to Scajaquada Creek.

4.3.2.3 Lower Scajaquada Creek Sediment Samples

Eight shallow and eight deeper samples were collected from the sediment boring locations at SED-LSC-1 through -8. The shallow sample was collected from the uppermost 6-inches of material at the bottom of the creek. The depths of the deeper samples below the sediment interface varied based on core recovery and field observations; typically, sediment/soil intervals that had visually suspected impacts were sampled. Elevations and the approximate depths below the sediment surface for each deep sediment sample are included on Table 5D.

Analytical data for the shallow sediment samples are summarized on Table 5C and screened relative to NYSDEC's freshwater sediment guidance values representative of the upper range of Class B sediment. As indicated on that table:

- Only one VOC (ethylbenzene) at one location (SED-LSC-3) exceeded its screening criterion.
- Several SVOCs, primarily PAHs, were detected in all of the shallow sediment samples. None of the individual SVOCs for which sediment screening values are available exceeded their respective screening levels. However, the total concentrations for 17 PAHs compounds summed by NYSDEC exceeded the sediment screening level (35,000 ug/kg) in four of the eight locations (SED-LSC-1, -2, -3, and -8). SED-LSC-1 through -3 are the samples collected from the Inlet area (backwater "slip" portion of the channel) and SED-LSC-8 represents the most upstream location. SED-LSC-8 forensic data

identified branched and cyclic alkanes and petroleum mixtures characteristic of accumulations of weathered fuel oils and heavy lubricating oils commonly found in urban sediment background. PAH concentrations at SED-LSC-3 were nearly 500 times higher than other shallow sediment samples. While not discussed, NOAA 34 PAH analytical results are summarized in Appendix D.2 for each of the shallow sediment samples and is presented for future use, if needed, to assess potential toxicologic effects to the benthic community.

- PCB Aroclors were detected in all of the samples, with three locations indicating total PCB concentrations above the screen criterion (1 mg/kg). The maximum detected concentration among the three samples was 1.23 mg/kg at SED-LSC-4.
- No herbicides or cyanide were detected in any of the samples.
- Three pesticides (DDT, DDE, and DDD) were detected at estimated concentration in the sample from location SED-LSC-1; none exceeded available screening criteria.
- Various metals were detected in all of the samples. Metals exceeding screening levels in one or more samples included copper, lead, nickel, and zinc. The highest levels of lead, mercury, nickel, and zinc were detected at SED-LSC-3.
- The samples were analyzed for petroleum hydrocarbon content. Volatile petroleum hydrocarbons were mostly not detected, with the exception of C_9-C_{12} aliphatics of SED-LSC-3. Extractable petroleum hydrocarbons were more frequently detected, with the highest concentrations detected at location SED-LSC-3. No NYSDEC standards are available for these hydrocarbon data, which were collected for forensic purposes.
- The highest concentrations of ammonia and sulfide were detected in samples collected from the Inlet area. Those constituents influence benthos toxicity.
- Total organic carbon content among the samples ranged from 4.67 to 13.5%.

Analytical data for the deeper sediment samples are summarized on Table 5D and screened relative to the various noted criteria. As indicated on that table:

- The deep sediment sample from location SED-LSC-4 (14-16') did not exceed any screening values for VOCs, SVOCs, total cyanide, pesticides, herbicides, or PCBs.
- BTEX constituents were detected in all of the remaining deep sediment samples, with highest BTEX concentrations detected in samples collected from the Inlet area. Benzene, ethylbenzene, and xylene concentrations exceeding one or more screening values in most samples. Benzene, ethylbenzene, and xylene exceeded freshwater sediment guidance values for Class B in at least two samples each.
- Isopropylbenzene was detected in four samples at concentrations exceeding the freshwater sediment screening value for this compound.
- Other VOCs detected in at least sample at concentrations exceeding one or more screening levels included cis-1,2-dichloroethene, trans-1,2-dichloroethene, and methyl ethyl ketone.
- Several SVOCs, primarily PAHs, were detected in all of the deeper sediment samples and several exceeded one or more screening values for individual compounds. The total

concentrations for 17 PAHs compounds summed for NYSDEC sediment criteria comparison exceeded the sediment screening level (35,000 ug/kg) in five deeper sediment samples (SED-LSC-1, -2, -3, -6, and -8) with sample SED-LSC-3 having the highest PAH concentrations. This is consistent with the shallow sediment samples, plus the addition of SED-LSC-6. TLM and/or sheen was identified at most of these locations.

- Target herbicides were not detected in any of the samples.
- Total cyanides were not detected in any samples at concentrations above screening levels.
- Two pesticides (DDT and DDD) were detected at concentrations above the unrestricted and protection of ecological resources SCOs. DDT exceeded the screening levels in the deep sediment sample from SED-LSC-6. DDD exceeded the screening value in the deep sediment samples from locations SED-LSC-3 and SED-LSC-6.
- Detected total PCB concentrations in two samples (SED-LSC-3 and SED-LSC-8) exceeded the Unrestricted SCO of 0.1 mg/kg.
- Various metals were detected in all of the samples. Metals exceeding screening levels in one or more samples included aluminum, cadmium, calcium, chromium, copper, lead, manganese, mercury, nickel, and zinc.
- Total organic carbon content among the samples ranged from 3.53 to 8.00%.

As a further evaluation of the shallow sediment data, Figure 10 identifies locations of shallow sediment samples collected in 2021 as part of this site characterization along with samples collected by NYSDEC and USACE in 2017 (NYSDEC/Empire GEO Services, June 2017) (see Section 2.4). It also plots distances along the approximate centerline of the creek beginning at the northwest end of the Inlet (Station 0+00), continuing toward the outlet to Black Rock Canal (Station 5+22), and extending upstream to the downstream end of the West Avenue bridge (Station 15+88). Using this stationing system, Figure 10 also includes four embedded charts that present surficial sediment concentrations versus distance along the stationing line. The charts present data for 2017 sample locations (orange) and 2021 sample locations (blue) by projecting the sample locations to their corresponding location along the centerline of the creek. The x-axis on each chart is the distance along the centerline measurement of the creek and the bar height is an indication of the measured total concentration at that point. The four charts compare data for mercury, lead, total PCBs, and total PAHs (based on the 16 PAHs summed in the 2017 dataset). These four COCs were selected for comparison because they have been identified as COCs for the Buffalo River, which is part of the broader Niagara River Area of Concern.

All of the 2021 samples plotted on Figure 10 were collected from a depth interval of 0-6" whereas the 2017 samples were collected as various intervals beginning at the sediment surface and extending up to 3.17 feet in thickness. Therefore, the samples intervals are not directly comparable between the two datasets. Regardless, the 2017 data almost always indicate higher concentrations than the 2021 results within a given reach of the creek. The one exception is a 2021 total 16 PAH concentration associated with sample location SED-LSC-3 (5,649 ppm). The generally lower concentrations measured in 2021 samples suggest either an overall improvement in conditions over the four years between sampling events or that the deeper sediment increments

included with the 2017 samples have higher concentrations relative to the shallower material. The latter would be an indication of recent cleaner sediment deposits. Note also that concentrations in the Inlet portion of the creek are generally much higher than the segment between the outlet and West Avenue, likely indicative of the depositional nature of this area since the natural outlet was modified during highway construction in the 1950s.

4.4 Pump Station Vault Debris and Discharged Water

4.4.1 Debris and Water Testing

As described in Section 3.9, a sheen was observed on Scajaquada Creek during discharge from the City of Buffalo Pump Station (see Figure 9A for location). The pumping station discharges groundwater and storm water from the topographically depressed Niagara Street beneath the at-grade rail crossing. A general schematic profile of the pumping station is provided on Figure 9B. A water sample was collected from Manhole #23 directly upstream of the pump station (BSA-MW-WATER) and a sediment/debris sample from the pump station vault (BSA-VAULT-DEBRIS). Analytical data for the water sample, which is representative of stormwater and groundwater flowing in the manhole, is summarized in Table 5B. Constituents detected above regulatory comparison criteria are identified below.

- The manhole water sample exhibited elevated concentrations of 1,4-dioxane (12,200 ug/L), a stabilizer used in chlorinated VOC products, when compared to the NYSDEC Interim Guidance Criteria of 0.35 ug/L.
- Concentrations of CVOCs, including chloroethane (60 J ug/L), 1,1- dichloroethane (140 ug/L), 1,1-dichloroethene (8.8 ug/L), cis-1,2-dichloroethene (1,700 ug/L), 1,1,1-trichloroethane (53 ug/L) and vinyl chloride (280 ug/L) were detected above AWQS.
- BTEX compounds and several PAHs were detected above AWQS. Naphthalene was detected below NYS guidance.
- Metals that exceeded AWQS included antimony, iron, lead and sodium as presented on Table 5B.
- PCBs were detected at an estimated (J-qualified) concentration of 0.066 ug/L.
- While PFAS was detected in the sample at concentrations similar to other groundwater samples, individual compounds were below NYS guidance values.

A sediment/debris sample was collected from the bottom of the pump station vault (BSA-VAULT-DEBRIS) laboratory analysis. A sample was not obtained from MH#23 as the material was gravel size and insufficient volume could be obtained for laboratory analysis by Alpha Analytical; however, sufficient volume was present for forensic analysis. Sediment/debris sample results for material at the bottom of the pump station vault are summarized in Table 5E. Comparison criteria are not provided on the table as the sample was not natural sediment or soil. Testing identified the following:

- The sediment/debris sample from the vault contained concentrations of CVOCs, including chloroethane (160 ug/kg), 1,1-dichloroethane (280 ug/kg), 1,1-dichloroethene (23 ug/kg), cis-1,2-dichloroethene (2,200 ug/kg), trans-1,2-dichloroethene (14 ug/kg), 1,1,1-trichloroethane (440 ug/kg), and vinyl chloride (450 ug/kg).
- BTEX compounds were detected in the vault sediment debris sample including benzene (1,800 ug/kg), toluene (2,900 ug/kg), ethylbenzene (62,000 ug/kg) and total xylenes (33,000 ug/kg).
- Total PAH 17 was less than 5 ppm.
- Total PCBs in the sediment/debris sample from the vault were detected at an estimated (J-qualified) concentration of 135 ug/kg.

Sufficient volume of sediment/debris was available from Manhole #23 for forensic analysis. Additionally, a sample of the debris within the pump station vault was submitted for forensic analyses. Both samples contained suspected TLM with a strong coal tar-like odor. The forensic testing results for these two samples are presented in Appendix D.2. Forensic analyses identified MAHs, including benzene, toluene, ethylbenzene, and xylenes, PAHs, and saturated hydrocarbons in each of the samples. Forensic laboratory detected compound concentrations are summarized below:

- BSA-MH (MH#23) – Total PAH 16[4] – 1,850 mg/kg; TPH – 9,680 mg/kg
- BSA-VAULT - Total PAH 16 – 1,880 mg/kg; TPH – 9,500 mg/kg
- Both samples contained weathered pyrogenic MAH and PAH tar-like patterns consistent with TLM in soil and DNAPL in wells. Low-level petrogenic character identified as Fluorine/Pyrene ratios were slightly higher than soil and DNAPL samples from wells.

4.4.2 Pump Station Operation and Suspected Influence

GEI submitted a FOIL request to the City of Buffalo and obtained design drawings for the local storm sewer network servicing the pump station. These drawings indicate storm sewer piping that is present below Niagara Street and that transmits water to the pump station was installed to approximate elevations ranging between 570 ft and 568 ft. Piping leads to Manhole #23 at elevation 565.9 ft and to the pump station vault with a bottom elevation of approximately 558 ft. Based on the observed piping configuration, it appears that the water level in the vault is maintained at an elevation no higher than approximately 567 ft to 568 ft (see Figure 9B). GEI observed a pump cycle discharge during sampling where the water level in the vault wet well was drawn down several feet, likely approaching an elevation of 560 ft.

Section 4.1.3 identified a depressed area of groundwater in the area of Niagara Street and the City of Buffalo Pump Station. Given that the storm sewer piping beneath Niagara Street is approximately 3 to 4 feet lower than the typical surface water elevation of Scajaquada Creek and approximately 1 to 2 feet lower than groundwater elevations in nearby wells, it is suspected that

[4] Total PAH 16 excludes 2-methylnapthalene where PAH 17 includes the compound in the sum.

the pump station cycling is affecting the elevation of groundwater in the area of the pump station. The observation of water flow in the storm sewer piping during a dry weather event suggests groundwater is collected and conveyed by the storm sewer effectively maintaining a depressed groundwater elevation beneath Niagara Street. Hydraulic testing and monitoring of the water table in the area of the pump station is required to validate this presumption.

Field observations and laboratory data described in Section 4.4.1 indicate TLM presence in the pump station vault and Manhole #23. This observation was somewhat unexpected because TLM and DNAPL in wells closest to the pump station was much deeper (i.e., more than 10 feet deeper). The mechanism for TLM entry into the vault and Manhole #23 is not fully understood at this time and requires additional assessment. Surcharge of the pump station vault and piping can occur when creek levels are five to six feet higher during seiche conditions. Backflow from the creek to the storm sewer is a plausible condition for TLM entry.

During pump station discharge cycles, stormwater and groundwater that has accumulated in the vault (Figure 9B) discharges to surface water in Scajaquada Creek by way of a 16-inch diameter cast-iron pipe installed in the concrete headwall on the creek side of the pump station at an estimated flow rate of approximately 2500 gpm. Limestone riprap blocks designed to mitigate erosion of the bank during discharge events are present directly below the pump station outfall as part of the original design specifications for the pump station. Observations made during the SC field investigation indicated the riprap below the outfall exhibited heavy staining on riprap material with suspected TLM, a sheen on pooled surface water within the riprap, and a strong coal tar-like odor.

The high rate of discharge from the pump station outfall causes turbulent flow at the creek edge directly downgradient of the outfall. GEI field staff observed the generation of a heavy petroleum-like sheen on the surface water of the creek during discharge cycles. The discharge events are suspected to scour near shore sediments. It is unknown if the observed sheen results from TLM presence in the pump station discharge or if nearshore sediment contains TLM and the discharge causes scour and resuspension of TLM in shallow sediment. Ebullition processes were also observed in the near-shore sediments in this area. The specific contributions of these factors have not been determined and further assessment would be necessary to characterize these pathways.

Shallow sediment sample SED-LSC-3 (0-0.5) (Figure 2) was collected from Scajaquada Creek sediments directly adjacent to the pump station outfall. Analytical results from this sample exhibited the highest concentrations of total PAHs (6,849 mg/kg) and EPH fractions (67,000 mg/kg) in shallow sediments analyzed during the SC investigation. The data suggest that stormwater discharge from the City of Buffalo pumping station may potentially influence shallow sediment quality in the Inlet area of Scajaquada Creek. Further assessment is required to understand if a correlation exists between pump station discharge and elevated constituent concentrations detected in this area.

4.5 Preliminary Conceptual Site Model

A preliminary conceptual site model was developed and is presented to understand the potential sources of contamination, constituents of potential concern, potentially affected media (soil, sediment, and groundwater), and preliminarily identify transport and exposure pathways that could impact human or ecological receptors. The conceptual site model synthesizes data collected by the NYSDEC, investigations at nearby BCP sites, and this investigation.

4.5.1 P-Site

A major source of contamination was not identified at the P-Site. Some minor contamination of deeper soil and groundwater related to diesel fuel was identified. Incidental releases from highway traffic are the probable cause of the petroleum-related impacts identified. Constituent concentrations in shallow sediment, and soil below the recent fluvial deposits (red-brown clay) did not exceed regulatory comparison criteria. Site investigation data indicate the P-Site is not a source of contamination and does not pose a significant threat to human health or the environment.

4.5.2 Lower Scajaquada Creek Area

VOCs and PAHs related to coal tar and petroleum-related compounds, PCBs, and several metals were detected in soil and creek sediments above regulatory comparison criteria in the Lower Scajaquada Creek area. In groundwater, BTEX and several PAH compounds as well as isopropylbenzene, styrene, vinyl chloride, 1,4-dioxane, and PFAS were detected above AWQS. TLM was identified in some soil and sediment borings and DNAPL was observed in several monitoring wells (see Figure 8). Based on the forensic identification of coal tar in soil and sediment, a discussion of historic transport follows.

Discussion of Historic and Possible Active Coal Tar Transport: As described in Section 4.2.2.1, the forensic evaluation of MAH and PAH chemical patterns from the analysis of soil and sediment samples containing TLM identified forensic chemical patterns similar to the DNAPL samples derived from historic coal gas manufacturing at the Iroquois Gas/Westwood Pharmaceutical Former MGP Terrestrial and Riparian Sites. It was also apparent that many of the sediment and soil samples contained varying degrees of mixtures with petroleum. It is presumed that releases of coal tar to the ground surface between MGP start-up (early 1900s) and termination of operations in 1955 caused contamination of soil, groundwater, and creek sediments in addition to historic releases of petroleum from former industrial sites that operated in the Black Rock Area and CSO discharges. The conditions at the Former MGP were mitigated following implementation of remedial actions in 2000. Prior to remediation, transport of coal tar occurred in soil and sediment. Physical conditions conducive for coal tar transport from the Former MGP toward the creek and migration toward the present-day creek Inlet include:

1. a convergent groundwater flow pattern with hydraulic gradients toward the creek,

2. coarse grain alluvial soils that have effective porosity and hydraulic conductivity suitable for coal tar migration,
3. the material density of the coal tar being slightly heavier than water, and
4. vertical confinement of the alluvial soils at its base by the area-wide red-brown clay layer with a topographic surface that slopes in a channel-like manner in a southwest and north direction.

Currently, the Terrestrial Site remediation was designed and constructed to mitigate coal tar migration through surface capping, a physical barrier (sheet pile wall), and a hydraulic barrier through operation of the groundwater collection trench on the land side of the site. On the Riparian side of the Site, (the NYSDEC specified the area of sediment cleanup to be between historic boring B-1 upstream and the West Avenue bridge downstream), contaminated sediments were excavated, a sediment cap was installed, and a physical barrier was installed immediately upstream from the West Avenue bridge (i.e. vertical sheet pile wall). Active DNAPL removal occurs upstream of the vertical barrier to remove remaining coal tar residuals upstream of the West Avenue bridge. These remedial measures were put in place to contain coal tar presence identified at the former MGP and adjacent creek sediments following historic site investigations.

Coal tar residuals in alluvial soil identified in two of the three NYSDEC wells installed along the bike path next to the Riparian Site, with DNAPL presence in well MW-100, is expected to be contained by current remedial controls and site geologic condition. The rapid rise in the clay surface elevation along the northwest side of the current creek channel (Figure 5) and a southeastward groundwater flow direction toward the creek would prevent coal tar migration beyond the bounds of the Riparian Site to areas beneath the 51-71 Tonawanda Street BCP Site. Migration of DNAPL at well MW-100 in a southern direction is expected to be contained by DNAPL removal by the South Vault, the vertical sheet pile barrier, and the concrete abutment of the West Avenue bridge.

Historic coal tar residuals remaining in alluvial sediments downstream from the West Avenue bridge has the potential to migrate laterally in a downstream direction within the lower portion of historic alluvial creek channel above the scoured surface of the red-brown clay. As shown in Figures 5 and 8, the deepest areas of the former creek channel are somewhat offset to the north side of the current creek edge, especially near the intersection of Niagara and Tonawanda Streets and northward paralleling Niagara Street (well locations MW-LSC-4, MW-LSC-5, 1660-MW-7, and 1660-MW-8). In this area, the clay surface elevation is deeper, and a groundwater depression occurs as groundwater beneath Niagara Street removed by the City of Buffalo Pump Station. These features can cause advective transport of non-residual coal tar toward this area. However, with remedial controls in place at the primary source area controlled, advective transport is expected to be diminished over time. Other mechanisms of coal tar transport considered viable in Scajaquada Creek is the scour and re-suspension of existing coal tar residual or direct discharge of coal tar blebs to the creek causing sheen. As described in Section 4.5, further assessment is needed to understand if these mechanisms are significant.

Non-MGP Related Constituent Loadings: In addition to PAHs and BTEX associated with TLM, several constituents of concern are non-MGP sourced chemicals that affect groundwater, soil, and sediment. These include chlorinated VOCs and 1,4-dioxane, PAHs and BTEX from non-MGP sources, PCBs, heavy metals, PFAS, and organic loading that affects nutrient levels in the shallow sediment. Sources of these constituents are BCP sites and point source and non-point source discharges. Mechanisms of transport include advective transport in groundwater, direct discharges from three BSA combined sewer overflow discharge pipes, roadway runoff from nearby streets and downspouts for the Scajaquada Expressway, and upstream sources beyond the Riparian Site.

The City of Buffalo Pump Station on Niagara Street discharges storm water and groundwater to the creek. Active transport of TLM with petroleum was identified in sediment/debris in the vault and a manhole (see Section 4.5). Water discharge contained elevated concentrations of chlorinated VOCs, 1,4-dioxane, PCBs and metals. This discharge affects shallow sediment quality in the Inlet portion of the creek.

Human Exposure Pathways: Scajaquada Creek is a Class B designated stream. Primary and secondary contact recreation and fishing exposure are pathways that could potentially impact human receptors. Coal tar impacted soils are typically deeper than 15 feet below the ground surface so human exposure would be limited to construction workers involved in deep excavation work such as major utility infrastructure development or building construction with deep foundations. Under these scenarios, human exposure routes for chemicals include:

- inhalation of VOCs volatized from groundwater (particularly CVOCs in the area of Niagara Street);
- dermal contact inhalation and incidental ingestion of soil/sediment particulates; and
- dermal contact with ground water/surface water.

Groundwater in the area is not a source of drinking water.

The following ecological exposure routes for chemicals include:

- inhalation of VOCs volatized from soil gas in burrow air (particularly CVOCs in the area of Niagara Street);
- incidental ingestion and dermal contact of creek sediment particulates; and
- ingestion and contact with contaminated surface water.

Additional evaluation of exposure pathways is required to determine if exposure pathways are complete.

5. Conclusions and Recommendations

5.1 P-Site

Site historical information indicate the P-Site contained a gas holder between 1896 and 1928. Historical information indicates coal gas was not manufactured on the property. During the mid-1950s, the property was developed for construction of the I-190 Thruway corridor and the on/off ramps for the I-198 Scajaquada Expressway. Construction involved soil removal and importation of construction quality fill suitable for highway road base and support structures. Substantial soil excavation of the pre-existing fill as well as native red-brown clay was required to construct the re-routed outlet of Scajaquada Creek during the highway construction project.

Site investigation did not identify buried structures and soil, groundwater, and sediment sampling results did not detect concentrations of chemical constituents which would pose a significant threat to the human health or the environment. The PAHs detected in suspected petroleum impacted soil at one monitoring well location were derived from a petrogenic source with a chemical fingerprint suggesting impact from diesel fuel. This is consistent with the property's current use supporting highway infrastructure. These findings suggest the P-Site does not pose a significant threat to human health or the environment. No further assessment is recommended.

5.2 Lower Scajaquada Creek

TLM was identified in many soil and sediment borings and DNAPL accumulation was observed in monitoring wells situated closest to Scajaquada Creek. Forensic analysis of MAH and PAH patterns indicate a pyrogenic source with influences from petroleum-related constituents. The surface geometry of the red-brown clay and hydraulic gradients confine the distribution of coal tar impacts to deeper alluvial soil in the area of the current creek channel. Coal tar residuals in soil and DNAPL accumulation was identified in wells where the historic creek channel was wider. This was the case in the subsurface near the intersection of Niagara and Tonawanda Streets and the area immediately west of Niagara Street closest to the City of Buffalo Pump Station.

BTEX and PAH compounds were detected in groundwater samples collected from wells near the creek between the Riparian Site and properties upgradient of Niagara Street at concentrations above AWQS where coal tar impacts were identified in soil. Similarly, BTEX and PAHs were detected in groundwater at well locations closer to the creek Inlet where TLM was present in soil. However, groundwater also contained several chlorinated VOCs at concentrations above AWQS, as well as 1,4-dioxane and PFAS at levels above screening criteria. This included water being discharged from the City of Buffalo Pump Station to Scajaquada Creek also was found to contain these chemicals above AWQS.

In creek sediments, shallow (upper six inches) and deeper sediments were characterized. Shallow sediments exhibited more impacts from coal tar in the Inlet area of the creek near the Pump Station compared to samples collected from the main creek channel. Sediment samples containing TLM typically exceeded sediment screening levels for PAHs as well as other constituents. The concentration of total 17 PAH compounds exceeded NYSDEC sediment screening levels in four of the eight shallow sediment locations sampled. PAH concentrations at SED-LSC-3 were nearly 500 times higher than other shallow sediment samples and influence from City of Buffalo Pump Station discharge is suspected. That particular sample also contained elevated levels volatile petroleum hydrocarbons and extractable petroleum hydrocarbons. Total PCB concentrations exceeded 1 mg/kg at three locations with a direct correlation of outfall pipes and the pump station. Metals that include mercury, copper, lead, nickel, and zinc exceeded screening criteria with the highest detected at SED-LSC-3. The highest concentrations of ammonia and sulfide were detected in samples collected from the Inlet area. Those constituents influence benthos toxicity.

In deeper sediments, coal tar impacted materials or sheen was identified in six of eight sediment borings. The highest concentrations of BTEX and PAH compounds in deeper sediments were detected in borings completed in the creek Inlet (borings SED-LSC-1 through SED-LSC-3) and sediment boring SED-LSC-6, which is situated near well MW-LSC-4 (which contained coal tar impacts with DNAPL accumulation). Concentrations of total 17 PAHs exceeding NYSDEC screening levels occurred in each of the deeper sediment samples collected from the Inlet area (concentrations were approximately 4 to 5 times higher than other detections) including and the samples collected from locations at SED-LSC-6 and SED-LSC-8 which also exceeded screening criteria. Pesticide compounds were detected above SCOs in samples analyzed from SED-LSC-3 and SED-LSC-6 and total PCB concentrations exceeded SCOs samples collected from SED-LSC-3 and SED-LSC-8. Metals exceeding screening levels in one or more samples included aluminum, cadmium, calcium, chromium, copper, lead, manganese, mercury, nickel, and zinc.

Site characterization findings indicate further evaluation of the Lower Scajaquada Creek Area is warranted to fully assess the overall threat to human health and the environment from the constituents detected in groundwater, soil, and sediment. Therefore, the completion of a Remedial Investigation and Feasibility Study (RI and FS) is recommended for the Lower Scajaquada Area.

An objective of the RI would be to fill key data gaps that include: further characterization of the overall extent of TLM in soil and creek sediments including fate and transport, identification of major infrastructure in the Lower Scajaquada Creek Area to assess possible migration pathways of utilities deep enough to be in contact with coal tar impacted soil, and investigation of the influence of discharge from the City of Buffalo Pump Station including evaluation of potential DNAPL mobilization during operation and other impacts of the discharge on creek sediment quality.

BSA-VAULT DEBRIS		1,3,4,5,6,7,8,9,10,11,12	11/18/2021

*See sediment boring logs for analytical sample elevations.

Analytical Notes:

1- TCL VOCs EPA SW8260C/5035
2- TCL SVOCs EPA SW8270D
3- Total Cyanide EPA SW9012A
4- Forensic Analysis EPA SW8270M/8015M
5- Pesticides and Herbicides EPA SW8081B/8151A
6- PCBs EPA SW8082A
7- TAL Metals EPA SW6010B/6020/7470
8- TCL SVOCs / NOAA34 PAHs EPA SW8270D SIM
9- VPH MADEP/EPH NJ EPH R3
10- Ammonia EPA SWSM4500
11- Sulfide EPA SW9030B
12- Total Organic Carbon EPA SW9060A
13- PFAS EPA SW8327

Abbreviations

VOCs - Volatile Organic Compounds
SVOCs - Semi-volatile Organic Compounds
PCBs - Polychlorinated biphenyls
PAHs - Polycyclic Aromatic Hydrocarbons
VPH -Volatile Petroleum Hydrocarbons
EPH -Extractable Petroleum Hydrocarbons
PFAS - Per- and Polyfluoroalkyl Substances
TCL - Target Compound List
TAL - Target Analyte List

Table 5A. Land Subsurface Soil Boring Sample Analytical Results
Site Characterization Report
Former Buffalo Gaslight Iroquois Gas Corp. Site
Buffalo, New York

Notes:
Depths are measured from ground surface
mg/kg = milligrams/kilogram or parts per million (ppm)
% = Percent
ug/kg = micrograms per kilogram

PAH = Polycyclic Aromatic Hydrocarbon

PCB = Polychlorinated Biphenyl
SVOC = Semi-Volatile Organic Compound
VOC = Volatile Organic Compound

CAS No. = Chemical Abstracts Service Number
ND = Not Detected
NE = Not Established

6 NYCRR = New York State Register and Official Compilation of Codes, Rules and Regulations of the State of New York

Comparison of detected results are performed against one or more of the following NYCRR, Chapter IV, Part 375-6 Soil Cleanup Objectives (SCO)s: Unrestricted Use, Restricted-Residential, Protection of Ecological Resources

Bolding indicates a detected result concentration
Shading and bolding indicates that the detected concentration is above the NYSDOH guidance it was compared to.
Samples collected entirely below 15' bgs are not compared to Table 375-6.8(b) or CP-51 SSCOs.

Validation Qualifiers:
J = The result is an estimated value.
R = The result is rejected.
U = The result was not detected above the reporting limit.
UJ = The results was not detected at or above the reporting limit shown and the reporting limit is estimated.

1,4-Dioxane - Rejected Data

Due to the extremely low calibration response factor for 1,4-dioxane under Method 8260C, this compound is typically rejected during validation as it does not meet the minimal criteria set for accurate quantitation. Non-detect results for 1,4-dioxane are rejected as the presence or absence of the compound cannot be verified. Positive results are estimated due to the high variability inherent in the quantitation when using an extremely low response factor.

Table 5B. Groundwater Sample Analytical Results
Site Characterization Report
Former Buffalo Gaslight Iroquois Gas Corp. Site
Buffalo, New York

Notes:

mg/L = milligrams/liter
ng/L = nanogram per liter (ppt)
ug/L = micrograms per liter or parts per billion (ppb)

PAH = Polycyclic Aromatic Hydrocarbon
PCB = Polychlorinated Biphenyl
SVOC = Semi-Volatile Organic Compound
VOC = Volatile Organic Compound

CAS No. = Chemical Abstracts Service Number
ND = Not Detected
NE = Not Established

NYS AWQS = New York State Ambient Water Quality Standards and Guidance Values for GA groundwater
* indicates the value is a guidance value and not a standard
NYSDEC Interim Groundwater Screening Levels based on NYSDEC guidance as follows:
- February 2019 (1,4-dioxane)
- June 2021 (PFAS)
Bolding indicates a detected result concentration
Shading and bolding indicates that the detected concentration is above the NYSDOH guidance it was compared to

Validation Qualifiers:
J = The result is an estimated value.
R = The result is rejected.
U = The result was not detected above the reporting limit.
UJ = The results was not detected at or above the reporting limit shown and the reporting limit is estimated.

Table 5C. Creek Shallow Sediment Boring Sample Analytical Results
Site Characterization Report
Former Buffalo Gaslight Iroquois Gas Corp. Site
Buffalo, New York

Notes:
Sample depth is upper 0.5 feet of surface sediment
mg/kg = milligrams/kilogram or parts per million (ppm)
% = Percent
ug/kg = micrograms per kilogram

PAH = Polycyclic Aromatic Hydrocarbon
PCB = Polychlorinated Biphenyl
SVOC = Semi-Volatile Organic Compound
VOC = Volatile Organic Compound

CAS No. = Chemical Abstracts Service Number
ND = Not Detected
NE = Not Established

Bolding indicates a detected result concentration
Shading and bolding indicate that the detected concentration is above the maximum range of sediment guidance values

Validation Qualifiers:
J = The result is an estimated value.
JN = The analyte is presumptively present at an approximated quantity.
R = The result is rejected.
U = The result was not detected above the reporting limit.
UJ = The results was not detected at or above the reporting limit shown and the reporting limit is estimated.

1,4-Dioxane - Rejected Data

Due to the extremely low calibration response factor for 1,4-dioxane under Method 8260C, this compound is typically rejected during validation as it does not meet the minimal criteria set for accurate quantitation. Non-detect results for 1,4-dioxane are rejected as the presence or absence of the compound cannot be verified. Positive results are estimated due to the high variability inherent in the quantitation when using an extremely low response factor.

Table 5D. Creek Deeper Sediment Boring Sample Analytical Results
Site Characterization Report
Former Buffalo Gaslight Iroquois Gas Corp. Site
Buffalo, New York

Notes:
Sample ID contains sample depth below the measuring point on barge; sample elevation interval provided for sample depth
mg/kg = milligrams/kilogram or parts per million (ppm)
% = Percent
ug/kg = micrograms per kilogram

BTEX = Benzene, Toluene, Ethylbenzene, and Xylenes
PAH = Polycyclic Aromatic Hydrocarbon
PCB = Polychlorinated Biphenyl
SVOC = Semi-Volatile Organic Compound
VOC = Volatile Organic Compound

CAS No. = Chemical Abstracts Service Number
ND = Not Detected
NE = Not Established

Bolding indicates a detected result concentration
Shading and bolding indicates that the detected concentration is above the Guidance it was compared to
6 NYCRR = New York State Register and Official Compilation of Codes, Rules and Regulations of the State of New York

Comparison of detected results are performed against one or more of the following NYCRR, Chapter IV, Part 375-6 Soil Cleanup Objectives (SCO)s: Unrestricted Use, Restricted-Residential, Protection of Ecological Resources

(1) Source: NYSDEC CP-51 Soil Cleanup Guidance as presented in Tables 1 through 3 dated October 2010 applying to the Inactive Hazardous Waste Disposal Site Remedial Program

Validation Qualifiers:
J = The result is an estimated value.
JN = The analyte is presumptively present at an approximated quantity.
U = The result was not detected above the reporting limit.
UJ = The results was not detected at or above the reporting limit shown and the reporting limit is estimated.
R = The results were rejected by laboratory (see **1,4-Dioxane, Pesticides Group**)

1,4-Dioxane - Rejected Data
Due to the extremely low calibration response factor for 1,4-dioxane under Method 8260C, this compound is typically rejected during validation as it does not meet the minimal criteria set for accurate quantitation. Non-detect results for 1,4-dioxane are rejected as the presence or absence of the compound cannot be verified. Positive results are estimated due to the high variability inherent in the quantitation when using an extremely low response factor.

Pesticides (SW 8081B) - Rejected Data
The pesticide nondetect results in sample SED-BGL-1/12-14, SED-LSC-1/11-15, SED-LSC-3/13-16, SED-LSC-5/14-16, and SED-LSC-7/12-18 were rejected (R) due to surrogate recovery less than 10%. These results should not be used for decision-making purposes.

Bentonite Chip Seal

Silica Sandpack

Client: NYSDEC

Location: 1660 Niagara Street Buffalo, NY

Site Name: 1660 Niagara Street
Site No.: C915311

NEW YORK STATE OF OPPORTUNITY | Department of Environmental Conservation

MONITORING WELL CONSTRUCTION DETAILS

Well Number: MW-3R

DRILLING SUMMARY

Geologist:
Steve Moeller

Drilling Company:
TREC Environmental

Driller:
Eric Hamman

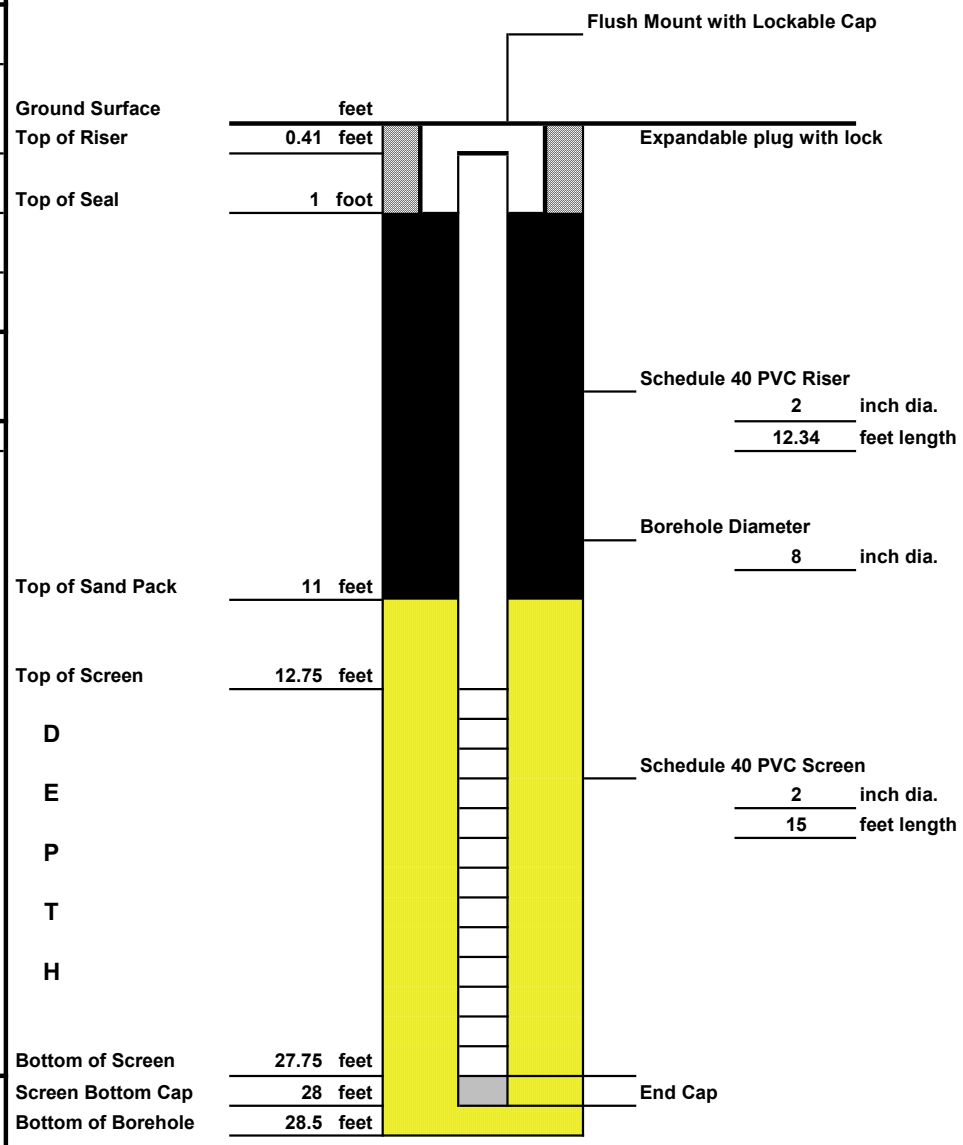
Rig Make/Model:
Geoprobe 6620 DT

Date:
September 21, 2020

GEOLOGIC LOG

Depth(ft.)	Description
	See log for soil boring SB-3R.

WELL DESIGN



SURFACE COMPLETION

Surface: 8-inch diameter steel flush-mount with 12-inch skirt

RISER MATERIAL

Type: 2-inch ID Schedule 40 PVC threaded with O-ring seal

Setting: 0.41 - 12.75 feet bgs

SCREEN MATERIAL

Type: 2-inch ID Schedule 40 PVC, threaded with O-ring seal

Slot Size: 0.010" machine slotted

Setting: 12.75 - 27.75 feet bgs

FILTER MATERIAL

Type: Filpro #00N Silica Sand

Setting: 12 - 28.5 feet bgs

SEAL MATERIAL

Type: CETCO PureGold Medium Bentonite Chips

Setting: 1 - 11 feet bgs

COMMENTS:

Well is a replacement for original well MW-5, and is in the northern portion of the site about 15 feet west of the site divider fence.

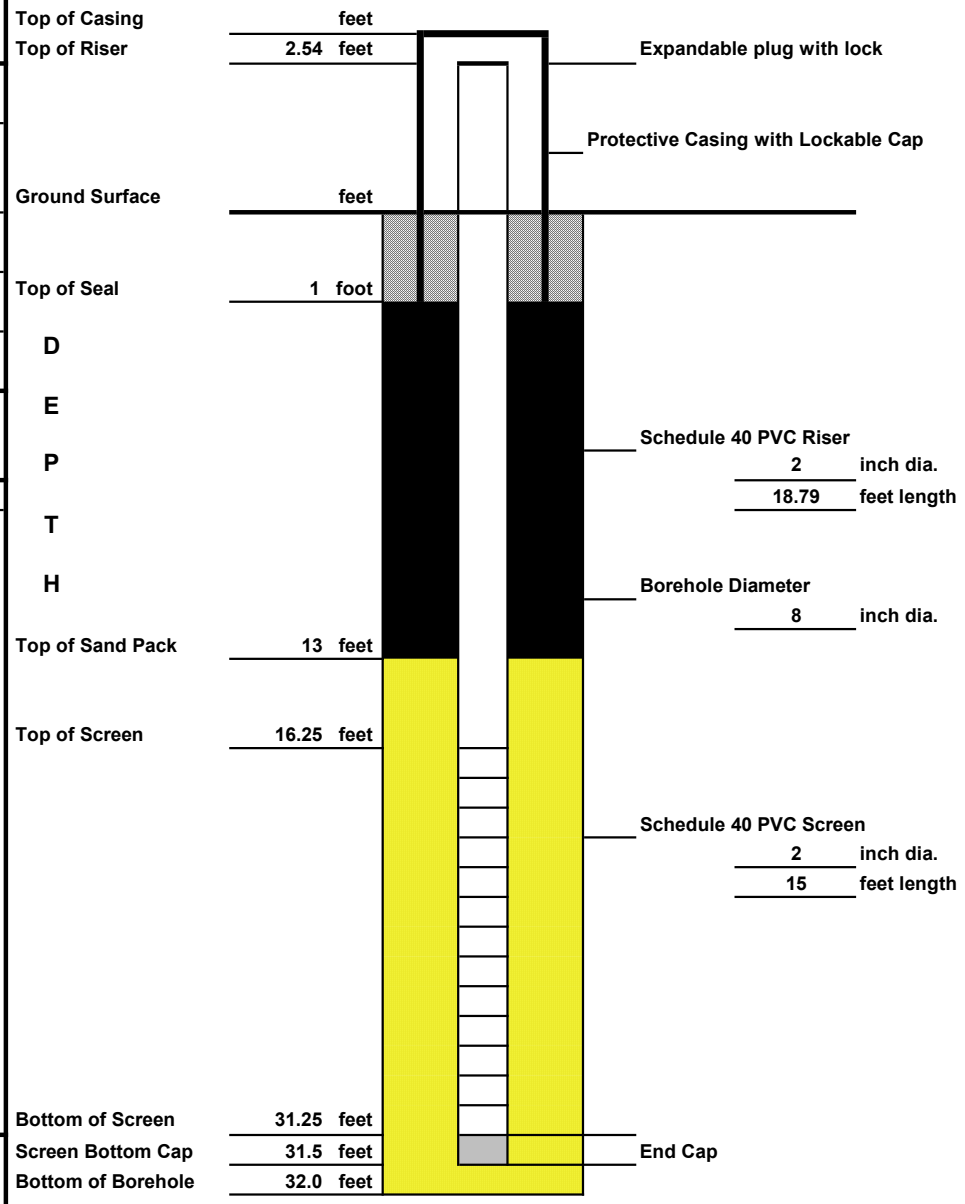
WELL DESIGN



SURFACE COMPLETION

Surface: 8-inch diameter steel flush-mount with 12-inch skirt

RISER MATERIAL

Type: 2-inch ID Schedule 40 PVC threaded with O-ring seal

Setting: -2.54 - 16.25 feet bgs

SCREEN MATERIAL

Type: 2-inch ID Schedule 40 PVC, threaded with O-ring seal

Slot Size: 0.010" machine slotted

Setting: 16.25 - 31.5 feet bgs

FILTER MATERIAL

Type: Filpro #00N Silica Sand

Setting: 13 - 32 feet bgs

SEAL MATERIAL

Type: CETCO PureGold Medium Bentonite Chips

Setting: 1 - 13 feet bgs

COMMENTS:

Well is located in the southeastern portion of the site about 15 feet west of the the BSA pump house building.

The subsurface information shown here was obtained for design and estimate purposes. It is made available so that users may have access to the same information available to the State. It is presented in good faith. By the nature of the exploration process, the information represents only a small fraction of the total volume of the material at the site. Interpolation between data samples may not be indicative of the actual material encountered.

1. Introduction

This Field Sampling Plan (FSP) presents the methods and procedures to be used for performing field activities during the Remedial Investigation/ Feasibility Study (RI/FS) at the Lower Scajaquada Creek Operable Unit in Buffalo, New York.

1.1. Overview of Field Activities

The following field activities will be performed:

- Reconnaissance – A reconnaissance will be performed to observe site conditions.
- Utility Locating – Subsurface utilities will be identified and marked in the field with cooperation from
- Soil Boring Advancement and Soil Sampling –Soil borings will be advanced using rotary drilling methods. Soil samples will be collected using Macrocore or 2-foot split spoon samplers
- Monitoring Well Installation and Groundwater Sampling – Some of the above-described soil borings will be converted into 2-inch diameter monitoring wells installed in the overburden. Each newly-installed well will be developed after which groundwater samples will be collected.
- Sediment Borings- Sediment borings will be completed within Scajaquada Creek and the Scajaquada Creek Inlet between West Ave. and the Black Rock Canal. The borings will be advanced using either rotary or direct-push methods by a drill rig mounted on a barge.
- Surface Water Elevation Monitoring – Surface elevation data will be obtained at a few locations along Scajaquada Creek.
- Surveying – The locations and elevations of each RI/FS investigation location including soil borings, monitoring wells and sediment investigation locations will be surveyed along with relevant Site features.

2. General Field Guidelines

2.1. Site Hazards

Potential on-site surface hazards, such as traffic, uneven work surfaces, sharp objects, work on and near water and overhead power lines will be identified prior to initiation of the field work. The potential hazards at the site will be identified during a site reconnaissance by the project team on the first day of the investigation field activities. Additional safety measures to be undertaken for the work performed during the investigation are described in the site-specific Health and Safety Plan (HASP).

2.2. Underground Utilities

Underground utilities, including electric lines, gas lines, storm and sanitary sewers, and communication lines will be identified prior to initiation of drilling and other subsurface work. Underground utility location will be accomplished as follows:

- All proposed investigation locations not occurring within Scajaquada Creek will be flagged or marked-out with white paint.
- Dig Safely of New York 800-272-4480 will be contacted to initiate the locating activities. New York State law requires that Dig Safely of New York be notified at least two working days, and not more than 10 working days, before subsurface work is performed.
- As part of the Dig Safely New York utility locating process, GEI will exercise the option to request a Site visit from member utilities to clearly identify the location of buried utilities. Specific attention will be given for the potential for utilities to cross or parallel Scajaquada Creek.
- Companies and municipalities with subsurface utilities present will locate and mark-out all subsurface utility lines.

2.3. Field Log Books

All field activities will be carefully documented in field log books. Entries will be of sufficient detail that a complete daily record of significant events, observations, and measurements is developed. The field log book will provide a legal record of the activities conducted at the site. Accordingly:

- Field books will be assigned a unique identification number.
- Field books will be bound with consecutively numbered pages.
- Field books will be controlled by the Site Manager while field work is in progress.
- Entries will be written with waterproof ink.
- Entries will be signed and dated at the conclusion of each day of field work.
- Erroneous entries made while field work is in progress will be corrected by the field person that made the entries. Corrections will be made by drawing a line through the error, entering the correct information, and initialing the correction.

- Corrections necessary after departing the field will be made by the person who entered the original information. Corrections will be made by drawing a line through the error, entering the correct information, and initialing and dating the time of the correction.

At a minimum, daily field book entries will include the following information:

- Location of field activity
- Date and time of entry
- Names and titles of field team members on site and site contacts
- Names, titles of any site visitors, as well as the date and time entering and leaving the site
- Weather information, for example: temperature, cloud coverage, wind speed, and direction
- Purpose of field activity
- A detailed description of the field work conducted
- Sample media (soil, sediment, groundwater, etc.)
- Sample collection method
- Number and volume of sample(s) taken
- Description of sampling point(s)
- Volume of groundwater removed before sampling
- Preservatives used
- Analytical parameters
- Date and time of collection
- Sample identification number(s)
- Sample distribution (e.g., laboratory)
- Field observations
- All field measurements made during soil screening with the photo-ionization detector (PID), and groundwater sampling (pH, temperature, conductivity, turbidity, etc.)
- References for all maps and photographs of the sampling site(s)
- Information pertaining to sample documentation such as:
    - Dates and method of sample shipments
    - Chain-of-custody record numbers
    - Federal Express or UPS air bill numbers

3. Field Equipment Decontamination and Management of Investigation-Derived Waste

3.1. Decontamination Area

A temporary decontamination area lined with polyethylene sheeting will be constructed for personal decontamination and for decontamination of the drilling and probing equipment. Wash water collected from the decontamination activities will be pumped from the pad with a sump pump or trash pump into 55-gallon drums or a bulk tank; and managed as described in Section 3.3. For land-based soil boring and monitoring well locations, the decontamination area will be located near each investigation location. For sediment-boring locations, the temporary decontamination area will be located on the barge/support craft or on-shore, near the sediment boring transect.

3.2. Equipment Decontamination

The following procedures will be used to decontaminate equipment used during the RI/FS activities:

- All drilling equipment including the drilling rig; augers; bits; rods; tools; split-spoon samplers; soil core collection tubes and tremie pipes will be cleaned with a high-pressure washing unit before beginning work.
- Tools, drill rods, samplers, and augers will be placed on polyethylene plastic sheets following pressure washing.
- All augers, samplers, rods, and tools will be decontaminated between each land-based investigation location.
- The back of the drill rig and all tools, augers, and rods will be decontaminated at the completion of the work and prior to leaving the site.

The following lists materials and methods for decontamination.

Suggested Materials

- Potable water
- Phosphate-free detergent (such as Alconox™ or Simple Green™)
- De-ionized water
- Aluminum foil
- Plastic/polyethylene sheeting
- Plastic buckets and brushes
- Personal protective equipment (PPE) in accordance with the HASP

Procedures

- Prior to sampling, all non-dedicated sampling equipment (bowls, spoons, interface probes, etc.) will be washed with potable water and a phosphate-free detergent (such as Alconox™). Decontamination may take place at the sampling location as long as all liquids are contained in pails, buckets, etc.
- The sampling equipment will then be rinsed with potable water followed by a de-ionized water rinse.
- Between rinses, equipment will be placed on polyethylene sheets or aluminum foil, if necessary. Washed equipment will not be placed directly on the ground.
- Equipment will be wrapped in polyethylene plastic or aluminum foil for storage or transportation from the designated decontamination area to the sampling location.

3.3. Management of Investigation-Derived Waste (IDW)

Management and staging of IDW is identified in Section 6.9 of the Remedial Investigation/ Feasibility Study Work Plan. Drill cuttings, sediments and plastic used for surface containment of spoils and fluids, purge water, drill cuttings, personal protective equipment, and disposable sampling equipment will be containerized in separate 55-gallon drums.

3.3.1. Decontamination Fluids and Development and Purge Water

Hot-water pressure wash, decontamination, and development and purge water will be collected in 55-gallon drums. The storage drums will be labeled as “pending analysis – investigation-derived residual decontamination water” and temporarily staged at 1660 Niagara Street pending characterization and proper disposal.

3.3.2. Soil Cuttings and Creek Sediments

Soil and Creek sediments generated during the advancement of soil and sediment borings will be contained in 55-gallon drums. The drums will be labeled as “pending analysis – investigation-derived residual – soil from drill cuttings”. Drums will be temporarily staged at 1660 Niagara Street pending characterization and proper disposal.

3.3.3. Personal Protective Equipment

All PPE will be placed in 55-gallon drums and temporarily staged at 1660 Niagara Street pending characterization of other IDW.

3.3.4. Disposable Sampling Equipment

All used soil, sediment and groundwater sampling equipment (e.g., Macrocore liners, disposable polyethylene bailer and polypropylene tubing) will be placed in the 55-gallon drums labeled “pending analysis – investigation-derived residual – sampling equipment” and temporarily staged at 1660 Niagara Street pending characterization of other IDW.

3.3.5. NAPL Management

If quantities of NAPL are collected in 5-gallon buckets, it will be transferred to a 55-gallon drum, labeled as “pending analysis – IDW - NAPL ” with appropriate well number and temporarily staged at the location identified in the RI/FS work plan pending characterization for disposal with other IDW.

4. Subsurface Soil and Sediment Sampling Procedures

4.1. Introduction

Subsurface investigation activities to be conducted at the site consist of:

- The advancement of overburden soil borings
- The installation of overburden monitoring wells
- The advancement of sediment borings

Procedures for these activities are described in the following sections.

4.2. Soil Borings and Subsurface Soil Sampling

The following methods will be used during installation of the soil borings:

Required Equipment

- Field book
- Project plans
- PPE in accordance with the HASP
- Stakes, flagging and marking paint
- Plastic bags for soil screening samples
- Tape measure
- Decontamination supplies
- Water level indicator
- PID with a 10.2 or 10.6 eV lamp
- Camera
- Clear tape, duct tape
- Laboratory sample bottles
- Coolers and ice
- Shipping supplies

4.2.1. Overburden Drilling and Geologic Logging Methods

- Soil borings will be advanced using 4-1/4 inch inside diameter hollow stem augers or using a Geoprobe traditional or dual-tube sampling system. Each soil boring will be completed through fill and native soil into low permeability clay exhibiting no visual impact or odors.

- Soil samples will be collected continuously from the ground surface to the bottom of the borings using 4-foot long, 2-inch diameter MacroCore™ samplers, or 2-foot long by 2-inch diameter split-spoon samplers.
- Soil samples retrieved from the borehole will be visually described on the soil boring log for: 1) percent recovery, 2) soil type, 3) color, 4) moisture content, 5) texture, 6) grain size and shape, 7) consistency, 8) visible evidence of staining or other hydrocarbon-related impacts, and 9) any other relevant observations. The descriptions will be in accordance with the USCS and the American Society for Testing and Materials (ASTM) guidelines.
- Immediately after describing the core, a representative portion of the sample will be placed in a re-sealable plastic (e.g., "ziplock") bag filled approximately half full. The bag will be labeled with the boring number and interval sampled.
- After allowing the bagged soil to warm, the tip of the sample probe attached to the PID will be inserted into the bag to measure the headspace for organic vapors.
- Soil remaining after completion of sample description, collection, and field screening will be disposed of properly as IDW.
- All borings will be sealed with bentonite hole plug or cement/bentonite grout following completion.
- All drilling equipment will be decontaminated between each boring in accordance with methods specified in Section 3.2.
- The drilling rig working platform/surface will be lined with plastic such that soil is contained while performing observations, measurements, and sampling.
- The field geologist will log borehole geology and headspace measurements in the field book and the Drilling Record and any other observations (e.g., DNAPL/LNAPL impacted soil; and coal tar-like odors, staining, or sheen, etc.).
- At two locations (SB-RI-9 and SB-RI-11) the soil borings will be advanced will be beneath the area wide clay unit to evaluate extent of DNAPL. Objective and rationale for each soil boring location is summarized on Table 1 in the RI/FS Work Plan.

4.2.2. Overburden Soil Sampling

- The number and frequency of samples to be collected from each boring and the associated analytical parameters are summarized in Table 2 in the RI/FS Work Plan.
- A minimum of two soil samples will be collected from each boring and submitted for laboratory analysis. A sample will be collected from the most apparently impacted interval based on PID screening and field observations. If impacts are not observed, a sample will be collected from the 1-foot interval immediately below the water table, and a second sample will be collected from the bottom of the boring (presumed to be from the upper red-brown clay unit. The analytical program for soil borings is provided in Table 2 of the RI/FS Work Plan.
- Samples for laboratory analyses will be collected directly from the acetate liners, or split spoons. For soil and sediment samples analyzed for VOCs, either Encore or Terracore samplers will be

used to collect and preserve the appropriate sample volume. Samples will be placed into appropriate containers and compacted to minimize headspace and pore space.

- Each soil boring that is not converted into a groundwater monitoring well will be backfilled with bentonite pellets to within 1 foot of ground surface with the remainder backfilled with clean topsoil, or asphalt patch where borings are advanced through pavement.
- The sample containers will be labeled, placed in a laboratory-supplied cooler, and packed with ice. The coolers will then be shipped to the laboratory for analysis.
- If there is a delay of sample shipment due to insufficient samples to warrant overnight delivery, the samples will be stored in a cool, secure place with sufficient ice to maintain a temperature of 4℃.
- Chain-of-custody procedures will be followed as outlined in the Quality Assurance Project Plan (QAPP) using the chain-of-custody form provided by the laboratory.
- The sampling equipment will be decontaminated between samples in accordance with procedures described in Section 3.
- Soil remaining after completion of sample description, collection, and field screening will be managed as IDW described further in Section 6.9 of the RI/FS Work Plan.
- The sample locations, descriptions, and depths will be recorded on the borelogs in the field book.

4.3. Scajaquada Creek and Inlet Sediment Sampling and Probing

Sediment borings will be completed in the Scajaquada Creek main channel and Inlet along 26 transects to evaluate sediment quality. Additionally, surface soil samples will be collected from the Creek bank in the Inlet to evaluate surface soil quality where sheens were observed on surface water near the City of Buffalo Pump House. Sediment and surface soil sampling procedures are outlined below.

4.3.1. Sediment Probing

The shallow sediments at each probe point will be probed (agitated) by hand using a one-inch diameter threaded PVC pipe with a fixed plate on the bottom. Probing will involve the following:

1. Use a survey grade GPS to identify the location of probing location along the transect.
2. Measure the depth to the top of sediment using a tape or graduated rod.
3. A threaded, one-inch diameter white PVC pipe (rod) with a fixed, weighted flat-plate will be used as the probing tool. The PVC rod will be pre-marked at 10 cm intervals to help measure the depth of soft sediment penetration.
4. The probe will be lowered to the depth of the sediment surface measured at that location and gently pushed into the sediment by hand as deep as possible. Record the depth of penetration from the graduated marks on the rod.
5. Agitate the shallow sediment with the probe and observe for the presence of hydrocarbon sheen or NAPL. Sheens will be characterized using a four-point scale as trace, light, moderate, or

heavy/NAPL. Observations of sediment characteristics will be recorded (such as soft, hard, loose, cohesive, sandy, rocky, etc.). It will also be noted if deeper probing liberates sheen.

Probing is generally to be performed from a boat, but where the water is shallow (less than 3 feet deep), or the boat cannot access the probing locations, this task will be performed by wading into the creek

4.3.2. Sediment Sampling

Individual sediment sampling locations are provided on Figures 8 through 10 of the RI Work Plan. Sediment borings will be advanced by a drill-rig mounted to a barge and will be advanced using 3-inch diameters flush-jointed casing or 2-3/4-inch diameter hollow stem augers. Casing or augers are specified because vibracore methods could not achieve the required depth of penetration to assess DNAPL presence above the area-wide clay layer. Sediment samples will be collected using a 4-foot Macrocore sampler or 2" diameter split spoon samplers. A sediment sample recovery goal of 70% has been adopted for sediment borings in accordance with GLLA guidelines. If sediment recovery is below 70%, a 3-inch diameter split spoon sampler can be utilized (in 3-inch diameter casing only). Additionally, sampling methods may be modified to include adjusting the cutting shoe on the sampler, varying core-catcher type, modifying the Macrocore liner type or configuration, and modifying the rate of sampler advancement to achieve the 70% recovery goal.

Upon retrieval of the core barrel the inner liner will be capped, and the liner removed from the outer barrel. The upper portion of the liner without sediment will be carefully drained, cut, and then capped immediately above the top of the sediment. If necessary for handling purposes, the cores will cut into two sub-sections before being delivered to shore. Cores will be transferred from the coring boat to the shore where a core processing area will be established. The cores will be measured and then placed into a trough or stand where they will be cut, split, and then logged and sampled. Each core will be logged and photographs taken. All information regarding soil/sediment type, presence of impacts and intervals sampled will be summarized on the sediment boring log.

Following logging and photographing, the cores will be sampled for laboratory analysis from the target intervals and specified analytes listed in Table 4 of the RI/FS Work Plan. VOC samples will be obtained directly from the cores using laboratory-supplied collection kits. The remainder of the sediment from each sample interval will be placed into a stainless-steel bowl, homogenized, and then transferred to laboratory-supplied jars for the specified analyses. The target intervals are generally the upper two feet of sediment and the most impacted interval observed in the core.

If it is found that the texture and consistency of the surface sediment is such that it cannot be recovered reliably by the core barrel, then a supplemental surface grab sample will be obtained location using a sediment dredge such as a Ponar sampler. This sampler will sample the top 6 inches of sediment. Excess sediment not used for sample analysis will be managed as IDW as described in Section 6.9 of the RI Work Plan.

All downhole drilling equipment including casing, augers, drill rods and samplers will be decontaminated between sediment boring locations using high pressure steam methods.

4.3.3. Creek Bank Soil Sampling

Surface soil samples will be collected from 10 locations identified on Figure 8 of the RI/FS Work Plan to assess potential impact to soils adjacent to the creek in the Inlet that have historically exhibited sheens due to daily fluctuations in surface water levels. GEI surface water monitoring data using a pressure transducer/data logger show typical daily water level fluctuations of approximately two feet between September 2, 2022 and January 24, 2023 with rising trend in typical daily high-water levels (elevation range of approximately 571.5 and 573.5 feet during the monitoring timeframes. Therefore, proposed surface soil samples shown on Figure 8 of the RI/FS Work Plan will be collected from the creek at an elevation of one to two feet higher than a creek elevation of 573 feet. At each surface soil sampling location the soil will be agitated using a dedicated probe (PVC rod or similar) to evaluate for DNAPL/oil presence and the potential for generating sheens on adjacent surface water. Sample collection locations will be prioritized to those areas that exhibit the potential for sheen generation. At each location, a sample will be collected from the 0–2-inch depth interval on the creek bank that is within approximately 1-foot of the typical water's edge. Locations will be determined based on observations such as shore erosion, vegetation growth or sediment type.

Samples for VOC analysis will be collected directly from the creek bank using TerraCore (or equivalent) sampling methods. Samples for other analyses will be collected using dedicated, disposable sampling equipment and homogenized prior to placement in laboratory-supplied containers.

Each surface soil sampling location will be staked in the field and labeled following sample collection for future survey.

4.4. Monitoring Well Installation and Development

The following methods will be used for drilling, installing, and developing the monitoring wells:

Required Equipment

- Field book
- Project plans
- PPE in accordance with the HASP
- Plastic bags for soil screening samples
- Tape measure
- Decontamination supplies
- Electronic oil/water interface probe
- PID
- Camera
- Clear tape, duct tape
- Aluminum foil

- Laboratory sample bottles
- Coolers and ice
- Shipping supplies
- Clear polyethylene disposable bailers (NAPL confirmation)
- Polyethylene disposable bailers (development)
- Polypropylene rope (development)
- Waterra™ pump or other purge pump (development)
- Submersible electric pump (development)
- Stainless steel or glass beakers (development)
- Turbidity meter (development)
- Temperature, conductivity, pH meter (development)

4.4.1. Overburden Monitoring Well Installation

The monitoring wells will be installed according to the following specifications:

- The monitoring well borings will be advanced with 4 ¼-inch ID HSAs
- Wells will be constructed with 2-inch ID, threaded, flush-joint, polyvinyl chloride (PVC) casings and screens.
- Screens will be 10-feet long with 0.02-inch slot openings and will be equipped with a 2-foot long DNAPL sump at the base. In areas where DNAPL-impacted soils were identified during the 2021/2022 site characterization (SC) and no shallow wells are present, monitoring wells MW-LSC-2S-RI and MW-LSC-4S-RI will be installed. The well screens at these locations will be positioned to monitor the upper 5 feet of the saturated zone, approximately at an elevation of 565 feet or 5 feet below the observed water table during drilling. Each well will have a 5-foot screen length to evaluate groundwater quality in the shallow groundwater near the water table and will not utilize a sump below the well screen
- The annulus around the 2-foot long DNAPL sump will be filled with bentonite chips. The bentonite chips will not be placed higher than the top of the sump, so that the well screen will not be blocked.
- The annulus around the screens will be backfilled with clean silica sand having appropriate size (e.g., Morie No. 0) to a minimum height of 2 feet above the top of the screen. Auger flights will be withdrawn as sand is poured in a manner that will minimize hole collapse and bridging.
- A bentonite chip seal with a minimum thickness of 2 feet will be placed above the sand pack. The bentonite seal will be hydrated with clean, potable water before placement of grout above the seal layer.
- The remainder of the annular space will be filled with cement-bentonite grout to ground surface. The grout will be allowed to set for a minimum of 24 hours before wells are developed.

- Each monitoring well will be a flush-mounted installation with a locking cap.
- The concrete seal or pad will be sloped to channel water away from the well, and be deep enough to remain stable during freezing and thawing of the ground.
- The top of the PVC well casing and ground surface will be marked and surveyed to 0.01 foot, and the elevation will be determined relative to a fixed benchmark or datum.
- The measuring point on all wells will be on the innermost PVC casing.
- Monitoring well construction details will be recorded in the field book and on the Monitoring Well Construction Log.

4.4.2. Monitoring Well Development

- After a minimum of 48 hours after installation, each newly-installed monitoring well will be developed using methods described below. The information generated during development will be recorded on the Monitoring Well Development Log (Attachment A).
- Prior to development, the wells will be checked for NAPL presence (LNAPL and DNAPL). If NAPL is encountered, the field observations (i.e., thickness and description) will be documented on the well development forms. If NAPL is present, the monitoring well will be developed using low-flow (peristaltic) development methods to minimize contact of NAPL with the well screen and riser. Low flow development will consist of lowering a section of ¼ or 3/8-inch tubing into the well screen taking caution to keep the tubing intake at least 2-feet above the level of NAPL.
- For wells that do not contain NAPL, surging will be performed periodically, across the lengths of screen in 2-foot increments prior to, at interim periods of pumping, and immediately before the final pumping. Pumping methods may include using a centrifugal, submersible, or peristaltic pump and dedicated polyethylene tubing, using a Waterra™ positive displacement pump and dedicated polyethylene tubing, or other methods at the discretion of the field geologist.
- Water levels will be measured in each well to the nearest 0.01 foot prior to development.
- The wells will be developed until the water in the well is reasonably free of visible sediment (50 nephelometric turbidity units (NTU) or less if possible) or until pH, temperature, and specific conductivity stabilize. Field parameters are considered stable when three consecutive readings are within the stabilization criteria for that parameter. The stabilization criteria are as follows: 3% for conductivity and temperature, and 0.1 unit for pH. A portable nephelometer will be used to make the turbidity measurement.
- Development water will be collected in 5-gallon buckets and transferred to 55-gallon drums per management as described in Section 3.3.
- Following development, wells will be allowed to recover for at least 14 days before groundwater is purged and sampled. All monitoring well development will be performed or overseen by a field geologist and recorded in the field book.

4.4.3. Non-Aqueous Phase Liquid (NAPL) Gauging and Mobility Assessments

NAPL gauging and NAPL mobility assessments will be conducted following monitoring well development and sampling. In each newly-installed monitoring well, NAPL presence will be evaluated using an oil/water interface probe, a clear plastic bailer, a weighted cotton rope, or a weighted PVC rod to measure thickness (depending on whichever field technique is most suitable). NAPL presence and thickness will be documented on Monitoring Well Sampling and Development Forms (Attachment A). Accumulated NAPL will then be removed to the greatest extent possible either using a bottom loading bailer or a peristaltic pump with down-hole tubing. NAPL will be collected in a 5-gallon bucket and containerized as investigation-derived waste, described further in Section 6.9.

Once NAPL has been evacuated from the well, the well will be checked periodically for NAPL presence and/or accumulation. The NAPL will be removed during each monitoring event to assess the rate of NAPL recovery. NAPL mobility assessment checks will be completed according to the schedule in the RI/FS Work Plan. NAPL thickness and the amount of NAPL removed from each well will be recorded on the Monitoring Well Development Forms (Attachment A) for each assessment event.

5. Groundwater Sampling Procedures

5.1. Introduction

Procedures for obtaining samples of groundwater are described in this section. Groundwater samples will be collected using low-flow, low-stress purge and sampling methods.

5.2. Groundwater Sampling

The number of the samples that will be collected for laboratory analysis from each well and the analytical parameters are listed in Section 6.3.3 of the RI/FS Work Plan.

The following method will be used to collect groundwater samples from monitoring wells:

Required Equipment and Supplies

- Field book
- Project plans
- PPE in accordance with the HASP
- Electronic oil/water interface probe
- Disposable polyethylene bailers and low-flow sampling pump
- Polypropylene rope
- Temperature, conductivity, and pH meter
- Turbidity meter
- Flow-through cell
- Decontamination supplies
- Peristaltic or submersible pump capable of achieving low-flow rates (i.e., 0.5 liters per minute or less)
- Plastic tubing
- Plastic sheeting
- PID
- Clear tape, duct tape
- Coolers and ice
- Laboratory sample bottles
- Federal Express or UPS labels

5.2.1. Groundwater Sampling Method

Purging

- Prior to sampling, the static water level and thickness of any LNAPL or DNAPL will be measured to the nearest 0.01 foot from the surveyed well elevation mark on the top of the PVC casing with a decontaminated oil/water interface probe. NAPL thickness will be confirmed using a clear bailer or a weighted string. The measurement will be recorded on the Monitoring Well Sampling and Development Form (Attachment A)
- The probe will be decontaminated between uses.
- Groundwater from the well will be purged until field parameters stabilize. Field parameters are considered stable when three consecutive readings are within the stabilization criteria for that parameter. The stabilization criteria are as follows: 3% for conductivity and temperature, and 0.1 unit for pH. The target turbidity values will be <10 NTUs, if possible.
- The flow rate measurement will be approximately 0.5 liter per minute or less.
- If the parameters do not stabilize, then the next step for the sampling will be to remove up to three well volumes, or to purge wells for at least 1 hour prior to sampling.
- If a well goes dry before the required volumes are removed, it will be allowed to recover and sampled when it recovers sufficiently.
- Purge water will be managed and disposed of properly in accordance with IDW management procedures.

Sampling

- Samples will be collected using dedicated ¼- or ⅜-inch polyethylene tubing.
- Prior to filling the sample bottles, the final temperature, pH, and conductivity will be measured within a flow-through cell. Turbidity will be measured with a hand-held turbidity meter. All measurements will be recorded in the field book.
- Groundwater samples will be collected into the appropriate laboratory-provided sampling containers.
- The sample containers will be labeled, placed in a laboratory-supplied cooler, and packed on ice (to maintain a temperature of 4˚C). The cooler will be shipped overnight or delivered to the laboratory for analysis.
- Chain-of-custody procedures will be followed as outlined in the QAPP using the chain-of-custody form.
- Well sampling data will be recorded on the Monitoring Well Sampling and Development Form (Attachment A).

6. Air Monitoring

6.1. Introduction

Two types of air monitoring will be performed during the site investigation: 1) work zone monitoring for protection of the workers performing the site investigation, and 2) community air monitoring at the perimeter of the work site for protection of the local community.

6.2. Breathing Zone Air Monitoring During Drilling and Sampling

Monitoring of air in the breathing zone within the work site will be conducted periodically during all drilling and sampling activities.

- A PID will be used to monitor for VOCs or other organic vapors in the breathing zone and borehole, and to screen the samples at each investigation location.
- Additional air monitoring may be required as specified in the site-specific HASP.
- The PID readings will be recorded in the field book and on the boring log during drilling activities. The procedure for the PID operation and calibration is included in the HASP. Note that equipment calibration will be performed as often as needed to account for changing conditions or instrument readings. The minimum frequency of calibration is specified in the HASP; more frequent calibration will be performed if spurious readings are observed or there are other problems with the instruments.

6.3. Community Air Monitoring

A Community Air Monitoring Plan (CAMP, Appendix B) has been prepared for the RI/FS Work Plan and requires real-time monitoring for VOCs, particulates (i.e., dust), and MGP-related odors at the downwind perimeter of each designated work area when certain activities are in progress at impacted sites. The community air monitoring is not intended for use in establishing action levels for worker respiratory protection. Rather, its intent is to provide a measure of protection for the downwind community (i.e., any and all off-site receptors including residences and businesses and on-site workers not directly involved with the subject work activities) from potential airborne contaminant releases as a direct result of investigative and remedial work activities. The action levels for community air monitoring require increased monitoring, corrective actions to abate emissions, and/or work shutdown. Additionally, community air monitoring helps to confirm that work activities do not spread contamination off site through the air.

The procedures and action levels for community air monitoring are presented in the CAMP that has been prepared for the Site (Appendix B).

7. Field Instruments and Calibration

All field analytical equipment will be calibrated immediately prior to each day's use and more frequently if required. The calibration procedures will conform to manufacturer's standard instructions. This calibration will ensure that the equipment is functioning within the allowable tolerances established by the manufacturer and required by the project. All instrument calibrations will be documented in the project field book and in an instrument calibration log. Records of all instrument calibration will be maintained by the Field Team Leader. Copies of all of the instrument manuals will be maintained on site by the Field Team Leader. All changes to instrumentation will be noted in the field log book.

The following field instruments will be used during the investigation:

- PID
- Particulate monitors
- pH, specific conductivity, oxidation-reduction potential and temperature meter
- Turbidity meter

7.1. Portable Photo-Ionization Analyzer

- The photo-ionization analyzer will be equipped with either a 10.2 or a 10.6 eV lamp. The PID is capable of ionizing and detecting compounds with an ionization potential of less than 10.6 eV. This accounts for up to 73% of the VOCs on the United States Environmental Protection Agency (EPA) Target Compound List (TCL).
- Calibration must be performed at the beginning of each day of use with a standard calibration gas having a concentration of 100 parts per million of isobutylene. If the unit experiences abnormal perturbation or erratic readings, more frequent or additional calibration will be required.
- All calibration data must be recorded in the project field notebooks.
- A battery check must be completed at the beginning and end of each working day.
- All changes to the PID will be noted in the field notes (such as lamp or filter cleaning or replacement or change of instrument).

7.2. pH Meter

- Calibration of the pH meter must be performed at the start of each day of use, and after very high or low readings as required by this Plan, according to manufacturer's instructions.
- National Institute of Standards and Technology - traceable standard buffer solutions which bracket the expected pH range will be used. The standards will be pH of 4.0, 7.0, and 10.0 standard units.

- The use of the pH calibration must be used to set the meter to display the value of the standard being checked.
- The calibration data must be recorded in the project field book.

7.3. Specific Conductivity Meter and Temperature Probe

- Calibration checks using the conductivity standard must be performed at the start of each day of use, after five to 10 readings or after very high or low readings as required by this Plan, according to manufacturer's instructions.
- The portable conductivity meter must be calibrated using a reference solution of 200 µohms/cm (or the manufacturer's specified concentration) on a daily basis. The date and lot number of the reference solution must be recorded. Readings must be within 5% to be acceptable.
- The thermometer of the meter must be calibrated against the field thermometer on a weekly basis.

7.4. Turbidity Meter

- The calibration of the turbidity meter must be checked and reestablished at the start of each day of use according to manufacturer's instructions.

8. Environmental Sample Analyses

Collection of samples for laboratory analysis will be recorded on sample collection logs (Attachment A). The laboratory samples to be collected during the project specific to each media, including the chemical analyses to be performed and a summary of quality control samples are summarized in Table 2 and Table 4 of the RI/FS Work Plan and the Quality Assurance Project Plan (Appendix C of the RI/FS Work Plan).

TOC	total organic carbon
TPH	total petroleum hydrocarbons
TPH-DRO	total petroleum hydrocarbons – diesel range organics
TPH-GRO	total petroleum hydrocarbons – gasoline range organics
TSCA	Toxic Substance Control Act
µg/kg	micrograms per kilogram
µg/L	micrograms per liter
µmol/g	micromole per gram
VOA	volatile organic analysis
VOC	volatile organic compound

1. Introduction

This Quality Assurance Project Plan (QAPP) is being submitted on behalf of National Fuel Gas Distribution Corporation (National Fuel) in support of the remedial investigation (RI) to be performed in the Lower Scajaquada Creek area in Buffalo, New York. The work is being performed under the Great Lakes Legacy Act (GLLA) per a Project Agreement between the United States Environmental Protection Agency (USEPA), New York State Department of Environmental Conservation (NYSDEC), and National Fuel dated January 6, 2025. Under this agreement:

1. The USEPA will conduct a Feasibility Study (FS) and potentially initiate Remedial Design (RD) with the NYSDEC for the Black Rock Canal Operable Unit (OU).

2. National Fuel will conduct a Remedial Investigation (RI) and FS (RI/FS) for the Lower Scajaquada Creek OU focused primarily on historical releases from the former manufactured gas plant (MGP) located upstream of the West Avenue bridge crossing.

3. NYSDEC will provide oversight of the work in the Scajaquada Creek OU and complete source investigations of non-coal tar-related contaminant sources in adjacent upland properties, some of which may be commingled with coal tar-related sources.

The QAPP includes information regarding analytical methods, laboratories, and procedures that will be used during RI activities. GEI Consultants, Inc. (GEI) will be the primary environmental consultant for the Lower Scajaquada Creek OU. Pace Analytical Laboratories has been retained to provide environmental chemical analysis, GeoTesting Express has been retained to provide geotechnical analytical data.

This QAPP is Appendix C of the Remedial Investigation/Feasibility Study Work Plan – Lower Scajaquada Creek Operable Unit (April 2025) (RI/FS Work Plan) and is designed to be used in conjunction with the RI/FS Work Plan and other supporting documents, including the Field Sampling and Analytical Plan (April 2025, Appendix B of the RI/FS Work Plan). The RI/FS Work Plan contains site background information and investigation work scope details. Several of the QAPP Worksheets reference figures presented in the RI/FS Work Plan. Because the QAPP is an Appendix to the RI/FS Work Plan, the figures are not reproduced in the QAPP. Where appropriate, references are made to the figures included as part of the RI/FS Work Plan.

1.1 Development of the Quality Assurance Project Plan

As described on USEPA's Quality System Website (https://www.epa.gov/sites/default/files/2019-03/documents/g5-final.pdf), the objective of a QAPP is to document the planning, implementation, and assessment procedures for a particular project, as well as specific quality assurance and quality control activities. It integrates the technical and quality aspects of the project to provide a "blueprint" for obtaining the type and quality of environmental data and information needed for a specific decision or use.

In March 2005, the Intergovernmental Data Quality Task Force developed a policy and guidance document to fulfill the project-specific requirements of Part B of the American National Standards Institute/American Society of Quality Control E4 (ANSI/ASQC E4), to assist Federal departments and agencies with producing consistent QAPPs that reflect a systematic planning approach to collection and use of environmental data. That guidance document – the Uniform Federal Policy for Quality Assurance Project Plans (UFP-QAPP) Manual V1, March 2005 (USEPA, 2005a), and Optimized UFP-QAPP Worksheets, March 2012 (USEPA, 2012) – was followed in the development of this QAPP. Additionally, the provisions of this QAPP were reviewed against the minimum quality assurance/quality control (QA/QC) activities identified in the guidance document Uniform Federal Policy for Quality Assurance Project Plans: Part 2B, Quality Assurance/Quality Control Compendium: Minimum QA/QC Activities V1, March 2005 (USEPA, 2005b).

Investigation and characterization activities to be performed as part of the work at the Scajaquada Creek OU require development and submission of this QAPP to describe sampling, analyses, and data handling requirements for samples collected during work as part of OU-specific efforts.

1.2 Applicability of the QAPP

This QAPP is applicable to sampling and analysis work to be carried out at the Lower Scajaquada Creek OU and will be updated as needed to support modifications and additions to sampling activities. The period of applicability for this QAPP is the duration of the RI/FS. Any revisions made to this QAPP will be distributed as described in Worksheets #3 and #5, and all prior versions will be maintained by the GEI Quality Assurance Manager.

2. Document Overview

The Part 1 UFP-QAPP guidance and Optimized Worksheets (USEPA 2005a, 2012) include a series of 37 worksheets that are used to present the critical information required in a QAPP. The worksheets "ensure consistent content and presentation of information in a project-specific QAPP and streamline the review of QAPPs by regulators and others" (USEPA, 2005a). This QAPP was developed using the worksheet-based methodology; the worksheets follow this brief introductory text. Collectively, the QAPP worksheets provide information associated with four key topics:

- Project management and objectives
- Measurement and data acquisition
- Assessment and oversight
- Data review

A series of appendices is also included with this QAPP. These attachments include the following:

- Example chain of custody forms
- Laboratory verifications
- Laboratory quality assurance management plans and SOPs (included electronically only)
- Field SOPs and project operating procedures

When elements required by Part 1 UFP-QAPP are presented in other documents (e.g., SOPs), cross-referencing of these other documents can be used in lieu of repeating information (USEPA 2005a). Following this guidance, this QAPP provides certain relevant information by reference. This QAPP was prepared with information specific to the current scope of sampling and analysis activities associated with the RI/FS Work Plan to be conducted at the Scajaquada Creek OU by GEI and laboratories referenced herein.

Worksheets 1 through 37 were prepared to present universal information specific to investigation activities. Select worksheets that present similar information were combined.

Other pertinent site-specific information is presented in conjunction with other site-specific documents, which include but are not limited to the Lower Scajaquada Creek RI/FS Work Plan (April 2025). A list of such documents is provided in the References Section (Section 3).

QAPP Worksheets #1, 2: Title and Approval Page

Site Name/Project Name: Lower Scajaquada Creek Operable Unit Great Lakes Legacy Act (GLLA) Remedial Investigation and Feasibility Study (RI/FS Work Plan) – Appendix C

Site Location: The Lower Scajaquada Creek Operable Unit (OU) is comprised of the lands adjacent to Scajaquada Creek, extending south from the West Avenue Bridge to the creek's mouth where is discharges into the Black Rock Canal. The Scajaquada Creek Slip Area (Inlet Area), which was historically the creek's discharge location, is also part of the OU. Upland areas include properties owned by the former Penn Central Railroad, New York State, and City of Buffalo that are used for transportation and infrastructure corridors including a railroad passenger and freight train corridor, the NYS Thruway I-190, The Route 198 Scajaquada Expressway, and City of Buffalo roadways (West Avenue, Tonawanda Street, and Niagara Street).

Site Number/Code: Great Lakes Legacy Act (GLLA) NYSDEC Contract No. C011665

Regulatory Agency: United States Environmental Protection Agency (USEPA) Great Lakes National Program Office (GLNPO) and New York State Department of Environmental Conservation (NYSDEC)

PROJECT FIELD PERSONNEL SIGN-OFF SHEET

I have read and understand the applicable information set forth in this QAPP for the tasks I am to perform. I agree to perform my work in accordance with this QAPP and applicable field standard operating procedures (SOPs). I also acknowledge that I have the necessary certifications and/or training required to perform the project tasks.

QAPP Worksheet #6: Communication Pathways

Communication Driver	Organization	Name	Contact Information	Procedure (timing, pathway, documentation, etc.)
Regulatory agency interface	National Fuel	Tanya Alexander National Fuel Project Manager	alexandert@natfuel.com	Communicate as needed with regulatory agencies via phone or email with documentation saved to the project file.
Field progress reports	GEI	Mike Cummings GEI Field Team Leader/Site Safety Manager	mcummings@geiconsultants.com	Communicate daily or as needed with GEI Project Manager, via email or phone.
Field health and safety meetings and updates (i.e., tailgate meetings)	GEI	Mike Cummings GEI Field Team Leader/Site Safety Manager	mcummings@geiconsultants.com	Communicate daily, or as needed, with field personnel and subcontractors directly, or via e-mail or phone.
Significant health and safety or other project-related work issues, including stop work due to safety issues	GEI	Mike Cummings GEI Field Team Leader/Site Safety Manager	mcummings@geiconsultants.com	Each member of the field team has the authority to stop work if an unsafe condition is perceived. Health and safety incidents will be reported according to GEI's current procedure. The GEI Field Team Leader will be notified immediately by phone or directly and will be responsible for communicating with the GEI Project Manager, who will notify other entities (National Fuel Project Coordinator, GEI management, GEI Health and Safety Regional Manager), depending on the type/ magnitude of the Incident.
QAPP changes prior to fieldwork	GEI	Richard Frappa GEI Project Manager Jennifer Bash GEI QA Manager	rfrappa@geiconsultants.com jbash@geiconsultants.com	Notify the National Fuel Project Coordinator USEPA-GLNPO, and NYSDEC in writing or via email prior to implementation.

Communication Driver	Organization	Name	Contact Information	Procedure (timing, pathway, documentation, etc.)
Field activity execution, including variances from this QAPP and field corrective actions (Cas)	GEI	Mike Cummings GEI Field Team Leader/Site Safety Manager	mcummings@geiconsultants.com	Communicate daily or as needed, with GEI field personnel, subcontractors, and GEI Project Manager directly, or via email or phone. Significant variances and/or proposed revisions will be documented, approved by the GEI Project Manager and GEI QA Manager, and submitted for approval to NYSDEC and USEPA GLNPO.
Sample receipt variances	Laboratory	Melissa Deyo/ Pace Analytical Laboratory Project Manager Jonathan Campbell/GeoTesting Express Laboratory Project Manager	Melissa.deyo@pacelabs.com jcampbell@geotesting.com	Communicate significant issues to the GEI Field Team Leader via phone or email, within 24 hours of sample receipt.
Laboratory QC variances and analytical Cas	Laboratory	Laboratory staff (technicians, analysts, group leaders, Laboratory QA Manager)		Communicate/resolve per the Laboratory QA Manual. Communicate significant issues to the GEI Project Manager via phone or email, as variances are identified; narrate in the laboratory report. Minor variances require narration only.
Electronic data deliverable (EDD) issues, e.g., omissions, discrepancies, variances from standard	GEI	Jaimie Wargo GEI Data Manager	jwargo@geiconsultants.com	Communicate/resolve by phone or email with laboratory Project Manager.
Data verification issues, e.g., incomplete records	GEI	Mike Cummings GEI Field Team Leader Jaimie Wargo GEI Data Manager	mcummings@geiconsultants.com jwargo@geiconsultants.com	Communicate/resolve by phone or email with responsible party, i.e., field staff or laboratory Project Manager.

Communication Driver	Organization	Name	Contact Information	Procedure (timing, pathway, documentation, etc.)
Data validation issues, e.g., noncompliance with procedures	GEI	Jaimie Wargo	jwargo@geiconsultants.com	Communicate/resolve with Laboratory Project Manager by phone. Issues potentially impacting achievement of project objectives will be communicated to the GEI Project Manager, who will notify National Fuel's Project Coordinator.
Subcontractor issues, e.g., scope, schedule, budget	GEI	Richard Frappa GEI Project Manager	rfrappa@geiconsultants.com	Communicate/resolve by phone or email on an as-needed basis.

Notes:
TBD = To be determined; CA = corrective action; QA = quality assurance; QC = quality control; EDD = electronic data deliverable; GEI = GEI Consultants, Inc.

Worksheet #8: Special Personnel Training Requirements Table

Project Function	Specialized Training – Title or Description of Course	Training Providers	Training Date	Personnel/Groups Receiving Training	Personnel Titles/Organizational Affiliation	Location of Training Records/Certifications[1]
HAZWOPER	40-hour initial training as per 29 CFR 1910.120	Outsourced to certified trainers	Various	Field personnel, Project Manager, and other key staff	Various GEI staff and drilling subcontractor field staff	GEI's SharePoint site
HAZWOPER	8-hour annual refresher as per 29 CFR 1910.120	Certified in-house and out-sourced providers	Various	Field personnel, Project Manager, and other key staff	Various GEI staff and drilling subcontractor field staff	GEI's SharePoint site
HAZWOPER	CPR and first aid training as per 29 CFR 1910.120	Outsourced to certified trainers	Various	Site-Safety Officer on site during field work	Various GEI field staff	GEI's SharePoint site

[1] If training records and/or certificates are on file elsewhere, document their location in this column. If training records and/or certificates do not exist or are not available, then this should be noted.

Worksheet #9: Project Scoping Session Summaries

Project/Site Name: Lower Scajaquada Creek Operable Unit
Site Location: Buffalo, New York
Projected Date(s) of Sampling: May 2025
Program Manager: Rick Frappa

Date of Session: June 1, 2023
Scoping Session Purpose: Lower Scajaquada Creek OU RI/FS Meeting with Niagara River AOC Sediment Group

NYSDEC will provide notice of acceptance of National Fuel's response to comments. Acceptance letter was forthcoming at the time of the meeting and was received on May 30, 2025.	NYSDEC	N/A
The QAPP was revised to address comments received from EPA on May 7, 2025. At the time of the meeting, the QAPP was under EPA review. Acceptance of the QAPP was received on June 9, 2025 via email.	GEI/USEPA	N/A

Worksheet #10: Conceptual Site Model

A detailed description of the Lower Scajaquada Creek OU is presented in the RI/FS Work Plan, which the QAPP is appended to. Appendix A of the Work Plan includes the Site Characterization Report (GEI, 2022) detailing known environmental information and the basis for Remedial Investigation. A summary is provided below.

Preliminary Conceptual Site Model

The 2021/2022 Site Characterization of the Lower Scajaquada Creek area identified contamination in soils, groundwater, creek sediments, and City of Buffalo infrastructure. This contamination is linked to historic dense non-aqueous phase liquid (DNAPL) transport from former manufactured gas plant (MGP) operations. Additionally, investigations by other parties and the NYSDEC at Brownfield Cleanup Program (BCP) sites revealed contamination of soil, groundwater, and sediments due to past industrial property use, described by the NYSDEC as commingled contamination.

Information from these investigations was used to develop a preliminary conceptual site model (CSM) for the Lower Scajaquada Creek OU. The CSM outlines potential sources of contamination, release mechanisms, exposure media, and exposure routes based on current and potential future land use. The CSM will be refined based on data collected in the RI.

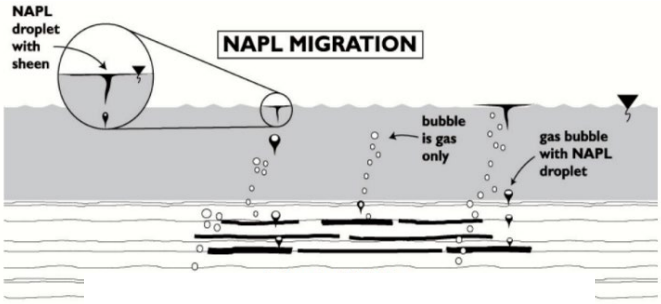
Previous investigations identified various chemical constituents in lower alluvial soil, groundwater, sediment, and City of Buffalo Pumphouse discharge in the Lower Scajaquada Creek OU. These environmental media could potentially serve as exposure media. The CSM provides a qualitative assessment of potential exposure via each medium for various types of receptors.

Data and findings from prior investigations indicate that sources of contamination affecting the Lower Scajaquada Creek originate from the former MGP operation, historic industrial use of nearby properties, and discharge to the creek from combined sewer outfall (CSOs) and the City of Buffalo Pumphouse. Contributions from upstream point and non-point sources are also likely given the highly urbanized status of the watershed.

Contamination release mechanisms refer to the processes by which contamination could be transferred from sources to environmental media. Contamination release mechanisms considered as part of the CSM are described below:

- Volatilization: volatile organic compounds (VOCs) from non-phase liquid (NAPL), contaminated soils, and/or groundwater that are released into air, including soil gas (i.e., the air entrained between soil particles in the vadose zone).

- DNAPL Migration: Gravity driven transport of DNAPL occurred as a result of product with specific gravity greater than 1.0 migrating vertically downward until encountering a low-permeability zone (i.e., clay) that precluded further vertical migration. When sufficient source existed, the DNAPL also spread laterally along the top of the clay confining layer, affecting a zone of coarser soil above the clay confining layer.
- Solubilization: Groundwater quality is affected through solubilization of contaminants from pooled or residual DNAPL. Once solubilized into groundwater, constituents are also transported with groundwater flow and may discharge into surface water.
- Discharges to the Creek: Surface water and groundwater collected in the City of Buffalo Pumphouse wet well was discharged to surface water as part of normal pumphouse operations (Pumphouse Interim Remedial Measure [IRMs] mitigated DNAPL entry into the system).
- Ebullition transport: NAPL migration from shallow DNAPL in creek sediments near the Pumphouse to the creek surface driven by gas bubbles caused by changes in hydraulic pressures (e.g., as created by Black Rock Canal lock operation). This contaminant release mechanism produces observed sheen on the surface water in the creek. Ebullition is conceptually shown graphically in the adjacent schematic.



Source: USEPA, 2015

Potential exposure describes the mechanism (exposure route) by which human receptors can be exposed to contamination during current or potentially foreseeable uses of the Lower Scajaquada Creek area. Such receptors include commercial workers, utility workers, construction workers, and passive recreational users of the creek and land adjacent to the waterway. Direct contact, ingestion, inhalation, and vapor intrusion/exposure are all exposure routes that could potentially impact receptors, depending on the nature of their specific activities and exposure areas.

Primary and secondary contact recreation and fishing exposure (i.e., consumption of fish caught from the creek) are pathways that could potentially impact human receptors. DNAPL-impacted soils are typically deeper than 15 feet below the ground surface, so human exposure to DNAPL in soil would be limited to construction workers involved in deep excavation work such as major utility infrastructure development or building construction with deep foundations. Under these scenarios, human exposure routes for chemicals include:

- inhalation of VOCs volatized from groundwater (particularly chlorinated volatile organic compounds [CVOCs] in the area of Niagara Street);
- dermal contact, inhalation, and incidental ingestion of soil/sediment particulates; and
- dermal contact and incidental ingestion of groundwater/surface water.

Groundwater in the area is not a source of drinking water. Scajaquada Creek surface water is also not a drinking water source.

Ecological exposure mechanisms in the Lower Scajaquada Creek are direct exposure to impacted sediments and pore water in the observed depositional areas and assimilation by a species (e.g., prey/food item) at one trophic level and transferred to a higher trophic level species through consumption. For certain types of chemicals, bioaccumulation can exacerbate this pathway at certain levels in the food chain. Based on the evaluation of exposure pathways, the key receptors of concern are benthic invertebrates, fish and semi-aquatic piscivorous mammals and avian species.
The key findings from the Site Characterization are summarized below and establish the preliminary CSM for the investigation area.

Soil Contamination

Soil Quality and DNAPL Presence: Pesticides, PCBs, herbicides, and cyanide were not detected in Site Characterization soil samples above NYSDEC's soil guidance values, regardless of the presence of DNAPL impacts. However, VOCs and semi-volatile organic compounds (SVOCs) (primarily polycyclic aromatic hydrocarbons [PAHs]) were found in soils affected by DNAPL. Certain metals, including arsenic, copper, lead, mercury, nickel, and zinc, were detected in some soil samples above soil guidance values. The presence of chemical impacts associated with DNAPL contamination did not correlate with elevated metal concentrations. Grossly contaminated soil and DNAPL were primarily found in deeper alluvial soils directly above the red-brown clay layer. DNAPL accumulation was observed in the sumps of several monitoring wells near Scajaquada Creek, with well screens monitoring the bottom of the alluvial soils above the clay layer.

The uniformity, thickness, and low permeability of the area-wide red-brown clay layer indicate that layer acts as a confining layer, preventing the downward vertical migration of DNAPL. DNAPL impacts extending into the red-brown clay layer were not identified during the Site Characterization. The extent to which the clay layer serves as a competent and contiguous vertical migration barrier will be further evaluated as part of the RI.

Source Analysis: Forensic analysis of DNAPL and grossly contaminated soil samples indicate a water gas tar source of pyrogenic origin. DNAPL impacts are confined to deeper alluvial soil due to the surface geometry of the red-brown clay and hydraulic gradients. DNAPL was not identified in shallow soil, suggesting lateral migration of DNAPL from an upgradient source on top of the red-brown clay layer. The DNAPL source is presumed to be historic migration from the Iroquois Gas/Westwood Pharmaceutical Terrestrial/Riparian Site, prior to the installation of engineering controls that contain and remove DNAPL from areas upstream of the West Avenue Bridge.

Chemical fingerprinting of the DNAPL found in borings and wells downstream from the Terrestrial/ Riparian Site engineering controls is similar to that recovered at the Iroquois Gas/Westwood Pharmaceutical Sites. DNAPL has not been detected in shallower soils or

sediments near the West Avenue Bridge, suggesting no ongoing releases are occurring. However, this will be further investigated as part of the RI. There is a possibility of CVOC DNAPL associated with historic industrial usage at BCP sites located at 31 Tonawanda St. and 1660 Niagara St. This is based on dissolved phase concentrations in groundwater of several chlorinated volatile organic compounds approaching 1% of their individual solubility limits.

Groundwater Contamination

MGP Constituent Detection: Site Characterization groundwater samples collected from the Lower Scajaquada Creek area contained benzene, toluene, ethylbenzene, and xylenes (BTEX) and PAH compounds of pyrogenic origin above New York State ambient water quality standards (AWQS). These constituents were detected in wells with wells screens intercepting the area-wide red-brown clay and where DNAPL was identified to accumulate in the bottom of the well.

Additional Contaminants: Petroleum-related (petrogenic) VOCs, CVOCs, 1,4-dioxane, and PFAS were also detected above AWQS in some wells located on and near BCP properties and near the Inlet. Where present with pyrogenic VOCs and PAHs, their presence is identified as comingled contamination. CVOCs and 1,4-dioxane were also present in the City of Buffalo Pumphouse discharge water at concentrations above AWQS. As described in Section 4 of the RI/FS Work Plan, an IRM was completed in 2022 to mitigate entry of DNAPL and comingled contamination into the manholes and conveyance piping.

Pesticides and herbicides were not detected in groundwater samples analyzed during the Site Characterization. Resource Conservation and Recovery Act (RCRA) metals were not detected above AWQS in most wells and none containing DNAPL.

Sediment Contamination

Shallow Sediments: DNAPL impacted recent fluvial deposits were observed in shallow sediments (0-6” depth) in the creek Inlet near the City of Buffalo Pumphouse discharge outlet. PAH concentrations in some shallow sediment samples were elevated, with the sample collected directly adjacent to the Pumphouse discharge outlet (SED-LSC-3; total PAH-16 concentration of 5,649 mg/kg). DNAPL was not identified in shallow sediments elsewhere in the creek during the Site Characterization.

Contaminant Levels: Shallow sediments exhibited elevated levels of volatile and extractable petroleum hydrocarbons, PCBs, and metals (copper, lead, nickel, zinc) when compared to sediment guidance values. Deeper sediments also showed significant contamination, particularly in the creek Inlet area, with high concentrations of BTEX, PAHs, polychlorinated biphenyls (PCBs), and metals (copper, lead nickel, mercury, zinc). DNAPL or sheens/ staining associated with suspected water gas tar residual was identified in deeper alluvial-derived soils below the recent fluvial deposits above the area-wide clay in five of nine sediment borings.

Data Gaps

Additional data are required to assess the nature and extent of impacts more fully in soil, groundwater, and sediments to evaluate remedial alternatives for the Lower Scajaquada Creek OU. Data gaps with RI objectives are summarized in Worksheet #11.

Worksheet #11: Data Quality Objectives/Systematic Planning Process Statements

Systematic Planning Process

Who will use the data?

National Fuel, GEI, and overseeing agencies will use the data to evaluate the extent of impacts and to identify and evaluate remedial alternatives through a feasibility study to support the design and completion of remedial actions for the Scajaquada Creek OU.

What will the data be used for?

The data will be used to 1) characterize and/or verify extent of vertical and horizontal contaminants; 2) develop remedial action objectives (RAOs); and 3) identify options for remedial actions that have the potential to fulfill the RAOs.

What types of data are required?

Data needs include the following:

- Contaminant concentration data from sediments, soils, and groundwater for purposes of defining and verifying extent of contamination to support the preparation of the feasibility study to evaluate remedial alternatives.
- Sediment and soil geophysical and geotechnical data to support geotechnical evaluations (e.g., stability of structures along the creek under certain remedial scenarios).
- Bathymetric, topographic, and hydrologic data to allow adequate characterization and design of remedial alternatives.
- Other physical and chemical data for purposes of compliance with disposal and reuse requirements.

How good does the data need to be?

Data needs to comply with the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) requirements, the quality assurance/quality control (QA/QC) requirements of this QAPP, and specific requirements of each associated work plan or field sampling and analytical plan (FSP). The data needs to be sufficient to make decisions based at the appropriate scale to achieve the goals for the areas and activities considered in this QAPP. See Worksheet #37 for information regarding the data usability assessment.

How much data is needed?

Sufficient data is needed to fill data gaps to assure that a comprehensive CSM can be developed to support the preparation of the feasibility study to evaluate remedial alternatives and for verification of remedy performance and for compliance with disposal or reuse, as needed. The number of borings, samples, and other data to be collected are described in Worksheets #17 and #18 and the RI/FS Work Plan (GEI, 2025). Actual numbers may vary based on field conditions, initial results, and whether additional sampling is necessary to achieve objectives.

Where, when, and how should the data be collected?

Sampling and analysis have been ongoing for many years and data will continue to be collected in the future. Locations and schedules are detailed in the RI/FS Work Plan and FSPs. Sampling will be conducted in accordance with the SOPs established in this QAPP and site-specific work plans.

Who will collect and generate the data?

GEI and its subcontractors will collect environmental samples in coordination with USEPA-GLNPO and NYSDEC. Pace Analytical Laboratory has been retained for environmental analytical requirements. GeoTesting Express will generate geotechnical analytical data. Other subcontractors may be retained for specialized needs.

How will the data be reported?

The data will be reported by laboratories in appropriate data packages and following validation by GEI Data will be provided in electronic data deliverables (EDDs) in EPA Region 5 EDD format and EquIS format which are compatible with USEPA and NYSDEC requirements.

How will the data be archived?

Electronic files will be maintained in their native forms on GEI's network servers physically located in Woburn, Massachusetts office and mirrored in multiple other offices throughout the Unites States.

Data Quality Objectives

Data quality objectives (DQOs) are required for environmental data collection activities. DQOs are statements that define the objectives of the project; the type, quality, quantity, purpose, and use of data to be collected; and are an important planning tool used to help support data credibility. The DQO process allows the site assessment team to determine the level of data quality needed for specific data collection activities, and to estimate the costs associated with these activities. The DQO process consists of seven steps, which are used during the planning of

the site assessment process to validate the field activities, data collection operations, and to demonstrate that resulting data meet the project objectives.

Step 1: State the Problem

The existing Project Agreement between the USEPA and NYSDEC (NYSDEC Contract No. C011665) was amended in 2024 to include work previously completed by National Fuel from 2021 to 2023 related to the Site Characterization (October, 2022), Interim Remedial Measures (March, 2023) completed to mitigate contamination discharge from a City of Buffalo Pumphouse, and the completion of the Scajaquada Creek RI and FS. National Fuel is the Lead Partner for the Scajaquada Creek OU, while the USEPA is the Lead Parter responsible for completing a FS for the Black Rock Canal OU. The NYSDEC provides project oversight and conducts certain source area investigations in the Scajaquada Creek OU.

The primary goal of the Scajaquada Creek OU investigation is to collect data to support conceptual design-level evaluations that will be presented as part of a FS. Generally, the objectives of the project are delineation of Site contaminants of concern (COCs), assessment of biological risks, and determination of disposal options.

Step 2: Identify the Goals of the Study

The goals for this program include, but are not limited to:

Adequacy of DNAPL Source Control

1. Assess the presence and mobility of DNAPL in the vicinity of the West Avenue bridge to evaluate the effectiveness of upstream physical barriers and DNAPL containment and/or collection and removal systems in preventing DNAPL transport to the south. While residual DNAPL is expected, it will be important to assess mobility and its potential to be a continuing source.

2. Inspect IRM work completed to seal the manholes and conveyance piping for DNAPL entry and groundwater infiltration, as feasible. Water quality will be evaluated by collecting samples from the stormwater conveyance manholes and water discharged at the Pumphouse outfall.

Identification of Utilities and Infrastructure as DNAPL Migration Pathways

1. Identify subsurface utilities that occur at depths where DNAPL has been identified and assess their potential as pathway for migration.

Extent of DNAPL in Shallow Creek Sediments

1. Use probing and cores to map the distribution DNAPL presence in shallow sediments near the Pumphouse discharge outfall. While DNAPL presence in shallow sediments was primarily observed in the creek Inlet, a comprehensive probing survey of the shallow creek sediments is needed for verification between the West Avenue bridge and the Black Rock Channel, including other areas of the Inlet.

2. Characterize sediment composition including total organic carbon content, DNAPL extents (lateral and vertical) and hydraulic influences from daily Black Rock canal water level fluctuations.

Sediment Quality and Ecological Risks

1. Assess sediment quality in the Lower Scajaquada Creek and Inlet with a detailed emphasis on known COCs including volatile and extractable petroleum hydrocarbons, PAHs, PCBs, and metals (mercury, copper, lead, nickel, and zinc) to evaluate the risks to benthos, fish, and wildlife. Identify the information needed to evaluate remedial alternatives aimed at removing beneficial use impairments (BUIs) in the creek.

Extent of DNAPL in Deeper Soil

1. Establish the horizontal and vertical extent of DNAPL in the OU in consideration of potential migration pathways in natural geologic materials and manmade pathways associated with buried urban infrastructure. This would include evaluating the northern extent of DNAPL in soils beyond the 1660 Niagara Street BCP site and the soil located near the former outlet of Scajaquada Creek to the Black Rock Canal below the I-190 Thruway. Fully characterizing the surface of the area-wide red-brown clay layer in the Lower Scajaquada Creek Area is important as it plays a major role in the fate and transport of DNAPL.

Shallow Groundwater Quality

1. Wells installed during the 2021/2022 SC were equipped with well screens extending through the deeper alluvial soils into the top of the clay layer. The presence of DNAPL impacts groundwater quality at this depth. Assess whether the presence of deeper DNAPL affects the groundwater quality near the water table, which is significantly shallower than the area-wide clay layer.

Information to Support the FS

1. Data should be collected in and near the Inlet to evaluate the eastern wall adjacent to 1660 Niagara Street, the sheet pile wall adjacent to the I-190 Thruway, and piers adjacent to the creek. Data will also be collected to characterize potential treatment and disposal options for media that may be considered for removal under FS alternatives.

Areas of the Site with concentrations above the respective screening level will be delineated. Screening levels used to evaluate chemical results from existing and proposed sampling are consistent with those used in the Site Characterization Report (GEI, 2022):

- Soil data will be compared to the New York State Register and Official Compilation of Codes, Rules and Regulations of the State of New York (6 NYCRR) Chapter IV, Part 375-6 Soil Cleanup Objectives (SCOs): Unrestricted use, Restricted-Residential, and Protection of Ecological Resources.

- Sediment data will be compared to the New York State Register and Official Compilation of Codes, Rules and Regulations of the State of New York (6 NYCRR) Chapter IV, Part 375-6 SCOs: Unrestricted Use, Restricted-Residential, Protection of Ecological Resources, and Freshwater Sediment Guidance Values Class B.

- Groundwater data will be compared to New York State Ambient Water Quality Standards and Guidance Values for GA groundwater (NYS AWQS) and NYSDEC Interim Groundwater Screening Levels based on NYSDEC guidance as follows:

    - March 2023 (1,4 Dioxane and per- and polyfluoroalkyl substances [PFAS])

For many individual PCB Aroclors and individual PAHs, screening levels are not available. Screening for total PCBs and PAHs will be performed by summing the individual analytes and comparing the total concentrations to the guidelines provided for total PAHs and total PCBs (Worksheet #15). The selected screening criteria are designed to be protective of the environment. Total PAH values will be calculated by summing the detected values and using a value equal to half the reporting limit (RL) for non-detects (non-detect = ½ RL). Total PCB values will be calculated by summing the detected values and using a value of zero for non-detects (non-detect = 0). The use of zero for non-detected PCBs assures that the total PCB concentration is not overestimated. Aroclor concentrations overlap each other, and many Aroclor mixtures are not common in the environment. The total PAH and PCB concentrations will be compared to the total PAH and total PCB sediment screening criteria.

Biological risks will be assessed via comparison of concentrations to screening levels, toxicity testing, and bioaccumulation testing, The results of the toxicity and bioaccumulation test will be statistically compared to the controls, reference, and pre-test (bioaccumulation testing only).

Step 3: Identify Information Inputs

Required data and information needed to meet the goals of the study:

Source Control Assessment

An assessment will be performed to verify the effectiveness of the Iroquois Gas/Westwood Pharmaceutical Terrestrial/Riparian Site Remedies in controlling DNAPL. This assessment will

include a review of the DNAPL collection records from the Southern DNAPL collection system at the Riparian Site, subsurface soil explorations, and assessments of DNAPL mobility, where identified. Subsurface soil investigations will be completed on land and in the creek and Inlet to assess the lateral and vertical extent of DNAPL impacted soils. Locations of the planned subsurface soil borings are included in Figures 5, 6, and 7 in the RI/FS Work Plan. Where DNAPL is encountered, wells will be installed to perform DNAPL mobility tests.

Subsurface Soil Investigation

Soil borings will be completed to evaluate the lateral and vertical extent of DNAPL presence in the subsurface soil. Locations of the planned subsurface soil borings are included in Figures 5, 6, and 7 in the RI/FS Work Plan. If DNAPL is encountered at the primary boring location, a contingency boring will be completed at a "Stepped out location" to satisfy the objective of mapping the extent of DNAPL. At select locations, soil borings will be completed as groundwater monitoring wells to evaluate the groundwater quality and for the assessment of DNAPL mobility.

At each proposed boring location, the boring will be advanced through fill and native soil and then a minimum of four feet into the red-brown clay unit. If DNAPL is observed within the top four feet of the native red-brown clay unit, the soil boring will be advanced until no visual evidence of impact is observed. Select deeper borings are proposed to evaluate the potential for DNAPL impacts below the red-brown clay unit into the underlying sand unit which directly overlies bedrock.

A minimum of two soil samples will be collected from each boring and submitted for laboratory analysis for the following:

- TCL VOCs – EPA Method 8260D/5035
- PAH-17 – EPA Method 8270E
- COC Metals (arsenic, copper, lead, mercury, nickel, and zinc) – EPA Method 6020B/7471B
- PCB – Aroclors – EPA Method 8082A
- Grain Size analysis – ASTM D422, Standard Penetration Testing (SPT) – ASTM D1586, Total Organic Carbon (TOC) –EPA Method 9060A/Lloyd Kahn

Groundwater Investigation

The groundwater investigation will be performed to assess groundwater quality in the unconfined water-bearing zone where DNAPL is known to exist. Locations of the planned monitoring wells are included in Figures 5, 6, and 7 in the RI/FS Work Plan. In areas where DNAPL presence is to

be investigated, well will be installed to screen the bottom of the alluvial soils directly above the area-wide clay layer which forms a barrier to vertical downward migration of DNAPL. These wells will also be used to support DNAPL mobility testing, if DNAPL is present.

In areas where DNAPL-impacted soils were identified and shallow wells are not present, monitoring wells will be installed with wells screens positioned to monitor the upper five feet of the saturated zone or five feet below the top of the water table as observed during drilling.

Following well development, new monitoring wells will be allowed to stabilize for at least two weeks and then sampled using low flow sampling methods.

Groundwater samples will be submitted for the following analyses:

- TCL VOCs – EPA Method 8260D
- TCL SVOCs – EPA Method 8270E including 1,4 dioxane by EPA Method 8270E – SIM with isotope dilution
- PFAS – EPA Method 1633
- PCB – Aroclors – EPA Method 8082A
- TAL Metals – EPA Method 6020B/7470A
- Total Cyanide – EPA Method 9012B

If NAPL is encountered in the new monitoring wells, and if observations based on olfactory and visual evidence, along with groundwater analytical testing results, indicate that the NAPL is inconsistent with previous findings (e.g., coal-tar like odor with elevated BTEX and naphthalene concentrations in the aqueous phase), a sample of the NAPL will be collected and submitted for forensic analysis using EPA Methods 8270E-SIM/8015D(M).

Inlet Creek Bank Surface Soil Investigation

Surface soil samples will be collected from the creek bank and analyzed for the following parameters:

- TCL VOCs – EPA Method 8260D/5035
- PAH-17 – EPA Method 8270E
- COC Metals (arsenic, copper, lead, mercury, nickel, and zinc) – EPA Method 6020B/7471B
- PCB – Aroclors – EPA Method 8082A

Locations of the planned surface soil samples are included in Figures 5, 6, and 7 in the RI/FS Work Plan.

Bathymetric Survey

A bathymetric survey of the investigation area will be performed using a single-beam bathymetric survey methodology with global positioning system (GPS) location. Sufficient points along the shore will be obtained so that the bathymetric survey can be tied to the upland topographic survey and a unified map of land and creek-bottom elevations.

Sediment Probing Transects

Systematic sediment probing will be performed to assess the thickness and quality of sediment within the investigation area and observe for sheen generation. Locations of the planned sediment probing transects are included in Figures 8, 9, and 10 in the RI/FS Work Plan.

Sediment Sampling

Sediment borings will be completed in the Scajaquada Creek main channel and Inlet to evaluate sediment quality. Locations of the planned sediment borings are included in Figures 8, 9, and 10 in the RI/FS Work Plan. At all sediment boring locations, the full length of recovered sediment/soil and underlying clay layer will be visually assessed. At certain locations, sediment will be collected from selected intervals for laboratory analysis. The target intervals for sampling are generally the upper two feet of sediment and the most impacted interval observed in the core. In the event the 0- to 2-ft depth interval is also most visibly impacted, or if no depth interval appears more impacted than others, the second sample will be collected from the 2-foot interval overlying the red-brown clay. Each sediment boring will advance a minimum of 4 feet into the area-wide red-brown clay layer.

Sediment samples will be analyzed for chemical, biological, waste profiling, and geotechnical purposes.

For COC delineation sediment samples, the associated analytical methods are:

- TCL VOCs – EPA Method 8260D/5035
- PAH-17 – EPA Method 8270E
- TCL SVOCs expanded National Oceanic and Atmospheric Administration (NOAA) PAH 34 – EPA Method 8270E-SIM
- PCB – Aroclors – EPA Method 8082A
- COC Metals (arsenic, copper, lead, mercury, nickel, and zinc) – EPA Method 6020B/7471B

- TAL Metals – EPA Method 6010D/7471B
- Total Cyanide – EPA Method 9012B
- TOC – EPA Method 9060A/Lloyd Kahn
- Extractable Petroleum Hydrocarbons (EPH) – MassDEP (MA-EPH)

For ecological risk assessment sediment samples, the associated analytical methods are:

- Ammonia – 4500NH3-BH
- TOC – EPA Method 9060A/Lloyd Kahn
- Sulfide – 9030B
- Acid Volatile Sulfide/Simultaneously Extracted Metals (AVS/SEM)
- Grain Size – ASTM D422

Standard benthic toxicity testing will include conducting chronic, 28-day whole-sediment toxicity test with the amphipod, *Hyalella azteca.* Endpoints measured in this chronic test will include effects on survival, growth, and reproduction from 28-day exposure to site sediments per "Methods for Measuring the Toxicity and Bioaccumulation of Sediment-Associated Contaminants with Freshwater Invertebrates" (USEPA, 2000) and "A Guidance Manual to Support the Assessment of Contaminated Sediments in Freshwater Ecosystems" (USEPA, 2002).

The evaluation of waste management costs in the FS requires evaluation of chemistry and characteristics for sediment that may be dredged from creek and subject to offsite disposal. These analyses, combined with the suite of area-wide chemical tests, will allow for evaluation for both landfill and thermal treatment disposal options. Analyses for waste characterization will be performed on composite samples created from the uppermost 4 feet or full thickness of depositional material retrieved at each location, whichever is less. The analytical methods are summarized below:

- TCL and TCLP VOCs – EPA Method 8260D/5035
- TCL and TCLP SVOCs – EPA Method 8270E
- TAL and TCLP Metals – EPA Method 6010D/7471B/6020B/7470A
- PCB-Aroclors – EPA Method 8082A
- pH, ignitability, sulfide and cyanide reactivity

- Corrosivity
- Total Cyanide – EPA Method 9012B
- Total Petroleum Hydrocarbons (TPH) – EPA Method 8015D
- Percent Sulfur – ASTM D4239
- BTU – ASTM D240-87

The evaluation of certain remedial technologies for the creek as part of the planned FS may require an assessment of the effects of each technology on the stability of roads and structures along the creek. Knowledge of geotechnical properties may also be pertinent to designing support facilities, sediment dewatering, excavation support, and other ancillary activities that may be needed to implement certain remedial technologies. To support this assessment, limited geotechnical testing will be performed and focus on the following areas:

- Along the bulkhead supporting highway I-190 and closing the former creek outlet.
- Between the State Route 198 on-ramp and Niagara Street bridge
- Adjacent to the West Avenue bridge

At each of these locations, samples will be collected from the clay at the bottom of the sediment core and analyzed for the following:

- Grain Size – ASTM D422
- Atterberg Limits
- Permeability (if intact Shelby tube samples can be recovered)

DNAPL Mobility Assessments

DNAPL mobility assessments will be conducted at:

- Wells installed during the RI containing DNAPL
- Temporary wells installed at creek borings (if DNAPL is observed)
- Existing monitoring wells identified during the 2021/2022 SC that contained DNAPL.

Evaluation of DNAPL Migration Pathways Associated with Infrastructure

During the 2022 SC, numerous utilities and below-grade infrastructure was identified in the lower Scajaquada Creek area. An IRM was implemented to minimize contaminated groundwater from nearby BCP sites from infiltrating the storm sewer system and to mitigate the entry of DNAPL, including accumulated DNAPL. Although sampling was conducted shortly after the IRM's completion, the performance of the IRM has not been quantified through analytical testing.

The following will be conducted to assess DNAPL/contaminant groundwater entry into the Niagara St. storm sewer servicing the City of Buffalo Pumphouse:

- Manholes #1 through #4 in Niagara Street, Manholes 21 and 23, and the Pumphouse vault will be visually inspected for coal-tar DNAPL presence. These features are included in Section 4 of the RI/FS Work Plan.

- Groundwater samples will be collected from Manholes 21 and 23 and the Pumphouse discharge and analyzed for the full suite of compounds.

Step 4: Define the Boundaries of Data Collection

The study area includes:

- The lands adjacent to Scajaquada Creek, extending south of the West Avenue Bridge to the creek's mouth where it discharges into the Black Rock Canal.

- The Scajaquada Creek Slip Area (Inlet Area), which was historically the creek's discharge location before being blocked during the construction of the I-190 New York State Thruway.

- Upland areas include properties owned by the former Penn Central Railroad, New York State, and City of Buffalo that are used for transportation and infrastructure corridors including a railroad passenger and freight train corridor, the NYS Thruway I-190, the Route 198 Scajaquada Expressway, and City of Buffalo roadways (West Avenue, Tonawanda Street, and Niagara Street).

- The upland areas also include privately owned properties, many of which were former industrial properties with environmental concerns, many of which have been investigated, and some remediated and developed for reuse in the NYSDEC Brownfield Cleanup Program or former Voluntary Cleanup Program.

Step 5: Develop the Analytical Approach

- **Sample type:** Sample types are expected to include, but are not necessarily limited to, the following:

    - Subsurface soil. Soil sampling may be conducted by mechanical means or manual means.

    - Creek and inlet area sediment. Sediment sampling may be conducted by mechanical (e.g., macrocore) means or manual means, and may be collected from a boat, barge, platform, or in dewatered areas.

    - Groundwater. Groundwater sampling may be collected by mechanical (e.g., low-flow sampling) or manual means.

    - Geotechnical information, to be collected by various means, needed for remedial alternatives analysis.

    - Additional soil, sediment, and/or groundwater samples for disposal or reuse purposes.

- **Anticipated analytical methods:** Analytical methods proposed during the RI/FS implementation include:

    - Soil Samples
        - TCL VOCs by EPA Method 8260D/5035
        - PAH-17 by EPA Method 8270E
        - PCB – Aroclors by EPA Method 8082A
        - COC Metals (arsenic, copper, lead, mercury, nickel, and zinc) by EPA Method 6020B/7471B
        - Grain Size Analysis, Standard Penetration Testing (SPT), Total Organic Carbon (TOC) (ASTM D422, D5186, EPA 9060A/Lloyd Kahn)
        - If LNAPL or DNAPL is encountered in any soil boring exhibiting properties inconsistent with prior findings of NAPL (characteristic of coal tar-like gross contamination), a sample will be collected and submitted for laboratory forensic analysis of 1,4-dioxane and total petroleum hydrocarbons (TPH) by EPA Method 8270E – SIM/8015D(M).
    - Groundwater Samples (including samples from monitoring wells and stormwater conveyance piping and pumphouse discharge):
        - TCL VOCs by EPA Method 8260D
        - TCL SVOCs by EPA Method 8270E including 1,4-dioxane by EPA Method 8270E-SIM with isotope dilution
        - PFAS by EPA Method 1633
        - PCB – Aroclors by EPA Method 8082A
        - TAL Metals by EPA Method 6020B/7470A

  - Total Cyanide by EPA Method 9012B
  - If NAPL is encountered in new monitoring wells, and if observations based on olfactory and visual evidence, along with groundwater analytical testing results, indicate that the NAPL is inconsistent with previous findings (e.g., coal-tar like odor with elevated BTEX and naphthalene concentrations in the aqueous phase), a sample of the NAPL will be collected and submitted for forensic analysis of 1,4-dioxane and TPH using EPA Methods 8270E-SIM/8015D(M).
- Inlet Creek Bank Soil Samples:
  - TCL VOCs by EPA Method 8260D
  - PAH-17 by EPA Method 8270E
  - PCB – Aroclors by EPA Method 8082A
  - COC Metals (arsenic, copper, lead, mercury, nickel, and zinc) by EPA Method 6020B/7471B
- Sediment Samples:
  - TCL VOCs by EPA Method 8260D
  - PAH-17 by EPA Method 8270E
  - TCL SVOCs expanded NOAA PAH 34 by EPA Method 8270E-SIM
  - PCB – Aroclors by EPA Method 8082A
  - COC Metals (arsenic, copper, lead, mercury, nickel, and zinc) by EPA Method 6020B/7471B
  - TAL Metals by EPA Method 6010D/7471B
  - Total Cyanide by EPA Method 9012B
  - TOC by EPA Method 9060A/Lloyd Kahn
  - Ammonia by Method 4500NH3-BH
  - Sulfide by EPA Method 9030
  - Acid Volatile Sulfide/Simultaneously Extracted Metals (AVS/SEM)
  - Grain Size by ASTM D422
  - EPH by MassDEP Method (MA-EPH)
- Sediment Toxicity Samples:
  - Standard toxicity testing will include conducting chronic, 28-day whole-sediment toxicity test with the amphipod, *Hyalella azteca.*
- Waste Characterization Samples:
  - TCL and TCLP VOCs by EPA Method 8260D
  - TCL and TCLP SVOCs by EPA Method 8270E
  - TAL and TCLP Metals by EPA Method 6010D/6020B/7470A/7471B
  - Pesticides by EPA Method 8081B
  - Herbicides by EPA Method 8151A
  - PCB – Aroclors by EPA Method 8082A
  - Ignitability by EPA Method 1030
  - Reactivity (Sulfide and Cyanide) by EPA Method 7.3
  - pH by EPA Method 9045

  - Total Cyanide by EPA Method 9012B
  - Percent Sulfur by ASTM D4239
  - BTU by ASTM D240-87
  - TPH by EPA Method 8015D
- Geotechnical Samples:
  - Grain Size by ASTM D422
  - Atterberg Limits
  - Permeability

- **Project quantification limits:** Achievable laboratory limits are specified in Worksheet #15.

- **Quality assurance/quality control:** Field QA/QC samples will be sampled at frequencies indicated in Worksheet #20. Laboratory QA/QC will be evaluated at the frequencies indicated in Worksheet #28. Worksheet #12 presents performance criteria. Chemical data will be verified and validated (Worksheets #34, 35, and 36).

- **Anticipated data evaluations:** Data evaluation needs include but are not limited to the following:

  - Delineate the vertical/horizontal extent of NAPL/DNAPL and associated dissolved phase contamination.

  - Assess the effectiveness of containment remedies previously installed upstream of West Avenue.

  - Assess the fate and transport of dissolved and non-aqueous phase contamination.

  - Evaluate utility/infrastructure potential migration pathways to the extent feasible, without causing damage or risking worker safety during investigation.

  - Evaluate potential exposure pathways.

  - Evaluate existing sediment chemistry and sediment depth data to define the extent of contamination and the estimate volumes.

  - Identify data gaps necessary to successfully complete the FS.

  - Identify and evaluate potential structural and hydraulic limitations and any other physical factors affecting the remedial decision-making process. For the Inlet, the evaluation should include, at a minimum, the eastern wall adjacent to 1660 Niagara Street and the I-190 expressway piers.

- Identify options for remedial actions that have the potential to fulfill the remedial action objectives (RAOs).
- Identify the necessary technologies and general process options for implementing each of the general remedial actions.

Step 6: Specify Performance/Acceptance Criteria

Performance and acceptance criteria for the data collected under these DQOs include data collection and data evaluation. For lab analysis, performance and acceptance criteria are detailed in Worksheets #12 and #15. Data usability criteria are detailed in Worksheet #37.

Step 7: Develop the Detailed Plan for Obtaining Data

The detailed plan for data collection is provided in Worksheet #17.

Worksheet #12-1: Measurement Performance Criteria (6010D – Metals)

Matrix: Aqueous, Solid, Sludges, and Groundwater
Analytical Group: 6010D – Metals
Laboratory Facility: Alpha Analytical, Mansfield, MA

Data Quality Indicators (DQIs)	QA Sample and/or Activity Used to Assess Measurement Performance	Measurement Performance Criteria	QC Sample Assesses Error for Sampling, Analytical, or Both
Overall Precision	Field Duplicates[1]	RPD ≤ 20% Aqueous; RPD ≤ 35% Solids	S
Analytical Precision (laboratory)	Laboratory Control Sample Duplicates	RPD ≤ 20%	A
Analytical Accuracy/Bias (laboratory)	Laboratory Control Samples[2]	Recovery range 80-120%	A
Analytical Accuracy/Bias (matrix interference)	Matrix Spike Duplicates[3]	Recovery range 75-125%	S&A
Overall Accuracy/Bias (contamination)	Equipment Blanks	No target analyte concentrations ≥ ½ LOQ	S&A
Sensitivity Precision	LOQ verification sample (spiked at LOQ)	Recovery within ±25% of LOQ	A
Completeness	Project-specific	Data completeness check	S&A

[2]Internally derived limits are updated periodically; current limits will be used at the time of analyses.
[3] MS and MSD must be client-provided (where applicable). Laboratory may select project samples to be spiked for batch accuracy and precision. LCS/LCSD performed when no MS/MSD are supplied.
DQI = data quality indicators; QC = quality control; QA = quality assurance; MDL = method detection limit; RL = reporting limit; PAL = project action limits; MS/MSD = matrix spike/matrix spike duplicate; LCS/LCSD = laboratory control spike/laboratory control spike duplicate; S = sampling; A = analytical; RPD = relative percent difference; %R = percent recovery; LOQ = limit of quantitation; SOP = standard operating procedure

Worksheet #12-5: Measurement Performance Criteria (9060A – Total Organic Carbon)

Matrix: Soils/Sediments
Analytical Group: 9060A/Lloyd Kahn – Total Organic Carbon
Laboratory Facility: Alpha Analytical, Mansfield, MA

Data Quality Indicators (DQIs)	QA Sample and/or Activity Used to Assess Measurement Performance	Measurement Performance Criteria	QC Sample Assesses Error for Sampling, Analytical, or Both
Overall Precision	Field Duplicates[1]	RPD ≤ 25% when TOC is detected in both samples ≥ sample-specific LOQ	S
Analytical Precision (laboratory)	Laboratory Control Sample Duplicates[2]	RPD ≤ 25%	A
Analytical Accuracy/Bias (laboratory)	Standard Reference Material/Laboratory Control Sample	75-125% Recovery	A
Analytical Accuracy/Bias (matrix interference)	Matrix Spike Duplicates[3]	75-125% Recovery	S&A
Overall Accuracy/Bias (contamination)	Method Blanks	No analyte at or above RL; "B" qualify if detected < 5x the blank concentration	A
Sensitivity	LOQ verification sample (spiked at LOQ)	Recovery within 90-110% of LOQ	A
Completeness	See Worksheet #34	See Worksheet #34	S&A

[1] Field duplicate data review guidance as referenced in Region 1 Environmental Data Review Supplement for Region 1 Data Review Elements and Superfund Specific Guidance/Procedures, June 2018 https://www.epa.gov/sites/production/files/2018-06/documents/r1-dr-supplement-june-2018.pdf.
[2]Internally derived limits are updated periodically; current limits will be used at the time of analyses.

[3] MS and MSD must be client-provided (where applicable). Laboratory may select project samples to be spiked for batch accuracy and precision. LCS/LCSD performed when no MS/MSD are supplied.
DQI = data quality indicators; QC = quality control; QA = quality assurance; RL = reporting limit; PAL = project action limits; MS/MSD = matrix spike/matrix spike duplicate; LCS/LCSD = laboratory control spike/laboratory control spike duplicate; S = sampling; A = analytical; RPD = relative percent difference; %R = percent recovery; LOQ = limit of quantitation

Worksheet #12-6: Measurement Performance Criteria (7470A – Mercury)

Matrix: Aqueous/Groundwater
Analytical Group: 7470A – Mercury
Laboratory Facility: Alpha Analytical, Westborough, MA

Data Quality Indicators (DQIs)	QA Sample and/or Activity Used to Assess Measurement Performance	Measurement Performance Criteria	QC Sample Assesses Error for Sampling, Analytical, or Both
Overall Precision	Field Duplicates[1]	RPD ≤ 20%	S
Analytical Precision (laboratory)	Laboratory Control Sample Duplicates[2]	RPD ≤ 20%	A
Analytical Accuracy/Bias (laboratory)	Laboratory Control Samples	Recovery range 80-120%	A
Analytical Accuracy/Bias (matrix interference)	Matrix Spike Duplicates[3]	Recovery range 70-130%	S&A
Overall accuracy/bias (contamination)	Equipment Blanks	No target analyte concentrations ≥ LOQ	S&A
Sensitivity Precision	% Relative Error	Low point 50%, mid-level 30%	A
Completeness	Project-specific	Data completeness check	S&A

[2]Internally derived limits are updated periodically; current limits will be used at the time of analyses.
[3] MS and MSD must be client-provided (where applicable). Laboratory may select project samples to be spiked for batch accuracy and precision. LCS/LCSD performed when no MS/MSD are supplied.
[4] Surrogate spike amount may vary by lab. Surrogate spike should be at the upper end of curve.
DQI = data quality indicators; QC = quality control; QA = quality assurance; RL = reporting limit; PAL = project action limits; MS/MSD = matrix spike/matrix spike duplicate; LCS/LCSD = laboratory control spike/laboratory control spike duplicate; S = sampling; A = analytical; RPD = relative percent difference; %R = percent recovery; LOQ = limit of quantitation

Worksheet #12-10: Measurement Performance Criteria (9045D – pH)

Matrix: Water/Soils
Analytical Group: 9045D – pH
Laboratory Facility: Alpha Analytical, Westborough, MA

Data Quality Indicators (DQIs)	QA Sample and/or Activity Used to Assess Measurement Performance	Measurement Performance Criteria	QC Sample Assesses Error for Sampling, Analytical, or Both
Overall Precision	Field Duplicates[1]	RPD ≤ 5%	S
Analytical Precision (laboratory)	Laboratory Control Sample Duplicates	NA	A
Analytical Accuracy/Bias (laboratory)	Laboratory Control Samples[2]	LCS 99-101 % (6.95-7.05)	A
Analytical Accuracy/Bias (matrix interference)	Matrix Spike[3]	NA	S&A
Overall accuracy/bias (contamination)	Equipment Blanks	No target analyte concentrations ≥ RL	S&A
Sensitivity	LOD verification[4] (spiked at 2-3xDL)	NA	A
Completeness	See Worksheet #34	See Worksheet #34	S&A

[1] Field duplicate data review guidance as referenced in Region 1 Environmental Data Review Supplement for Region 1 Data Review Elements and Superfund Specific Guidance/Procedures, June 2018 https://www.epa.gov/sites/production/files/2018-06/documents/r1-dr-supplement-june-2018.pdf.
[2]Internally derived limits are updated periodically; current limits will be used at the time of analyses.
[3] MS and MSD must be client-provided (where applicable). Laboratory may select project samples to be spiked for batch accuracy and precision. LCS/LCSD performed when no MS/MSD are supplied.
[4] Surrogate spike amount may vary by lab. Surrogate spike should be at the upper end of curve.
DQI = data quality indicators; QC = quality control; QA = quality assurance; RL = reporting limit; PAL = project action limits; MS/MSD = matrix spike/matrix spike duplicate; LCS/LCSD = laboratory control spike/laboratory control spike duplicate; S = sampling; A = analytical; RPD = relative percent difference; %R = percent recovery; LOQ = limit of quantitation

Worksheet #12-11: Measurement Performance Criteria (8260D/5035 – VOCs)

Matrix: Water/Soils
Analytical Group: 8260D/5035 – VOCs
Laboratory Facility: Alpha Analytical, Westborough, MA

Data Quality Indicators (DQIs)	QA Sample and/or Activity Used to Assess Measurement Performance	Measurement Performance Criteria	QC Sample Assesses Error for Sampling, Analytical, or Both
Analytical Precision (laboratory)	Laboratory Control Sample Duplicates[1]	RPD ≤ 20%	A
Analytical Precision (laboratory)	Matrix Spike Duplicates[2] (at client's request)	RPD ≤ 30%	S&A
Analytical Accuracy/Bias (laboratory)	Laboratory Control Samples[1]	Generally, 70-130%R – analyte specific	A
Analytical Accuracy/Bias (matrix interference)	Matrix Spike/ Matrix Spike Duplicates[2] (at client's request)	Generally, 40-140%R – analyte specific	S&A
Accuracy/Extraction efficiency	Surrogates[3]	70-130%R	A
Analytical Accuracy	Internal Standards[1]	50-200% of the IS area count in the CCV	A
Overall accuracy/bias (contamination)	Method blank	No target compounds ≥ RL	A
Sensitivity	Method Detection Limit	MDL < RL	A
Completeness	See Worksheet #34	See Worksheet #34	S&A

[1]Internally derived limits are updated periodically; current limits will be used at the time of analyses.
[2]MS and MSD must be client-provided (where applicable). Laboratory may select project samples to be spiked for batch accuracy and precision. LCS/LCSD performed when no MS/MSD are supplied.
[3] Surrogate spike amount may vary by lab. Surrogate spike should be at the upper end of curve.
DQI = data quality indicators; QC = quality control; QA = quality assurance; MDL = method detection limit; RL = reporting limit; PAL = project action limits; MS/MSD = matrix spike/matrix spike duplicate; LCS/LCSD = laboratory control spike/laboratory control spike duplicate; S = sampling; A = analytical; RPD = relative percent difference; %R = percent recovery; LOQ = limit of quantitation

Worksheet #12-12: Measurement Performance Criteria (8270E – SVOCs)

Matrix: Solids
Analytical Group: 8270E – SVOCs
Laboratory Facility: Alpha Analytical, Westborough, MA

Data Quality Indicators (DQIs)	QA Sample and/or Activity Used to Assess Measurement Performance	Measurement Performance Criteria	QC Sample Assesses Error for Sampling, Analytical, or Both
Overall Precision	Field Duplicates (at client's request)[1]	RPD ≤ 30% for target compounds > 5x LOQ	A
Analytical Precision (laboratory)	Laboratory Control Sample Duplicates[2]	RPD ≤ 30%	A
Analytical Precision (laboratory)	Matrix Spike Duplicates (at client's request)[3]	RPD ≤ 30%	S&A
Analytical Accuracy/Bias (laboratory)	Laboratory Control Samples[2]	40-140%R (Base/Neutral), 30-130%R (Acid Compounds)	A
Analytical Accuracy/Bias (matrix interference)	Matrix Spike/Matrix Spike Duplicates[3] (at client's request)	40-140%R (Base/Neutral), 30-130%R (Acid Compounds)	S&A
Accuracy/Extraction Efficiency	Surrogates[4]	30-130%R	A
Overall Accuracy/Bias (contamination)	Method Blank	No target compounds ≥ LOQ	A
Sensitivity	LOD verification[4] (spiked at 1-4x LOD)	Detected	A
Completeness	See Worksheet #34	See Worksheet #34	S&A

[1] Field duplicate data review guidance as referenced in Region 1 Environmental Data Review Supplement for Region 1 Data Review Elements and Superfund Specific Guidance/Procedures, June 2018 https://www.epa.gov/sites/production/files/2018-06/documents/r1-dr-supplement-june-2018.pdf.
[2]Internally derived limits are updated periodically; current limits will be used at the time of analyses.
[3] MS and MSD must be client-provided (where applicable). Laboratory may select project samples to be spiked for batch accuracy and precision. LCS/LCSD performed when no MS/MSD are supplied.

Worksheet #13: Secondary Data Criteria and Limitations Table

Secondary Data	Data Source (Originating Organization, Report Title, and Date)	Data Generator(s) (Originating Organization, Data Types, Data Generation/Collection Dates)	How Data Will Be Used	Limitations on Data Use
Site Characterization	Site Characterization Report Former Buffalo Gaslight Iroquois Gas Corp. Site and Lower Scajaquada Creek (GEI Consultants, Inc. P.C. June 2022, Revised October 2022)	GEI Consultants, Inc.	Soil, sediment, and groundwater characterization	None
Site Characterization	Pre-Design Investigation and Interim Remedial Measures Report – Lower Scajaquada Creek City of Buffalo Pumphouse (GEI Consultants, Inc. P.C. March 2023)	GEI Consultants, Inc.	Soil and groundwater characterization	None
Sediment sampling in inlet	Sediment Sampling – Scajaquada Creek Slip behind 1654 Niagara Street (NYSDEC/Empire GEO Services, 2015)	NYSDEC/Empire Geo Services, Inc.	Sediment characterization	None
DNAPL in Wells at 1660 Niagara St.	Phase II Environmental Site Assessment, 1660 Niagara Street (Labella Associates, 2016)	Labella Associates, P.C./NYSDEC	DNAPL extent	None
Sediment sampling in main channel and inlet	Summary Report for Sediment Screening Assessment Within the Lower Scajaquada Creek Corridor and Black Rock Canal (NYSDEC/Empire GEO Services, 2017)	NYSDEC/Empire Geo Services, Inc.	Sediment characterization	None

Worksheet #14: Summary of Project Tasks

Sampling Tasks:

- Sample soil using hollow stem augers or using a Geoprobe traditional or dual-tube sampling system for collection of samples for chemical analysis.
    - Soil borings will be completed to evaluate the lateral and vertical extent of DNAPL in the subsurface soil.
    - A total of 28 borings are identified as either Primary or Contingency borings.
        - Primary borings will be completed to refine the extent of known DNAPL presence.
        - If DNAPL is identified at the Primary boring location, a Contingency boring will be completed at a "stepped out location" to satisfy the objective of mapping the extent of DNAPL. If the Contingency boring contains DNAPL, a "stepped out location" will be completed with consultation with the NYSDEC.
        - At select locations, soil borings will be completed as groundwater monitoring wells to evaluate groundwater quality, flow direction, and for the assessment of DNAPL mobility.
- Sample sediment using drilling methods described in the FSP for collection of samples for chemical analysis (Appendix B of the RI/FS Work Plan). If recovery is poor (e.g., less than 50%), alternate sample collection methods may be employed.
- Sample bank soil samples from the creek using drilling methods and sampling systems described in the FSP for collection of samples for chemical analysis (Appendix B of the RI/FS Work Plan).
- Sample groundwater using low flow sampling methods for chemical analysis.
- Sample soil, sediment, and groundwater for waste characterization analysis.
- Sample sediment at locations adjacent to structures that may be most susceptible to being destabilized by certain remedial activities, with a focus on the following areas:
    - Along the bulkhead supporting highway I-190 and closing the former creek outlet (T2A, T3A, and T5A);

  - Between the State Route 198 on ramp and Niagara Street bridge (T16B); and
  - Adjacent to the West Avenue bridge (T26A and T26B).

- Digitally photograph sampling locations, recovered sample cores, and sampling activities.
- Install monitoring wells in areas where DNAPL-impacted soils are to be investigated, and shallow wells are not present.
  - Well screens will be positioned to monitor the upper 5 feet of the saturated zone.
- Install monitoring wells to determine DNAPL presences and assess groundwater quality in the unconfined water-bearing zone where DNAPL is known to exist.
  - Well screens will be positioned to monitor the bottom of the alluvial soils directly above the area-wide clay layer which forms a barrier to vertical downward migration of DNAPL.
- Develop newly installed monitoring wells and check for NAPL presence (LNAPL and DNAPL).
  - If NAPL is encountered, the field observations will be documented and an assessment of NAPL presence and mobility will be conducted.
- Perform slug testing using rising head methods from RI monitoring wells and monitoring wells installed during the 2021/2022 SC.
- Perform mapping and surveying work by a combination of standard Geographical Information Services (GIS) mapping combined with survey-grade GPS methods and bathymetric surveying.
- Inspecting Manholes #1 through #4 in Niagara Street, Manholes #21 and #23, and the Pumphouse vault.
- Sample water from Manholes #21 and #23 and the Pumphouse discharge.
- Collect groundwater elevation measurements (synoptic rounds) monthly for a duration of six months and quarterly for one year afterward.
- Perform community air monitoring to provide real-time measurements of total VOCs and particulate (airborne dust) concentrations in air at the downwind perimeter of each designated work area when intrusive activities are in progress.

Sample Processing and Analysis Tasks:

- Process, prepare, and analyze soil samples for:
    - TCL VOCs by EPA Method 8260D/5035
    - PAH-17 by EPA Method 8270E
    - PCB – Aroclors by EPA Method 8082A
    - COC Metals (arsenic, copper, lead, mercury, nickel, and zinc) by EPA Method 6020B/7471B
    - Grain Size Analysis, Standard Penetration Testing (SPT), Total Organic Carbon (TOC) (ASTM D422, D5186, EPA 9060A)
    - If LNAPL or DNAPL is encountered in any soil boring exhibiting properties inconsistent with prior findings of NAPL (characteristic of coal tar-like gross contamination), a sample will be collected and submitted for laboratory forensic analysis by method 8270E – SIM/8015D(M).
- Prepare and analyze groundwater samples for:
    - TCL VOCs by EPA Method 8260D
    - TCL SVOCs by EPA Method 8270E-SIM including 1,4 Dioxane by EPA Method 8270E-SIM with isotope dilution
    - PFAS by EPA Method 1633
    - PCB – Aroclors by EPA Method 8082A
    - TAL Metals by EPA Method 6010D/7470A
    - Total Cyanide by EPA Method 9012B
    - If NAPL is encountered in new monitoring wells, and if observations based on olfactory and visual evidence, along with groundwater analytical testing results, indicate that the NAPL is inconsistent with previous findings (e.g., coal-tar like odor with elevated BTEX and naphthalene concentrations in the aqueous phase), a sample of the NAPL will be collected and submitted for forensic analysis using EPA Methods 8270E-SIM/8015D(M).
- Process, prepare, and analyze soil samples collected in the Inlet Creek Bank for:
    - TCL VOCs by EPA Method 80260D
    - PAH-17 by EPA Method 8270E

  - PCB – Aroclors by EPA Method 8082A
  - COC Metals (arsenic, copper, lead, mercury, nickel, and zinc) by EPA Method 6020B/7471B

- Process, prepare, and analyze sediment samples collected for COC delineation for:
  - TCL VOCs by EPA Method 80260D
  - TCL SVOCs expanded NOAA PAH 34 – EPA Method 8270E-SIM
  - PAH-17 by EPA Method 8270E
  - PCB – Aroclors by EPA Method 8082A
  - COC Metals (arsenic, copper, lead, mercury, nickel, and zinc) by EPA Method 6020B/7471B
  - TAL Metals by EPA Method 6010D/7471B
  - Total Cyanide by EPA Method 9012B
  - TOC by EPA Method 9060A/Lloyd Kahn
  - EPH by MassDEP Method (MA-EPH)
- Process, prepare, and analyze select sediment samples for:
  - Ammonia by Method 4500NH3-BH
  - TOC by EPA Method 9060A
  - Sulfide by EPA Method 9030B
  - Acid Volatile Sulfide/Simultaneously Extracted Metals (AVS/SEM)
  - Grain Size by ASTM D422
- Process, prepare, and analyze select sediment samples for laboratory toxicity testing.
  - Standard toxicity testing will include conducting chronic, 28-day whole-sediment toxicity test with the amphipod, *Hyalella azteca.*
- Process, prepare, and analyze soil, sediment, and groundwater waste characterization samples for:

  - TCL and TCLP VOCs by EPA Method 8260/5035D
  - TCL and TCLP SVOCs by EPA Method 8270E
  - TAL and TCLP Metals by EPA Method 6010D/6020B/7470A/7471B
  - Pesticides by EPA Method 8081B
  - Herbicides by EPA Method 8151A
  - PCB – Aroclors by EPA Method 8082A
  - Ignitability by EPA Method 1030
  - Reactivity (Sulfide and Cyanide) by EPA Method 7.3
  - pH by EPA Method 9045D
  - Total Cyanide by EPA Method 9012B
  - Percent Sulfur by ASTM D4239
  - BTU by ASTM D240-87
  - TPH by EPA Method 8015D
- Process, prepare, and analyze sediment geotechnical sample for:
  - Grain Size by ASTM D422
  - Atterberg Limits
  - Permeability

Quality Control Tasks:

- Samples collected during investigation activities will be collected, handled, and disposed of in accordance with field SOPs presented as an appendix to this QAPP (Appendix A).

Secondary Data:

- See Worksheet #13.

Other Data:

- Other data may be acquired or consulted as needed to meet project objectives.

Data Management Tasks:

- GEI will manage the analytical data in data spreadsheets and/or relational databases.
- A comprehensive electronic database will be maintained for all laboratory analytical data and survey data generated throughout the lifespan of the project. This electronic database shall be shared with the RPM quarterly.

Documentation and Records:

Project data and information will be tracked and managed from its generation in the field to storage.

Document Control

- Official and original documents relating to the investigation must be properly stored in a centralized project file location.
- Relevant hard and electronic copies, records, reports, correspondence, logs, field logbooks, photographs, subcontractor reports, data, etc. will be maintained by the GEI Project Manager (and GEI Project QAM) in a secured, limited access area, in accordance with contract specifications and GEI's records retention policy.
- As part of the document control system, the QAPP will be reviewed and updated by the GEI Project Quality Assurance Manager (QAM), as necessary, if project activities substantially change or if new activities are authorized.
- Documents, records, photographs, and information relating to field activities will be maintained in the project file via electronic files and/or hard copy. Field data will be captured in compliance with the GLLA Data Report Standard Guidance Document, the Locational Data Checklist, Metadata Reporting Form, and the Great Lakes National Program Office (GLNPO) Requirements for Submission of Field Data for Sediment Projects (Appendix D). Field logbooks, field forms, and photographs will be scanned/uploaded daily and stored electronically.
- Other records of sample collection activities will include data collection logs, chain-of-custody records, custody seals, sample labels, phone conversation records, airbills, and corrective action reports. Chain-of-custody records will be used to document the progression of field samples and QC samples. These records will be uploaded and stored electronically by a GEI field team member.

Computer and Hardcopy Storage

- Electronic files and project deliverables will be maintained in a centralized location and retained for a minimum of 10 years. In addition, electronic data will be backed up on a nightly basis.

- Hard copy project files and data, such as original field forms and calculations, will be stored in a centralized project file location in the GEI office in Buffalo, New York. Hardcopy files will be maintained for a minimum of 10 years.

- Should questions arise concerning the data at any point in the project, Rick Frappa (GEI Project Manager) can be contacted at rfrappa@geiconsultants.com for support.

Field Documentation and Records

- **Field Sample Identification –** The following nomenclature will be used for field sample identification will be described in Work Plans or Field Sampling Plans for the Site.

    - Sample Locations: Landside Investigation

        | Sample Type | - | Core/Unique Identification (ID) and/or Number |

            - The sample type will be referenced using an identifier as outlined below:

                - MW – monitoring well (groundwater)

                - SB – soil boring (soil)

                - SS – surface soil (soil)

        Example:

        Monitoring Well: MW-RI-1

        Soil Boring: SB-RI-1

    - Analytical Samples: Landside Investigation

        | Sample Media | - | Core/Unique ID | (For Soil Samples Only: Depth or Depth Interval) |

    - Sample Locations: Waterside Investigation

        | Sample Type | Transect Number | Unique ID |

- The sample type will be referenced using an identifier as outlined below:
    - T – creek transect location (soil/sediment)

Example:

Sediment Transect – T1A

- Analytical Samples: Waterside Investigation

| Sample Type | Transect Number | Unique ID | (Depth or Depth Interval)

- QA/QC Samples: Landside and Waterside Investigations

Field Duplicate

| DUP | - | Unique Number |

Example :

Parent Sample : SB-RI-1(0-5)

Field Duplicate: DUP-01

Field duplicates will be submitted as blind samples and identified using "DUP" + unique number. Numbering is consecutive for each type of sample media. Numbers will be assigned to each field team when multiple teams are working simultaneously. The linkage to the source analytical sample is recorded in the field notes.

Equipment Blanks

| EB | - | Collection Date - | Unique Number |

Example:

EB-03152025-01

Equipment blank numbering is consecutive within each type of sample media. Numbers will be assigned to each field team when multiple teams are working simultaneously.

Matrix Spike/Matrix Spike Duplicate

| Analytical Sample ID | | MS or MSD |

Example:

Parent Sample: SB-RI-1(0-5)

MS: SB-RI-1(0-5)MS

MSD: SB-RI-1(0-5)MSD

For MS and MSD samples, the suffix "MS" or "MSD" will be added to the extra sample containers based on the parent sample ID.

- **Field Documentation** – During field investigation activities, documentation and records will be prepared and maintained to cover the various tasks required to support core advancement, core processing, sampling, and submittal. The documentation generated will allow for tracking of field activities and core/sample handling by the field team. Originally generated documents and records will be retained in the designated centralized project location (i.e., electronic, or physical location).

- **Field Reporting –** Collected field data, including observations, measurements, calibrations, etc., will be recorded in project-specific field notebooks. Hard copies of boring/core logs will be reviewed by the appropriate field or data manager for consistency and adherence to the task work plan and QA/QC procedures. Corrections or improvements will be discussed with the project manager and field team members, corrected where necessary, then processed.

- **Field Records –** Field records such as logbooks and instrument logs are considered part of the project's permanent records. Logbook entry errors will be crossed out in a single line stroke, initialed, and dated. Errors will not be corrected using white-out or overwriting. Unused portions of pages will be completely lined out, initialed, and dated.

    - The field logbooks will contain the following as a minimum:

        - Date/time/weather.
        - GEI personnel.
        - Purpose of visit/daily objectives.
        - People (client, contractor, landowners, etc.) present upon GEI arrival.
        - Site number and name.
        - Locations and descriptions of sampling points.
        - Sample identification number and date and time of sample collection.
        - Type of sample.
        - Field equipment calibration information.
        - Any field measurements taken.
        - Use of field data sheets or electronic logging equipment (e.g., boring logs, monitoring well sampling logs, etc.).
        - References for maps and photographs of the sample site.

- Recommendations made to the client representative and GEI Project Manager.
- Summary of work completed/work remaining.
- Any procedural steps taken that deviate from those presented in this QAPP.

Laboratory Documentation and Records

The analytical laboratory will be responsible for maintaining analytical logbooks and laboratory data. Raw laboratory data files and electronic and hard copy data will be inventoried and maintained by the laboratory for a minimum of 10 years. Laboratory analytical data packages will contain the following information at a minimum: case narrative, completed chain-of-custody forms, calibration summary and raw data, mass spectrometer tuning data (as applicable), gas chromatogram (as applicable), QC summary forms and raw data, blank results, and method and instrument DLs. The laboratory will provide an electronic copy of the data, which will follow EPA Region 5 EDD format.

- **Laboratory Project Files –** Each laboratory conducting project work will establish a centralized filing system for storage of digital and hard copy documentation. The laboratory will retain project files for a minimum of 10 years.
    - Documents and records include data such as chain-of-custody forms, correspondence, data packages, lab technician workbooks, bench sheets, and instrument logbooks that include calibration logs, instrumentation printouts, and sample tracking. Data records such as logbooks and instrument logs are considered part of the laboratory permanent record, and each page or entry should be initialed at the time of entry by the analyst. Entry errors will be crossed out in a single stroke, initialed, and dated. Each analyst will provide dated notes regarding the sample, performed analytical procedures, and testing results on laboratory forms or personal notebook pages. These logs and notebooks will be periodically reviewed by the appropriate laboratory leader for accuracy, completeness, and conformity to this QAPP. Entries, calculations, and results will be verified by the appropriate laboratory group leader. Once verified, the laboratory group leader will initial and date the pages or corrective action that will be taken to rectify the errors.
- **Laboratory Data Reporting –** Data reports for project parameters will at a minimum include the following:
    - Narrative – sample information included during analysis are as follows:
        - Laboratory name and address.
        - Sample delivery group.

- Sample receipt date.
- Cross reference of laboratory identification number to contractor sample identification.
- Analytical methods.
- Deviations from specific protocol.
- Corrective actions taken.
- Sample handling documents (field and/or internal chain-of-custodies and sample condition receipt forms).

- Analytical results – soil and sediment data will be reported on a dry-weight basis. Results will be reported uncorrected for blank contamination. Analytical results will be reported based on analysis type/method and include the following:

  - Sample ID.
  - Laboratory ID.
  - Collection date.
  - Sample receipt date.
  - Sample extraction date.
  - Sample analysis date.
  - Detection limits (reporting and method).
  - Associated methods and sample QC results.
  - Dilution factor and associated analyte-specific results.
    - The laboratory is not required to run samples undiluted if there is a risk of instrument damage. As site contaminant concentrations are often unknown, laboratories should screen samples and submit results of the screening in the laboratory data package. Laboratories should document the decision to not run the samples undiluted in the laboratory case narrative, and provide supporting information (e.g., screening chromatograms, pictures, description of the samples).
  - Re-extractions and re-analyses with a single reportable result clearly identified.
  - Data report levels.
    - Level 1 – minimum reporting: "results only" reporting for analyses performed. To be used either by their nature (field monitoring) or intended data use (i.e., preliminary screening), and therefore, extensive supporting documentation is not required. Geotechnical analytical data used for remedy design also is reported at Level 1.
    - Level 4 – Full reporting: full Contract Laboratory Program (CLP) reporting for analyses performed requiring full documentation. Chemical analytical data is reported at Level 4.

- Data associated with CLP-equivalent reporting will also include necessary documentation to meet a CLP-equivalent package. The additional documentation will include the following:

    - Raw data to recalculate results.
    - Instrument printouts.
    - Quantitation reports.
    - Calibration standards.
    - Analytical results calculations.
    - Sample extraction.
    - Digestion.
    - Other preparation logs.
    - Standard preparation logs.
    - Instrument run logs.
    - Moisture content calculations.
    - Analytical runs (i.e., dilutions) included in the raw data of the data package.
    - When manual peak integrations are being performed, include blown up versions of before and after chromatograms to demonstrate adequate peak resolution.

- The laboratory must report the results of all analytical runs, including all dilutions, re-extractions, and re-analyses. Laboratories should use best professional judgement to identify the Reportable Results for each specific analyte and must designate which results is reportable in the electronic data deliverable (EDD). This is typically achieved by including a "Reportable" field with a Y/N valid value.

- Laboratory data deliverables should be provided in accordance with this QAPP, including a portable document format (PDF) of the complete supplemental laboratory data package (i.e., raw data).

Data Submittals

- Spatial data will be submitted in the ESRI File Geodatabase format with a defined coordinate system. If applicable, submissions should include the collection method(s). Each geodatabase should be accompanied by Federal Geographic Data Committee (FGDC) compliant metadata.

- The analytical laboratories will submit electronic data deliverables (EDDs) for evaluation and compliance. The EDDs will be self-checked by the laboratories using their self-inspection tool prior to submitting to GEI. GEI will then convert the lab EDDs into an EPA Region 5 EDD format and will conduct data validation.

- A Data Usability Memorandum will be submitted by GEI to the EPA in PDF format following the completion of data validation. This submittal will include an overall summary report on the usability of the data, individual validation narrative/checklists for each individual data package, and marked-up data forms showing the data validation flags and the GLNPO checklists. In addition, analytical report narratives and data validation reports will be included in the RI Data Summary Report. A Final Data Package will be submitted following the completion of the Final Data Usability Memorandum. The Final Data Package includes the Region 5 EDD (Chemical analysis), supplemental attachments, data validation reports and narratives, data qualifier definitions, location data checklist, core logs, and additional reports that will be uploaded to GLSED. GEI will verify that the Final Data Package deliverables, including the EDDs containing toxicity and bioaccumulation data, are compatible with the most recent version of the GLLA Data Reporting Standard.

    - Additionally, the data review should include validator qualifiers, final interpreted data qualifiers, qualifier definitions, and information on summation schemes or correction factors, including how non-detects were accounted for.

- GEI will prepare an RI Data Summary Report that provides the findings of the investigation, including but not limited to, data tables and maps summarizing results and analysis. Additionally, GEI will also identify deviations and step-out locations not sampled.

    - This deliverable will be submitted in PDF describing the number, location, results, data analysis, and recommendation from the assessment. It will also document sampling changes made in the field along with any issues, concerns, or problem encountered during data collection and analysis.

Project Data Assessment Records

- Records of project assessments will be maintained by the GEI Project Manager and GEI Project QAM, including field technical systems audit checklists, field performance audit checklists, laboratory performance audit checklists, data validation reports, internal reviewer sign-off, phone conversation records, and corrective action reports.

Assessment/Audit Tasks

Field and laboratory audits of the performance and systems will be completed during investigation activities as described in the following paragraphs and Worksheets #31 and #32.

- **Field Audits –** The following performance and system audits will be performed throughout the project:

- The appropriate field team lead will be responsible for monitoring field performance. Field audits will be performed by the GEI project director, GEI project manager, or their designee. Field audits will be documented in field performance audit summaries that provide field activity evaluations based on their established work plans and procedures. The frequency of the audits will be determined by the project manager and field team lead and may fluctuate throughout the duration of the project. Observations noted during the performance audit that either deviate from established project protocols or processes identified as improvements to established project protocols will be recorded and documented.

- The data manager or their designee will perform period review of equipment and trip blank results to identify if field decontamination and sampling procedures are being executed effectively. In addition, review of the QA/QC sampling activities will be reviewed for accuracy and consistency with this QAPP. Deficiencies will be discussed with the project manager and addressed for compliance with this QAPP and associated work plans.

- **Laboratory Audits –** The laboratory QA manager will be responsible for performing periodic internal laboratory audits to assess the overall performance of the laboratory staff to the performance criteria outlined in the laboratory plans and SOPs. Audit results will be summarized and provided to each laboratory department manager, the laboratory manager, and laboratory director. In addition, the data QA manager will also conduct periodic system audits of each laboratory as needed to ensure that the laboratory complies with the procedures detailed in the QA management plans and SOPs.

    - Audits will be performed in accordance with state and federal certification programs by the regulatory agency issuing the laboratory certifications. These audits are typically performed annually and focus on performance to the specific program procedures and methodology for which the laboratory is seeking certification. During the audit, documentation related to sample handling and tracking, analytical methodologies, analytical supportive summaries, and final reports are reviewed. Audit findings are formally documented and outline necessary corrective action to the laboratory.

- **Corrective Action –** If during field of laboratory audits, corrective actions are implemented for activities not in compliance with objectives and procedures outline in this QAPP, the corrective actions will include immediate investigation/evaluation, documentation, and corrections to the appropriate procedures as detailed below.

    - **Field Procedures –** If the field crew or audit findings identify a condition which has the potential to cause adverse effects on data quality, this condition will be immediately brought to the attention of the program director or designee. A

corrective action form will be prepared by the program director or designee who will document the condition, the root cause, appropriate information points, and the corrective action that should be implemented. The field team lead will immediately report the identified condition, review status, and corrective action to the program director, project manager, and QA data manager. Examples of conditions which may require corrective actions include:

- Procedures and methodologies are not being executed by the field team in accordance with this QAPP and appropriate work plans.
- Field conditions change or were different than anticipated, requiring modification of field procedures.
- Equipment is dysfunctional or inadequate for the task or is not properly calibrated.

- **Laboratory Procedures –** If a condition in the laboratory is identified by laboratory staff or during audits that is or has the potential to cause an adverse effect on data quality, the laboratory project manager will be notified immediately. The condition will be reviewed and documented by the laboratory project manager or designee. The documentation will include the identified condition, cause, corrective action taken, and additional pertinent information. Conditions and corrective action will be reported to GEI project manager and data quality manager. Examples of conditions that may require corrective actions include:

  - Procedures and methodologies are not being executed in accordance with this QAPP, SOPs, and appropriate work plans.
  - Pre-determined data acceptance and usability standards are not obtained.
  - Equipment is dysfunctional or not calibrated properly.
  - Analytical results are not completely traceable, or QC requirements are not being met.

Data Review Tasks

See Worksheets #36 and #37.

Notes:

[1] Based on Project Action Limits defined in the 2022 Site Characterization Report (GEI 2022).

[2]Established to align with the New York State Register and Official Compilation of Codes, Rules and Regulations of the State of New York (6 NYCRR) Chapter IV, Part 375-6 Soil Cleanup Objectives (SCOs): Unrestricted Use, Restricted-Residential, Protection of Ecological Resources. PAL is based on the lower regulatory criteria.

The Project Action Limit (PAL) is the regulatory screening level established for the Site. Reported concentrations above the corresponding PAL for that analyte will trigger a closer review of the data, including potential mitigation efforts at the sample location.

The Project Quantification Limit (PQL) is the minimum concentration to which a detection for the corresponding analyte must be reported and corresponds to the Reporting Limit for that analyte.

MDL = Method Detection Limit; RL = Reporting Limit; mg/kg = milligrams per kilogram; µg/kg = micrograms per kilogram; PAL = project action limit; RSL = regional screening level; CAS = chemical abstract service; SCO = Soil Cleanup Objectives; NE = not established; N/A = not applicable.

Notes:
[1] Based on Project Action Limits defined in the 2022 Site Characterization Report (GEI 2022).
[2]Established to align with the New York State Register and Official Compilation of Codes, Rules and Regulations of the State of New York (6 NYCRR) Chapter IV, Part 375-6 Soil Cleanup Objectives (SCOs): Unrestricted Use, Restricted-Residential, Protection of Ecological Resources. PAL is based on the lower regulatory criteria.
The Project Action Limit (PAL) is the regulatory screening level established for the Site. Reported concentrations above the corresponding PAL for that analyte will trigger a closer review of the data, including potential mitigation efforts at the sample location.
The Project Quantification Limit (PQL) is the minimum concentration to which a detection for the corresponding analyte must be reported and corresponds to the Reporting Limit for that analyte.
MDL = Method Detection Limit; RL = Reporting Limit; mg/kg = milligrams per kilogram; µg/kg = micrograms per kilogram; PAL = project action limit; RSL = regional screening level; CAS = chemical abstract service; SCO = Soil Cleanup Objectives; NE = not established; N/A = not applicable.

2,6-Dichlorophenol	87-65-0	NE	N/A	10	2.57	10

Notes:

[1] Quantitation limit is greater than the calculated regulatory level. The quantitation limit therefore becomes the regulatory level (40 CFR §261.24).

The Project Action Limit (PAL) is the regulatory screening level established for the Site. Reported concentrations above the corresponding PAL for that analyte will trigger a closer review of the data, including potential mitigation efforts at the sample location.

The Project Quantification Limit (PQL) is the minimum concentration to which a detection for the corresponding analyte must be reported and corresponds to the Reporting Limit for that analyte.

MDL = Method Detection Limit; RL = Reporting Limit; mg/kg = milligrams per kilogram; µg/kg = micrograms per kilogram; PAL = project action limit; RSL = regional screening level; CAS = chemical abstract service; NE = not established; N/A = not applicable; TCLP = Toxicity Characteristic Leaching Procedure.

Notes:
[1] Based on Project Action Limits defined in the 2022 Site Characterization Report (GEI 2022).
[2]Established to align with the New York State Register and Official Compilation of Codes, Rules and Regulations of the State of New York (6 NYCRR) and NYCRR, Chapter IV, Part 375-6 Soil Cleanup Objectives (SCOs): Unrestricted Use, Restricted-Residential, Protection of Ecological Resources, and Freshwater Sediment Guidance Values Class B. PAL is based on the lower regulatory criteria.
The Project Action Limit (PAL) is the regulatory screening level established for the Site. Reported concentrations above the corresponding PAL for that analyte will trigger a closer review of the data, including potential mitigation efforts at the sample location.
The Project Quantification Limit (PQL) is the minimum concentration to which a detection for the corresponding analyte must be reported and corresponds to the Reporting Limit for that analyte.
MDL = Method Detection Limit; RL = Reporting Limit; mg/kg = milligrams per kilogram; µg/kg = micrograms per kilogram; PAL = project action limit; RSL = regional screening level; CAS = chemical abstract service; SCO = Soil Cleanup Objectives; NE = not established; N/A = not applicable.

Worksheet #15-21: Reference Limits and Evaluation Table – Reactive Cyanide in Soil/Sediment

Matrix: Soil/Sediment
Analytical Method: 7.3 – Cyanide, Reactive

Analyte	Chemical Abstracts Service (CAS) Number	Project Action Limit (PAL)	PAL Reference	Project Quantification Limit (mg/kg)	Achievable Laboratory Limits	
					MDL (mg/kg)	RL (mg/kg)
Cyanide, Reactive	57-12-5	N/A	N/A	10	10	10

Notes:
The Project Action Limit (PAL) is the regulatory screening level established for the Site. Reported concentrations above the corresponding PAL for that analyte will trigger a closer review of the data, including potential mitigation efforts at the sample location.
The Project Quantification Limit (PQL) is the minimum concentration to which a detection for the corresponding analyte must be reported and corresponds to the Reporting Limit for that analyte.
MDL = Method Detection Limit; RL = Reporting Limit; mg/kg = milligrams per kilogram; µg/kg = micrograms per kilogram; PAL = project action limit; RSL = regional screening level; CAS = chemical abstract service; SCO = Soil Cleanup Objectives; NE = not established; N/A = not applicable.

Worksheet #15-22: Reference Limits and Evaluation Table – Reactive Sulfide in Soil/Sediment

Notes:
[1] Based on Project Action Limits defined in the 2022 Site Characterization Report (GEI 2022).
[2]Established to align with New York State Ambient Water Quality Standards and Guidance Values for GA groundwater (NYS AWQS) and NYSDEC Interim Groundwater Screening Levels based on NYSDEC guidance as follows:

- March 2023 (PFAS and 1,4-Dioxane)

PAL is based on the lower regulatory criteria.
The Project Action Limit (PAL) is the regulatory screening level established for the Site. Reported concentrations above the corresponding PAL for that analyte will trigger a closer review of the data, including potential mitigation efforts at the sample location.
The Project Quantification Limit (PQL) is the minimum concentration to which a detection for the corresponding analyte must be reported and corresponds to the Reporting Limit for that analyte.
MDL = Method Detection Limit; RL = Reporting Limit; mg/kg = milligrams per kilogram; µg/kg = micrograms per kilogram; PAL = project action limit; RSL = regional screening level; CAS = chemical abstract service; NYS AWQS = New York State Ambient Water Quality Standards; PFAS = per- and polyfluoroalkyl substances; NE = not established; N/A = not applicable.

Worksheet #16: Project Schedule/Timeline Table

Schedules for specific phases of work will be provided in Work Plans and Field Sampling Plans for the Site.

Activity	Responsible Party	Planned Start Date	Planned Completion Date	Deliverable(s)	Deliverable Due Date
Mobilization	GEI	5/19/2025	7/1/2025	N/A	N/A
Investigation Field Work	GEI	5/19/2025	12/31/2025	RI Data Submission Report	6/1/2026
Interim Meeting	GEI	4th Wednesday of each month	11/30/2027	N/A	N/A
Preparation of Report	GEI	8/1/2025	11/1/2027	RI/FS Report	11/15/2027

Worksheet #17: Sampling Design and Rationale

GEI has designed the following sampling program to meet the objectives outlined in Worksheet #11. Tasks outlined below will be completed during RI implementation, based on the project Schedule outlined in Worksheet #16.

Subsurface Soil Investigation

Soil borings will be completed at locations shown on Figures 5 through 7 of the RI Work Plan and summarized in Table 1 of the RI/FS Work Plan to evaluate the lateral and vertical extent of DNAPL presence in the subsurface soil. A total of 28 borings are identified as either Primary or Contingency borings. Primary borings will be completed to refine the extent of known DNAPL presence and address other objectives as identified in Table 1 of the RI/FS Work Plan. If DNAPL is identified at the primary boring location, a contingency boring will be completed at a "stepped out location" to satisfy the objective of mapping the extent of DNAPL.

Primary and Secondary Soil Borings

Including primary borings to be converted to monitoring wells, twenty-one (21) primary borings (inclusive of 2 creek borings T26A and T26B to evaluate Source Control) will be completed during the investigation. As shown on Figures 5 through 7 in the RI Work Plan, groundwater monitoring wells will be installed in seven of the soil borings. As many as seven (7) contingency borings may be added to step-out locations if needed to satisfy investigation objectives in the Scajaquada Creek OU. Boring termination depth for Primary and Secondary borings are summarized in Table 1 of the RI/FS Work Plan.

Groundwater Investigation

The goal of the groundwater investigation is to assess groundwater quality in the unconfined water-bearing zone where DNAPL is known to exist. In areas where DNAPL presence is to be investigated, well screens will be positioned to monitor the bottom of the alluvial soils directly above the area-wide clay layer which forms a barrier to vertical downward migration of DNAPL. To achieve this objective, five (5) new monitoring wells (MW-RI-1 through MW-RI-5) will be installed at the proposed locations shown on Figures 5, 6, and 7 of the RI/FS Work Plan to supplement the existing network of monitoring wells in the Lower Scajaquada Creek OU. Each well will be constructed using 2-inch diameter Schedule 40 PVC with a screened section consisting of 0.02-inch sized slow opening.

The bottom of the well will terminate in the area-wide red-brown clay layer. Wells monitoring the top of the clay layer will be equipped with a 2-foot DNAPL collection sump extending into the area-wide clay layer below the well screen.

In areas where DNAPL-impacted soils were identified and shallow wells are not present, proposed monitoring wells MW-LSC-2S-RI and MW-LSC-4S-RI will be installed with well screens positioned to monitor the upper 5 feet of the saturated zone. These wells will have 5-foot screen lengths to assess groundwater quality in shallow groundwater near the water table.

Creek and Inlet Area Sediment Investigation

Inlet Creek Bank Surface Soil

Surface water sheens have historically (prior to IRMs) been observed on the creek bank due to daily fluctuations in surface water levels in the Inlet. When sheen was present on the surface water in the Inlet Area near the City of Buffalo Pumphouse, the sheen residue was observed to be deposited on the shoreline at the water/bank interface. Surface soil samples will be collected, after shallow soil probing, from the creek bank at 10 locations identified on Figure 8 of the RI/FS Work Plan.

Sediment Probing Transects

Systematic sediment probing will be performed to assess the thickness and quality of sediment within the investigation area and observe sheen for generation. Probing will be conducted along 26 transects, spaced approximately 50 to 100 feet apart, as shown on Figures 8 through 10 of the RI/FS Work Plan. The endpoints of each transect, each probing location along the transect, and the water surface elevation will be established using survey-grade GPS.

Sediment Sampling

Sediment borings will be completed in the Scajaquada Creek main channel and Inlet along 26 transects to evaluate sediment quality. Target sediment sampling locations are provided on Figures 8 through 10 of the RI/FS Work Plan. The final location of each sediment boring may be adjusted in the field based on the presence of utilities buried beneath the Creek channel, accessibility with the sampling barge, obstructions (rip-rap, large debris), or if poor sample recovery occurs. Sediment sample locations will generally be collected at the nearest (relative to target locations on Figures 8 through 10 of the RI/FS Work Plan) 10-foot probing locations along each transect, and the sediment sampling effort will replace the physical proving at those locations.

The target intervals for sampling are generally the upper two feet of sediment and the most impacted interval observed in the core. In the event the 0- to 2-foot depth interval is also the most visibly impacted, or if no depth interval appears more impacted than others, the second sample will be collected from the 2-foot interval overlying the red-brown clay. Each sediment boring will be advanced a minimum of 4 feet into the area-wide red-brown clay layer which occurs more than 15 feet below the soft sediment surface.

Sediment Analysis – COC Delineation Samples

As indicated on Figures 8 through 10 of the RI Work Plan, there are 29 locations where analyses target a list of COCs potentially affecting the Lower Scajaquada Creek area based on the findings of prior investigations in and near the creek. The primary purpose of these samples is to delineate the nature and extent of impacts. At each of those locations, two sample intervals are proposed for analysis, totaling 58 samples. Of those, 47 are proposed for analysis of the focused COC Parameters analyte list and 11 are proposed for analysis of an expanded Full Suite COC analyte list. The analytes associated with each list are indicated in Table 4 of the RI/FS Work Plan.

Sediment Analysis – Benthic Toxicity Analysis

Sediment samples will be collected from the uppermost six inches of sediment (i.e., the most biologically active zone) at a subset of 26 of the 29 locations where COC-related sampling is planned. In addition to collecting COC-related information at these locations, additional parameters will also be analyzed to better assess other factors that may affect benthic toxicity apart from identified COCs. The additional analytical parameters at these locations are indicated in Table 4 of the RI/FS Work Plan.

In addition, sediment will be collected from the upper six inches of sediment at three locations for the purpose of laboratory toxicity testing. The three target locations include T9B, T15B, and T26B (Figures 8 through 10 of the RI/FS Work Plan), although adjustments may be made based on the results of the Ecological Risk Assessment Parameters analysis indicated above.

Waste Characterization

The evaluation of waste management costs in the FS requires evaluation of chemistry characteristics for sediment that may be dredged from the creek and subject to offsite disposal. Three sediment boring locations are proposed for collection of waste characterization samples. These locations (T2B, T6B, and T23A; Figures 8 and 10 of the RI/FS Work Plan) focus on the Inlet area where the greatest volume of deposition sediment is anticipated and where prior data suggests the majority of chemical impacts are present. These

analyses, combined with the suite of area-wide chemical tests, will allow for evaluation of both landfill and thermal treatment options. Analyses for waste characterization will be performed on composite samples created from the uppermost 4 feet or full thickness of depositional material retrieved at each location, whichever is less. One composite sample will be collected at each of the three locations; three samples in total will be analyzed for waste characterization parameters.

Geotechnical

The evaluation of certain remedial technologies for the creek as part of the planned FS may require an assessment of the effects of each technology on the stability of roads and structures along the creek. Knowledge of geotechnical properties may also be pertinent to designing support facilities, sediment dewatering, excavation support, and other ancillary activities that may be needed to implement certain remedial technologies. To support this assessment, limited geotechnical testing is proposed at six locations as part of the sediment investigation scope. The six locations were selected to be adjacent to structures that may be most susceptible to being destabilized by certain remedial activities, and focus on the following areas:

- Along the bulkhead supporting highway I-190 and closing the former creek outlet (T2A, T3A, and T5A)
- Between the State Route 198 on-ramp and Niagara Street bridge (T16B)
- Adjacent to the West Avenue bridge (T26A and T26B)

Soil Boring and Monitoring Well Rationale Table

Location	Primary/Contingency*	Objective/Rationale	Boring Termination Depth
Primary Borings/Monitoring Wells			
MW-RI-1	Primary	Groundwater Quality/Verification of Source Control and Evaluate Extent of DNAPL.	AWRBCL
MW-RI-2	Primary	Groundwater Quality/Verification of Source Control and Evaluate Extent of DNAPL (combine boring information from Creek Sediment Investigation Transect T-26).	AWRBCL
MW-RI-3	Primary	Groundwater Quality/Evaluate Extent of DNAPL/Geotechnical Data (destroyed 31 Tonawanda well MW-4R).	AWRBCL
MW-RI-4	Primary	Groundwater Quality/Evaluate Extent of DNAPL and Assess Potential for Northern Migration Pathway/Geotechnical Data.	AWRBCL
MW-RI-5	Primary	Groundwater Quality/Evaluate Extent of DNAPL and Assess Potential Historic Migration Pathway (former Scajaquada Creek outlet).	AWRBCL
MW-LSC-2S-RI	Primary	Evaluate groundwater quality in upper saturated zone above DNAPL impacted soil.	Screen upper 5 feet of Saturated Zone (Elevation 565 ft)
W-LSC-4S-RI	Primary	Evaluate groundwater quality in upper saturated zone above DNAPL impacted soil.	Screen upper 5 feet of Saturated Zone (Elevation 565 ft)
Soil Borings			
T26A	Primary	Creek Boring – Evaluation of Source Control and assess extent of DNAPL (temporary well install/testing for potential mobility).	AWRBCL
T26B	Primary	Creek Boring – Evaluation of Source Control and assess extent of DNAPL (temporary well install/testing for potential mobility).	AWRBCL
SB-RI-1	Contingency	Evaluation of Source Control and assess extent of DNAPL/Step-out location if MW-RI-1 impacts are observed.	AWRBCL

Location	Primary/Contingency*	Objective/Rationale	Boring Termination Depth
SB-RI-2	Primary	Evaluate Source Control and assess extent of DNAPL. If DNAPL encountered install well to assess mobility.	AWRBCL
SB-RI-3	Contingency	Evaluation of extent DNAPL.	AWRBCL
SB-RI-4	Contingency	Evaluation of extent if DNAPL is observed at MW-RI-2.	AWRBCL
SB-RI-5	Primary	Evaluate extent of DNAPL.	AWRBCL
SB-RI-6	Contingency	Evaluation of extent if DNAPL is observed at SB-RI-5.	AWRBCL
SB-RI-7	Primary	Evaluate extent of DNAPL (install well if alluvial soils are identified and contain DNAPL).	AWRBCL
SB-RI-8	Contingency	Evaluation of extent if DNAPL is observed at SB-RI-7.	AWRBCL
SB-RI-9	Primary	Evaluate extent of DNAPL – (install well if alluvial soils are identified and contain DNAPL) Complete Evaluation of Sand below AWRBCL if no DNAPL.	BCL
SB-RI-10	Contingency	Evaluation of extent if DNAPL is observed at SB-RI-9.	AWRBCL
SB-RI-11	Primary	Evaluate Extent of DNAPL – Complete Evaluation of Sand below AWRBCL.	BCL
SB-RI-12	Contingency	Evaluation of extent if DNAPL is observed at MW-RI-5 in Historic Creek Outlet.	AWRBCL
SB-RI-13	Primary	Evaluate Northern Extent of DNAPL near Historic Creek Outlet.	AWRBCL
SB-RI-14	Primary	Assess Potential for Northern Migration Pathway.	AWRBCL
SB-RI-15	Primary	Assess Potential Migration Pathway toward Black Rock Canal.	AWRBCL
SB-RI-16	Primary	Assess Potential Migration Pathway toward Black Rock Canal.	AWRBCL
SB-RI-17	Primary	Evaluate shallow impact at MW-LSC-3	AWRBCL
SB-RI-18	Primary	Evaluate Extent of DNAPL.	AWRBCL
SB-RI-19	Primary	Evaluate Extent of DNAPL.	AWRBCL

Notes:
1. AWRBCL – Area-wide red-brown clay layer at assumed elevation between elevation 550 and 558 ft. Boring will be terminated at a minimum depth of 4 feet into the clay: beyond any visual evidence of DNAPL.
2. BCL – Below Clay Layer (AWRBCL): Boring will completely penetrate AWRBCL until till layer above bedrock encountered.

*Primary wells and borings to be completed during the RI, Contingency boring locations to completed if RI objective is not satisfied by Primary.

Worksheet #18: Sampling Locations and Methods

Soil/Groundwater/NAPL

The following table summarizes samples to be collected for soil, groundwater, and NAPL.

Matrix	Parameter	Analytical Method		Method	Target Sample Interval*	Sampling SOP
Subsurface Soil Samples	TCL VOCs	EPA SW	8260D/5035	Grab	A	SM-001 SM-002 SM-003
	PAH-17	EPA SW	8270E			
	COC Metals (arsenic, copper, lead, mercury, nickel, and zinc)	EPA SW	6020B/7471B			
	PCBs	EPA SW	8082A			
	Grain Size analysis, Standard Penetration Testing (SPT), TOC	ASTM D422 – sieve & hydrometer, D1586 SPT, TOC – 9060A/Lloyd Kahn				
Creek Bank Surface Soil Samples	TCL VOCs	EPA SW	8260D/5035	Grab	A	SM-001 SM-002 SM-003
	PAH-17	EPA SW	8270E			
	PCBs	EPA SW	8082A			
	COC Metals (arsenic, copper, lead, mercury, nickel, and zinc)	EPA SW	6020B/7471B			
Groundwater Samples (Monitoring Wells)	TCL VOCs	EPA SW	8260D	Grab	Screen interval	GW-001 GW-003 GW-004 GW-005 GW-006 GW-007
	TCL SVOCs	EPA SW	8270E			
	Total Cyanide	EPA SW	9012B			
	TAL Metals	EPA SW	6020B/7470A			
	1,4 Dioxane	EPA SW	8270E SIM			
	PCBs	EPA SW	8082A			
	PFAS	EPA SW	1633			
Groundwater Samples (City of Buffalo Pumphouse/Conveyance Piping)	TCL VOCs	EPA SW	8260D	Grab	B	
	TCL SVOCs	EPA SW	8270E			
	Total Cyanide	EPA SW	9012B			
	TAL Metals	EPA SW	6020B/7470A			
	1,4 Dioxane	EPA SW	8270E SIM			
	PCBs	EPA SW	8082A			
	PFAS	EPA SW	1633			
NAPL Samples	Forensic Analysis	EPA SW	8270E/8015D(M)	Grab	C	GW-002

***Target Sample Interval:**

A – A minimum of two soil samples will be collected from each boring. A sample will be collected from the most apparently impacted interval based on PID screening and field observations. If impacts are not observed, a sample will be collected from the 1-foot interval immediately below the water table, and a second sample will be collected from the bottom of the boring (presumed to be from the upper red-brown clay unit).

B – Water samples will be collected directly from Manholes 21 and 23 and the Pumphouse discharge.

C – If LNAPL or DNAPL is encountered in any soil boring exhibiting properties inconsistent with prior findings of NAPL (characteristics of coal-tar-like gross contamination), a sample will be collected.

Sediment

The following table summarizes samples to be collected for sediment.

Matrix	Sample Location	Parameter	Analytical Method	Visual Assessment/Characterization	Method[1]	Target Sample Interval*	Sampling SOP

Target Sample Interval Key:
A: (0-6") samples and/or depth interval of interest = the deeper boring depth selected based on work plan criteria (approximate depth 5 to 10 feet below top of sediments).
B: Geotechnical parameters will be collected in clay.
C: Eco Risk Assessment will be collected in (0-6") samples.
D: Waste Characterization samples will be collected at the (0-4') interval or full depositional thickness of sediment, whichever is less.
E: Full Suite COC samples will be collected in (0-6") samples.
F: Benthic Toxicity samples will be collected in (0-6") samples.

Notes:

1. If sediment recovery is poor, alternate sampling methods may be used, as described in the FSP (Appendix B of the RI/FS Work Plan).

Worksheet #19, 30: Analytical SOP Requirements and Analytical Services Table

Laboratory: Pace Analytical/Alpha Analytical, **320 Forbes Blvd., Mansfield, MA** 02048-1806, Project Manager, 508-898-9220

- **Point of Contact:** Melissa Deyo

List required accreditations/certifications: National Environmental Laboratory Accreditation Program (NELAP)

Back-up Laboratory: N/A

Sample Delivery Method: Lab courier or third-party courier (FedEx, UPS, etc.)

Analyte/Analyte Group	Method/Standard Operating Procedure (SOP)	Container(s) (minimum sample size)[1]	Preservation	Preparation Holding Time[2]	Analytical Holding Time	Data Package Turnaround
Aqueous						
Total Metals	6020B/26797-4-224123-1	500mL plastic or glass container	2mL 1:1 Nitric Acid per liter of sample to pH ≤ 2, Room temperature or 4° ± 2°C	6 months	6 months	10-20 days
Mercury	7470A/25923-2-224115-1	500mL plastic or glass container	2mL 1:1 Nitric Acid per liter of sample to pH ≤ 2, Room temperature or 4° ± 2°C	28 days	28 days	10-20 days
Semivolatile Organic Compounds	8270E/31164-3-222810-1	Two 1L Amber Glass jar	Non-preserved, 4° ± 2°C	7 days	40 days	10-20 days
Polychlorinated Biphenyls	8082A/222809-2	Two 1L Amber glass bottle	Non-preserved, 4°C	7 days	40 days	10-20 days
1,4-Dioxane	8270E/2164-18-222793-1	Two 1L Amber Glass jar	Non-preserved, 4°C	7 days	40 days	10-20 days

Analyte/Analyte Group	Method/Standard Operating Procedure (SOP)	Container(s) (minimum sample size)[1]	Preservation	Preparation Holding Time[2]	Analytical Holding Time	Data Package Turnaround
PFAS	1633/4582-6-234829-4	Two 500 ml HDPE container with unlined plastic screw cap	Store at 0-6°C	28 days	28 days	10-20 days
Soil/Sediment						
Polynuclear Aromatic Hydrocarbons	8270E/32324-2-222806-1	Pre-cleaned, 250mL glass jar w/ Teflon lined screw cap	4° ± 2°C or -20° ± 5°C	14 days (Freezing extends hold time)	40 days	10-20 days
Semivolatile Organic Compounds	8270E/31164-3-222810-1	Glass jar w/Teflon lined screw cap	4° ± 2°C or -20° ± 5°C	14 days (Freezing extends hold time)	40 days	10-20 days
Total Metals	6010D/26797-4-224123-1	10g of sample in a glass jar	4° ± 2°C	6 months	6 months	10-20 days
COC Metals	6020B/26797-4-224123-1	10g of sample in a glass jar	4° ± 2°C	6 months	6 months	10-20 days
Total Mercury	7471B/7471-2139-7-224128-1	10g of sample in glass jar	4° ± 2°C	28 days	28 days	10-20 days
Polychlorinated Biphenyls	8082A/222809-2	4oz glass soil jars	4° ± 2°C or -20° ± 5°C	14 days (Freezing extends hold time)	40 days	10-20 days
Total Organic Carbon	9060A/2182-25-222834-2	Glass jar	4° ± 2°C	N/A	28 days	10-20 days
AVS-SEM	EPA-821-R-91-100/26797-4-224123-1	10g of sample in a glass jar	4° ± 2°C	14 days	14 days	10-20 days
Grain Size	ASTM D422-63/2183-10-222829-1	500g in a Ziploc bag	N/A	N/A	N/A	10-20 days
Pesticides	8081B/8081-2158-14-222800-1	Glass jar	4° ± 2°C or -20° ± 5°C	14 days (Freezing extends hold time)	40 days	10-20 days
Total Petroleum Hydrocarbons	8015D/8015-222811-2	Pre-cleaned 250mL soil jar	4°C	14 days	40 days	10-20 days

Notes:
1. Multiple analyses may be performed from the same container if the container and preservative are identical and sufficient sample volume is available.
2. Holding times begin starting from the collection date and time except for CLP methods which are based on Validated Time of Sample Receipt (VTSR).
SOP = standard operating procedure; N/A = not applicable; COC = site-specific contaminants of concern

Notes:
1. Matrix spike (MS)/matrix spike duplicates (MSDs) will be client-provided where applicable. Laboratory may select project samples to be spiked for batch accuracy and precision. When no MS/MSDs are supplied, laboratory control sample (LCS)/laboratory control sample duplicates (LCSDs) will be performed.
2. One equipment blank per day or one per 20 samples, whichever is more frequent. Equipment blanks are not required when dedicated or disposable sampling equipment are utilized.
3. Number of sampling locations and samples will be determined by area or task in the field sampling plan.
Waste characterization samples are not included in the table due to no field QC samples bring proposed for these parameters.
N/A = not applicable; TBD = to be determined.

Worksheet #21: Project Sampling SOP References Table

SOP # or Reference[1]	Title, Revision, Date, and URL (if available)	Originating Organization	SOP Option or Equipment Type (if SOP provides options)	Modified for Project? Y/N	Comments
AR-001	General Guidance on Work Zone Monitoring Methods.	GEI	See SOP for specific equipment needs	N	Describes general guidance on work zone air monitoring methods.
AR-002	Air Sampling for Dust (Particulate Matter) Using the MIE DataRAM™ Real-Time Aerosol Monitor	GEI	MIE DataRAM™ model DR-2000 real-time aerosol monitor	N	Describes procedures for real-time monitoring of airborne particulate matter.
AR-005	Hydrogen Cyanide Work Zone Air Monitoring Procedures.	GEI	Handheld meter in conjunction with the Dräger Chip Measuring System (CMS). V-RAE or Mini-Warn used in conjunction with CMS Dräger tubes for continuous monitoring.	N	Describes real-time monitoring of hydrogen cyanide gas.
AR-006	Air Sampling for Volatile Organic Compounds (VOCs) Using Summa Canisters.	GEI	See SOP for specific equipment needs	N	Describes collection of ambient air samples for VOC analysis using Summa canisters. Typically, U.S. EPA Method TO-15 for laboratory analysis.
DM-001	General Guidance on Determination of Appropriate Drilling Methods.	GEI	See SOP for specific equipment needs	N	Describes guidance for determining appropriate drilling method with consideration of potential sample collection requirements.
DM-002	Hollow Stem Auger.	GEI	See SOP for specific equipment needs	N	Describes common hollow-stem auger drilling procedures for overburden soil borings.

SOP # or Reference[1]	Title, Revision, Date, and URL (if available)	Originating Organization	SOP Option or Equipment Type (if SOP provides options)	Modified for Project? Y/N	Comments
DM-003	Air Rotary Drilling with Casing.	GEI	See SOP for specific equipment needs	N	Not anticipated for project.
DM-004	Sonic Drilling.	GEI	See SOP for specific equipment needs	N	Not anticipated for project.
DM-006	GeoProbe® Direct Push Boring.	GEI	See SOP for specific equipment needs	N	Describes procedures for drilling overburden soil borings using Geoprobe® and Macro Core® technologies.
DM-007	Monitoring Well Construction and Installation.	GEI	See SOP for specific equipment needs	N	Describes procedures for installation of monitoring wells screened across or below groundwater table. Assumes wells will be constructed of flush-joint PVC pipe and screened section with factory-slotted openings.
DM-008	Telescoped Drilling	GEI	See SOP for specific equipment needs	N	Describe telescoped drilling used to prevent the connection of two stratigraphic layers during boring advancement and/or monitoring well installation.
DM-009	Monitoring Well Development.	GEI	See SOP for specific equipment needs	N	Describes procedures to develop monitoring wells and maximize groundwater movement.
FD-001	Field Notebook.	GEI	See SOP for specific equipment needs	N	Describes methods for documentation of field activities.
FD-002	Field Observation Report.	GEI	See SOP for specific equipment needs	N	Describes methods to generate a field observation report.
FD-003	Sample Management and Chain of Custody.	GEI	See SOP for specific equipment needs	N	Describes general methods of labelling and managing samples and chain-of-custody preparation.

SOP # or Reference[1]	Title, Revision, Date, and URL (if available)	Originating Organization	SOP Option or Equipment Type (if SOP provides options)	Modified for Project? Y/N	Comments
					Additionally addresses sample transport.
FD-004	Photo Documentation.	GEI	See SOP for specific equipment needs	N	Describes methods to document and retain photographic records.
FD-006	Handheld Global Positioning Receiver Operation.	GEI	See SOP for specific equipment needs	N	Describes procedures for conducting GPS surveys.
GW-001	Water Level and NAPL Measurement.	GEI	Water level meter or oil/water interface probe	N	Describes procedures to measure depth to water and NAPL.
GW-003	Low Flow (Low Stress) Groundwater Sampling.	GEI	See SOP for specific equipment needs	N	Describe methods to collect groundwater samples representative of aquifer conditions in wells exhibiting no continuous drawdown.
GW-004	pH and Temperature Measurement.	GEI	Combination pH/temperature meter	N	Describes methods to measure pH and temperature of liquids.
GW-005	Turbidity Measurement.	GEI	Hach nephelometer/ turbidimeter	N	Describes calibration and method to measure turbidity.
GW-006	Specific Conductance Measurement.	GEI	Field conductivity meter	N	Describes calibration and method to measure conductivity.
GW-007	Dissolved Oxygen Measurement.	GEI	Dissolved oxygen (DO) meter	N	Describes calibration and method to measure DO.
GW-008	Temporary Groundwater Sampling Points.	GEI	See SOP for specific equipment needs	N	Describes procedures for installation of temporary groundwater sampling points.
PM-001	Utility Mark Out and Clearance	GEI	See SOP for specific equipment needs	N	Describes utility mark out/clearance procedures.

SOP # or Reference[1]	Title, Revision, Date, and URL (if available)	Originating Organization	SOP Option or Equipment Type (if SOP provides options)	Modified for Project? Y/N	Comments
QA-001	Equipment Decontamination.	GEI	See SOP for specific equipment needs	N	Describes methods used to decontaminate core collection equipment and reusable sampling equipment for projects that require collection of organic and inorganic samples.
QA-002	Field Quality Control Samples.	GEI	See SOP for specific equipment needs	N	Describes procedures for field quality control (QC) samples.
SC-001	Environmental Sample Types and Sampling Strategies	GEI	See SOP for specific equipment needs	N	Describes sample types and strategic approaches to sample locations.
SC-002	Environmental Sample Handling.	GEI	See SOP for specific equipment needs	N	Describes procedures related to the collection and transportation of environmental samples.
SC-003	Investigation Derived Waste.	GEI	See SOP for specific equipment needs	N	Describes characterization and management of investigation derived waste resulting from investigation activities.
SC-004	Headspace VOC Screening.	GEI	Photoionization detector (PID) or flame ionization detector (FID)	N	Describes methods to measure total VOCs present in headspace.
SG-001	General Guidance on Soil Vapor Intrusion Evaluations.	GEI	See SOP for specific equipment needs	N	Describes methods used to evaluation soil vapor intrusion exposure pathways.
SG-002	Soil Vapor Sample Collection.	GEI	See SOP for specific equipment needs	N	Describes the general steps to collect soil vapor samples.
SG-003	Sub-slab Soil Vapor Collection.	GEI	See SOP for specific equipment needs	N	Describes general steps to collect sub-slab soil vapor samples.

SOP # or Reference[1]	Title, Revision, Date, and URL (if available)	Originating Organization	SOP Option or Equipment Type (if SOP provides options)	Modified for Project? Y/N	Comments
SG-004	Ambient Air Sample Collection.	GEI	See SOP for specific equipment needs	N	Describes method to collect ambient air samples.
SM-001	Soil Sampling Techniques Including Split-Spoon.	GEI	See SOP for specific equipment needs	N	Describes the standard procedure for the collection of surface and subsurface soil samples using traditional sampling methods.
SM-002	VOC Soil Collection and Preservation Method.	GEI	See SOP for specific equipment needs	N	Describes methods to collect and preserve soil samples for the analysis of VOCs in accordance with the EPA Method 5035.
SM-003	Classification of Soil Samples in the Field.	GEI	See SOP for specific equipment needs	N	Describes methods to classify soil samples collected in the field in a consistent manner.
SS-001	Sediment Sampling Using a Sediment Grab Sampler.	GEI	See SOP for specific equipment needs	N	Describes the use of sediment grab samplers for collection of surficial sediment.
SS-002	Sediment Sampling Using Vibracore Equipment.	GEI	See SOP for specific equipment needs	N	Describes collection of sediment samples using Vibracore methods.
SW-001	Surface Water Sampling.	GEI	See SOP for specific equipment needs	N	Describes methods to collect surface water samples.

Notes:
[1] GEI field standard operating procedures (SOPs) are presented in Appendix A of this QAPP. Revisions to GEI field sampling SOPs will be approved by the United States Environmental Protection Agency (EPA) prior to use.
Y = yes; N = no; GPS = global positioning system; ID = identification; SOP = standard operating procedure; VOC = volatile organic compound; QC = quality control.

Worksheet #22: Field Equipment Calibration, Maintenance, Testing, and Inspection Table

Field Equipment	Calibration Activity	Maintenance Activity	Testing Activity	Inspection Activity	SOP Reference	Frequency	Acceptance Criteria	Corrective Action	Responsible Person
Photo-ionization Detector	HASP and Operator's Manal	As per Operator's Manual	As per Operator's Manual	As per Operator's Manual	HASP and Operator's Manual	Daily and if instrument provides erratic results	N/A	Replace or re-calibrate	Field Team Leader
Particulate Meter	HASP and Operator's Manal	As per Operator's Manual	As per Operator's Manual	As per Operator's Manual	HASP and Operator's Manual	Daily and if instrument provides erratic results	N/A	Replace or re-calibrate	Field Team Leader
Multi-Gas Meter	HASP and Operator's Manal	As per Operator's Manual	As per Operator's Manual	As per Operator's Manual	HASP and Operator's Manual	Daily and if instrument provides erratic results	N/A	Replace or re-calibrate	Field Team Leader
GPS Unit	In accordance with manufacturer's instructions	As required by manufacturer specification	Coordinates at known benchmark	Batteries charged, acceptable memory	FD-006 – Handheld Global Positioning Receiver Operation.	Twice daily	+/- 0.5 foot horizontal; +/- 1 foot vertical	Replace or re-calibrate	Field Team Leader
Multi-probe water quality meter	In accordance with manufacturer's instructions	As required by manufacturer specification	As per Operator's Manual	As per Operator's Manual	Operator's Manual	Daily	pH ±0.3 with buffer solution true values; conductivity 10% of standard DO ±0.5 milligram per liter (mg/L) of saturation in air	Replace or re-calibrate	Field Team Leader

Field Equipment	Calibration Activity	Maintenance Activity	Testing Activity	Inspection Activity	SOP Reference	Frequency	Acceptance Criteria	Corrective Action	Responsible Person
Turbidity Meter	In accordance with manufacturer's instructions	As required by manufacturer specification	As per Operator's Manual	As per Operator's Manual	Operator's Manual	Daily	±10%	Replace or re-calibrate.	Field Team Leader
Oil/water interface probe and water level meter	In accordance with manufacturer's instructions	As required by manufacturer specification	As per Operator's Manual	As per Operator's Manual	Operator's Manual	Prior to use and if instrument provides erratic results	±10%	Replace or re-calibrate	Field Team Leader
Cell phone with camera	N/A	N/A	N/A	Batteries charged, acceptable memory and general camera function	FD-004 – Photo Documentation	N/A	N/A	N/A	Field Team Leader

SOP = standard operating procedure; N/A = not applicable; GPS = global positioning system; HASP = health and safety plan.

Worksheet #23: Analytical SOP References Table

SOP #[1]	Title	Date	Definitive or Screening Data	Matrix/Analytical Group	SOP Option or Equipment Type	Modified for Project? Y/N
2164-18-222793-1	1,4-Dioxane	1/12/2022	Definitive	Water/1,4-Dioxane	GC/MS	N
SIM-2247-12-222798	Analysis of Parent and Alkylated Polynuclear Aromatic Hydrocarbons, Selected Heterocyclic Compounds, Steranes, Triterpanes, and Triaromatic Steriods by GC/MS – SIM	11/1/2022	Definitive	Sediment/PAHs	GC/MS	N
2140-5-224120-1	Acid Volatile Sulfides and Simultaneously Extracted Metals in Sediments	1/7/2020	Definitive	Sediment/AVS-SEM	See SOP	N
D4318	Standard Test Method for Liquid Limit, Plastic Limit, and Plasticity Index of Soils	1/31/2018	Screening	Soil/Plastic Limits	See SOP	N
1633-305197-1	Preparation and Analysis of PFAS in Aqueous, Solid, and Tissue by EPA Method 1633	8/7/2024	Definitive	Soil, Sediment, Water/PFAS	LC-MS/MS	N
GTX-SVP-13	Atterberg Limit Device, Grooving Tool, Gauge, Glass Plate	10/31/2012	Definitive	Soil/Atterberg Limit	See SOP	N
2238-6-224580-1	Ignitability of Solids	10/20/2023	Definitive	Soil, Sediment/Ignitability	See SOP	N
26797-4-224114	Inductively Coupled Plasma – Mass Spectrometry 6020B	1/25/2022	Definitive	Soil, Sediment/Metals	ICP-MS	N
25923-2-224115	Mercury in Liquid Waste	1/13/2020	Definitive	Water/Mercury	Automated Cold Vapor	N
25924-4-224116	Mercury in Solid or Semisolid Waste	7/7/2022	Definitive	Soil, Sediment/Mercury	Manual Cold Vapor	N

SOP #[1]	Title	Date	Definitive or Screening Data	Matrix/Analytical Group	SOP Option or Equipment Type	Modified for Project? Y/N
26796-6-224118-1	Inductively Coupled Plasma – Atomic Emission Spectrometry	6/13/2023	Definitive	Water/Metals	ICP/AES	N
2206-12-224606-1	Nitrogen Ammonia	1/3/2022	Definitive	Water/Ammonia	See SOP	N
8081-224528-2	Organochlorine Pesticides by Capillary Column Gas Chromatography	1/6/2025	Definitive	Sediment, Soil/Pesticides	GC	N
2183-10-222829-1	Particle Size Analysis of Soils – with/without Hydrometer	10/25/2022	Definitive	Sediment, Soil/Particle Size	See SOP	N
8082-224529-2	PCBs	11/14/2024	Definitive	Sediment, Soil, Water/PCB	See SOP	N
2203-9-224577-1	pH, Soil and Waste	9/8/2023	Definitive	Sediment, Soil/pH	pH meter	N
32637-4-224532-1	PAHs by SIM EPA 8270E	7/13/2023	Definitive	Sediment, Soil, Water/PAH	GC/MS	N
2228-6-224619-1	Reactive Sulfide and Reactive Cyanide	1/24/2020	Definitive	Sediment, Soil/Reactivity	See SOP	N
31162-3-224534-1	Semivolatile Organic Compounds by GC/MS	7/13/2023	Definitive	Soil, Sediment, Water/SVOC	GC/MS	N
2133-19-224483-1	TCLP Extraction Metals and Semi-Volatile Organics	6/5/2023	Definitive	Soil, Sediment/TCLP Metals and SVOCs	See SOP	N
2112-12-224555-1	TCLP/SPLP Extraction – VOCs EPA 1311/1312	6/2/2023	Definitive	Soil, Sediment/TCLP VOCs	See SOP	N
2182-25-222834-2	TOC and Soot in Soil, Sediment	11/15/2024	Definitive	Soil, Sediment/TOC	CHNS/O Analyzer	N
2125-12-224535-1	TPH – Diesel Range Organics	7/27/2020	Definitive	Soil, Sediment, Water/TPH	GC	N
26801-6-224553	TPH – Gasoline Range Organics 8015 D	8/28/2023	Definitive	Soil, Sediment, Water/TPH	GC	N

SOP #[1]	Title	Date	Definitive or Screening Data	Matrix/Analytical Group	SOP Option or Equipment Type	Modified for Project? Y/N
32639-8-224558-1	VOC by GC/MS	11/8/2022	Definitive	Soil, Sediment, Water/VOC	GC/MS	N
ENV-SOP-ASHE-0015	Determination of Calorific Value (BTU/LB) of Waste Materials Using a Parr 6300/6400 Oxygen Bomb Calorimeter	12/14/2021	Definitive	Soil, Sediment/BTU	Calorimeter	N
ENV-SOP-ASHE-0009 v03	Sulfur by ASTM D4239	4/10/2023	Definitive	Soil, Sediment/Sulfur	Analyzer	N
2214-11-224593-1	Inorganic Anions by Ion Chromatography	2/2/2022	Definitive	Soil, Sediment, Water/Metals	See SOP	N
ENV-SOP-WES2-0062	Biochemical Oxygen Demand	1/7/2025	Screening	Water/BOD	See SOP	N
267100-1	Balance Calibration Verification	4/18/2024	Screening	Soil, Sediment, Water/Various	Balance	N
3743-3-224600-1	Free Cyanide	8/14/2015	Screening	Soil, Sediment, Water/Cyanide	See SOP	N
2204-11-224601-1	Hexavalent Chromium	2/16/2023	Screening	Soil, Sediment, Water/Metal	See SOP	N
224604-2	Nitrate, Nitrite, and Nitrate-Nitrite Nitrogen	10/17/2024	Definitive	Water/Metal	See SOP	N

Notes:

[1] Laboratory Analytical SOPs are provided in Appendix B

Worksheet #24-1: Analytical Instrument Calibration Table – Gas Chromatography/Mass Spectrometry

Instrument	Calibration Procedure	Calibration Range	Frequency of Calibration	Acceptance Criteria	Corrective Action (CA)	Responsible Person for CA	SOP Reference
GC/MS-SIM (PCB Homologs/ Aroclors/ Pesticides)	Perfluorotributyl-amine (PFTBA) tune	Water: 0.5-500 ng/L Solid: 0.3-400 ug/kg PUF: 5-5000 ng/cart	Prior to each Initial Calibration (ICAL)	m/e 69 – Base Peak with > 150,000 m/e 219 40% to 90% of Base Peak m/e 502 4% to 10% of Base Peak	Re-tune manually; Perform instrument/source maintenance as necessary	Analyst	2162-16-222801-1
	Decafluorotriphenyl-phosphine (DFTPP) tune		Prior to each ICAL; At the beginning of analytical sequence ; Every 12-18hrs	Perform in full SCAN mode; Maximum sensitivity criteria – see SOP; DDT breakdown < 20% (Pesticides only)	Perform instrument/injection port maintenance as necessary; Retune instrument		
	Initial Calibration [1](ICAL)		Initial instrument setup; After non-routine instrument service and; CCV/ICV criteria are not met	Minimum of 5 standards; Low standard must be ≤ RL; %RSD ≤ 20 except for 10% of compounds may be > 20 but ≤ 30% RSD, or r ≥ 0.99 (linear regression), or $r^2 \geq 0.99$ (non-linear regression); Single point calibration factors are used for PCB Aroclors	Review integrations and calculations; Perform and document remedial action as required; Repeat calibration		
	Initial Calibration[1] Verification (ICV)		Immediately after each ICAL	%D ≤ 30; exclusions apply – see SOP; Prepared using standard source	Re-analyze ICV if analytical error is suspected;		

Instrument	Calibration Procedure	Calibration Range	Frequency of Calibration	Acceptance Criteria	Corrective Action (CA)	Responsible Person for CA	SOP Reference
				different than used for initial calibration	Recalibrate as needed		
	Continuing Calibration Verification (CCV)		At the beginning and end of every analytical sequence; Every 12-18 hours	%D ≤ 20 except for 20% of compounds may be > 20 but ≤ 30%D; Area counts of internal standards must be within 50 – 200% of the mid-level initial calibration standard.	Review integrations and calculations; Evaluate samples bracketed by failing CCV for obvious matrix interference; Re-analyze samples as needed		
GC/MS (Semi-VOA)	Decafluorotriphenyl-phosphine (DFTPP) tune	Compound specific; Water: 0.5-25 ug/L Solid: 33-1670 ug/kg PUF: 10-100 ug/cart	Prior to each ICAL; At the beginning of analytical sequence ; Every 12hrs	SW846 criteria (See SOP);	Perform instrument/injection port maintenance as necessary; Retune instrument	Analyst	31164-3-222810-1
	Initial Calibration[1] (ICAL)		Initial instrument setup; After non-routine instrument service; CCV/ICV criteria are not met	Minimum of 5 standards; Low standard must be ≤ RL; %RSD ≤20, or r ≥ 0.99 (linear regression), or if linear regression is used, recalculated concentration of the lowest calibration point is within 30% of the true value; All RFs must meet the minimum RFs listed in Table C of the SOP	Review integrations and calculations; Perform and document remedial action as required; Repeat calibration		
	Initial Calibration Verification (ICV)		Immediately after each ICAL	%D ≤ 30; Up to 5 sporadic marginal failures accepted;	Re-analyze ICV if analytical error is suspected;		

Instrument	Calibration Procedure	Calibration Range	Frequency of Calibration	Acceptance Criteria	Corrective Action (CA)	Responsible Person for CA	SOP Reference
				Prepared using standard source different than used for initial calibration	Recalibrate as needed;		
	Continuing Calibration Verification (CCV)		At the beginning of every analytical sequence; Every 12 hours	%D ≤ 20 All RFs must meet the minimum RFs listed in Table C of the SOP; Area counts of internal standards must be within 50 – 200% of the mid-level initial calibration standard; The retention times of the internal standards must be within +0.05 RRT of the previous daily standard.	Review integrations and calculations; Evaluate samples bracketed by failing CCV for obvious matrix interference; Re-analyze samples as needed		
GC/MS-SIM (1,4-Dioxane)	Decafluorotriphenyl-phosphine (DFTPP) tune	Water: 150-100000 ng/L Solid: 8-8000 ug/kg	Prior to each ICAL; At the beginning of analytical sequence; Every 12 hrs	Perform in full SCAN mode; SW846 criteria (see SOP)	Perform instrument/injection port maintenance as necessary; Retune instrument	Analyst	2164-18-222793-1
	Initial Calibration[1] (ICAL)		Initial instrument setup; After non-routine instrument service; CCV/ICV criteria are not met	Minimum of 5 standards; Low standard must be ≤ RL; %RSD ≤ 20 or r ≥ 0.99 (linear regression)	Review integrations and calculations; Perform and document remedial action as required; Repeat calibration		
	Initial Calibration Verification (ICV)		Immediately after each ICAL	%D ≤ 30; Prepared using standard source different than used for initial calibration	Re-analyze ICV if analytical error is suspected; Recalibrate as needed		

Instrument	Calibration Procedure	Calibration Range	Frequency of Calibration	Acceptance Criteria	Corrective Action (CA)	Responsible Person for CA	SOP Reference
	Continuing Calibration Verification (CCV)		At the beginning of every analytical sequence; Every 12 hours	%D ≤ 20 RFs > 0.05 Area counts of internal standards must be within 50 – 200% of the mid-level initial calibration standard. The retention times of the internal standards must be within +0.05 RRT of the previous daily standard.	Review integrations and calculations; Evaluate samples bracketed by failing CCV for obvious matrix interference; Re-analyze samples as needed		

[1]Calibration factor should be averaged, not forced through zero.
When batch, instrument, or sample QC fails, re-analysis shall be done. If upon reanalysis the QC item fails again, the samples shall be reextracted/reanalyzed, the laboratory shall detail the failure and corrective actions in the Case Narrative and report the data as qualified. For MS/MSD failures, re-analysis or re-extractions are not required provided that the associated LCS recovery is within the acceptance criteria, demonstrating a matrix interference.
SOP = standard operating procedure; PCB = polychlorinated biphenyl; RSD = Relative Standard Deviation; N/A = not applicable; GC = gas chromatography; MS = mass spectrometry; SIM = selected ion monitoring.

Worksheet #24-2: Analytical Instrument Calibration Table – Liquid Chromatography/Mass Spectrometry

Instrument	Calibration Procedure	Calibration Range	Frequency of Calibration	Acceptance Criteria	Corrective Action (CA)	Responsible Person for CA	SOP Reference
LC/MS-MS (PFAS by 1633)	Initial Calibration[1] (ICAL)	0.5-250 ng/ml (ppb)	Initial instrument setup. After non-routine instrument service. CCV/ICV criteria are not met	Must meet one of the curve fit options presented in SOP	Review integrations and calculations. Perform and document remedial action as required. Repeat calibration	Analyst	ENV-SOP-MANS-0111V01
	Initial Calibration Verification (ICV)	Mid-Level Cal STD, Second Source	Immediately after each ICAL	±30% recovery of the true values Prepared using standard source different than used for initial calibration.	Re-analyze ICV if analytical error is suspected. Recalibrate as needed		
	Continuing Calibration Verification (CCV)	Alternating Low and Mid-Level Standard	Daily before sample analysis, after every 10 samples, and at end of analytical sequence.	All native and isotopically labelled compounds within ±30% recovery.	Review integrations and calculations; Evaluate samples bracketed by failing CCV for obvious matrix interference; Re-analyze samples as needed		

[1]Calibration factor should be averaged, not forced through zero.
When batch, instrument, or sample QC fails, re-analysis shall be done. If upon reanalysis the QC item fails again, the samples shall be reextracted/reanalyzed, the laboratory shall detail the failure and corrective actions in the Case Narrative and report the data as qualified. For MS/MSD failures, re-analysis or re-extractions are not required provided that the associated LCS recovery is within the acceptance criteria, demonstrating a matrix interference.
SOP = standard operating procedure; LC = liquid chromatography; MS = mass spectrometry

Worksheet #24-3: Analytical Instrument Calibration Table – Inductively Coupled Plasma Mass Spectrometry

Instrument	Calibration Procedure	Calibration Range	Frequency of Calibration	Acceptance Criteria	Corrective Action (CA)	Responsible Person for CA	SOP Reference
ICP-MS	Tune verification ; External; multipoint	Varies by element	Daily or as required	Per SOP	Clean, inspect, adjust/recalibrate	ICP-MS Analyst, Dept. Manager	26797-4-224114
ICP	Response verification; External; single or multi-point	Varies by element	Daily or as required	Per SOP	Clean, inspect, adjust/recalibrate	ICP Analyst, Dept. Manager	26796-6-224118-1
CVAA	External; multi-point	Varies	Daily or as required	Per SOP	Clean, inspect, adjust/recalibrate	CVAA Analyst, Dept. Manager	25923-2-224115/25924-4-224116

When batch, instrument, or sample QC fails, re-analysis shall be done. If upon reanalysis the QC item fails again, the samples shall be reextracted/reanalyzed, the laboratory shall detail the failure and corrective actions in the Case Narrative and report the data as qualified. For MS/MSD failures, re-analysis or re-extractions are not required provided that the associated LCS recovery is within the acceptance criteria, demonstrating a matrix interference.
SOP = standard operating procedure; N/A = not applicable; ICP = inductively coupled plasma; MS = mass spectrometry; CVAA = cold vapor atomic absorption

Worksheet #24-4: Analytical Instrument Calibration Table – Inductively Coupled Plasma Mass Spectrometry

Instrument	Calibration Procedure	Calibration Range	Frequency of Calibration	Acceptance Criteria	Corrective Action (CA)	Responsible Person for CA	SOP Reference
ICP-MS	Daily performance check, initial and continuing calibration per SOP	Linear Dynamic Range: Per analyte and confirmed with linear check standard	Performance check daily, ICAL daily, CCV every 10 samples	Per SOP	Inspect system, correct problem, rerun calibration and affected samples	Analyst	26797-4-224114
CVAF/CVAA (Mercury	Initial and continuing calibration per SOP	Per SOP	ICAL daily; CCV every 10 samples	Per SOP	Inspect system, correct problem, rerun calibration and affected samples	Analyst	25923-2-224115/25924-4-224116 7474-2142-10-224126-1/7474-2143-9-224127-1
Hydride (As and Se)	Initial and continuing calibration per SOP	Per SOP	ICAL daily; CCV every 10 samples	Per SOP	Inspect system, correct problem, rerun calibration and affected samples	Analyst	2141-6-224122-1
CVAF (Low-Level Mercury)	Initial and continuing calibration per SOP	Per SOP	ICAL daily; CCV every 10 samples	Per SOP	Inspect system, correct problem, rerun calibration and affected samples	Analyst	7900-6-224124-1

When batch, instrument, or sample QC fails, re-analysis shall be done. If upon reanalysis the QC item fails again, the samples shall be reextracted/reanalyzed, the laboratory shall detail the failure and corrective actions in the Case Narrative and report the data as qualified. For MS/MSD failures, re-analysis or re-extractions are not required provided that the associated LCS recovery is within the acceptance criteria, demonstrating a matrix interference.
SOP = standard operating procedure; N/A = not applicable; ICP = inductively coupled plasma; CVAF = cold vapor atomic fluorescence; CVAA = cold vapor atomic absorption

Worksheet #24-5: Analytical Instrument Calibration Table – Total Organic Carbon

Instrument	Calibration Procedure	Calibration Range	Frequency of Calibration	Acceptance Criteria	Corrective Action (CA)	Responsible Person for CA	SOP Reference
TOC #1 (9060)	K-FACTORS	100%	Daily	+/- 3.0%	Recalibrate	Analyst	2182-25-222834-2
TOC #2 (9060)	K-FACTORS	100%	Daily	+/- 3.0%	Recalibrate	Analyst	2182-25-222834-2
TOC #3 (9060)	K-FACTORS	100%	Daily	+/- 3.0%	Recalibrate	Analyst	2182-25-222834-2
TOC #1 (Lloyd Kahn)	Linear regression	4.0%	Daily	0.995	Recalibrate	Analyst	2182-25-222834-2
TOC #2 (Lloyd Kahn)	Linear regression	4.0%	Daily	0.995	Recalibrate	Analyst	2182-25-222834-2
TOC #3 (Lloyd Kahn)	Linear regression	4.0%	Daily	0.995	Recalibrate	Analyst	2182-25-222834-2

When batch, instrument, or sample QC fails, re-analysis shall be done. If upon reanalysis the QC item fails again, the samples shall be reextracted/reanalyzed, the laboratory shall detail the failure and corrective actions in the Case Narrative and report the data as qualified. For MS/MSD failures, re-analysis or re-extractions are not required provided that the associated LCS recovery is within the acceptance criteria, demonstrating a matrix interference.
SOP = standard operating procedure; N/A = not applicable; TOC = total organic carbon

Worksheet #24-6: Analytical Instrument Calibration Table – Gas Chromatography

Instrument	Calibration Procedure	Calibration Range	Frequency of Calibration	Acceptance Criteria	Corrective Action (CA)	Responsible Person for CA	SOP Reference
VOA (GC/MS) 8260D	4-Bromofluoro benzene (BFB) tune	Water: 5-1000ng Solid: 5-1500ng	Prior to each ICAL; At the beginning of analytical sequence; Every 12hrs	Perform in full SCAN mode; See SOP for BFB acceptance criteria;	Perform instrument/injection port maintenance as necessary; Retune instrument	Analyst	32639-8-224558-1
	Initial Calibration[1] (ICAL)		Initial instrument setup; After non-routine instrument service; CCV/ICV criteria are not met	Minimum of 5 standards; Low standard must be ≤ RL; %RSD ≤ 20 except for 10% of compounds may be > 20% but ≤ 30% RSD; r ≥ 0.99 (linear regression); r^2 ≥ 0.99 (non-linear regression)	Review integrations and calculations; Perform and document remedial action as required; Repeat calibration		
	Initial Calibration Verification (ICV)		Immediately after each ICAL	%D ≤ 30; exclusions apply – see SOP; Prepared using standard source different than used for initial calibration	Re-analyze ICV if analytical error is suspected; Recalibrate as needed		
	Continuing Calibration Verification (CCV)		At the beginning of every analytical sequence; Every 12 hours	%D ≤ 20 except for 20% of compounds may be > 20 but ≤ 30%D; Area counts of internal standards must be within 50–200% of the mid-level initial calibration standard	Review integrations and calculations; Re-analyze samples as needed		

Instrument	Calibration Procedure	Calibration Range	Frequency of Calibration	Acceptance Criteria	Corrective Action (CA)	Responsible Person for CA	SOP Reference
SVOC (GC/MS) and (GC/MS-SIM)	Decafluorotriphenyl-phosphine (DFTPP) tune	Water / Soil (Full Scan) 1-200 ug/mL Water / Soil (SIM) 0.05-20 ug/mL	Prior to each ICAL; At the beginning of analytical sequence; Every 12 hours	Criteria listed in Table 3 of SW-846 8270E. Perform in full SCAN mode. DDT breakdown must be ≤20%. Pentachlorophenol and benzidine peak tailing factor must be ≤2.	Perform instrument/injection port maintenance as necessary. Retune instrument	Analyst	31162-3-224534-1 Full Scan 32637-4-224532-1 SIM
	Initial Calibration[1] (ICAL)		Initial instrument setup; After non-routine instrument service; CCV/ICV criteria are not met	Minimum of 5 standards, 6 if non-linear regression is used; Low standard must be ≤ RL; %RSD ≤ 20% or r ≥ 0.995 (linear regression) or r^2 ≥ 0.99 (non-linear regression); If %RSD ≤20, linear/non-linear must be used. Minimum RF's as per Table 4 of SW-846 8270E. If linear or non-linear regression used, verify the LOQ by recalculating lowest calibration standard using curve. (50-150%R)	Recalibrate if >10% of target analytes exceed %RSD, r, or r^2 criteria. If ≤10% of compounds exceed criteria, recalibration is not required as long as %RSD <40, r >0.98, or r^2 >0.98. If recalculated concentrations are outside of 50-150%R, report RL as estimated value or raise the RL to next highest calibration standard.		
	Initial Calibration Verification (ICV)		Immediately after each ICAL	70-130%, 40-160%R for difficult analytes. Prepared using standard source different than used for initial calibration	Locate source of problem. Recalibrate if >10% of all analytes are outside of criteria.		
	Continuing Calibration Verification (CCV)		At the beginning of every analytical sequence; Every 12 hours	%D ≤ 20 except difficult compounds may exhibit %D <60; Minimum RF per Table 4 in SW-846 8270E. Area counts of internal standards must be within	Recalibrate if >20% of all target analytes or >15% of analytes from a particular class (base-neutral or acid) exceed %D criteria.		

Instrument	Calibration Procedure	Calibration Range	Frequency of Calibration	Acceptance Criteria	Corrective Action (CA)	Responsible Person for CA	SOP Reference
				50–200% of the mid-level initial calibration standard	If IS is outside of criteria, locate the source of problem and re-analyze the CCV. If ≤20% of compounds exceed criteria, recalibration is not required if %D <40 (or <60 for difficult analytes.)		
PCB, Pesticides, Herbicides (GC/ECD)	Initial Calibration[1] (ICAL)	Method specific PCBs 0.1-10 ug/mL	Initial instrument setup; After non-routine instrument service; CCV/ICV criteria are not met	Minimum of 5 standards; Low standard must be ≤ RL; %RSD ≤ 20 or r ≥ 0.99 (linear regression), If linear regression is used, recalculated concentration of the lowest and mid calibration point is within 30% of the true value	Review integrations and calculations; Perform and document remedial action as required; Repeat calibration	Analyst	8082-224529-2 8081-224528-2 2128-10-224526-1
	Initial Calibration Verification (ICV)	Pesticides 0.0005-0.2 ug/mL	Immediately after each ICAL	PCBs, Pesticides and Herbicides %D ≤ 20; Prepared using standard source different than used for initial calibration	Re-analyze ICV if analytical error is suspected; Recalibrate as needed		
	Continuing Calibration Verification (CCV)	Herbicides 0.05–2.0 ug/mL	At the beginning and end of every analytical sequence; Every 12 hours	PCBs and Pesticides %D ≤ 20; Herbicides %D ≤ 15; Area counts of internal standards must be within 50–150% of the mid-level initial calibration standard. The retention times of the internal standards must be within +0.05 RRT of the previous daily standard.	Review integrations and calculations; Evaluate samples bracketed by failing CCV for obvious matrix interference; Re-analyze samples as needed		

Instrument	Calibration Procedure	Calibration Range	Frequency of Calibration	Acceptance Criteria	Corrective Action (CA)	Responsible Person for CA	SOP Reference
TPH/EPH (GC/FID)	Initial Calibration[1] (ICAL)	Individual Alkanes 3-500 ug/mL Range: 42-7000 ug/mL	Initial instrument setup; After non-routine instrument service ; CCV/ICV criteria are not met	Minimum of 5 standards; Low standard must be ≤ RL; %RSD ≤ 20% or r ≥ 0.99 (linear regression)	Review integrations and calculations; Perform and document remedial action as required; Repeat calibration	Analyst	2125-12-224535-1
	Initial Calibration Verification (ICV)		Immediately after each ICAL	%D ≤ 30%; Prepared using standard source different than used for initial calibration	Re-analyze ICV if analytical error is suspected; Recalibrate as needed		
	Continuing Calibration Verification (CCV)		At the beginning of every analytical sequence; Every 12 hours	%D ≤ 20%	Review integrations and calculations; Evaluate samples bracketed by failing CCV for obvious matrix interference; Re-analyze samples as needed		

[1]Calibration factor should be averaged, not forced through zero.
When batch, instrument, or sample QC fails, re-analysis shall be done. If upon reanalysis the QC item fails again, the samples shall be reextracted/reanalyzed, the laboratory shall detail the failure and corrective actions in the Case Narrative and report the data as qualified. For MS/MSD failures, re-analysis or re-extractions are not required provided that the associated LCS recovery is within the acceptance criteria, demonstrating a matrix interference.
SOP = standard operating procedure; PCB = polychlorinated biphenyl; RSD = Relative Standard Deviation ; N/A = not applicable; GC = gas chromatography; MS = mass spectrometry; FID = flame ionization detection

Worksheet #24-7: Analytical Instrument Calibration Table – Miscellaneous Laboratory Instruments

Instrument	Calibration Procedure	Calibration Range	Frequency of Calibration	Acceptance Criteria	Corrective Action (CA)	Responsible Person for CA	SOP Reference
Lachat (Ammonia and TKN)	Blank and 10 standards. Second-source ICV.	0.05-20 mg/l	Daily	CC ≥ 0.995; low and high ICV, CCV ± 10%	Inspect system, correct problem, re-run calibration and ICV's	Analyst	2206-12-224606-1, 2207-12-224607-1
Lachat (Cyanide)	Blank and 7 standards. Second-source ICV.	0.004-0.5 mg/l	Daily	CC ≥ 0.995; low and high ICV, CCV ± 10%	Inspect system, correct problem, re-run calibration and ICV's	Analyst	2210-14-224624-1
Lachat (Nitrate and Nitrite)	Blank and 6 standards. Second-source ICV.	0.05-8.0 mg/l	Daily	CC ≥ 0.995; low and high ICV, CCV ± 10%	Inspect system, correct problem, re-run calibration and ICV's	Analyst	224604-2
Lachat (Chloride)	Blank and 6 standards. Second-source ICV.	1.0-100 mg/l	Daily	CC ≥ 0.995. 3 levels for ICV, CCV ± 10%	Inspect system, correct problem, re-run calibration and ICV's	Analyst	2216-10-224590-1
DO meter (BOD)	Per manufacturer's instructions.	NA	Daily	Per manufacturer's instructions	Inspect probe, change probe, if needed	Analyst	ENV-SOP-WES2-0062
pH electrode (pH)	Blank and 3 standards.	Buffer 4,7,10	Daily	ICV within 0.05 PH units; CCV	Inspect probe and buffers, correct problem,	Analyst	2202-11-224615-1,

Instrument	Calibration Procedure	Calibration Range	Frequency of Calibration	Acceptance Criteria	Corrective Action (CA)	Responsible Person for CA	SOP Reference
	Second-source ICV.			±2%(waters); ±2 units for soils	re-run calibration and ICV		2203-9-224577-1
TOC analyzer (TOC, DOC)	Blank and 4 standards. Second-source ICV.	0.5 mg/l-10 mg/l	Every 6 months or after a significant change to instrument.	Correlation Coefficient ≥ 0.995. ICV/CCV ±10%	Inspect system, correct problem, re-run calibration and ICV	Analyst	2215-15-224626-1
Spectrometer (Sulfate)	Blank and 3 standards. Second-source ICV.	10-40 mg/l	Daily	Correlation Coefficient ≥ 0.995. ICV/CCV ±10%	Inspect system. Correct problem. Re-run calibration and ICV.	Analyst	224621-2
Spectrometer (Phosphorus)	Blank and 5 standards. Second-source ICV.	0.01-1.0 mg/l	Daily	Correlation Coefficient ≥ 0.995 ICV/CCV ±10%	Inspect system. Correct problem. Re-run calibration and ICV.	Analyst	2226-12-224628-1
Spectrometer (Hexavalent Chromium)	Blank and 7 standards for liquids. Blank and 4 standards for soils. Second-source ICV.	Liquids 0.005-0.5 mg/l Soils 0.01-1.0 mg/kg	Every 12 months or after a significant change to instrument	Correlation Coefficient ≥ 0.995 ICV/CCV ±15%	Inspect system. Correct problem. Re-run calibration and ICV.	Analyst	2204-11-224601-1
Spectrometer (Phenol)	Blank and 4 standards. Second-source ICV.	Phenol: 0.025-2.5 mg/L	Daily	Correlation Coefficient ≥ 0.995 ICV/CCV ±15%	Inspect system. Correct problem. Re-run calibration and ICV.	Analyst	2211-9-224582-1
Spectrometer (Free Cyanide)	Blank and 8 standards. Second-source ICV.	2.0-300 ug/L	Daily	Correlation Coefficient ≥ 0.995. ICV/CCV ±15%	Inspect system, correct problem, re-run	Analyst	3743-3-224600-1

Instrument	Calibration Procedure	Calibration Range	Frequency of Calibration	Acceptance Criteria	Corrective Action (CA)	Responsible Person for CA	SOP Reference
					calibration and ICV.		
Spectrometer (Sulfide)	Blank and 7 standards. Second-source ICV.	0.055-1.755 mg/l	Annual, after significant instrument maintenance, or if CCVs fail	Correlation Coefficient ≥ 0.995. ICV/CCB ±25%	Inspect system, correct problem, re-run calibration and ICV	Analyst	2221-11-224632-1
Spectrometer (COD)	High-Level COD: Blank and 8 standards. Low-Level COD: Blank and 7 standards. Second-source ICV.	High-Level COD: 20-1250 mg/l Low-Level COD: 5-500 mg/l	Every 6 months, after significant instrument maintenance, or new lot of COD tubes, or if CCVs fail.	Correlation Coefficient ≥ 0.995. ICV/CCV ±10% (EPA 410.4) ICV/CCV within control limits (SM 5220D)	Inspect system, correct problem, re-run calibration and ICV	Analyst	2208-15-224589-1
Spectrometer (Nitrite)	Blank and 4 standards. Second-source ICV.	0.02-0.3 mg/l	Daily, or if CCVs fail	Correlation Coefficient ≥ 0.995. ICV/CCV ±10%	Inspect system, correct problem, re-run calibration and ICV	Analyst	2243-8-224605-1
Ion Chromatography (Anions: Fluoride, Bromide, Chloride, Nitrate, Sulfate)	Blank and 6 standards. Second-source ICV.	Fluoride, Bromide, Nitrate: 0.025-5 mg/l Chloride: 0.25-50 mg/l Sulfate: 0.5-100 mg/l	Calibrated every 6 months, or after significant instrument maintenance, if retention time shifts or CCVs fail.	Correlation Coefficient ≥ 0.995. ICV/CCV ±10%	Inspect system, correct problem, re-run calibration and ICV	Analyst	2214-11-224593-1
Balance (Oil and Grease, Total Petroleum Hydrocarbons, BTU)	The calibration of the analytical balance must be verified with Class S weights prior to and at the conclusion of the	2mg-1000mg	Daily, Prior to use	Calibration shall be within ±10% (i.e., ± 0.2 mg) at 2mg and ± 0.5 % (i.e., ± 5 mg) at 1000mg.	If values are not within these limits, check for debris around the balance, and check the bubble	Analyst	267100-1

Instrument/Equipment	Maintenance Activity	Testing Activity	Inspection Activity	Frequency	Acceptance Criteria	Corrective Action	Responsible Person[1]	SOP Reference
pH electrode	Rinse; store in buffer 7.	Analytical standards	Instrument performance	Prior to use	LCS: 6.95-7.05	Recalibrate, condition probe	Analyst	2203-9-224577-1, 2202-11-224615-1
Conductivity meter	Rinse, check for cracks and scratches	Analytical standards	Instrument performance	Prior to use	LCS: ±1% of true value	Rinse; recalibrate	Analyst	2230-9-224620-1
Spectrometer	Replace lamp as needed, rinse and wipe cells	Blank and Analytical standards	Instrument performance	As needed	LCS is within control, Re-zero for Blank	Wipe, change lamp, recalibrate	Analyst	Various SOPs
TOC analyzer	Inspect tubing, scrubber, syringe, injection needle. Prime instrument	Blank and Analytical standards	Instrument performance	Daily or as needed	LCS is within control, Blank is below RL	Replace parts as needed, re-calibrate	Analyst	2215-15-224626-1
Lachat	Rinse tubing, change tubing as needed, check for blockage, O-rings changed as needed	Monitoring baseline, timing, and peak shape	Instrument performance	Daily or as needed	Baseline is flat, peaks have the correct shape, timing is correct	Replace parts as needed, recalibrate	Analyst	Various SOPs
Ion Chromato-graph	Replace column and suppressor as needed, check eluent level, check for leaks	Analytical standards	Check baseline and retention time	Daily or as needed	Flat baseline, correct retention time, LCS within ±10% of true value	Replace lines, column, or suppressor	Analyst	2214-11-224593-1
ORP meter	Rinse probe, inspect for cracks	Analytical Standards	Instrument performance	Prior to use	LCS ± 10%	recalibrate	Analyst	2237-4-224612-1
Balance	Check for debris and level working surface	Weighing samples	Visual	Daily	± 10% for daily check of certified weights	Clean, Level Balance	Analyst	Various SOPs

Notes:
Laboratory QC limits established at the time of analysis will be used.
All limits and procedures defer to the current lab SOPs established at the time of sample analysis.
LCS = laboratory control spike; TOC = total organic carbon; RL = reporting limit; ORP = oxidation-reduction potential; SOP = standard operating procedure

Worksheet #26: Sample Handling System

Sampling Organization: GEI Consultants, Inc.

Laboratories: Pace Analytical Laboratories/Alpha Analytical/Geo Testing Express

Method of Sample Delivery (shipper/carrier): Laboratory courier or third-party courier (FedEx, UPS, etc.)

Number of Days from Reporting Until Sample Disposal: As described in the attached laboratory QA Manual (Appendix C).

Activity	Organization and Title or Position of Perform Responsible for the Activity	SOP Reference[1]
Sample Collection, Packaging, and Shipment		
Sample Collection	Lead Field Geologist/Engineer/GEI Field Support Staff, GEI	FD-003 – Sample Management and Chain of Custody
Sample Labeling	Lead Field Geologist/Engineer/GEI Field Support Staff, GEI	FD-003 – Sample Management and Chain of Custody
Chain-of-custody form completion	Lead Field Geologist/Engineer/GEI Field Support Staff, GEI	FD-003 – Sample Management and Chain of Custody
Sample Packaging	Lead Field Geologist/Engineer/GEI Field Support Staff, GEI	FD-003 – Sample Management and Chain of Custody
Coordination of Shipment	Lead Field Geologist/Engineer/GEI Field Support Staff, GEI	FD-003 – Sample Management and Chain of Custody
Sample Receipt and Analysis		
Sample Receipt, Inspection, and Log-in	Laboratory Sample Receiving Technician	ENV-MAN-WES2-0001 v02 – Quality Manual, ENV-SOP-WES2-0002 – Sample Custody and Tracking
Sample Custody and Storage	Laboratory Sample Receiving Technician	ENV-MAN-WES2-0001 v02 – Quality Manual, ENV-SOP-WES2-0002 – Sample Custody and Tracking
Sample Preparation	Laboratory Sample Receiving Technician	ENV-MAN-WES2-0001 v02 – Quality Manual, ENV-SOP-WES2-0002 – Sample Custody and Tracking
Sample Determinative Analysis	Laboratory Sample Receiving Technician	ENV-MAN-WES2-0001 v02 – Quality Manual, ENV-SOP-WES2-0002 – Sample Custody and Tracking
Sample Archiving		
Sample Storage	Laboratory Analyst	ENV-MAN-WES2-0001 v02 – Quality Manual, ENV-SOP-WES2-0002 – Sample Custody and Tracking
Sample Extract/Digest Storage	Laboratory Analyst	ENV-MAN-WES2-0001 v02 – Quality Manual, ENV-SOP-WES2-0002 – Sample Custody and Tracking
Sample Disposal		
Personnel/Organization	Laboratory Analyst As Per QA Manual and Method SOP	ENV-MAN-WES2-0001 v02 – Quality Manual, ENV-SOP-MANS-0077 – Hazardous Waste Management and Sample Disposal, and Method SOPs

Activity	Organization and Title or Position of Perform Responsible for the Activity	SOP Reference[1]
Number of Days from Analysis	Laboratory Analyst As Per QA Manual and Method SOP	ENV-MAN-WES2-0001 v02 – Quality Manual, ENV-SOP-MANS-0077 – Hazardous Waste Management and Sample Disposal, and Method SOPs

[1] GEI SOPs are in Appendix A. Pace/Alpha SOPs are located in Appendix B.
[2] Examples of a chain-of-custody form and sample packaging are included in SOP FD-003 – Sample Management and Chain of Custody.
[3] Project-specific contractual agreements may require a longer retention period. Project samples should not be disposed of until authorized by the GEI Project Manager.

Worksheet #27: Sample Custody Requirements

Field Sample Custody Procedures (sample collection, packaging, shipment, and delivery to laboratory):

Each environmental sample will be properly identified and individually labeled. Label will be filled out in indelible ink with at least the following information: sample identification, date and time of sample collection, initials of sampler(s), analysis/test required, preservation (as appropriate). The sample label will be securely attached to the sample container.

Environmental samples being analyzed by the analytical laboratory will be properly packaged and shipped for analysis. Following labeling, the sample bottles will be sealed with custody deals, and enclosed in clear sealable plastic bags (i.e., Ziploc© bags), through which identifying labels is visible.

The sample containers, sealed bags, will then be placed in a hard-plastic cooler, an effort will be made to fill in voids with either ice or packaging material (i.e., bubble wrap). Samples are to be placed with sufficient ice (enclosed in double-bagged sealable plastic bags) to cool the samples to 4±2°C. Additionally, each iced cooler will be packed with a cooler temperature blank. Lastly, the cooler will be filled with adequate cushioning to minimize the possibility of container breakage.

Laboratory Sample Custody Procedures (receipt of sample, archiving, disposal):

Laboratory custody procedures are described in the attached laboratory QA Manual (Appendix C), when applicable.

Sample Identification Procedures:

The method of identification of a sample depends on the type of measurement or analysis performed. When field screening measurements are made, data will be recorded directly in logbooks or on field investigation forms. Identifying information such as project name, station number, station location, date and time, name of sampler, field observations, remarks, or other pertinent information will be recorded.

Samples collected for laboratory analysis during the field investigation will be specifically designated by GEI personnel for unique identification. Each sample will be designated by an alpha-numeric code which will identify the sampling location, type, or as necessary, depth. Information regarding sample nomenclature and identification can be found in Worksheet #14.

Chain-of-Custody Procedures:

A completed chain-of custody form must be included with sample transfers/shipments. An example chain-of custody form is included in Appendix B.

When analytical samples are being shipped by an overnight delivery service to the laboratory, the chain-of custody form and other paperwork will be checked against the sample labels and field documentation and then placed in a waterproof sealable plastic bag and taped securely to the inside lid of the cooler. The cooler must then be secured, with custody seals affixed over the lid in at least two locations, and the cooler wrapped with strapping tape (without obscuring the custody seals). Orientation "this end up" arrows will be drawn or attached on two sides of the cooler, and a completed overnight delivery service shipping label will be attached to the top or handle of the cooler. Wide, clear tape should be used to secure the label to the lid of the cooler to prevent the shipping address label from being accidentally peeled off the cooler.

Samples to be shipped by an overnight delivery service will be shipped within 24 hours of sample collection and arrive at the laboratory within 24 hours of sample shipment. A member of the field team will contact the laboratory directly, to notify them of a sample shipment, and again the next day to confirm receipt. In addition, an electronic version of the chain-of custodies will be sent to the laboratory either electronically or by mail.

If the laboratory is going to courier the samples directly from the site or the samples are being delivered directly to the laboratory by GEI, the chain-of custody form will not be placed inside the cooler. The chain-of custody form must be signed by the receiver (i.e., the laboratory courier, or the laboratory sample custodian) when he/she accepts possession of the samples.

Worksheet #28-1: Analytical Quality Control and Corrective Action – PFAS

Laboratory Facility: Alpha Analytical, Mansfield, MA
Matrix: Water, Soil, Biosolid, Tissue
Analytical Group: PFASs
Analytical Method/SOP Reference: EPA 1633 / SOP# ENV-SOP-MANS-0111 V01

QC Sample	Number/Frequency	Method/SOP Acceptance Criteria	Corrective Action	Title/Position of Person Responsible for Corrective Action	Measurement Performance Criteria
Method Blank (MB)	One per preparatory batch of up to 20 samples	No analyte greater than the reporting limit.	Identify source and attempt to eliminate. Re-extract and/or reanalyze blank and affected samples (if sufficient sample remains). Qualify data as needed. Report data if sample results >10x blank or sample results ND. If contamination is widespread or reoccurring, analyses must be stopped and the source of contamination must be eliminated or reduced before analyses can continue.	Analyst/ Laboratory Quality Assurance Officer	<RL
Laboratory Control Sample (LCS) and Laboratory Control Sample Duplicate (LCSD)	One each per preparatory batch of up to 20 samples. Alternate spiking concentration from batch to batch at a low, medium and high concentration.	Per SOP	Correct problem, re-prep and reanalyze LCS and all samples in associated batch for failed analytes. If problem persists, contact Project Manager.	Analyst/ Laboratory Quality Assurance Officer	Per SOP
Matrix Spike (MS)	One per preparatory batch of up to 20 samples. Alternate spiking concentration from batch to batch at a low, medium and high concentration.	Per SOP	Report if associated with passing LCS and CCV. Discuss in narrative.	Laboratory Analyst/Section Supervisor	Per SOP
Field Duplicate (D) or Matrix Spike Duplicate (MSD)	One per preparatory batch of up to 20 samples.	RPD ≤ 30% for compounds > than 2x the RL. RPD ≤ 50% for compounds above the RL but < than 2x the RL.	Evaluate during data validation.	Data validation staff	RPD ≤ 30% for compounds > than 2x the RL. RPD ≤ 50% for compounds above the RL but < than 2x the RL.
Extracted Internal Standard (EIS)	All field samples and QC samples	Per SOP	Check 1) calculations to locate possible errors, 2) standard solutions for degradation, 3) contamination, and 4)	Laboratory Analyst/Section Supervisor	Per SOP

QC Sample	Number/Frequency	Method/SOP Acceptance Criteria	Corrective Action	Title/Position of Person Responsible for Corrective Action	Measurement Performance Criteria
			instrument performance. For CCVs and QC elements spiked with all target analytes, if the recovery of the corresponding target analytes meet the acceptance criteria for the EIS in question, the data can be used but all potential biases in the recovery of the EIS must be documented in the sample report. If the associated target analytes do not meet the acceptance criteria, the data must be reanalyzed.		
Non-Extracted Internal Standard (NIS)	All field samples and QC samples	Per SOP	N/A	Laboratory Analyst/Section Supervisor	Per SOP

*Internally derived limits are updated periodically; current limits will be used at the time of analysis.
**The lab EDD must identify sample QC and batch identifier to relate individual samples to the batch and QC samples.
DQI = data quality indicators; QC = quality control; QA = quality assurance; QL = quantitation limit; RL = reporting limit; PAL = project action limits; MS/MSD = matrix spike/matrix spike duplicate; LCS/LCSD = laboratory control spike/laboratory control spike duplicate; S = sampling; A = analytical; RPD = relative percent difference; %R = percent recovery; LOQ = limit of quantitation; LOD = limit of detection, N/A = not applicable

Worksheet #28-2: Analytical Quality Control and Corrective Action – Metals

Laboratory Facility: Alpha Analytical, Mansfield, MA
Matrix: Soil
Analytical Group: Metals
Analytical Method/SOP Reference: 6020B/SOP 26797-4-224114

QC Sample	Number/Frequency	Method/SOP Acceptance Criteria	Corrective Action	Title/Position of Person Responsible for Corrective Action	Measurement Performance Criteria
Method Blank	1 per prep batch of up to 20 samples.	No target analytes >RL	Reprep and reanalyze the method blank and all samples processed with the contaminated blank. Report results if sample results are > 10x blank result or sample results < RL	Analyst/Section Supervisor	Same as Method/SOP QC Acceptance Limits
LCS (All Targets)	One per prep batch of up to 20 samples.	80-120%	Correct problem, reprep and reanalyze LCS and all samples in associated batch for failed analytes.	Analyst/Section Supervisor	Same as Method/SOP QC Acceptance Limits
LCSD (All Targets)	Must be requested by client. One per batch of up to 20 samples	80-120% Recovery ≤30 RPD	Reanalyze; if reanalysis is not within criteria and LCS is in control, no corrective action necessary. If LCS and LCSD are not within control, reprep and reanalyze LCS and all samples in associated batch for failed analytes.	Analyst/Section Supervisor	Same as Method/SOP QC Acceptance Limits
Duplicates	One per batch of up to 20 samples	RPD ≤ 20%	Qualify data as needed.	Analyst/Section Supervisor	Same as Method/SOP QC Acceptance Limits
MS	One per batch of up to 20 samples	75-125%	Flag data. Discuss in narrative. Analyze post-spike if recoveries <30% and serial dilution fails	Analyst/Section Supervisor	Same as Method/SOP QC Acceptance Limits
MSD	Must be requested by client. One per batch of up to 20 samples	75-125% Recovery ≤ 20% RPD	Flag data. Discuss in narrative.	Analyst/Section Supervisor	Same as Method/SOP QC Acceptance Limits
Serial Dilution	One per batch of up to 20 samples as needed	RPD ≤ 10% if analyte > 50x MDL; No criteria if < 50x MDL	Flag data. Discuss in narrative.	Analyst/Section Supervisor	Same as Method/SOP QC Acceptance Limits
SRM (Certified Targets Only)	Must be requested by client. One per batch of up to 20 samples	Supplier Certified Limits	Correct problem, reprep and reanalyze LCS and all samples in associated batch for failed analytes.	Analyst/Section Supervisor	Same as Method/SOP QC Acceptance Limits

*Internally derived limits are updated periodically; current limits will be used at the time of analysis.
**The lab EDD must identify sample QC and batch identifier to relate individual samples to the batch and QC samples.
DQI = data quality indicators; QC = quality control; QA = quality assurance; QL = quantitation limit; RL = reporting limit; PAL = project action limits; MS/MSD = matrix spike/matrix spike duplicate; LCS/LCSD = laboratory control spike/laboratory control spike duplicate; S = sampling; A = analytical; RPD = relative percent difference; %R = percent recovery; LOQ = limit of quantitation; LOD = limit of detection

Worksheet #28-3: Analytical Quality Control and Corrective Action – Total Organic Carbon

Laboratory Facility: Alpha Analytical, Mansfield, MA
Matrix: Sediments/Soil
Analytical Group: Wet Chemistry
Analytical Method/SOP Reference: 9060A/Lloyd Kahn – Total Organic Carbon/2182-25-222834-2

QC Sample	Number/Frequency	Method/SOP Acceptance Criteria	Corrective Action	Title/Position of Person Responsible for Corrective Action	Measurement Performance Criteria
Method Blank	1 per prep batch of up to 20 samples.	No TOC detected at reporting limit (RL), 10x the amount measured in any sample, or 10x the regulatory limit, whichever is greater.	Reanalyze the method blank and if still fails Recalibrate inst.	Analyst	All analytes in the method blank must be ≤ 0.01%
SRM	One per analytical batch of up to 20 samples.	QC acceptance criteria specified in DoD QSM v4.2, if available. Otherwise use in-house limits.	Correct problem, reanalyze SRM	Analyst	All analytes in samples found to be within +/- 20% of the PAL's on WS#15 MUST pass method/SOP criteria.
Method Blank	1 per prep batch of up to 20 samples.	No TOC detected at reporting limit (RL), 10x the amount measured in any sample, or 10x the regulatory limit, whichever is greater.	Reanalyze the method blank and if still fails Recalibrate inst.	Analyst	No TOC detected at reporting limit (RL), 10x the amount measured in any sample, or 10x the regulatory limit, whichever is greater.
SRM	One per analytical batch of up to 20 samples.	75%-125% Recovery	Correct problem, recalibrate, reanalyze SRM and all associated samples.	Analyst	75%-125% Recovery
Sample Duplicate	1 per prep batch of up to 20 samples.	RPD ≤ 25%	Reanalyze sample and duplicate if additional sample is available	Analyst	N/A

*Internally derived limits are updated periodically; current limits will be used at the time of analysis.
**The lab EDD must identify sample QC and batch identifier to relate individual samples to the batch and QC samples.
DQI = data quality indicators; QC = quality control; QA = quality assurance; QL = quantitation limit; RL = reporting limit; PAL = project action limits; MS/MSD = matrix spike/matrix spike duplicate; LCS/LCSD = laboratory control spike/laboratory control spike duplicate; S = sampling; A = analytical; RPD = relative percent difference; %R = percent recovery; LOQ = limit of quantitation; LOD = limit of detection; TOC = total organic carbon

Worksheet #28-4: Analytical Quality Control and Corrective Action – Nitrogen/Ammonia

Laboratory Facility: Alpha Analytical, Westborough, MA
Matrix: Water and Soil/Sediment
Analytical Group: Wet Chemistry
Analytical Method/SOP Reference: 4500NH3-BH – Nitrogen, Ammonia/SOP 2206-12-224606-1

QC Sample	Number/Frequency	Method/SOP Acceptance Criteria	Corrective Action	Title/Position of Person Responsible for Corrective Action	Measurement Performance Criteria
Method Blank	One per batch of up to 20 samples	No analyte at or above the reporting limit.	Identify source and attempt to eliminate. Re-prep and reanalyze blank and affected samples (if sufficient sample remains). If results for the Distillation Blank are greater than the reporting limit, and all sample results for the batch are greater than 10x the Blank result, sample results may be reported with a narrative to be included in the final report. Otherwise, all samples must be redistilled and reanalyzed	Analyst / Supervisor/Laboratory Quality Assurance Officer	<RL
LCS	One per batch of up to 20 samples.	80-120% for method 4500 waters; 90-110% for method 350 waters, 83-115% for soils	Correct problem, reanalyze once. If still failing re-prep and reanalyze LCS and all samples in associated batch for failed analytes. If problem persists, contact Project Manager.	Analyst / Supervisor/Laboratory Quality Assurance Officer	83-155%
Matrix Spike	One per batch of up to 20 samples.	80-120% for method 4500 waters; 90-110% for method 350 waters; 55-144% for soils	Report if associated with passing LCS. Discuss in narrative.	Laboratory Analyst/Section Supervisor	55-144%
Laboratory duplicate	One per batch of up to 20 samples	<20% waters and soils	Report with narrative	Laboratory Analyst/Section Supervisor	<20%

*Internally derived limits are updated periodically; current limits will be used at the time of analysis.
**The lab EDD must identify sample QC and batch identifier to relate individual samples to the batch and QC samples.
DQI = data quality indicators; QC = quality control; QA = quality assurance; QL = quantitation limit; RL = reporting limit; PAL = project action limits; MS/MSD = matrix spike/matrix spike duplicate; LCS/LCSD = laboratory control spike/laboratory control spike duplicate; S = sampling; A = analytical; RPD = relative percent difference; %R = percent recovery; LOQ = limit of quantitation; LOD = limit of detection

Worksheet #28-5: Analytical Quality Control and Corrective Action – Ignitability

Laboratory Facility: Alpha Analytical, Westborough, MA
Matrix: Water and Soil/Sediment
Analytical Group: Wet Chemistry
Analytical Method/SOP Reference: 1030 – Ignitability/SOP 224598

QC Sample	Number/Frequency	Method/SOP Acceptance Criteria	Corrective Action	Title/Position of Person Responsible for Corrective Action	Measurement Performance Criteria
Method Blank	One per batch of up to 20 samples	> 150°F	Identify source and attempt to eliminate. Re-prep and reanalyze blank and affected samples (if sufficient sample remains).	Analyst / Supervisor/Laboratory Quality Assurance Officer	> 150°F
LCS	One per batch of up to 20 samples.	98-106% (81 ± 3°F)	Correct problem; re-prep and reanalyze LCS and all samples in associated batch for failed analytes. If problem persists, contact Project Manager.	Analyst / Supervisor/Laboratory Quality Assurance Officer	98-106% (81 ± 3°F)
Laboratory duplicate	All samples that flash below 150°F	NA	NA	Laboratory Analyst/Section Supervisor	NA

*Internally derived limits are updated periodically; current limits will be used at the time of analysis.
**The lab EDD must identify sample QC and batch identifier to relate individual samples to the batch and QC samples.
DQI = data quality indicators; QC = quality control; QA = quality assurance; QL = quantitation limit; RL = reporting limit; PAL = project action limits; MS/MSD = matrix spike/matrix spike duplicate; LCS/LCSD = laboratory control spike/laboratory control spike duplicate; S = sampling; A = analytical; RPD = relative percent difference; %R = percent recovery; LOQ = limit of quantitation; LOD = limit of detection

Worksheet #28-6: Analytical Quality Control and Corrective Action – VOCs

Laboratory Facility: Alpha Analytical, Westborough, MA
Matrix: Water and Soil/Sediment
Analytical Group: VOCs
Analytical Method/SOP Reference: 8260D/5035 – VOCs/SOP#32639-8-224558-1

QC Sample	Number/Frequency	Method/SOP Acceptance Criteria	Corrective Action	Title/Position of Person Responsible for Corrective Action	Measurement Performance Criteria
Method Blank	Once every 12-hour period and prior to any sample analysis.	No analyte at or above the reporting limit.	Identify source and attempt to eliminate. Reanalyze blank and affected samples (if sufficient sample remains). Qualify data as needed. Report data if sample results >10x blank or sample results ND. If contamination is widespread or reoccurring, analyses must be stopped, and the source of contamination must be eliminated or reduced before analyses can continue.	Analyst	Same as Method/SOP QC Acceptance Limits
LCS/LCSD	One each per batch of up to 20 samples.	Generally, 70-130% Recovery; 20% RPD – analyte specific	Correct problem; reanalyze LCS/LCSD and all samples in associated batch for failed analytes. If problem persists, contact Project Manager.	Analyst	Same as Method/SOP QC Acceptance Limits
MS/MSD	One per batch of up to 20 samples. Per Client's Request	Generally, 70-130% Recovery; 20% RPD – analyte specific	Report if associated with passing LCS/LCSD. Discuss in narrative.	Analyst	Same as Method/SOP QC Acceptance Limits

*Internally derived limits are updated periodically; current limits will be used at the time of analysis.
**The lab EDD must identify sample QC and batch identifier to relate individual samples to the batch and QC samples.
DQI = data quality indicators; QC = quality control; QA = quality assurance; QL = quantitation limit; RL = reporting limit; PAL = project action limits; MS/MSD = matrix spike/matrix spike duplicate; LCS/LCSD = laboratory control spike/laboratory control spike duplicate; S = sampling; A = analytical; RPD = relative percent difference; %R = percent recovery; LOQ = limit of quantitation; LOD = limit of detection

Worksheet #28-7: Analytical Quality Control and Corrective Action – pH

Laboratory Facility: Pace Analytical, Westborough, MA
Matrix: Water and Soil/Sediment
Analytical Group: Wet Chemistry
Analytical Method/SOP Reference: 9045 – pH/SOP 2203-9-224577-1

QC Sample	Number/Frequency	Method/SOP Acceptance Criteria	Corrective Action	Title/Position of Person Responsible for Corrective Action	Measurement Performance Criteria
LCS	One per batch of up to 20 samples.	99-101% (6.95 – 7.05)	Correct problem; re-prep and reanalyze LCS and all samples in associated batch for failed analytes. If problem persists, contact Project Manager.	Analyst / Supervisor/Laboratory Quality Assurance Officer	6.95-7.05
Laboratory duplicate	One per batch of up to 20 samples.	5%	Report with narrative	Laboratory Analyst/Section Supervisor	5%

*Internally derived limits are updated periodically; current limits will be used at the time of analysis.
**The lab EDD must identify sample QC and batch identifier to relate individual samples to the batch and QC samples.
DQI = data quality indicators; QC = quality control; QA = quality assurance; QL = quantitation limit; RL = reporting limit; PAL = project action limits; MS/MSD = matrix spike/matrix spike duplicate; LCS/LCSD = laboratory control spike/laboratory control spike duplicate; S = sampling; A = analytical; RPD = relative percent difference; %R = percent recovery; LOQ = limit of quantitation; LOD = limit of detection

Worksheet #28-8: Analytical Quality Control and Corrective Action – Reactive Sulfide and Cyanide

Laboratory Facility: Pace Analytical, Westborough, MA
Matrix: Water and Soil/Sediment
Analytical Group: Wet Chemistry
Analytical Method/SOP Reference: 7.3 – Sulfide, Reactivity & Cyanide, Reactivity/SOP 2228-6-224619-1

QC Sample	Number/Frequency	Method/SOP Acceptance Criteria	Corrective Action	Title/Position of Person Responsible for Corrective Action	Measurement Performance Criteria
Method Blank	One per batch of up to 20 samples	No analyte at or above the reporting limit.	Identify source and attempt to eliminate. Re-prep and reanalyze blank and affected samples (if sufficient sample remains).	Analyst / Supervisor/Laboratory Quality Assurance Officer	<RL
LCS	One per batch of up to 20 samples.	30-125% for Reactive Cyanide; 60-125% for Reactive Sulfide	Correct problem; re-prep and reanalyze LCS and all samples in associated batch for failed analytes. If problem persists, contact Project Manager.	Analyst / Supervisor/Laboratory Quality Assurance Officer	30-125% CN 60-125% Sulfide
Laboratory duplicate	One per batch of up to 20 samples.	25% for waters; 40% for soils	Report with narrative	Laboratory Analyst/Section Supervisor	25% water; 40% soil

*Internally derived limits are updated periodically; current limits will be used at the time of analysis.
**The lab EDD must identify sample QC and batch identifier to relate individual samples to the batch and QC samples.
DQI = data quality indicators; QC = quality control; QA = quality assurance; QL = quantitation limit; RL = reporting limit; PAL = project action limits; MS/MSD = matrix spike/matrix spike duplicate; LCS/LCSD = laboratory control spike/laboratory control spike duplicate; S = sampling; A = analytical; RPD = relative percent difference; %R = percent recovery; LOQ = limit of quantitation; LOD = limit of detection; CN = cyanide

Worksheet #28-9: Analytical Quality Control and Corrective Action – PAH-17

Laboratory Facility: Alpha Analytical, Mansfield, MA
Matrix: Solid/Water
Analytical Group: SVOCs
Analytical Method/SOP Reference: PAH-17/SOP 31164-3-222810-1

QC Sample	Number/Frequency	Method/SOP Acceptance Criteria	Corrective Action	Title/Position of Person Responsible for Corrective Action	Measurement Performance Criteria
Method Blank	One per preparatory batch of up to 20 samples	No analyte at or above the reporting limit.	Identify source and attempt to eliminate. Re-extract and/or reanalyze blank and affected samples (if sufficient sample remains). Qualify data as needed. Report data if sample results > 5x blank or sample results ND. If contamination is widespread or reoccurring, analyses must be stopped and the source of contamination must be eliminated or reduced before analyses can continue.	Analyst/ Laboratory Quality Assurance Officer	Same as Method/SOP QC Acceptance Limits
LCS/LCSD	One each per preparatory batch of up to 20 samples	40-140% Recovery. 30% RPD.	Correct problem, reprep and reanalyze LCS/LCSD and all samples in associated batch for failed analytes. If problem persists, contact Project Manager.	Analyst/ Laboratory Quality Assurance Officer	Same as Method/SOP QC Acceptance Limits
MS/MSD	One each per preparatory batch of up to 20 samples. Per Client's Request	40-140% Recovery, 30% RPD	Report if associated with passing LCS/LCSD. Discuss in narrative.	Laboratory Analyst/Section Supervisor	Same as Method/SOP QC Acceptance Limits
Field Duplicate	One per preparatory batch of up to 20 samples. Per Client's Request	RPD ≤ 30% for compounds > than 5x the RL	Evaluate during data validation.	Data validation staff	Same as Method/SOP QC Acceptance Limits
SRM	One per preparatory batch of up to 20 samples. Per Client's Request	40-140% Recovery	List outliers in project narrative.	Project Analyst/ Laboratory Staff	Same as Method/SOP QC Acceptance Limits

*Internally derived limits are updated periodically; current limits will be used at the time of analysis.
**The lab EDD must identify sample QC and batch identifier to relate individual samples to the batch and QC samples.
DQI = data quality indicators; QC = quality control; QA = quality assurance; QL = quantitation limit; RL = reporting limit; PAL = project action limits; MS/MSD = matrix spike/matrix spike duplicate; LCS/LCSD = laboratory control spike/laboratory control spike duplicate; S = sampling; A = analytical; RPD = relative percent difference; %R = percent recovery; LOQ = limit of quantitation; LOD = limit of detection; SRM = sample ratio mismatch

Worksheet #28-10: Analytical Quality Control and Corrective Action – SVOCs

Laboratory Facility: Alpha Analytical, Mansfield, MA
Matrix: Solid/Water
Analytical Group: SVOC
Analytical Method/SOP Reference: 8270E / SOP 31162-3-224534-1

DQI = data quality indicators; QC = quality control; QA = quality assurance; QL = quantitation limit; RL = reporting limit; PAL = project action limits; MS/MSD = matrix spike/matrix spike duplicate; LCS/LCSD = laboratory control spike/laboratory control spike duplicate; S = sampling; A = analytical; RPD = relative percent difference; %R = percent recovery; LOQ = limit of quantitation; LOD = limit of detection

Worksheet #28-11: Analytical Quality Control and Corrective Action – Mercury

Laboratory Facility: Pace Analytical, Westborough, MA
Matrix: Water and Soil/Sediment
Analytical Group: Mercury – CVAF
Analytical Method/SOP Reference: 7471B & 7470A/SOP 25923-2-224115 & SOP 25924-4-224116

QC Sample	Number/Frequency	Method/SOP Acceptance Criteria	Corrective Action	Title/Position of Person Responsible for Corrective Action	Measurement Performance Criteria
Method Blank	One per prep batch of up to 20 samples.	Target analyte > RL	Reprep and reanalyze the method blank and all samples processed with the contaminated blank. Report results if sample results are >10x blank result or sample results <RL	Analyst/Section Supervisor	Same as Method/SOP QC Acceptance Limits
LCS	One per prep batch of up to 20 samples.	80-120%	Correct problem, reprep and reanalyze LCS and all samples in associated batch for failed analytes.	Analyst/Section Supervisor	Same as Method/SOP QC Acceptance Limits
LCSD	Must be requested by client. One per batch of up to 20 samples	80-120% Recovery ≤30 RPD	Reanalyze; if reanalysis is not within criteria and LCS is in control, no corrective action necessary. If LCS and LCSD are not within control reprep and reanalyze LCS and all samples in associated batch for failed analytes.	Analyst/Section Supervisor	Same as Method/SOP QC Acceptance Limits
Duplicates	One per batch of up to 20 samples	RPD ≤ 20%	Qualify data as needed.	Analyst/Section Supervisor	Same as Method/SOP QC Acceptance Limits
MS	One per batch of up to 20 samples	75-125%	Flag data. Discuss in narrative	Analyst/Section Supervisor	Same as Method/SOP QC Acceptance Limits
MSD	Must be requested by client. One per batch of up to 20 samples	75-125% Recovery; ≤20 RPD	Flag data. Discuss in narrative.	Analyst/Section Supervisor	Same as Method/SOP QC Acceptance Limits
SRM (Soil & Tissue Only)	Must be requested by client. One per batch of up to 20 samples	Supplier Certified Limits	Correct problem, reprep and reanalyze SRM and all samples in associated batch for failed analytes.	Analyst/Section Supervisor	Same as Method/SOP QC Acceptance Limits

*Internally derived limits are updated periodically; current limits will be used at the time of analysis.
**The lab EDD must identify sample QC and batch identifier to relate individual samples to the batch and QC samples.

DQI = data quality indicators; QC = quality control; QA = quality assurance; QL = quantitation limit; RL = reporting limit; PAL = project action limits; MS/MSD = matrix spike/matrix spike duplicate; LCS/LCSD = laboratory control spike/laboratory control spike duplicate; S = sampling; A = analytical; RPD = relative percent difference; %R = percent recovery; LOQ = limit of quantitation; LOD = limit of detection

Worksheet #28-12: Analytical Quality Control and Corrective Action – Grain Size

Laboratory Facility: Alpha Analytical, Mansfield, MA
Matrix: Soil/Sediment
Analytical Group: Wet Chemistry
Analytical Method/SOP Reference: ASTM D422 – Grain Size/SOP 2183-10-222829-1

QC Sample	Number/Frequency	Method/SOP Acceptance Criteria	Corrective Action	Title/Position of Person Responsible for Corrective Action	Measurement Performance Criteria
Sample Duplicate	1 per prep batch of up to 20 samples.	RPD $\leq$ 25%	Reanalyze sample and duplicate if additional sample is available	Analyst	N/A

*Internally derived limits are updated periodically; current limits will be used at the time of analysis.
**The lab EDD must identify sample QC and batch identifier to relate individual samples to the batch and QC samples.
DQI = data quality indicators; QC = quality control; QA = quality assurance; RPD = relative percent difference

Worksheet #28-13: Analytical Quality Control and Corrective Action – 1,4 Dioxane

Laboratory Facility: Alpha Analytical, Westborough, MA
Matrix: Soils/Waters
Analytical Group: VOA
Analytical Method/SOP Reference: 1,4 Dioxane 8260E-SIM/SOP 2164-18-222793-1

QC Sample	Number/Frequency	Method/SOP Acceptance Criteria	Corrective Action	Title/Position of Person Responsible for Corrective Action	Measurement Performance Criteria
Method Blank	Once every 12-hour period and prior to any sample analysis.	No analyte at or above the reporting limit.	Identify source and attempt to eliminate. Reanalyze blank and affected samples (if sufficient sample remains). Qualify data as needed. Report data if sample results >10x blank or sample results ND. If contamination is widespread or reoccurring, analyses must be stopped, and the source of contamination must be eliminated or reduced before analyses can continue.	Analyst	Same as Method/SOP QC Acceptance Limits
LCS/LCSD	One each per batch of up to 20 samples.	40-140% Recovery, 30% RPD	Correct problem; reanalyze LCS/LCSD and all samples in associated batch. If problem persists, contact Project Manager.	Analyst	Same as Method/SOP QC Acceptance Limits
MS/MSD	One per batch of up to 20 samples Per Client's Request	40-140% Recovery, 30% RPD	Report if associated with passing LCS/LCSD. Discuss in narrative.	Analyst	Same as Method/SOP QC Acceptance Limits

*Internally derived limits are updated periodically; current limits will be used at the time of analysis.
**The lab EDD must identify sample QC and batch identifier to relate individual samples to the batch and QC samples.
DQI = data quality indicators; QC = quality control; QA = quality assurance; QL = quantitation limit; RL = reporting limit; PAL = project action limits; MS/MSD = matrix spike/matrix spike duplicate; LCS/LCSD = laboratory control spike/laboratory control spike duplicate; S = sampling; A = analytical; RPD = relative percent difference; %R = percent recovery; LOQ = limit of quantitation; LOD = limit of detection

Worksheet #28-14: Analytical Quality Control and Corrective Action – Pesticides

Laboratory Facility: Alpha Analytical, Westborough, MA
Matrix: Soils/Waters
Analytical Group: Pesticides
Analytical Method/SOP Reference: 8081B/SOP 2158-14-222800-1

QC Sample	Number/Frequency	Method/SOP Acceptance Criteria	Corrective Action	Title/Position of Person Responsible for Corrective Action	Measurement Performance Criteria
Method Blank	One per preparatory batch of up to 20 samples	No analyte at or above the reporting limit.	Identify source and attempt to eliminate. Re-extract and/or reanalyze blank and affected samples (if sufficient sample remains). Qualify data as needed. Report data if sample results >10x blank or sample results ND. If contamination is widespread or reoccurring, analyses must be stopped and the source of contamination must be eliminated or reduced before analyses can continue.	Analyst / Laboratory Quality Assurance Officer	Same as Method/SOP QC Acceptance Limits
LCS/LCSD	One each per preparatory batch of up to 20 samples	30-150% Recovery. Aqueous RPD 30%, Soil RPD 50%	Correct problem, reprep and reanalyze LCS/LCSD and all samples in associated batch for failed analytes. If problem persists, contact Project Manager.	Analyst / Laboratory Quality Assurance Officer	Same as Method/SOP QC Acceptance Limits
MS/MSD	One each per preparatory batch of up to 20 samples. Per Client's Request	30-150% Recovery, Aqueous RPD 30%, Soil RPD 50%	Report if associated with passing LCS/LCSD. Discuss in narrative.	Laboratory Analyst/Section Supervisor	Same as Method/SOP QC Acceptance Limits

*Internally derived limits are updated periodically; current limits will be used at the time of analysis.
**The lab EDD must identify sample QC and batch identifier to relate individual samples to the batch and QC samples.
DQI = data quality indicators; QC = quality control; QA = quality assurance; QL = quantitation limit; RL = reporting limit; PAL = project action limits; MS/MSD = matrix spike/matrix spike duplicate; LCS/LCSD = laboratory control spike/laboratory control spike duplicate; S = sampling; A = analytical; RPD = relative percent difference; %R = percent recovery; LOQ = limit of quantitation; LOD = limit of detection

Worksheet #28-15: Analytical Quality Control and Corrective Action – PCB Aroclors

Laboratory Facility: Alpha Analytical, Westborough, MA
Matrix: Soils/Waters
Analytical Group: PCBs
Analytical Method/SOP Reference: 8082A/SOP 8082-224529-1

QC Sample	Number/Frequency	Method/SOP Acceptance Criteria	Corrective Action	Title/Position of Person Responsible for Corrective Action	Measurement Performance Criteria
Method Blank	One per preparatory batch of up to 20 samples	No analyte at or above the reporting limit.	Identify source and attempt to eliminate. Re-extract and/or reanalyze blank and affected samples (if sufficient sample remains). Qualify data as needed. Report data if sample results >10x blank or sample results ND. If contamination is widespread or reoccurring, analyses must be stopped and the source of contamination must be eliminated or reduced before analyses can continue.	Analyst / Laboratory Quality Assurance Officer	Same as Method/SOP QC Acceptance Limits
LCS/LCSD	One per preparatory batch of up to 20 samples	QC acceptance criteria 40-140% Recovery, Aqueous RPD 30%, Soil RPD 50%	Correct problem, reprep and reanalyze LCS/LCSD and all samples in associated batch for failed analytes. If problem persists, contact Project Manager.	Analyst / Laboratory Quality Assurance Officer	Same as Method/SOP QC Acceptance Limits
MS/MSD	One each per preparatory batch of up to 20 samples. Per Client's Request	40-140% Recovery, Aqueous RPD 30%, Soil RPD 50%	Report if associated with passing LCS/LCSD. Discuss in narrative.	Laboratory Analyst/Section Supervisor	Same as Method/SOP QC Acceptance Limits

*Internally derived limits are updated periodically; current limits will be used at the time of analysis.
**The lab EDD must identify sample QC and batch identifier to relate individual samples to the batch and QC samples.
DQI = data quality indicators; QC = quality control; QA = quality assurance; QL = quantitation limit; RL = reporting limit; PAL = project action limits; MS/MSD = matrix spike/matrix spike duplicate; LCS/LCSD = laboratory control spike/laboratory control spike duplicate; S = sampling; A = analytical; RPD = relative percent difference; %R = percent recovery; LOQ = limit of quantitation; LOD = limit of detection

Worksheet #28-16: Analytical Quality Control and Corrective Action – Herbicides

Laboratory Facility: Alpha Analytical, Westborough, MA
Matrix: Soils/Waters
Analytical Group: Herbicides
Analytical Method/SOP Reference: 8151A/SOP 2128-10-224526-1

QC Sample	Number/Frequency	Method/SOP Acceptance Criteria	Corrective Action	Title/Position of Person Responsible for Corrective Action	Measurement Performance Criteria
Method Blank	One per preparatory batch of up to 20 samples	No analyte at or above the reporting limit.	Identify source and attempt to eliminate. Re-extract and/or reanalyze blank and affected samples (if sufficient sample remains). Qualify data as needed. Report data if sample results >10x blank or sample results ND. If contamination is widespread or reoccurring, analyses must be stopped and the source of contamination must be eliminated or reduced before analyses can continue.	Analyst / Laboratory Quality Assurance Officer	Same as Method/SOP QC Acceptance Limits
LCS/LCSD	One each per preparatory batch of up to 20 samples	QC acceptance criteria 30-150% Recovery, Aqueous RPD 25%, Soil RPD 50%	Correct problem, reprep and reanalyze LCS/LCSD and all samples in associated batch for failed analytes. If problem persists, contact Project Manager.	Analyst / Laboratory Quality Assurance Officer	Same as Method/SOP QC Acceptance Limits
MS/MSD	One each per preparatory batch of up to 20 samples. Per Client's Request	QC acceptance criteria 30-150% Recovery, Aqueous RPD 25%, Soil RPD 50%	Report if associated with passing LCS/LCSD. Discuss in narrative.	Laboratory Analyst/Section Supervisor	Same as Method/SOP QC Acceptance Limits

*Internally derived limits are updated periodically; current limits will be used at the time of analysis.
**The lab EDD must identify sample QC and batch identifier to relate individual samples to the batch and QC samples.
DQI = data quality indicators; QC = quality control; QA = quality assurance; QL = quantitation limit; RL = reporting limit; PAL = project action limits; MS/MSD = matrix spike/matrix spike duplicate; LCS/LCSD = laboratory control spike/laboratory control spike duplicate; S = sampling; A = analytical; RPD = relative percent difference; %R = percent recovery; LOQ = limit of quantitation; LOD = limit of detection

Worksheet #28-17: Analytical Quality Control and Corrective Action – TPH-GRO/TPH-DRO

Laboratory Facility: Alpha Analytical, Westborough, MA
Matrix: Soils/Waters
Analytical Group: TPH
Analytical Method/SOP Reference: 8015D(M)/SOP 2125-12-224535-1

QC Sample	Number/Frequency	Method/SOP Acceptance Criteria	Corrective Action	Title/Position of Person Responsible for Corrective Action	Measurement Performance Criteria
Method Blank	One per preparatory batch of up to 20 samples	No analyte at or above the reporting limit.	Identify source and attempt to eliminate. Re-extract and/or reanalyze blank and affected samples (if sufficient sample remains). Qualify data as needed. Report data if sample results >5x blank or sample results ND. If contamination is widespread or reoccurring, analyses must be stopped and the source of contamination must be eliminated or reduced before analyses can continue.	Analyst / Laboratory Quality Assurance Officer	Same as Method/SOP QC Acceptance Limits
LCS/LCSD	One each per preparatory batch of up to 20 samples	QC acceptance criteria 40-140% Recovery. 40% RPD.	Correct problem, reprep and reanalyze LCS/LCSD and all samples in associated batch for failed analytes. If problem persists, contact Project Manager.	Analyst / Laboratory Quality Assurance Officer	Same as Method/SOP QC Acceptance Limits
MS/MSD	One each per preparatory batch of up to 20 samples. Per Client's Request	QC acceptance criteria 60-140% Recovery. 40% RPD.	Report if associated with passing LCS/LCSD. Discuss in narrative.	Laboratory Analyst/Section Supervisor	Same as Method/SOP QC Acceptance Limits

*Internally derived limits are updated periodically; current limits will be used at the time of analysis.
**The lab EDD must identify sample QC and batch identifier to relate individual samples to the batch and QC samples.
DQI = data quality indicators; QC = quality control; QA = quality assurance; QL = quantitation limit; RL = reporting limit; PAL = project action limits; MS/MSD = matrix spike/matrix spike duplicate; LCS/LCSD = laboratory control spike/laboratory control spike duplicate; S = sampling; A = analytical; RPD = relative percent difference; %R = percent recovery; LOQ = limit of quantitation; LOD = limit of detection

Worksheet #28-18: Analytical Quality Control and Corrective Action – Total Cyanide

Laboratory Facility: Alpha Analytical, Westborough, MA
Matrix: Soils/Waters
Analytical Group: Cyanides, Total
Analytical Method/SOP Reference: 9012B/SOP 2210-14-224624-1

QC Sample	Number/Frequency	Method/SOP Acceptance Criteria	Corrective Action	Title/Position of Person Responsible for Corrective Action	Measurement Performance Criteria
Method Blank	One per preparatory batch of up to 20 samples	No analyte at or above the reporting limit	Identify source and attempt to eliminate. Re-extract and/or reanalyze blank and affected samples (if sufficient sample remains). Qualify data as needed. Report data if sample results >5x blank or sample results ND. If contamination is widespread or reoccurring, analyses must be stopped and the source of contamination must be eliminated or reduced before analyses can continue.	Analyst / Laboratory Quality Assurance Officer	Same as Method/SOP QC Acceptance Limits
LCS/LCSD	One each per preparatory batch of up to 20 samples	Within ±15% for liquids and ±20% for soils RPD ≤ 20% for liquids and < 35% for soils	Correct problem, reprep and reanalyze LCS/LCSD and all samples in associated batch for failed analytes. If problem persists, contact Project Manager.	Analyst / Laboratory Quality Assurance Officer	Same as Method/SOP QC Acceptance Limits
MS/MSD	One each per preparatory batch of up to 20 samples. Per Client's Request	%R within ±20% for liquids and ±35% for solids RPD ≤20% for liquids and <35% for solids	Report if associated with passing LCS/LCSD. Discuss in narrative.	Laboratory Analyst/Section Supervisor	Same as Method/SOP QC Acceptance Limits

*Internally derived limits are updated periodically; current limits will be used at the time of analysis.
**The lab EDD must identify sample QC and batch identifier to relate individual samples to the batch and QC samples.
DQI = data quality indicators; QC = quality control; QA = quality assurance; QL = quantitation limit; RL = reporting limit; PAL = project action limits; MS/MSD = matrix spike/matrix spike duplicate; LCS/LCSD = laboratory control spike/laboratory control spike duplicate; S = sampling; A = analytical; RPD = relative percent difference; %R = percent recovery; LOQ = limit of quantitation; LOD = limit of detection

Worksheet #28-19: Analytical Quality Control and Corrective Action – Total Sulfide

Laboratory Facility: Alpha Analytical, Westborough, MA
Matrix: Soils/Waters
Analytical Group: Total Sulfide
Analytical Method/SOP Reference: 9030B/SOP 2221-11-224632-1

QC Sample	Number/Frequency	Method/SOP Acceptance Criteria	Corrective Action	Title/Position of Person Responsible for Corrective Action	Measurement Performance Criteria
Method Blank	One per preparatory batch of up to 20 samples	No analyte at or above the reporting limit	Identify source and attempt to eliminate. Re-extract and/or reanalyze blank and affected samples (if sufficient sample remains). Qualify data as needed. Report data if sample results >5x blank or sample results ND. If contamination is widespread or reoccurring, analyses must be stopped and the source of contamination must be eliminated or reduced before analyses can continue.	Analyst / Laboratory Quality Assurance Officer	Same as Method/SOP QC Acceptance Limits
LCS/LCSD	One each per preparatory batch of up to 20 samples	%R must be within 75-125% %RPD ≤25%	Correct problem, reprep and reanalyze LCS/LCSD and all samples in associated batch for failed analytes. If problem persists, contact Project Manager.	Analyst / Laboratory Quality Assurance Officer	Same as Method/SOP QC Acceptance Limits
MS/MSD	One each per preparatory batch of up to 20 samples. Per Client's Request	%R must be within in-house control limits %RPD ≤25%	Report if associated with passing LCS/LCSD. Discuss in narrative.	Laboratory Analyst/Section Supervisor	Same as Method/SOP QC Acceptance Limits

*Internally derived limits are updated periodically; current limits will be used at the time of analysis.
**The lab EDD must identify sample QC and batch identifier to relate individual samples to the batch and QC samples.
DQI = data quality indicators; QC = quality control; QA = quality assurance; QL = quantitation limit; RL = reporting limit; PAL = project action limits; MS/MSD = matrix spike/matrix spike duplicate; LCS/LCSD = laboratory control spike/laboratory control spike duplicate; S = sampling; A = analytical; RPD = relative percent difference; %R = percent recovery; LOQ = limit of quantitation; LOD = limit of detection

Worksheet #28-20: Analytical Quality Control and Corrective Action – AVS/SEM

Laboratory Facility: Alpha Analytical, Westborough, MA
Matrix: Sediments
Analytical Group: AVS/SEM
Analytical Method/SOP Reference: 9030B/SOP 2221-11-224632-1

QC Sample	Number/Frequency	Method/SOP Acceptance Criteria	Corrective Action	Title/Position of Person Responsible for Corrective Action	Measurement Performance Criteria
Method Blank	One per preparatory batch of up to 20 samples	No analyte at or above the reporting limit	Identify source and attempt to eliminate. Re-extract and/or reanalyze blank and affected samples (if sufficient sample remains). Qualify data as needed. Report data if sample results >5x blank or sample results ND. If contamination is widespread or reoccurring, analyses must be stopped and the source of contamination must be eliminated or reduced before analyses can continue.	Analyst / Laboratory Quality Assurance Officer	Same as Method/SOP QC Acceptance Limits
LCS/LCSD	One each per preparatory batch of up to 20 samples	%R must be within 85-115% %RPD ≤20%	Correct problem, reprep and reanalyze LCS/LCSD and all samples in associated batch for failed analytes. If problem persists, contact Project Manager.	Analyst / Laboratory Quality Assurance Officer	Same as Method/SOP QC Acceptance Limits
MS/MSD	One each per preparatory batch of up to 20 samples. Per Client's Request	%R must be within 75-125% %RPD ≤20%	Report if associated with passing LCS/LCSD. Discuss in narrative.	Laboratory Analyst/Section Supervisor	Same as Method/SOP QC Acceptance Limits

*Internally derived limits are updated periodically; current limits will be used at the time of analysis.
**The lab EDD must identify sample QC and batch identifier to relate individual samples to the batch and QC samples.
DQI = data quality indicators; QC = quality control; QA = quality assurance; QL = quantitation limit; RL = reporting limit; PAL = project action limits; MS/MSD = matrix spike/matrix spike duplicate; LCS/LCSD = laboratory control spike/laboratory control spike duplicate; S = sampling; A = analytical; RPD = relative percent difference; %R = percent recovery; LOQ = limit of quantitation; LOD = limit of detection

Worksheet #28-21: Analytical Quality Control and Corrective Action – Metals

Laboratory Facility: Alpha Analytical, Mansfield, MA
Matrix: Solids/Water
Analytical Group: Metals
Analytical Method/SOP Reference: 6010D/SOP 26796-6-224118-1

QC Sample	Number/Frequency	Method/SOP Acceptance Criteria	Corrective Action	Title/Position of Person Responsible for Corrective Action	Measurement Performance Criteria
Method Blank	One per preparatory batch of up to 20 samples	Less than ½ of the LLOQ for all analytes of concern	Identify source and attempt to eliminate. Re-extract and/or reanalyze blank and affected samples (if sufficient sample remains). Qualify data as needed. Report data if sample results >5x blank or sample results ND. If contamination is widespread or reoccurring, analyses must be stopped and the source of contamination must be eliminated or reduced before analyses can continue.	Analyst / Laboratory Quality Assurance Officer	Same as Method/SOP QC Acceptance Limits
LCS/LCSD	One each per preparatory batch of up to 20 samples	%R must be within ±20% %RPD ≤20%	Correct problem, reprep and reanalyze LCS/LCSD and all samples in associated batch for failed analytes. If problem persists, contact Project Manager.	Analyst / Laboratory Quality Assurance Officer	Same as Method/SOP QC Acceptance Limits
MS/MSD	One each per preparatory batch of up to 20 samples. Per Client's Request	%R must be within 75-125% %RPD must be within in-house control limits	Report if associated with passing LCS/LCSD. Discuss in narrative.	Laboratory Analyst/Section Supervisor	Same as Method/SOP QC Acceptance Limits

*Internally derived limits are updated periodically; current limits will be used at the time of analysis.
**The lab EDD must identify sample QC and batch identifier to relate individual samples to the batch and QC samples.
DQI = data quality indicators; QC = quality control; QA = quality assurance; QL = quantitation limit; RL = reporting limit; PAL = project action limits; MS/MSD = matrix spike/matrix spike duplicate; LCS/LCSD = laboratory control spike/laboratory control spike duplicate; S = sampling; A = analytical; RPD = relative percent difference; %R = percent recovery; LOQ = limit of quantitation; LOD = limit of detection

Worksheet #28-22: Analytical Quality Control and Corrective Action – Percent Sulfur

Laboratory Facility: Pace Analytical, Asheville, NC
Matrix: Sediments
Analytical Group: Percent Sulfur
Analytical Method/SOP Reference: ASTM D4239/ENV-SOP-ASHE-0009

QC Sample	Number/Frequency	Method/SOP Acceptance Criteria	Corrective Action	Title/Position of Person Responsible for Corrective Action	Measurement Performance Criteria
N/A	N/A	N/A	N/A	N/A	N/A

N/A = not applicable

Worksheet #28-23: Analytical Quality Control and Corrective Action – BTU

Laboratory Facility: Pace Analytical, Asheville, NC
Matrix: Sediments
Analytical Group: Calorific Value (BTU)
Analytical Method/SOP Reference: ASTM D240-87/SOP ENV-SOP-ASHE-0015

QC Sample	Number/Frequency	Method/SOP Acceptance Criteria	Corrective Action	Title/Position of Person Responsible for Corrective Action	Measurement Performance Criteria
Method Blank	Two per batch of 20 samples	RPD ≤10%	Report results with appropriate footnote.	Analyst	Same as Method/SOP QC Acceptance Limits

*Internally derived limits are updated periodically; current limits will be used at the time of analysis.
**The lab EDD must identify sample QC and batch identifier to relate individual samples to the batch and QC samples.
DQI = data quality indicators; QC = quality control; RPD = relative percent difference; SOP = standard operating procedure

Worksheet #28-24: Analytical Quality Control and Corrective Action – EPH

Laboratory Facility: Pace Analytical, Westborough, MA
Matrix: Sediment
Analytical Group: EPH
Analytical Method/SOP Reference: MA-EPH / ENV-SOP-WEST-0040

QC Sample	Number/Frequency	Method/SOP Acceptance Criteria	Corrective Action	Title/Position of Person Responsible for Corrective Action	Measurement Performance Criteria
Method Blank	One per preparatory batch of up to 20 samples	No analyte at or above the reporting limit.	Identify source and attempt to eliminate. Re-extract and/or reanalyze blank and affected samples (if sufficient sample remains). Qualify data as needed. Report data if sample results >10x blank or sample results ND. If contamination is widespread or reoccurring, analyses must be stopped and the source of contamination must be eliminated or reduced before analyses can continue.	Analyst / Laboratory Quality Assurance Officer	Same as Method/SOP QC Acceptance Limits
LCS/LCSD	One each per preparatory batch of up to 20 samples	QC acceptance criteria 40-140% Recovery (except nonane 30%-140%). 25% RPD.	Correct problem, reprep and reanalyze LCS/LCSD and all samples in associated batch for failed analytes. If problem persists, contact Project Manager.	Analyst / Laboratory Quality Assurance Officer	Same as Method/SOP QC Acceptance Limits
MS/MSD	One each per preparatory batch of up to 20 samples. Per Client's Request	QC acceptance criteria 40-140% Recovery (except nonane 30%-140%). 50% RPD.	Report if associated with passing LCS/LCSD. Discuss in narrative.	Laboratory Analyst/Section Supervisor	Same as Method/SOP QC Acceptance Limits

*Internally derived limits are updated periodically; current limits will be used at the time of analysis.
**The lab EDD must identify sample QC and batch identifier to relate individual samples to the batch and QC samples.
DQI = data quality indicators; QC = quality control; RPD = relative percent difference; SOP = standard operating procedure

Worksheet #29: Project Documents and Records

Sample Collection and Field Records

Record	Generation	Verification	Storage Location/Archival
Field logbooks or data collection sheets[1]	GEI Field Team Lead	GEI Project Manager	Project File
Chain-of-Custody Forms	GEI Field Team Lead	GEI Project Manager	Project File
Shipping Records	GEI Field Team Lead	GEI Project Manager	Project File
Photographs	GEI Field Team Lead	GEI Project Manager	Project File

1 Data collection sheets may include, but are not limited to, field sampling forms, soil boring logs, test pit logs, monitoring well installation forms, monitoring well development forms, and groundwater sampling forms.

2 Electronic data will be submitted in accordance with the GLLA Project Agreement and in a format specified by the Environmental Protection Agency (USEPA) remedial project manager. Electronic data will be uploaded to the GLLA electronic data upload submission site on GLNPO.net. Electronic files and project deliverables will be maintained in a centralized location and retained for a minimum of 10 years. In addition, electronic data will be backed up on a nightly basis. Hard copy project files and data, such as original field forms and calculations, will be stored in a centralized project file location in the GEI offices in Buffalo, NY and Raleigh, NC. Hardcopy files will be maintained for a minimum of 10 years.

Worksheet #31: Assessments and Corrective Action

Assessment Type	Frequency	Internal or External	Organization Performing Assessment	Person(s) Responsible for Performing Assessment (Title and Organizational Affiliation)	Person(s) Responsible for Responding to Assessment Findings (Title and Organizational Affiliation)	Person(s) Responsible for Identifying and Implementing Corrective Actions (CA) (Title and Organizational Affiliation)	Person(s) Responsible for Monitoring Effectiveness of CA (Title and Organizational Affiliation)
Data review	Upon Receipt of data	Internal	Analytical Laboratory	Jason Hebert/QA Lab Manager Michael Pratt/QA Lab Manager	Senior Chemist for affected laboratory procedure	Melissa Deyo/Laboratory Project Manager	Jason Hebert/QA Lab Manager Michael Pratt/QA Lab Manager
Data review	Upon Receipt of Data	External	GEI	Jennifer Bash/GEI Quality Assurance Manager[1]	Rick Frappa/GEI Project Manager	Jennifer Bash/GEI Quality Assurance Manager	Jennifer Bash/GEI Quality Assurance Manager
GPS Data Review	Upon receipt of data	External	GEI	Jennifer Bash/GEI Quality Assurance Manager[1]	Rick Frappa/GEI Project Manager	Jennifer Bash/GEI Quality Assurance Manager	Jennifer Bash/GEI Quality Assurance Manager

[1]The Quality Assurance Manager will operate independently of all other entities involved with field work, laboratory analysis, and reporting. The QAM will independently review all data and documents prior to signing or approving any reports.

Worksheet #33: QA Management Reports Table

Type of Report	Frequency (daily, weekly, monthly, quarterly, annually, etc.)	Projected Delivery Date(s)	Person(s) Responsible for Report Preparation (Title and Organizational Affiliation)	Report Recipient(s) (Title and Organizational Affiliation)
Data Summary Reports	As needed	3 months after receipt of analytical data	Rick Frappa/GEI Project Manager	Client Project Manager Regulatory Remedial Project Manager EPA Project Manager
Data Validation Reports	As specified in the Data Assessment section based on intended use of the data and required percentage to meet project DQOs	As generated throughout project	Bethany Russel and Darionna Malone, GEI Data Validators	Rick Frappa/GEI Project Manager Jennifer Bash/GEI Quality Assurance Manager[1] EPA Project Manager
Field Sampling Technical Systems Audit Report	1/year	NA	Mike Cummings/GEI Field Team Lead	Rick Frappa/GEI Project Manager Jennifer Bash/GEI Quality Assurance Manager[1] EPA Project Manager
Contract Laboratory Technical Audit Report	As needed during project	NA	Bethany Russel and Darionna Malone, GEI Data Validators	Rick Frappa/GEI Project Manager Jennifer Bash/GEI Quality Assurance Manager[1] EPA Project Manager

GEI Consultants, Inc. will perform corrective action measures, including deviations from plans and procedures that are of an immediate nature that may require work stoppage in accordance with GEI's Quality Management Plan (GEI, 2018).

[1]The Quality Assurance Manager will operate independently of all other entities involved with field work, laboratory analysis, and reporting. The QAM will independently review all data and documents prior to signing or approving any reports.

Worksheet #34: Data Verification and Validation Inputs

Item	Description	Verification (completeness)	Validation (conformance to specifications)
	Planning Documents/Records		
1	Approved QAPP	X	X
2	Field SOPs	X	
3	Laboratory SOPs	X	
	Field Records		
4	Field notes and logbooks	X	X
5	Field data collection sheets	X	X
6	Instrument calibration records	X	X
7	Instrument testing and maintenance records	X	X
8	Chain-of-custody records	X	X
9	Sampling diagrams/maps	X	X
10	Drilling logs	X	X
11	Sediment core and grab logs	X	X
12	Photographs	X	X
13	Subcontractor reports	X	X
14	Communication records	X	X
15	Change orders/deviations	X	X
16	Field audit reports	X	X
17	Field CA reports	X	X
	Laboratory Data Package		
18	Cover sheet (laboratory identification, job number, etc.)	X	X[1]
19	Cross reference (field sample ID to laboratory ID)	X	X[1]

[2]Refer to Worksheet #29 for applicability.

Worksheet #35: Sampling and Analysis Validation (Step Iia and Iib) Process Table

Step of Validation	Validation Input	Description	Responsible for Validation (Name, Organization)
Iia	Sampling methods and procedures	Establish that required sampling procedures and field measurements meet performance criteria and that deviations were documented. Verify that sampling methods/procedures were followed (in accordance with GEI Field SOPs (Appendix A), and that deviations were noted/approved in accordance with Worksheets #31 and 32.	Jennifer Bash/GEI Quality Assurance Manager Bethany Russel and Darionna Malone, GEI Data Validators
Iib	SOPs	Determine potential impacts from noted/approved deviation, regarding project quality objectives (DQOs; Worksheets #10 and #11).	Jennifer Bash/GEI Quality Assurance Manager
Iia	Chain-of-custody	Examine chain of-custody forms against QAPP and laboratory contract requirements (i.e., analytical methods, sample identification, etc.)	Jennifer Bash/GEI Quality Assurance Manager Bethany Russel and Darionna Malone, GEI Data Validators
Iia	Laboratory data package	Examine packages against QAPP and laboratory contract requirements, and against chain-of-custody forms (i.e., holding times, sample handling, analytical methods, sample identification, data qualifiers, QC samples, etc.)	Jennifer Bash/GEI Quality Assurance Manager Bethany Russel and Darionna Malone, GEI Data Validators
Iib	Analytical method and procedures	In addition to the required review items listed in Stage 2A/2B, the following review is performed: Verification and validation checks for the compliance of instrument-related QC: initial and continuing calibration verification standard frequency and result criteria, instrument blank results, and method specific instrument performance checks.	Bethany Russel and Darionna Malone, GEI Data Validators
III (Modified)	Analytical method and procedures	Verification of instrument outputs of sample quantitation report versus laboratory reports results, and appropriateness of calibration model applied. Manual recalculations are not required.	Bethany Russel and Darionna Malone, GEI Data Validators
IV	Analytical method and procedures	In addition to the required review items listed in Stage 3, the following review is performed:	Bethany Russel and Darionna Malone, GEI Data Validators

Step of Validation	Validation Input	Description	Responsible for Validation (Name, Organization)
		Verification and validation of instrument and sample results and comparison of recalculated results to those reported and review of the actual instrument outputs is performed on a subset of data.	
Iia, Iib, III, and IV	Issue resolution	Data issues which may adversely impact the data will be reported to the GEI PM, client, regulator, and laboratory in an effort to mitigate the impact on the project data.	Bethany Russel and Darionna Malone, GEI Data Validators

Notes:
Step Iia – Compliance with methods, procedures, and contracts.
Step Iib – Compliance with QAPP quality objectives.
Guidelines for reporting data verification/validation efforts are discussed in Worksheet #37 of this QAPP.

Worksheet #36: Sampling and Analysis Validation (Stage 3) Summary Table

Validation Level	Matrix	Analytical Group	Concentration Level	Validation Criteria	Data Validator (Title and Organizational Affiliation)
Stage 3	Inclusive	Inclusive	Inclusive	Qualitative data review according to Worksheets No. 11, 12, 19, 28. Level III data validation according to Worksheet No. 37 EPA National Functional Guidelines for Organic and Inorganic Superfund Methods Data Review, EPA-540-R-2017-002 (Organic) and EPA-540-R-2017-001 (Inorganic), January 2017 Guidance for Labeling Externally Validated Laboratory Analytical Data for Superfund Use, EPA-540-R-08-005, January 2009	Bethany Russel and Darionna Malone, GEI Data Validators

Notes:
Guidelines on reporting data verification/validation efforts are discussed in Worksheet #37 of this QAPP.
100 percent of project chemical data will undergo data validation at Stage 3.

Worksheet #37: Data Usability Assessment

A Data Usability Assessment will be performed by GEI for all data associated with the RI investigation and FS. These usability assessments will consist of data validation checklists and overall usability summaries captured within a Data Validation Report.

The data usability assessment will be performed at the conclusion of data collection activities, using the outputs from data verification and data validation. It is the data interpretation phase, which involves a qualitative and quantitative evaluation to determine if the project data are of the right type, quality, and quantity to support the decisions to be made.

Personnel (organization and position/title) responsible for participating in the data usability assessment.

Rick Frappa, GEI Project Manager

Jennifer Bash, GEI Quality Assurance Manager

Jaimie Wargo, GEI Data Manager

Bethany Russel and Darionna Malone, GEI Data Validators

The data usability assessment process will include the following to be completed following investigation and document in the report.

Step 1	Review of the project objectives and sampling design to determine if the project data are of the right type and quantity to support the decisions that need to be made.
Step 2	Review of the field data verification and data verification and validation outputs: Verification is the process by which sampling information and laboratory data are reviewed for completeness and adherence to the project requirements. Data validation, as outlined in Worksheets #35 and #36, entails a review of the sample collection, handling, laboratory QC data, and the raw data to verify that the laboratory operated within required method and project specified limits; analytical results were correctly transcribed from the instrument read-outs; and which (if any) environmental samples were related to non-conforming QC samples and the effect (uncertainty/bias) of these results on the data.
Step 3	Data usability assessment report preparation: The data usability assessment evaluates whether the sources of uncertainty have been accounted for and are acceptable and the results can be used as intended and are sufficient to meet the project needs and data quality objectives. A data assessment report will be issued by the project manager or designee documenting the review of the project team.

Each assessment will include field data verification and laboratory data verification and validation. Data verification involves review of laboratory results to confirm that the quality control steps outlined in this QAPP, and appropriate SOPs were performed to meet the project QC objectives.

The key elements of the field data verification process will include the following:

- Field sampling, sample handling, and analysis activities documentations (e.g., signatures, QC checklists).
- Internal verification of sampling, handling, on-site analytical and off-site laboratory data at the data-generator level.

The key elements of the laboratory verification and validation process will include the following:

- Sample collection, handling, and analysis procedures.
- Laboratory data (e.g., laboratory-qualified data).
- Data package deliverable completeness.
- Case narrative review.
- Analytical data reporting.
- QC sample data summaries.
- Applicable raw data (when required).

Required data deliverables must be present in the data packages to proceed to the next step of data validation.

Data validation entails a review of the sample collection, handling, field analysis and QC data, and the raw data to verify that the laboratory operated within required limits; analytical results were correctly transcribed from the instrument read-outs; and which (if any) environmental samples were related to non-conforming QC samples. The objective of data validation is to identify suspect or invalid laboratory measurements.

The data quality indicators (DQIs) used to evaluate conformance with the project data quality objectives (DQOs) are presented below.

DQIs are generally defined in terms of seven (7) parameters:

1. Precision
2. Accuracy
3. Representativeness
4. Comparability
5. Completeness
6. Sensitivity
7. Selectivity

Each parameter is defined below. Specific objectives for the site actions are presented in other sections of this QAPP, as referenced below.

Precision

Precision is a measure of agreement among individual measurements of the same property, under prescribed conditions. Sampling precision is measured for this project through the collection of field duplicates and is expressed in terms of Relative Percent Difference (RPD). Precision is expressed in terms of analytical variability and will be calculated intra-laboratory. For this project, analytical variability will be measured as RPD between analytical replicates/duplicates (i.e., field or laboratory) and between the MS MSD analytical results. Analytical precision is measured by evaluation of MS/MSD pairs, dual column PCB results, LCS/LCSD, and/or laboratory-generated sample replicates.

The RPD is calculated using the following equations:

$$RPD = \frac{(C1-C2)*100\%}{(C1+C2)/2}$$

Where:

C1 = The larger of the two observed values
C2 = The smaller of the two observed values.

The RPDs will be reviewed during the data quality review, deviations from specified limits will be notes, and the effect on reported data will be commented upon by the data reviewed.

Accuracy

Accuracy is the amount of agreement between the measured value and the true value. It will be measured as the percent recovery (%R) of the MS/MSD, LCS, and surrogate spike compounds. It will also be measured using the analytical results of instrument calibration and other laboratory internal standards.

Accuracy will be calculated as the %R of analytes as follows:

$\%R = (y/x) *100$

Where:

%R = percent recovery

Y = measured analyte concentration (measured – original sample concentration)

X = known analyte concentration

The resultant percent recoveries will be compared to acceptance criteria, and deviations from specified limits will be reported. If the objective criteria are not met, the laboratory will supply a justification of why the acceptability limits were exceeded and implement the appropriate corrective actions. Percent recoveries will be reviewed during the data quality review, deviations from the specified limits will be noted, and the effect on reported data will be comments upon by the data reviewer.

Representativeness

Representativeness is the degree to which data is accurately and precisely represents a parameter variation at a sampling point or an environmental condition. Results from analyses will be used to evaluate the data to determine whether the samples were collected in a manner that the results appropriately describe the area investigated.

Comparability

Comparability is the degree to which data from one study can be compared with data from other similar studies, reference values (such as background), reference materials, and screening values. This goal will be achieved by using standard techniques to collect and analyze representative samples, reporting analytical results in appropriate units, and comparing past and future results.

Completeness

Completeness is defined as the percentage of usable data from the total amount of data generated. Analytical completeness is a measure of the number of overall accepted analytical results (valid results), including estimated values, compared to the total number of analytical results requested on samples submitted for analysis after review of the analytical data. Less than 100% completeness could result if samples require dilution, resulting in an increase in project-required detection/quantitation limits for some parameters. Highly contaminated environments can also be sufficiently heterogeneous to prevent the achievement of specified precision and accuracy criteria. Therefore, the target goal for completeness as a whole shall be 90% for both field and laboratory analytical methods. Completeness is calculated on a per sample delivery group basis for this project. Project-specific data needs will be defined on an individual batch basis and will consist of data for which all QC criteria were net.

Completeness will be calculated as follows:

$$\%C = (A/I)*100\%$$

Where:

%C = percent completeness (analytical)
A = actual number of samples collected/valid analyses obtained
I = intended number of samples/analyses requested

Invalid data (i.e., data qualified as "R" rejected) will be identified during the QA review.

Sensitivity

As used in this context, sensitivity refers to the ability of project analytical procedures to identify and quantify target analytes at concentrations low enough to meet project data needs. Specific indicators of sensitivity in analytical measurements include the method detection limit (MDL) and the reporting limit (RL) for organics and inorganics.

The MDL is a purely statistical value, which is defined by EPA as the concentration at which an analytical system has a 99 percent probability that the analyte is present, but there is a high probability of false non-detections at or around the MDL. MDLs are determined by preparation and analysis of a minimum of seven replicate portions of a low-level standard. EPA revised their definition of MDLs in December 2016 (EPA, 2016) to: The MDL is defined as the minimum measured concentration of a substance that can be reported with 99% confidence that the measured concentration is distinguishable from method blank results. Per the new definition (and procedure), the MDL is determined using multiple replicates of low-level standards and method blanks throughout the year; the MDL is higher of the two values; the MDL lies in a region of high quantitative uncertainty; and results near the MDL must be considered as estimates.

The RL is normally set at a factor of 5 to 10 times the MDL. The exact number depends on the lowest concentration that a laboratory can successfully use as a low calibration standard. The RL is considered the lowest concentration that a laboratory can report with reasonable quantitative accuracy, although results less than 5 times the RL can still be highly variable.

Selectivity

Selectivity is the ability of an analytical procedure to accurately identify an analyte, and to distinguish that analyte from interferences. The complexity of the project sample matrix and the presence of multiple, closely related compounds make selectivity an important data quality issue for this project. So that project data needs are met, the subcontracted laboratories will discuss compound identification issues with the designated project personnel as soon as they are identified.

Data Validation and Usability

GEI will validate data generated referencing the most recent versions of the EPA National Functional Guidelines (EPA, 2020) where applicable. These procedures and criteria may be modified, as needed, to address project-specific method-specific criteria, control limits, and procedures. Data validation will consist of data screening, checking, reviewing, editing, and interpretation to document analytical data quality and to determine whether the quality is sufficient to meet DQOs.

The data validator will verify that reduction of laboratory measurements and laboratory reporting of analytical parameters is in accordance with procedures specified for the analytical method and/or specified in this QAPP. Deviations from the analytical method or special reporting requirements apart from those specified in this QAPP will be detailed on COC forms.

Upon receipt of laboratory data, the following information will be checked by the data validator:

- Evaluate completeness of data package.
- Verify that field COC forms were completed and that samples were handled properly.
- Verify that holding times were met for requested parameters. Holding time exceedances, should they occur, will be documented. Data for samples exceeding holding time requirements will be flagged as either estimated or rejected. The decision as to which qualifier is more appropriate will be made on a case-by-case basis.
- Verify that parameters analyzed according to the methods specified.
- Review QA/QC data (i.e., confirm that duplicates, blanks, and spikes were analyzed on the required number of samples as specified in the method, and verify that duplicate and MS recoveries are acceptable).
- Investigate anomalies identified during review. When anomalies are identified, they will be discussed with the Project Manager and/or Laboratory Manager, as appropriate.
- If data appear suspect, investigate the specific data of concern. Calculations will be traced back to raw data. If calculations do not agree, the cause will be determined and corrected.

Deficiencies discovered as a result of the data review, as well as the corrective actions implemented in response, will be documented and submitted in a written report addressing the following topics, as applicable to the methods:

- Assessment of the data package.
- Description of protocol deviations.
- Failures to reconcile reported and/or raw data.
- Assessment of compromised data.
- Overall appraisal of the analytical data.
- Table of site name, sample quantities, matrix, and fractions analyzed.

Quantified results do not necessarily invalidate data. The goal to produce the best possible data does not necessarily mean that data must be produced without QC qualifiers. Qualified data can provide useful information.

During the validation process, laboratory qualified, and unqualified data are verified against the supporting documentation. Based on this evaluation, validation qualifiers are applied to the project data. Examples of codes that will be used to qualify results include:

U	The analyte was analyzed for but was not detected above the reported sample quantitation limit.
J	The result was positively identified; however, the associated numerical value is an estimated concentration only.
J+	The analyte was positively identified; the associated numerical value is an approximate concentration of the analyte but may be biased high.
J-	The analyte was positively identified; the associated numerical value is an approximate concentration of the analyte but may be biased low.
JN	The analysis indicates the presence of a compound for which there is presumptive evidence to make a tentative identified. The associated numerical value is an estimated concentration only.
N	The analysis indicates the presence of an analyte for which there is presumptive evidence to make a tentative identification.
R	The data are unusable. A sample result is rejected when associated QC analysis results exceed the expanded control limits of the QC criteria. The rejected data are known to contain significant errors based on documented information. The data user must not use the rejected data to make environmental decisions. The presence or absence of the analyte cannot be verified.
UJ	The analyte was not detected. However, the reported quantitation limit is approximate and may or may not represent the actual limit of quantitation.

Resolution of issues regarding laboratory performance or deliverables will be handled between the laboratory and the data validator. Suggestions for re-analysis may be made by the QA lead.

Validation Reports

The data validation reports will identify deficiencies and the potential impact on the results. The Validation and Data Project team will amend qualifiers generated during the validation process to the database. The validation checklists and the database will be the primary location of applicable data qualifiers.

Qualifiers will not be applied to the hard copy analytical reports.

Field Data Review

Field data are generated from in-field measurements, which may include geophysical survey activities, water quality monitoring, and air quality monitoring. The quality objective for the in-field measurement activities is to obtain accurate measurements of sample characteristics, including pH, conductivity, temperature, turbidity, dissolved oxygen, and/or redox potential, using appropriate equipment. Data are recorded in field logbooks or on field sampling sheets and calibration logs.

Calibration logs will be reviewed with other field documentation to identify potential impacts to data quality and usability.

Field logbooks/field forms are reviewed as part of the QC inspections.

Reconciliation with Data Usability Requirements

The data results will be examined to determine the performance that was achieved for the data usability criteria. The performance will then be compared with the project objectives and DQOs. Deviations from objectives will be noted. Additional action may be warranted when performance does not meet performance objectives for critical data. Options for corrective action relating to incomplete information, questionable results, or inconsistent data may include the following:

- Retrieval of missing information.
- Request for additional explanation or clarification.
- Reanalysis of sample from extract (when appropriate).
- Recalculation or reinterpretation of results by the laboratory.

These actions may improve data quality, reduce uncertainty, and eliminate the need to qualify or reject data. If these actions do not improve the data quality to an acceptable level, the following actions may be taken:

- Extrapolation of missing data from existing data points.
- Use of historical data.
- Evaluation of the critical/noncritical nature of the sample.

If the data gap cannot be resolved by these actions, the data bias and potential for false negatives and positives can be evaluated. If the resultant uncertainty level is unacceptable, the following action must be taken:

- Additional sample collection and analysis.

Appendix A GEI Field SOPs

STANDARD OPERATING PROCEDURES

AR-001 General Guidance on Work Zone Monitoring Methods

1. Objective

Protect human health by measuring air quality at the perimeter of a work area.

2. Execution

Walk-around perimeter and work zone monitoring for Total Volatile Organic Compounds (TVOC), Respirable Particulate matter less than 10 microns (RPM_{10}), and odor will occur along the perimeter of the project site on a regular and as-needed basis. Specific site conditions that will trigger walk-around perimeter or work zone monitoring include:

- visible dust
- odor complaints
- detection of TVOCs and/or RPM_{10} at levels approaching or exceeding action levels
- direction by the site oversight consultant or client

Perimeter air monitoring and work zone monitoring, in the absence of any specific triggering criteria, will be conducted on a regular basis during the normal work day. Particular attention will be given to the direction of any residences or other sensitive receptors.

At the time when a triggering condition is observed, the walk-around perimeter and work zone monitoring will occur continuously until the conditions that triggered the monitoring have subsided. Additional temporary monitoring points may be established due to changing site or meteorological conditions.

TVOC concentrations will be monitored and recorded using a Rae Systems MiniRAE 2000 Portable Ionization Detector (PID) or equivalent. RPM_{10} will be measured and recorded using a MIE personal DataRAM 1200 (PDR-1200) portable real-time aerosol monitor equipped with a PM-10 monitor and Gilian personal air sampling pump. AR-002 Suspended Particulate Matter in Ambient Air using the MIE DataRAM Real-time Aerosol Monitor (Portable) provides guidance on the use of this meter. Odors will be noted based on the n-butanol scale, as adapted from ASTM E544-99.

At each monitoring point, the 15-minute average value of TVOC and RPM_{10}, sample time, and sample location will be collected and recorded. The odor intensity based on the n-butanol scale will be monitored over a 15-minute period and recorded. At each location, air temperature, wind direction, and wind speed may be monitored and recorded using a hand-held wind meter.

Odors as a function of naphthalene concentration will be monitored over a 15-minute period and recorded. To measure naphthalene concentrations, the zNose™ Model 4200 system will be used. The zNose™ is an ultra-fast gas chromatograph (GC) that is capable of analyzing airborne concentrations of VOCs and SVOCs in less than one minute. The zNose™ uses a surface acoustic wave (SAW) detector that changes in vibration frequency as compounds elute from the column and condense onto the surface of the detector.

The zNose™ is a portable instrument and will be positioned downwind of the remedial activities. Up to five samples will be analyzed for naphthalene concentrations over a 15-minute period. The concentrations will be averaged to produce a 15-minute result. The calibration will be checked at the start of the day, at mid-day, and at the end of the day. An air blank will be run every two hours. A blank will also be run if a reading exceeds the calibration range of the instrument.

The zNose™ also has the capability of generating fingerprint images of the chemical constituents in the vapor called VaporPrints™. A VaporPrint™ of an air sample can be collected through a headspace analysis. This VaporPrint™ can be compared to others generated at the perimeter and off-site to see if remedial operations are the source of the odors. VaporPrints™ can allow for identification of odors that may not be affiliated with remedial operations.

To monitor cyanide (as hydrogen cyanide gas), a real-time hand-held meter in conjunction with the Dräger Chip Measuring System (CMS) will be used. Types of continuously monitoring equipment include the V-RAE by Rae Systems and the Mini-Warn by Dräger Safety Systems and are available from rental equipment suppliers. Due to potential interference from sulfur compounds, hydrogen sulfide gas (H_2S) will also be monitored for comparison to the hydrogen cyanide gas levels detected. Hydrogen cyanide gas detections will also be confirmed with CMS Dräger tubes due to this interference. The Dräger CMS can quantify other gases that could potentially provide false positives for hydrogen cyanide gas (including sulfur dioxide, hydrogen sulfide, phosphine gas, chlorine, and nitrogen dioxide) detected by the real-time meter.

At each location, air temperature, wind direction, and wind speed will be monitored and recorded using a hand-held wind meter.

STANDARD OPERATING PROCEDURE

AR-002 Air Sampling for Dust (Particulate Matter) using the MIE DataRAM™ Real-Time Aerosol Monitor

1. Objective

Describe standard procedures for the real-time monitoring of airborne particulate matter using a MIE DataRAM™ model DR-2000 real-time aerosol monitor.

The MIE DataRAM™ is a real-time, portable monitor that measures airborne particulate matter. It is capable of monitoring total suspended particulate matter, particulate matter less than 10 microns (PM_{10}), and particulate matter less than 2.5 microns ($PM_{2.5}$) by using an appropriate orifice to control the size of the particles being measured. The DataRAM can be programmed to collect continuous real-time data, or to record time averaged data.

2. Materials

- MIE DataRAM™ model DR-2000
- Shelter/Enclosure - a pre-constructed enclosure capable of protecting the instrumentation from severe weather conditions during sample collection
- Omnidirectional inlet
- Inlet heater
- $PM_{2.5}/PM_{10}$ impactor
- IBM compatible computer loaded with MIE DataRAM™ software
- Field notebook

3. Meter Calibration

- Assemble all necessary DataRAM™ attachments.
- Make sure the power selector switch on the rear panel is in the “on” position. Turn on the power by pressing the “on” button on the front display panel of the DataRAM™. “Main Menu I” will appear on the screen.
- Activate the zero mode by pressing the button indicating zero.
- When the screen indicates the zero mode is complete, activate the span check mode by pressing the button indicated, and follow the prompts that appear on the screen.
- Record the time of the zeroing and the calibration difference percent in the field notebook. If the zeroing procedure takes longer than 5 minutes press “exit” and then “off,” and then put the power switch on the rear panel of the instrument in the “off” position. Wait several minutes, turn on the power and zero the instrument again. If the calibration difference percent is more than ±5% then follow the “Calibr Diff” Resetting Procedure in the DataRAM™ Instruction Manual.
- Set the DataRAM™ to automatically log data. Refer to the Instruction Manual for details on how to set the data logging function.

- Record the instrument flow rate from the parameters menu in the field notebook.

4. Sample Collection

- Set the DataRAM™ at the predetermined sampling location in a rain or weatherproof containment, with only the inlet tubing exposed to ambient air.
- Start the run.
- When sampling is completed, terminate run and download data using the RS-232 cable connector and the MIE DR-COM software.
- Once the data file has been successfully downloaded and saved in an appropriate location, clear the data from the instrument memory.

5. Limitations

Each instrument must be calibrated using the internal reference standard and zeroed at the start of each sampling event and at a frequency of once per day throughout the duration of the sampling event.

The DataRAM™ can be programmed to collect continuous real-time data, or can collect "averaged" real-time data. These various options should be addressed prior to field operations and must be referenced in an approved work plan. This work plan must be available to all field personnel.

Project objectives will usually dictate the sampling location. In general, for air monitoring, meters are usually placed near breathing height and away from objects that can interfere with air motions. Since the DataRAM™ is measuring particulate matter, placement of the instrument directly on the ground should be avoided to prevent the sampling of dust concentrations that may not be representative of the air that is intended to be sampled (e.g. air at breathing height).

STANDARD OPERATING PROCEDURE

AR-005 Hydrogen Cyanide Work Zone Air Monitoring Procedures

1. Objective

Describe real-time monitoring of hydrogen cyanide gas during field activities.

2. Equipment

To monitor cyanide (as hydrogen cyanide gas), the GEI field representative should utilize a real time handheld meter in conjunction with the Dräger Chip Measuring System (CMS) during subsurface activities including subsurface excavations, borings and monitoring well installation, materials handling, and groundwater sampling in areas with confirmed or suspected cyanide impacts.

Continuous monitoring equipment includes the V-RAE by Rae Systems and the Mini-Warn by Dräger Safety Systems, and are available from rental equipment suppliers. Due to potential interference from sulfurs, hydrogen sulfide gas (H_2S) should also be monitored for comparison to the hydrogen cyanide gas levels detected. Hydrogen cyanide gas detections will also be confirmed with CMS Dräger tubes due to this interference. The Dräger CMS can quantify other gases that could potentially provide false positives for hydrogen cyanide gas (including sulfur dioxide, hydrogen sulfide, phosphine gas, chlorine, and nitrogen dioxide) detected by the real time meter.

3. Calibration

Prior to commencing work on-site, the real-time cyanide meter should be calibrated in accordance with the equipment manufacturer's specifications. If the meter is calibrated in the field, the daily calibration results should be recorded in the field notebook.

4. Execution

Cyanide will be monitored around the perimeter of the work zone on a regular basis. Continuous monitoring should be completed every fifteen minutes if sulfur odor or suspected purifier waste material (former MGP sites only) is encountered. Measurements should be monitored in the breathing zone and should be recorded into the field notebook or on an applicable form. In the event that hydrogen cyanide is detected, the GEI field representative should proceed as follows:

4.1. Action Level: HCN ≤1 ppm for 15-minute average using real time meter

- Run CMS Dräger tube.
- Continue monitoring with real time meter.
- Continue work if CMS Dräger tube for hydrogen cyanide reads <2 ppm.

4.2. Action Level: 1 ppm < HCN < 2ppm for 15-minute average using real time meter.

- Run CMS Dräger using hydrogen cyanide gas chip and confirm <2 ppm concentration.
- Continue monitoring with real time meter.
- Run CMS Dräger tube using sulfur dioxide, hydrogen sulfide phosphine chip to evaluate potential interference.
- Recalibrate the real time meter and continue to monitor the work zone.

4.3. Action Level: HCN 2 ppm on CMS Dräger tube

- Stop work and move (with continuous monitoring meter) at least 25 feet upwind from excavation or until continuous monitoring meter registers <1 ppm.
- Run CMS Dräger hydrogen cyanide chip and re-evaluate activities
- Continue monitoring with real time meter.
- Allow area to ventilate and continue to monitor while returning to the work zone.
- Do not move into an area when readings are >1 ppm without confirming with additional CMS Dräger measurement.
- May resume work if Dräger tube for cyanide reads <2 ppm.

5. Limitations

No air purifying respiratory protection is available for hydrogen cyanide gas.

The American Conference of Industrial Hygienists (ACGIH) Threshold Limit Value (TLV) for Hydrogen Cyanide is 4.7 ppm.

STANDARD OPERATING PROCEDURE

AR-006 Air Sampling for Volatile Organic Compounds (VOCs) using Summa Canisters

1. Objective

Describe standard procedures for the collection of ambient air samples to be analyzed for volatile organic compounds (VOCs) using Summa canisters. Typically, U.S. EPA Method TO-15 is used for laboratory analysis. The site-specific Work Plan should be consulted for proposed sample locations and sampling duration.

2. Materials

- Sampling canister
- Flow controller
- Vacuum gauge
- Wrench for removing fittings and assembling the sample train
- Data sheets for recording the sampling location, date, duration, starting and stopping times, and calculated sample volume
- Camera and measuring tape
- Weather station data
- PID

3. Sampling

This section details the sampling methodology and the media preparation by the analytical laboratory.

3.1. Sampling Equipment Overview

- The laboratory prepares the canister for sampling by cleaning and then evacuating the contents to a vacuum of approximately 29.9 inches of Mercury (in. Hg). Opening the stainless steel bellows valve allows the air sample to enter the canister. When the target volume of sample is collected, close the valve and return the canister to the laboratory.
- A flow controller is used as part of the sample train to control the amount of air allowed to flow into the container over time. Flow controllers are typically set to a flow rate that collects a sample continuously over a 1-hour (hr), 8-hr, or 24-hr interval. The sampling duration needs to be communicated to the laboratory prior to sampling, so that the laboratory can provide the appropriate flow controller.
- Summa canisters are typically used and named after the “Summa” process which describes the electro polishing of the interior surface of the canister to prepare it for sampling.
- The holding time for a standard VOCs list of EPA Method TO-15 is 30 days after sample collection, although some projects may require a shorter hold time.

3.2. Document Field Conditions

Document pertinent field conditions prior to sample collection:

- Record weather information, if available (such as precipitation, temperature, barometric pressure, relative humidity, wind speed, and wind direction) at the beginning of the sampling event. Record substantial changes to these conditions that may occur during the course of sampling. The information may be measured with on-site equipment or obtained from a reliable source of local measurements (e.g., a local airport). Data should be obtained for at least the past 12 hours.
- Sketch the site, area streets, neighboring commercial or industrial facilities (with estimated distance to the site), outdoor air sampling locations (if applicable), and compass orientation (North).
- Record pertinent observations, such as odors and readings from field instrumentation.

3.3. Sample Collection

- Collect samples in a clean Summa canister (or equivalent) using a flow controller calibrated for the anticipated sample duration (e.g. 8-hour, 24-hour, etc.). The flow controller flow rate should not exceed 0.2 liters per minute.
- Verify the initial vacuum of the canister using the vacuum gauge. If the canister vacuum is less than 25 in. Hg, do not use it. The procedure to verify the initial pressure is simple, and a missed step can compromise the validity of the sample media.
    i. Confirm the canister's bellows valve is closed by turning the knob clockwise to tighten.
    ii. Remove the brass cap from the canister inlet.
    iii. Attach the vacuum gauge.
    iv. Open and close the bellows valve quickly (a few seconds).
    v. Read and record the vacuum on the gauge as 'Initial vacuum' on the chain-of-custody (COC).
    vi. Confirm the bellows valve is closed by turning the knob clockwise to tighten.
    vii. Remove the vacuum gauge and replace the brass cap.
- <u>Begin Sampling</u>
    i. Confirm the bellows valve is open by turning the knob counter-clockwise to loosen.
    ii. Remove the brass cap.
    iii. Attach the flow controller.
    iv. Attach a "J"-shaped sampling cane to prevent precipitation from entering the canister.
    v. Place the canister at the sampling location open the bellows valve. If the sample is collected from breathing height (e.g., 3 to 5 feet above ground), then mount the canister on a stable platform such that the sample inlet should be at the proper height.

vi. Record the start date and time on the COC.
vii. Record the identification numbers for the canister and flow controller and the vacuum gage.

- Begin Sampling (with a field duplicate)
  i. Confirm the bellows valve is closed by turning the knob clockwise to loosen on both canisters.
  ii. Remove the brass cap from both canisters.
  iii. Attach a flow controller on both canisters.
  iv. Attached a "T"-shaped sample train designed for field duplicates to both canisters.
  v. Attach a "J"-shaped sampling cane to the common end of the sampling "T" to limit precipitation entering the canisters.
  vi. Place the attached primary and duplicate canisters at the sampling location open the bellows valve. If the sample is collected from breathing height (e.g., 3 to 5 feet above ground), then mount the canister on a stable platform such that the sample inlet should be at the proper height.
  vii. Record the start date and time on the COC.
- Monitoring Sample progress
  i. At regular intervals, record the vacuum on the flow controller to confirm that the vacuum is decreasing in the canister. If the vacuum reads 5 in. Hg or less the bellows valve should be closed and the sample interval ended.
  ii. Some residual vacuum is important to maintaining sample integrity. If there is no vacuum remaining, call the laboratory and discuss the sample viability with them. Evaluate whether another sample will be taken after sharing the laboratory's opinion with your project manager.
- End Sampling
  i. Sampling will end when the time interval (e.g., 8-hr period) is completed, or when the canister vacuum reads 5 in. Hg or less.
  ii. Close the bellow valve by turning the knob clockwise to tighten.
  iii. Remove the "J"-shaped sampling cane.
  iv. Remove the flow controller.
  v. Attach the vacuum gauge.
  vi. Open and close the bellows valve quickly (a few seconds).
  vii. Read and record the vacuum on the gauge as 'Final vacuum' on the chain-of-custody (COC).
  viii. Confirm the bellows valve is closed by turning the knob clockwise to tighten.
  ix. Remove the vacuum gauge and replace the brass cap.
- Sample Transport
  i. Return the canister, flow controller, and sampling cane to the laboratory in the boxes provided.
  ii. Fill out the COC and relinquish samples properly with flow controller and canister numbers on the COC.

iii. Place the COC in the box and retain a copy of the COC for your records.
iv. Tape the box shut.
v. Deliver or ship the samples to the laboratory as soon as practical to adequately meet the holding time of the sample.

4. General Guidance

- This method may be modified for indoor air sampling.
- Field Blank: Do not collect a field blank.
- Trip Blank: Do not collect a trip blank. The canister is prepared for sampling by evacuating the contents to a vacuum of, so no air exists for a trip blank to provide meaningful information.

STANDARD OPERATING PROCEDURES

DM-001 General Guidance on Determination of Appropriate Drilling Methods

1. Objective

There are multiple drilling methods which can be employed based on the type of stratum (e.g. overburden or bedrock) and the end use of borehole. End uses include geotechnical investigation, subsurface soil sampling, and monitoring well installation or a combination thereof.

The following text describes different methods of drilling with considerations for their use to collect groundwater and/or subsurface soil samples. Profiles of subsurface conditions encountered and well installation details must be recorded on logs. Procedures for field documentation are provided in Section 4 - Field Documentation.

2. Hollow-Stem Augers (HSAs)

Borings can be installed in unconsolidated formations using solid-stem or hollow-stem augers (HSAs). The augers are advanced by rotation and the drill cuttings are brought to the surface by travelling up the outside of the auger flights in a screw-like manner. HSAs have the advantage of allowing the well to be installed inside the hollow stem of the auger, which prevents the borehole from collapsing. Upon reaching the planned well depth, the casing and screen are placed inside the HSAs and the flights are individually removed while the annular space around the well is filled with the filter pack and grout, as appropriate. Conversely, solid-stem augers must be completely removed from the borehole before well installation, which can lead to collapse of the borehole. For this reason, solid stem augers are seldom used for installation of monitor wells.

HSAs come in a variety of sizes and allow collection of soil samples utilizing split spoons or Shelby tubes. Samples are collected ahead of the augers for determining soil/sediment type, stratigraphy, depth to the water table, and for collecting soil samples for chemical analysis. During this process, the standard penetration test (SPT, ASTM Method D 1586) can also be performed. The HSA method also has an advantage over mud-rotary drilling techniques in that drilling mud is not used. Drilling mud can contaminate the soil samples and potentially reduce the yield of the wells.

A disadvantage of the method is that HSAs cannot be used to drill into competent bedrock or through large boulders. Also, "heaving or running sands" can be forced up inside the augers as a result of strong vertical groundwater gradients, which can hamper efforts to collect soil samples or complete well installation. Furthermore, the maximum depth achievable using HSAs, which is generally shallower than other methods, is dependent not only on the ability of the rig (e.g., horsepower, rig-torque, weight of augers etc.), but also the lithology of the material drilled.

3. Rotary Drilling

Rotary drilling methods include both direct rotary and reverse-circulation rotary. Direct rotary is more commonly used in environmental investigations, whereas reverse-circulation rotary is used in drilling large-diameter water supply wells. In direct rotary drilling the borehole is advanced by rotating the drill pipe (rods) and bit to produce a cutting action. The cuttings are removed from the borehole by continuous circulation of a drilling fluid. The fluid or "mud" is pumped down the inside of the drill pipe and is circulated back to the surface on the outside of the pipe. The fluid removes the drill cuttings from the borehole and cools and lubricates the bit. Mud used during direct rotary consists of additives (e.g., bentonite), water, or air.

Reverse-circulation rotary drilling is similar to direct rotary except the drill rigs are larger and the flow of the drilling fluid is reversed. The drilling fluid moves upward inside the drill pipes and circulates back to the borehole via settling pits. The drilling fluid returns to the borehole via gravity and moves downward in the annular space between the drill pipe and borehole wall. Drilling fluids for reverse-circulation rotary are generally water and any suspended particles picked up from the surrounding formations.

Mud-rotary methods can be used to drill in both unconsolidated and consolidated (bedrock) formations. In addition, drilling mud stabilizes the borehole and limits the potential for borehole collapse. Disadvantages of using the mud-rotary method include the difficulty in determining the depth to the water table, the potential for drilling mud to impact soil samples and dragging of contamination into deeper zones since the drill cuttings are re-circulated in the borehole. Wells installed using this method typically take longer to develop than wells installed using the HSA or air-rotary methods due to the invasion of mud filtrate into the formation.

In air-rotary drilling, compressed air is directed down the inside of the drill pipe. As in mud-rotary drilling, air removes the cuttings and lubricates the bit. However, since air has no viscosity, it cannot be used to stabilize a borehole therefore, casing must be advanced in unconsolidated formations to keep the borehole open. This is why air rotary methods are best suited for drilling in bedrock formations. The percussion-type air-rotary "hammer" bit provides the best penetration rate when drilling bedrock consisting of crystalline rock. However, when drilling above the water table, an air-rotary bit can grind the soil and bedrock to a fine powder which is blown out of the hole with air and which has the potential to be inhaled. Therefore, drilling above the water table using air-rotary methods requires the addition of potable water to the borehole for dust control. In addition, the air compressor should be of the oil-less variety, or have a filter to prevent any oil from entering the borehole.

A disadvantage of using rotary methods while drilling in unconsolidated formations is the requirement of pulling the drill pipe out of the hole each time a split-spoon soil sample is collected (and the SPT is performed). This adds up to considerable amounts of time when deep wells are being installed or when continuous split-spoon

sampling is being performed. As stated above, split-spoons used to collect soil samples can become contaminated when they are advanced down a mud-filled borehole.

A special type of rotary drilling is bedrock coring, wherein a special core bit and barrel are used to retrieve relatively undisturbed core samples of the bedrock. Coring allows better characterization of bedrock lithology and other features including orientation of fractures and bedding planes, which can control contaminant migration. Core barrels can either be unoriented or oriented. An oriented core is scribed with respect to magnetic north. Although more expensive than collecting an unoriented core, this method gives the true orientation of the features encountered in the core.

Drilling fluids are generally air (air-rotary) or bentonite and/or water (mud-rotary). Water added to a borehole must be of potable quality. The source of the potable water used during the installation (and development) of monitor wells should be documented (e.g., in the Remedial Investigation Report).

Bentonite is high swelling clay with sodium montmorillonite as its primary clay mineral. Bentonite is added to water to increase the viscosity of the drilling fluid so that drill cuttings can be removed from the borehole more effectively. At the same time, the viscosity must be low enough to allow cuttings and coarse-grained particles to settle out once they are circulated out of the hole. Bentonite also adds weight to the drilling fluid, which helps to maintain borehole stability.

4. Sonic Drilling

The method involves driving a core barrel using vibration, rotation, and a downward force to collect soil samples. A sonic drill rig looks and operates very much like a conventional top-drive rotary or auger rig. The main difference is that a sonic drill rig has a specially designed, hydraulically powered drill head or oscillator, which generates adjustable high-frequency vibrational forces. The oscillator uses two eccentric, counter-rotating balance weights or rollers that are timed to direct 100 percent of the vibrational energy at 0 and 180 degrees. There is an air spring system in the drill head that insulates or separates the vibration from the drill rig itself. The sonic head is attached directly to the drill pipe or outer casing, sending the high-frequency vibrations down through the drill pipe to the bit.

A core barrel is advanced using vibration, rotation, and downward force to collect continuous soil cores up to 20 feet in length. The bit at the end of the core barrel contains carbide teeth allowing the core barrel to be advanced through most overburden, soft bedrock, and minor obstructions such as bricks and boulders. Once the core barrel has been advanced, a secondary or "over-ride" casing is advanced down to the same depth as the inner core barrel. The over-ride casing keeps the borehole from collapsing while the inner core barrel is removed. Once the core barrel is removed, the soil core is pushed out of the core barrel through the use of

vibration and either air or water pressure. Soil core diameters are dependent on the size of core barrel used and range from 3 to 12 inches. The use of multiple over-ride casings of increasing diameter allows the borehole to be telescoped down through multiple confining units. The setup used in sonic drilling makes this drilling method amendable to collecting soil cores and installing wells in angled boreholes. With only the bottom of the inner and outer core barrel exposed to the aquifer at any given time, determining the location of the water table can be difficult.

While this drilling method has the capability of drilling through and providing samples of coarse gravels, boulders, and tight clays, these situations will result in slow drilling or advancement of the core barrel. The result is a hotter core barrel and a longer contact time between the core barrel and the encased soil core. The aforementioned conditions will increase the probability that the sonic method will raise the temperature of the soil core and facilitate VOC and SVOC loss.

The ability to quickly install deep borings and wells, while generating a large-diameter continuous soil core, makes this drilling technique invaluable when continuous soil sampling is needed to assess deep or complex geological situations. However, sonic drilling's high cost, relative to other drilling methods, may be prohibitive for small projects or shallow boreholes. The higher cost of the drilling method should be weighed against the cost savings incurred due to its faster drilling rate and high quality of the soil core produced.

5. GeoProbe®-Direct Push

The method involves hydraulically pushing hollow rods into the subsurface for the purpose of collecting soil and/or groundwater samples (e.g., Geoprobe®). The method can be used to collect discrete soil samples or install small-diameter wells used to collect groundwater samples.

Advantages of the direct-push method include the relatively quick collection of groundwater samples and, when used along with a mobile laboratory, collection of data in “real” time. The method allows for collection of multiple samples in a day with the potential for achieving contaminant delineation in one mobilization of the field equipment. The data can also be used to select locations of permanent monitor wells.

Disadvantages of the method include the fact that the data quality achieved is often suitable only for screening purposes. Direct-push methods typically result in very turbid samples since an oversize borehole is not produced and a filter pack is not used. Turbid samples can produce higher metal concentrations in groundwater samples since metals are typically adsorbed onto soil particles. Use of direct-push methods can also cause cross-contamination since contamination from shallow zones may be driven down to deeper zones. Due to the narrow diameter of the direct-push rods, samples are often collected with peristaltic pumps. When samples are collected for volatile organic compounds (VOCs) using peristaltic pumps, some

of the volatiles may be lost due to the pressure drop produced by the suction lift. In such cases, the VOC data must be qualified accordingly. For this reason, use of the peristaltic pump for collecting groundwater samples for VOC analysis is not recommended and approval for its use should first be obtained from the project manager or geologist.

Another disadvantage of using direct-push technology for collecting groundwater samples is the potential to breech confining units. To prevent this, soil sampling using direct-push technology or conventional split-spoon sampling techniques should first be performed to identify the presence, depth and lateral extent of confining units. Pushing through confining units should be avoided if the presence of dense, non-aqueous-phase liquid (DNAPL) or very soluble compounds such as Methyl Tertiary Butyl Ether (MTBE) are suspected or the contaminant plume appears to be diving in the aquifer.

6. Contact

Gary Fuerstenberg

STANDARD OPERATING PROCEDURE

DM-002 Hollow-Stem Auger

1. Objective

Describe standard operating procedures for drilling of overburden soil borings using hollow-stem augers.

2. Execution

- Confirm that the appropriate measures have been taken for clearance of potential subsurface utilities. The responsibility for clearance may vary, depending on the client.
- Inspect the drilling rig to make sure it is clean and that the down-hole equipment has been steam-cleaned or pressure-washed. Record observations in the field notebook (See SOP FD-001).
- Observe that the augers are vertical when the first section is advanced into the ground.
- Use a 140-lb hammer to drive the sampler, unless conditions necessitate using a 300-lb hammer (see SOPs SM-001, *Split-Spoon Sampling* and SM-0003, *Soil Classification,* for details). Count and record the number of blows per 6-inch increments, confirming blow counts with driller if necessary).
- Decontaminate the split-spoon sampler after each use (see *Equipment Decontamination,* SOP QA-001) or use another decontaminated split-spoon sampler.
- Ensure that the drillers advance the augers only after they have inserted the auger plug (to prevent soil from entering the augers while advancing to the next sample interval).
- Request that the drillers remove the auger cutting bit/plug and insert the split-spoon sampler into the interior of the augers. Measure the stick-up of the rods attached to the sampler to ensure that the nose of the spoon is in virgin soil below the augers.
- Watch for signs of a soil strata change at depth during drilling (i.e., change in blow counts, change in soil color, soil wetness, soil contamination, bouncing of the drill rig, etc.). If important to the investigation, stop drilling and collect a soil sample.
- If subsurface soil samples are being collected with split-spoon samplers, ensure that the drillers use a 30-inch drop of the 140-pound hammer. The number of blow-counts for each 0.5 foot penetration provides important geotechnical data.
- Repeat until the borehole has been drilled to the desired depth.
- If a monitoring well is not installed in the soil boring, fill the boring with either cement/bentonite grout or properly-tamped and hydrated bentonite. Check with Project Manager and/or the appropriate regulatory personnel before using drill cuttings to backfill the boring.

- If a monitoring well will be installed, refer to SOP DM-007.
- Complete boring log and, if necessary, well installation logs (SOP SM-003, *Soil Classification*).
- Record boring locations on a site map and in a field notebook sketch. If the boring location will not be surveyed, measure each location from on-site reference points and record the information in the field notebook so that the location can be plotted on site figures.

3. Limitations

- In areas of significant soil contamination, hollow-stem augers may cross-contaminate upper soil layers as contaminated cuttings move up the auger flights. The potential also exists for contaminated augers to carry contamination to deeper soil strata
- If significant unanticipated contamination is encountered during drilling, stop drilling to confer with the project manager and evaluate health and safety conditions. If the borehole is to be advanced below the contaminated strata, use telescoping techniques (see SOP DM-008 *Monitoring Well Telescoping Techniques*) to avoid cross-contaminating underlying geologic strata.
- When drilling below the groundwater table in fine to medium sands, the potential exists for the phenomenon of “running sands” or “blow in” to occur. Frequent measurements inside the hollow-stem augers after the drill bit/plug is removed will indicate if running sands are present. If sands start to flow into the auger, pour clean water into the augers and keep the augers filled during sampling.
- If necessary, arrange for the storage of contaminated soil cuttings and water in drums or other appropriate containers in a secure place at the site. Containers should be labeled.
- Plan the drilling program to drill borings from the least- to most-contaminated areas. Be prepared in advance and know where alternative drilling locations are in the event that problems are encountered at each planned soil boring location. Alternative locations will need to have utility clearance.
- Down-hole drilling equipment should be steam cleaned or pressure-washed between holes unless otherwise directed by the project manager.
- Record when standard operating procedures are deviated from. The drilling inspector should also record any detected odor from the boring and depth encountered.

STANDARD OPERATING PROCEDURE

DM-003 Air Rotary Drilling with Casing

1. Objective

Describe standard operating procedures (SOP) for drilling of soil borings using casing by either the rotary method or air method.

2. Execution

- Confirm that appropriate measures have been taken for clearance of potential subsurface utilities. The responsibility for clearance may vary, depending on the client.
- Inspect the drilling rig to make sure it is clean and that the down-hole equipment has been steam-cleaned or pressure-washed. Record condition of down-hole drilling equipment. Record all observations in the field notebook (See SOP FD-001).
- Confirm that the casing (i.e., the borehole) is vertical when the first section of casing is advanced into the ground.
- For all soil samples, use a 140-lb hammer to drive the sampler, unless conditions necessitate using a 300-lb hammer (see SOP SM-001 *Split-Spoon Sampling* and SOP SM-003 *Soil Classification*–for details). Count and record the number of blows per 6-inch increments, confirming blow counts with driller if necessary.
- Decontaminate the split-spoon sampler after each use (see SOP QA-001 *Equipment Decontamination).*
- Advance the casing with the drive hammer and periodically clean out cuttings using a pneumatic hammer. A water spray and shield may be used for dust control and to control rock chips.
- Potable water should be used as the drilling fluid. If subsurface soil is sufficiently permeable to require a thicker fluid, drilling mud may be used to increase fluid viscosity, with prior approval from the project manager.
- To continue advancing the boring, additional lengths of casing are added one at a time, repeating this sequence until the required depth is reached.
- If an obstruction is encountered, the driller should attempt to penetrate the obstruction with a pneumatic hammer.
- If a monitoring well is not installed in the soil boring, fill the boring with either cement/bentonite grout or properly-tamped and hydrated bentonite. Check with Project Manager before using drill cuttings to backfill the boring.
- If a monitoring well will be installed, follow SOP DM-007.

- If the boring location is not going to be surveyed, measure each location from on-site reference points in the field notebook so that it can be relocated and plotted on figures.

3. Limitations

- To advance the boring, it may be necessary to use casing to maintain air pressure. Additional lengths of casing are then added one at a time, repeating this sequence until the required depth is reached.
- If unanticipated contamination is encountered, stop drilling to confer with the project manager and evaluate health and safety conditions.
- If the borehole is to be advanced below the contaminated strata, use telescoping techniques (see DM-008 Monitoring Well Telescoping *Techniques)* to avoid cross-contaminating underlying geologic strata.
- When drilling below the groundwater table in fine to medium sands, the potential exists for the phenomenon of "running sands" to occur. A head should be kept on the borehole at all times.
- Arrange for the storage of contaminated soil cuttings and water in drums or other appropriate containers in a secure place at the site (see SOP SC-003, *Investigation Derived Waste Management*).
- Plan the drilling program to drill borings from the least to most contaminated areas. Be prepared in advance and know where alternative drilling locations are in the event that problems are encountered at each planned soil boring location. These locations must also have been cleared by the state utility service prior to drilling.
- Document variations from standard operating procedures.

Cathy Johnson

STANDARD OPERATING PROCEDURE

DM-004 Sonic Drilling

1. Objective

Describe common sonic drilling procedures.

Prior to drilling confirm that utility clearance has been completed and that the drilling rig has been appropriately decontaminated.

2. Execution

- Collect soil cores in runs of 5 to 10 feet. Some sonic rigs can collect a 20 foot sample, but the process generates a significant amount of heat that may degrade sample quality.
- Classify and sample the soil located within the liner.
- Excess soil should be placed in a 55-gallon drum for disposal.
- The core barrel should be cleaned with tap water following each use.
- The core barrel is then advanced within the isolation casing to collect the next soil core interval.
- Add water between the inner core barrel and the outer override casing. This will reduce friction between the casings and adsorb heat.
- Maximize drilling advance rate. The faster the core barrel is advanced, the less likely the core barrel will heat up. Drilling with a 3-inch diameter core barrel and a 5-inch diameter override casing, instead of the standard 4-inch core barrel and 6-inch over-ride casing, may increase advance rates and reduce the potential for soil core heating.
- If a significant decrease in drilling advance rate is observed, stop drilling and remove soil that has accumulated in the core barrel. Resume drilling through the resistant material (gravel, boulder, hard clay, etc.). When the resistant material has been penetrated and the drilling advance rate increases, stop drilling and remove what material has accumulated in the core barrel.
- Wash down the core barrel with cool water to cool the core barrel and associated casing, and resume drilling.
- If a well is to be installed in the borehole, the sandpack and grout are placed as the core-barrel and over-ride casing(s) are selectively vibrated out of the ground. The vibratory action should facilitate settlement of the sandpack and grout. Upon completion, no casing is left in the ground other than the well casing and screen.

3. Limitations

- Disturbance of the soil core is most likely to occur during removal of the soil core from the core barrel. The soil cores are usually vibrated out of the core barrel into plastic bags approximately 5 feet in length. As the plastic bags are

a little larger than the soil core itself, fragmentation of the soil core may occur as the core is extruded into the bag or while the bagged core is being moved in an unsupported manner. Soil conditions that are prone to disturbance include wet or dry zones that contain little or no fines, and well graded sands that contain significant volumes of water.

- If integrity of the soil core is of concern, the following procedures should be implemented:
  - Measures should be taken to ensure that the core, from the time it is extruded from the core barrel, is rigidly supported through the use of some type of cradle or carrying device.
  - The core should not be removed from its cradle until all sampling of the core has been completed. Acrylic liners are available for some core sizes and can be used to hold the core together upon removal from the core barrel.
  - If the soil is to be sampled for volatile organic compounds (VOCs), acrylic liners must be used.
  - Sampling of the soil core for VOCs or semi-volatile organic compounds (SVOCs) must be approved on a case by case basis. Proposals for VOC or SVOC soil core sampling must include provisions to minimize core fragmentation and heat generation, such as:
    - Acetate liners in the core barrel so that the soil core does not have to be extruded out of the core barrel.
    - Limit the length of soil core generated during a given downhole run.
    - Implement practices to reduce the residence time of the soil core in the core barrel.
- For the analysis of SVOCs, the use of the acetate liners is not required.
- The large diameter of the core barrel enables ground water sampling equipment to be placed inside the core barrel so that discrete depth groundwater samples can be collected during borehole advancement.

STANDARD OPERATING PROCEDURE

DM-006 Geoprobe® Direct Push Boring

1. Objective

Describe standard operating procedures (SOP) for drilling of overburden soil borings using Geoprobe® and MacroCore® technologies.

2. Execution

- Confirm that appropriate measures have been taken for clearance of potential subsurface utilities. The responsibility for clearance may vary, depending on the client.
- Inspect the drilling rig to make sure it is clean and that the down-hole equipment has been decontaminated (QA-001). Record condition of all down-hole drilling equipment.
- Make sure the sampler is fitted with a piston rod assembly to block the sample tube until the desired subsurface sample interval is attained. Upon reaching the target sample depth, the piston tip will be released and the discrete sampler device is then advanced to collect the representative sample. This reduces the volume of slough that is collected.
- When the sampler is brought to the ground surface, it should be opened immediately, and the length of recovery should be measured and recorded.
- Log the soil sample using USCS procedures (SOP SM-003). Collect analytical samples if necessary (SOP SM-001).
- Decontaminate the cutting shoe if necessary (SOP QA-001 Equipment Decontamination) and have driller reassemble the parts with a new liner.
- Repeat the procedure described above until refusal or the boring is terminated.
- Periodically verify that depths cited by drillers are accurate.

3. Limitations

- If significant unanticipated contamination is encountered during drilling, stop drilling to confer with the project manager and re-evaluate health and safety conditions.
- Arrange for the storage of contaminated soil cuttings and water in drums or other appropriate containers in a secure place at the site (see SOP SC-003, *Investigation Derived Waste Management*).
- If possible, plan the drilling program to drill borings from the least to most contaminated areas. Be prepared in advance and know where alternative drilling locations are in the event that problems are encountered at soil boring locations. These locations must also have been cleared by the state or local utility service prior to drilling.

STANDARD OPERATING PROCEDURE

DM-007 Monitoring Well Construction and Installation

1. Objective

Describe installation procedures for overburden monitoring wells screened across or below the groundwater table.

Well dimensions (well diameter, screen length, and screen slot-diameters) will be specified in the Work Plan. This SOP assumes the monitoring wells will be constructed of flush-joint PVC pipe and the screened section will have factory-slotted openings.

2. Execution

Attachment A provides a diagram of typical shallow, intermediate, and deep groundwater monitoring well construction detail. A Groundwater Monitoring Well Installation Log is in Attachment B.

- Measure and record the depth of the completed soil boring before beginning the well installation.
- If possible, measure the depth to groundwater in the borehole over a 10 to 15 minute period to ensure that the groundwater elevation has approximately stabilized. Compare the saturated soil depth estimated from split-spoon samples to the measured water level in the borehole. If drilling water has been used during boring advancement, pump the water out of the borehole to the static water depth, based on examination of the soil samples, and monitor the recovery of groundwater until the level has stabilized.
- If it is not possible to accurately measure the depth to groundwater in the borehole due to low permeability in the formation, use the saturated soil depth observed in the collected samples or measured water depth in a nearby existing monitoring well to estimate the depth to water in the borehole.
- For shallow monitoring wells, select the monitoring well screen and riser lengths so that the slotted section of the screen intersects the groundwater table. Screen lengths of 15 feet or less are preferred and 10 foot screens are most common. If the water table is seasonally high or low or if the well is in a location where the water table is likely to be tidally influenced, appropriately place the screened section to allow for the screen to intersect likely future water tables.
- For intermediate or deep wells screened entirely below the water table, select the monitoring well screen and riser lengths as described in the Work Plan. Screen lengths of 10 feet or less are preferred.
- If the borehole is deeper than the desired well depth or the bottom of the well is close to a change in soil strata, then fill the base of the borehole with bentonite. Keep in mind that bentonite swells when hydrated, and that filter

sand should be placed at the bottom of the borehole above the bentonite before installing the well.

- Prevent well materials from contacting foreign substances during installation. Precautions may include requiring the driller to wear clean gloves while handling well materials and requiring that well materials not be placed onto the ground or pavement without a protective barrier such as polyethylene sheeting being present
- Confirm that the driller installs a minimum one-inch sump with a bottom cap to the bottom of the well screen. See the Work Plan for locations that may require larger sumps.
- Monitoring wells can be constructed of either 1, 1.5, 2 or 4 inch inner diameter (ID) Schedule 40 threaded flush-jointed PVC. Refer to the work plan for the site-specific requirements. Flush-threaded well materials should be used. Do not allow the driller to use glues, as they typically contain solvents that could affect on groundwater quality.
- Stainless steel well materials may be used if required in the Work Plan. Select slot size based on grain size of the formation and on requirements in the Work Plan.
- Confirm that the driller places at least 12 inches of clean uniformly graded medium quartz filter sand pack into the base of the borehole, if required in the Work Plan.
- The driller should remove the drilling casing/augers from the borehole slowly, at a maximum of 2-foot intervals, at the same time that filter sand is added. The drillers should take frequent measurements of the depth to sand.
- Confirm that the driller has added adequate sand to surround the area around the slotted section. The filter sand should extend at least 2 feet above the top of the slotted section.
- The driller should place a bentonite seal above the filter pack. If the seal is above the water table, use at least 5-gallons of potable water to hydrate the bentonite before grouting the remaining annular space, or otherwise backfilling the remaining annular space as discussed with the Project Manager. Tamp seal. It should extend 1 to 2 feet above the filter sand.
- If required by the Work Plan, the driller should use bentonite-cement and grout the annular space from the top of the bentonite seal to the ground surface. Bentonite cement grout should be placed using tremie methods. Grout should be mixed in approximately the following proportions: 7.5 gallons water to one 94-lb bag of cement to 2-4 lbs of pulverized bentonite. The grout must be mixed using a pump (such as one on the rig) to ensure proper mixing.
- The drillers should cut the monitoring well riser at an angle or make "V"-notch in the riser pipe as a benchmark for surveying and groundwater measurements. The driller should cut the well riser so that the top of the well will be approximately 3 inches below the top of protective casing. The top of

the riser should be close enough to the top of the surface casing to allow reading of depth markings on a water level indicator tape.

- The protective surface casing is either a flush-mounted roadbox or a steel "stick up" pipe. The base of either type of casing should extend at least 1 foot into the grout below the ground surface (below the frost line) whenever possible.
- The protective casing should be set by placing cement in the annular space between the protective casing and the borehole up to the ground surface. If possible, the driller should slope the cement radially away from the protective casing at the ground surface to promote surface water runoff.
- In areas of high traffic or areas of parking lots and/or roadways where plowing occurs, set the roadbox flush with the ground surface to avoid damage to the well.
- If the well is installed in a high-traffic area and is completed with a steel "stick up" pipe, additional protection such as steel pole bumpers around the steel "stick up" pipe may be necessary.
- If possible a locking cap should be placed on the steel "stick up" pipe. If the surface casing is flush mounted, a locking expansion plug should be placed, if possible, inside the top of the well riser pipe.
- All well locations should be photodocumented in accordance with SOP FD-004 Photodocumentation.
- Label the outside of the protective well casing with a paint pen. If the well is not going to be surveyed, measure the location to nearby landmarks so that the well may be located in the future and plotted on figures. Make sure to enter this information in the field notebook). If possible, place a brightly colored stake or other identifier adjacent to the well.
- Develop the well (see SOP DM-009, *Monitoring Well Development*).

3. Limitations

- Do not screen across different hydrostratigraphic units (for example, outwash sands, confining layers or till) unless specified in the Work Plan or approved by the Project Manager.

- If the formation is composed of a material that is uniformly coarser than the filter sand, the grain size of the filter sand should be increased. Consideration should also be given to changing the slot size on the well screen. Differences in average grain size should generally not be greater than a factor of two to four times.

- Do not use drill cuttings to backfill during monitoring well installation unless specified by the work plan or project manager.

STANDARD OPERATING PROCEDURE

DM-008 Telescoped Drilling

1. Objective

Describe telescoped drilling used to prevent the connection of two stratigraphic layers during boring advancement and/or monitoring well installation. This type of drilling is commonly used to prevent higher density contaminants (such as in coal tar or chlorinated solvents) from migrating downward in a boring.

Telescoped drilling is used with air rotary drilling (SOP DM-003) and drive-and-wash drilling (SOP DM-005). Refer to these SOPs for procedures to be performed prior to installing casing.

2. Execution

- Confirm that drilling tools have been appropriately decontaminated.
- Drill or core at least four feet into the stratigraphic unit (bedrock, till, etc.) to confirm the unit and provide a "socket" into which permanent casing can be grouted.
- The socket diameter should be at least two inches larger that the casing to be installed.
- The casing that will be installed should be large enough to allow smaller diameter drilling tools inside it to advance deeper, without the possibility of cross-contamination or hydraulic connection between the shallower and deeper units. For example, a six-inch casing is large enough for use of 4-inch tools inside it.
- Freshly mixed grout is required to set the large-diameter casing into the unit to be isolated. Depending on application, a mixture of Portland cement and bentonite meets most grouting requirements. For proper consistency, use no more than 6 gallons of water per 94-pound sack of cement. Add a few pounds of bentonite or hydrated lime per sack of cement for better flow.
- The driller should use a tremie pipe to deliver grouting outside the casing. Follow these steps to complete grouting using this method:
    i. Lower the casing to the bottom of the borehole. Make sure that the lower end of the casing is tightly seated at the bottom.
    ii. Mix a sufficient quantity of grout and pump it through the tremie pipe. As the grout is placed, lift the tremie pipe slowly, but keep the lower end submerged in the grout.
    iii. Fill the casing with water as the grout is placed to balance the fluid pressure inside and outside the casing. Doing so prevents grout from leaking under the bottom of the casing.

iv. Allow the grout to set for a minimum of 24 hours. Some regulatory agencies require 48 hours.
v. Using smaller diameter drilling tools, advance through the existing casing into the underlying unit to continue investigation. Install additional casing or PVC into the unit, or leave it as an open borehole.

3. Limitations

- If dense non-aqueous phase liquid (DNAPL) and/or dissolved contamination is suspected in the shallow (weathered) bedrock, then installation of casing in the rock may not be wise. It could hide the DNAPL from detection and/or result in cross-contamination of deeper rock. A shallow bedrock well may be called for to characterize the impacts. Consult with the Project Manager.
- Other casing installation methods, such as pressure-grouting may be more appropriate. Consult with the Project Manager.

STANDARD OPERATING PROCEDURE

DM-009 Monitoring Well Development

1. Objective

Describe standard procedures to remove fluids from monitoring wells (introduced during drilling) and maximize the movement of groundwater into the well by removing fine particles in the well and sand pack around the screen.

2. Execution

To prevent cross contamination between monitoring wells, use dedicated equipment and/or appropriately decontaminated equipment to perform monitoring well development. See SOP QA-001 Equipment Decontamination and the Work Plan for more information.

For deep or large diameter monitoring wells, it may be necessary to use a re-usable pump system, such as a Grundfos pump, to develop monitoring wells.

- Calculate the volume of water in the monitoring well (one well volume) using the following table:

Well diameter (inches)	Volume (gal/ft)
1	0.04
1.5	0.09
2	0.16
3	0.36
4	0.65
6	1.50

  The equation used to establish these volumes is presented in Section 4.

- Calculate or estimate the amount of water introduced to the borehole during drilling. At a minimum, this is the amount of water that should be removed during development. Removing less water than was introduced and allowing additional time for the surrounding formation to clear of injected drilling fluids may be considered as an alternative if the volume of introduced water was large.

- Record the volume of water purged in the field notebook or on the Monitoring Well Sampling Form (Attachment A).

- Collect a sample of water from the monitoring well with the selected submersible pump (e.g. 12-volt whale pump or Grundfos pump), a bailer, or a

Waterra system. Record the physical properties (color, turbidity, odors, etc.) of the sample.

- The volume of water that should be removed will depend on the work plan, local regulatory guidance, and/or the volume of water that was introduced during drilling and well installation. Typical guidance for the removal volume includes:

    - Ten well volumes.
    - The volume of fluid added during drilling.
    - The volume required to remove enough suspended particles so that the turbidity of the water is less than 50 nephelometric turbidity units.

If needed, pump the ground water into a 5-gallon pail so that the volumetric flow rate and total water volume from the pump or bailer can be calculated.

Measure the groundwater level in the well during development to assess if the pumping rate is sufficient to create a drawdown in the well.

Observe the groundwater every few well volumes during the pumping and record the physical properties (color and turbidity).

If required by the Work Plan, conduct surging in the monitoring well. See the Work Plan for the method of well surging to be used. If surging is necessary, do so only after initial pumping at the well has occurred and fine sediments have been removed.

Slowly move the surge block up and down in the well. Periodically remove the surge block and purge the groundwater until it is relatively clear again. Start at a slow pace and progress to a faster surging action through time.

3. Limitations

Always remove groundwater with fine particles from the well before surging. The fine particles may be forced into the well screen by the surging action. They may also damage the pump.

If the ground water in the monitoring well is contaminated, the water removed during well development may need to be placed in a properly-labeled drum and disposed of in accordance with local, state, and federal regulations (see SC-003 Investigation Derived Waste).

If the soils around the well screen are composed of fine-grained silts and clays, over-pumping and mechanical surging is not recommended since these more vigorous

techniques can cause mixing of the fines into the filter pack. To develop these wells, use of a bailer is recommended.

There are occasions when the turbidity of groundwater cannot be meaningfully reduced. On these occasions, a minimum of ten volumes should be removed, and the Project manager should be consulted.

Sampling of groundwater should generally not occur within one week after development. In some regions or regulatory jurisdictions, a minimum of two weeks may be required before sampling. If no water was introduced to the formation during drilling, this waiting period may be shortened if required by the project. See the Work Plan for additional information.

STANDARD OPERATING PROCEDURE

FD-001 Field Notebook

1. Objective

Describe methods for documentation of field activities.

Documentation of site activities is a crucial part of the field investigation process. The field notebook serves as the record of field activities performed or observed during the project. It provides a factual basis for preparing field observation reports, if required, and reports to clients and regulatory agencies. Example field notes are provided in Attachment A.

2. Execution

- Use a separate all-weather bound notebook for each site/location/project number. Spiral notebooks should not be used because pages can be easily removed.
- Write neatly using black or blue pen, preferably a waterproof pen. Use of pencil is also acceptable only with approval of the project manager, such as in but not limited to, certain field conditions [e.g., cold or wet weather].
- Write the project name, project number, book number (i.e., 1 of 3), and date on the front cover. On the inside cover, identify the project name, project number, and "Return Book To:" the office address of the project manager.
- Number all of the pages of the field book starting with the first entry.
- Record activities as they occur. Record only facts and observations, regardless of whether they appear to be relevant at that time.
- Identify conditions or events that could affect/impede your ability to observe conditions (e.g. snow-covered ground surface, inability to access areas of interest).
- Neatly cross out mistakes using a single line and initial them. Erasures are not permitted.
    - If an error is made on an entry in the field notebook, the individual who made the entry should make the corrections. The corrections must be initialed and dated by the person making the correction.
- Sign or initial and date the bottom of every page with an entry if the project requires such documentation.
- Place a diagonal line through unused portions of a page.
- Record the following information upon each arrival at the site:
    - Date/time/weather.
    - GEI personnel.
    - Purpose of visit/daily objectives.
    - People (client, contractor, landowners, etc.) present upon GEI arrival.

- Record the following information during the course of the day:
  - Conversations with contractors/subcontractors, clients, visitors, GEI staff, landowners (site or abutters). If possible, record complete names, titles, and affiliations.
  - Time of arrival and departure of individuals.
  - Activities as they occur.

- Additional examples of observations to record may include and are not limited to:
  - Type and quantity of monitoring well construction materials used.
  - Use of field data sheets or electronic logging equipment (e.g. boring logs, monitoring well sampling logs, etc.).
  - Ambient air monitoring data.
  - Field equipment calibration information.
  - Locations and descriptions of sampling points.
  - Contractor/Subcontractor progress.
  - Sample media (soil, sediment, groundwater, etc.).
  - Sample collection method.
  - Number and volume of sample(s) collected and sample bottle preservatives used.
  - Sample identification number (s) and date and time of sample collection.
  - Approximate volume of groundwater removed before sampling.
  - Any field observations made such as pH, temperature, turbidity, conductivity, water level, etc.
  - References for maps and photographs of the sampling site(s).
  - Information pertaining to sample documentation: bottle lot numbers/ dates, method of sample shipments, chain-of custody record numbers, and overnight shipping numbers.
  - Surveying data (including sketches with north arrows).
  - Changes in weather.
  - Rationale for critical field decisions.
  - Recommendations made to the client representative and GEI Project Manager.
  - Site sketch of conditions at the end of the day.
  - Summary of work completed/work remaining.
  - Allow time at the end of the day to complete entries in the notebook.

STANDARD OPERATING PROCEDURE

FD-002 Field Observation Report

1. Objective

Describe methods to generate a Field Observation Report.

The Field Observation Report is used to record a summary of activities, observations, and decisions made during the day's field work. The daily field observation report serves as a permanent record of the day's activity for the Project Manager (PM), In-House Consultant (IHC), and/or client.

2. Execution

- If required, at the close of the day's field work, a Field Observation Report should be prepared by the individual responsible for the field notebook. This report should be completed before leaving work for the day. Contents of the report should include, at a minimum, the following information:
    - A record of person(s) present at the site, time of arrival, departure times (e.g., GEI, contractor(s), client, etc.).
    - A record of the daily objective(s) and the activities performed (e.g., drilled five borings in the overburden).
    - A summary of deviation(s) from the field plan or objectives.
    - A summary of field decisions made, who made them, and the basis for such decisions.
    - A diagram, sketch, and/or map showing the location and extent of the work or other significant observation(s) made during the day.
    - Recommendations that may result from field observations and actions that may result from implementation of those recommendations.
    - A summary listing and field sketch showing location(s) of field activity.
- Submit a draft report to the PM/IHC for review. Complete any editorial changes, sign, date, and submit the report to PM/IHC for approval/signature. Field Observation Reports should be written neatly. They are not required to be typed unless specifically requested by the PM.

3. Limitations

- The Field Observation Report is not a substitute for the field notebook.
- Not all projects require daily Field Observation Reports.
- The Field Observation Report should be based primarily on factual information. Opinions, if necessary, should be identified as such. Any speculation should be clearly noted in the report as such.

- The Field Observation Report should never be released to anyone other than the PM/IHC prior to review and sign-off unless explicitly authorized by the PM/IHC.

Contractor:	ABC Contracting	**Page:**	1 of 2
Subcontractor:	NA	**GEI Proj. No.**	99999-0

SOP FD-002 - Attachment A – Example Field Observation Report

Time of Arrival: 0700 **Departure: 1440** **Weather: Overcast, Raining, 55^{0}F**

Persons Contacted, Company
Jane Doe, ABC Contracting

GEI Representatives
Bill Smith

Purpose of Site Visit: To observe excavation of soils for new guard booth and sidewalk.

Observations:

1. **Excavation**
   a. Areas for guard booth and sidewalk were laid out by ABC with stakes, string, and spray paint. Locations were between the pavement and wetland area; no excavation occurred in the wetland area.
   b. Staging area for soil stockpile was located to the west of the excavation, along the fenceline; polyethylene sheeting was placed beneath the pile.
   c. HDPE membrane delivered to site; stored in garage area through the inside fence.
   d. ABC crew began hand digging area for sidewalk and guard booth. Sidewalk area measured 22 feet long by 4 feet wide by 4 inches deep. Guard booth area measured 12 feet long by 10 feet wide by 9 inches deep. Utility pole and bollard locations started today.
   e. Rain continued to get worse in the afternoon; ABC covered the entire excavation and soil stockpile with poly sheeting and secured the sheeting with grade stakes.

2. **Subgrade Preparation**
   a. Subgrade preparation for the sidewalk and guard booth areas at the site is complete.

3. **Dewatering**
   a. No dewatering occurred today.

4. **Air Monitoring**
   a. During excavation, I monitored the breathing zone of the workers with an organic vapor meter (OVM). No headspace readings were measured in soil samples S-1 through S-8.

STANDARD OPERATING PROCEDURE

FD-003 Sample Management and Chain of Custody

1. Objective

Describe methods to label sample containers, manage the samples, and prepare Chain of Custody documentation for the samples. Sample transport is also addressed.

2. Project Setup

When setting up a sampling event, inform the recipients of the samples (laboratories) and recipients of laboratory results (data group and project managers). Discuss with the laboratory the sampling media, turnaround times, and reporting limits for appropriate regulatory criteria for the site. Include the data group on correspondence so that turnaround times, data validation, and project deliverable schedules can be tracked successfully.

- Laboratory - Number of samples, analyses needed: bottle orders and holding times, turnaround times needed, reporting limits needed for regulatory criteria.
- Data group - Number of samples, analyses requested, turnaround times and reporting limits requested, data validation needed, regulatory criteria to use for tabulating results, deliverables needed, and project name and number.
- Schedule - Inform the laboratory and Data Group of schedule delays, changes to analyses, and expediting.

3. Sampling Execution

- Review the work plan prior to sampling to determine the following:
  - Sample matrix and sampling method.
  - Required analysis and sample volumes.
  - Sample container type and preservative requirements.
  - Required analysis methods and/or report formats.
  - The turnaround time required by the project.
  - If the data will be sent directly from the laboratory to the data validator, Project Manager, or Data Group.
  - Holding time restrictions for sampling media and analytical methods.
  - Sample naming convention used for this project site.
- Sample labels should be filled out using a waterproof or permanent marker or pen. Required information includes:
  - Sample ID.
  - Date and time (military time) of sample collection.
  - Project number.
  - Sample preservatives.
  - Sampler's initials.
  - Laboratory analytical methods.

- Place the label on the jar or bottle, not on the cap. Sample custody begins at this time.
- Record the above information in the field notebook.
- Individually wrap sample jars with packing material, if needed. See SOP SC-002 for guidance on packaging samples for shipment to the laboratory by way of common carrier. Place samples in a cooler with bagged ice or freezer packs (blue ice) immediately after collection. Add sufficient ice or freezer packs to cool samples to approximately 4°C.
- Complete a chain of custody (COC) for the samples as described below. GEI or laboratory COCs may be used as long as they contain fields for all required sample information as described in Section 2.1.

3.1. Chain-of-Custody (COC) Completion

- Fill out COC neatly and in permanent ink. Alternatively, an Excel version of the GEI COC is available and can be filled out electronically.
- Certain analyses (i.e. air analysis by TO-15) require specialized, laboratory issued COCs. Make sure any specialized COCs are available before sample collection.
- Record the project name and number, the sampler's name(s) and the state where the samples were collected.
- For each sample, enter the sample identification number, date and time (military time) collected, the number of sample containers, and any additional information to fulfill project, client or regulatory requirements.
- Record the type of analysis (including laboratory method; e.g. EPA-SW846 Method XX) requested and the preservative (if appropriate) in the vertical boxes.
- Field duplicates should be anonymous to the laboratory, but must be recorded for use by the Data Group. To keep track of this information, link the field duplicate with the proper sample in the field notebook. If required by the Project Manager or Data Group, also document this information on or attach a note to the GEI copy of the COC.
- Trip blanks for large sites should be named similar to the samples they are collected with so that there are not two of the same sample name for the same site. For example, "OU1TB-122509" and "OU3TB-122509" would avoid any mistakes.
- Strike incorrect entries on the COC with a single line, followed by the initials of the person making the correction, the date, and the correct entry.
- When sample custody is ready to be relinquished, complete the bottom of the form with date and time (military time) and signatures of relinquisher and receiver of samples as indicated. The sample collector is always the first signature while the analytical laboratory is the final signature. Theoretically, all individuals handling the samples between collection and laboratory should sign the form; however, if a common carrier (i.e., Federal Express, UPS) is used for shipping, GEI must identify the carrier in the 'Received by' box on the

COC. If the sampler hand delivers the samples to the laboratory, the received box must be signed by the laboratory.

- If the samples are placed in a designated secure area (e.g. GEI sample fridge), note this location in the "Received by" box on the COC.
- GEI uses both single sheet and triplicate COCs. If using the triplicate COCs (white, yellow, and pink copies), the pink copy should be retained by the sampling personnel and provided to the Data Group for proper filing. The white and yellow copies should accompany the samples to the laboratory.
- If you are using the single sheet COC, make a copy of the COC after it has been signed by the lab courier and forward it to the Data Group.
- Prior to sample shipment by common carrier, the COC must be placed inside the cooler in a Ziplock bag or other watertight package.
- If a common carrier such as FedEx is used to transport the samples to the laboratory, include the carrier tracking number and identify the carrier in the "Received by" box on the COC.
- If a courier is used to transport samples to the laboratory (lab courier or GEI personnel), the courier signs the COC in the "Received by" box.
- Place a custody seal on the cooler if shipping via common carrier.
- Transport samples to the laboratory as soon as possible. It is preferable to transport the samples directly to the laboratory from the field. Samples brought back to the office for storage prior to submission to the laboratory must be kept cold (4° C).
- Unused sampling containers/media that are sent back to the lab should be included on a separate COC.
- After the samples are sent to the laboratory, the GEI copy of the COC must be forwarded to the Data Group: datagroup@geiconsultants.com.

4. Limitations

- Keep the number of people involved in handling samples to a minimum.
- Where practical, only allow people associated with the project to handle the samples.
- Always document the transfer of samples from one person to another on the COC.
- The COC should always accompany the samples.
- Give samples positive identification at all times that is legible and written with waterproof or permanent ink.
- When sending samples via a common carrier, use one COC per package.
- Where practical, avoid sending samples from more than one site with separate COCs in a single package.

TestAmerica
THE LEADER IN ENVIRONMENTAL TESTING

PACKING SAMPLES FOR SHIPMENT BACK TO THE LABORATORY

A. Line cooler with bubble wrap and large plastic bag. Use absorbent pad inside the bag if bottles contain preservatives.

B. Wipe outside of bottles and put glass in individual bubble bags & seal. Place bottles & the temperature blank into cooler. Leave room for ice in between bottles & on top.

C. Place double bagged or loose ice randomly around bottles throughout the cooler.

D. Place large bag of ice or loose ice on top of the bottles. In warm weather, the cooler should be packed with as much ice as possible.

E. Close outer bag, compress excess air out of bag, twist top and knot. If necessary, use more bubble wrap to fill the dead air spaces. Place chain of custody (COC) and other paperwork in plastic bag and seal. Place on top of cooler.

F. Close cooler, place signed and dated Custody Seals over opening. Tape over the Custody Seal and seal cooler securely. Fill out overnight shipping waybill and attach to the top or handle of the cooler. Attach Saturday delivery stickers if needed. Ship according to DOT regulations.

STANDARD OPERATING PROCEDURE

FD-004 Photo Documentation

1. Objective

Describe methods to document and retain photographic records.

Keeping a record of photographs taken is crucial to their validity as a representation of existing conditions.

2. Execution

- Photographs of a site, individual samples, or other observations should be taken using a digital camera.
- Set the camera to record the time and date for each photograph.
- All photographic records, along with the following information, should be recorded in the field notebook (SOP FD-001).
    - If applicable, the compass direction describing the direction the photograph was taken (e.g. looking southeast). This may not apply to photographs of individual samples.
    - Brief description of what the photograph is intended to show.
- The field notebook should note who took the photographs.
- The photographs should be electronically backed up on a computer or other data storage device.
- If photographs will be used in a report, memo, or letter, they should be placed on a photograph record template and the relevant information describing the photograph should be inserted into the caption section for each photograph.

3. Limitations

- Some clients and regulatory agencies require photographs of every subsurface soil sample collected. These photographs typically include a “whiteboard” which indicates the site, the boring ID, and the depth of the sample, while logging details are recorded in the field notebook. Under these circumstances, it is not necessary to include compass directions or descriptions.

STANDARD OPERATING PROCEDURE

FD-006 Handheld Global Positioning Receiver Operation

1. Objective

Use handheld global positioning system (GPS) receivers to locate sample points and site features with "Mapping-Grade" accuracy.

Use handheld GPS receivers to "stake out" proposed sample point locations within the limits of "Mapping Grade" accuracy.

2. Execution

- Handheld GPS receivers provide a low-cost and user-friendly method for locating sample points and site features with a fair degree of horizontal accuracy.
- In simplistic terms, GPS works by measuring the distance from numerous orbiting satellites to a point on the earth surface. Individual satellites broadcast their real-time location in terms of x,y and z coordinates, and the distance from each satellite is measured as a function of the length of time that a time-stamped signal takes to reach the receiver. Built-in GPS software derives new points by intersecting the distances from known orbital locations – in much the same way that points are located by intersecting tape-measured distances from building corners or other pre-existing site features.
- Late-model handheld GPS receivers utilize a real-time differential correction technique called WAAS (Wide Area Augmentation System). This system was designed to provide greater confidence and reliability in using GPS data for commercial aircraft landing approaches, and the additional correction improves all GPS operations.
- Handheld GPS receivers display navigational information on a variety of standard pages. Although each manufacturer uses slightly different formats, all receivers toggle back and forth between the following visual presentations:
- A "satellite" page displays the relative orbital location of all GPS satellites that are currently being tracked by the receiver. The display may include information on the real-time geometrical strength of the solution: satellite intercepts that cross at right angles provide more accurate solutions than intercepts that cross at acute or obtuse angles.
- A "track" page that displays the travel path of the receiver while it is turned on, along with the relative location of recorded points. Many GPS models have a "track-back" function that will guide the user on the same path back to the starting point
- A "navigation" page that displays instantaneous location and the real-time direction and velocity of travel. Some units provide two pages to display this information in different formats. Most units will report the overall "course

made good" (straight-line bearing and distance from the starting point) at any point.

- A "waypoint" page that allows users to "Go To" a created point or previously recorded point by providing a straight-line bearing and distance to the point. The information is instantaneously updated as the user moves along; some units display a pointing arrow that directs the user to the direction of travel. Be careful of go-to lines that lead through swamps or over cliffs – if you will be travelling in difficult terrain have a paper copy of the USGS quadrangle and a compass on hand for navigation.
- Signal strength degrades significantly next to buildings and underneath tree canopy. Most GPS receivers have an "averaging" function to improve the accuracy of shielded locations. GPS users can also improve precision by locating points three times, at different times of the day. Two of the solutions will generally be closer to each other than to the third and can be averaged for a more reliable fix.
- Most GPS receivers default to latitude and longitude, but data is more accurate and easier to input and when expressed in UTM coordinates to the nearest meter. The handheld GPS setup will have a function somewhere to change to UTM. Most of Connecticut is in UTM Zone 18 but the easternmost parts are in Zone 19.
- Consult "Corpscon" the datum translator available from the National Geodetic Survey website. Corpscon translates instantly from latitude/longitude to UTM coordinates to state plane coordinates and provides tools to identify UTM Zones. Also consult the Trimble, Garmin and Magellan websites for technological improvements and discussion of advanced techniques.

3. Limitations

- Handheld GPS receivers operating in unobstructed locations are currently reckoned to provide 2-5 meter accuracy, meaning that the true location of measured points lie within an "error ellipse" with axes of 2-5 meters centered on the measured location. In other words, even under the best of conditions a real-time GPS solution may be as much as 20 feet off the true horizontal location of a point.
- Due to geodetic restrictions, vertical locations (elevations) have less than half the accuracy of horizontal locations, meaning that even under the best of conditions, a surface elevation displayed on a handheld GPS receiver may be off by more than 50 feet.
- Horizontal and vertical data derived from handheld GPS receivers should never be considered more than relatively accurate, and this level of uncertainty should be identified in any discussion of positional tolerance.

STANDARD OPERATING PROCEDURE

GW-001 Water Level and NAPL Measurement

1. Objective

Describe procedures to measure the depth to water and non-aqueous phase liquid (NAPL) thickness in an open borehole, cased borehole, monitoring well or piezometer.

2. Equipment and Materials

Field forms and/or field notebook.

- Decontamination fluids
- Bailer
- Weighted cotton string
- Oil/Water interface probe
- Water level meter (if oil/water interface probe is not available)

Water level and NAPL measurements can be collected by a variety of methods. A water level meter is used to collect depth to water measurements however an oil/water interface probe or other methods must be used to gauge NAPL depths. An electronic oil/water interface meter, consists of a cable divided into incremental measurements of 0.01 feet, and probe that consists of an infra-red circuit that detects the presence of a liquid, and a conductivity circuit that differentiates between conductive liquid (water) and non-conductive liquid (LNAPL or dense non-aqueous phase liquid [DNAPL] product). Typically, a steady tone and light indicate a non-conductive liquid (e.g. product) and an intermittent tone and light indicate a conductive liquid (e.g. water). Refer to the manufacturer's instructions for details. Alternately, water level and NAPL measurements can be collected using a water level meter, clear bailer and weighted cotton string. Each method of data collection is described below.

3. General Information

- The water level in a monitoring well or piezometer should be allowed to stabilize for a minimum of 24 hours after development or construction before groundwater elevation and/or NAPL measurements are collected. The water level in a borehole can be measured during drilling; however, this should be noted in the field notebook.
- Water levels in multiple wells should be collected within the shortest timeframe practicable.
- Water and NAPL levels should be measured from the designated survey point as specified by the surveyor or highest point (or "V" notch) on the PVC. If the well is new, mark the datum point with an indelible marker and note reference location in

field book. Discuss with the project manager what reference point should be used to collect water measurements for specific sites.

- Water level and/or NAPL measurements should be made before any water is removed from wells because doing so may influence groundwater levels in the area of the investigation.
- Measurements should be made approximately three times to confirm the measurement. Each time a measurement is made it should be determined to the nearest one-hundredth of a foot (0.01).
- Water level and/or NAPL measurements should first be collected at the wells that are least contaminated and proceed towards the wells that are most contaminated. Decontaminate the water level meter or oil/water interface probe prior to initial use and after use at each location. If NAPL is encountered at a well where it was previously not observed, contact your project manager before continuing.
- Refer to the oil/water interface probe or water level meter instruction manual for guidance on indicator signals, as these may differ by manufacturer.

4. Execution

4.1 Water Level and NAPL Measurements Using Interface Probe

- Open wells to the atmosphere and allow them to equilibrate prior to collecting LNAPL depth measurements.
- LNAPL Depth (if present): Measure the LNAPL/air interface by slowly lowering the interface probe to the LNAPL surface. Be ready to stop as soon as the probe signals the LNAPL surface.
- Record the depth to LNAPL.
- Groundwater Depth: Continue slowly lowering the probe until it signals the presence of water.
- Record the depth to water.
- The LNAPL thickness is determined by subtracting the water depth from the LNAPL depth.

The depth and thickness of DNAPL can sometimes be determined by slowly lowering the interface probe past the LNAPL (if present) and water layers. Record the depth to the DNAPL layer. Finally, measure the depth to the well bottom.

The DNAPL thickness is determined by subtracting the DNAPL depth from the depth to well bottom.

- Decontaminate the interface probe and tape according to SOP QA-001.
- Dispose of any NAPL-impacted debris properly.
- Check with the Project Manager if you are uncertain of the appropriate disposal method.

4.2 LNAPL Measurements Using Clear Bailer

If LNAPL is suspected at a site, an oil/water interface probe should be used when gauging water level and NAPL measurements. However, a water level meter and a clear bailer may be used instead to estimate approximate LNAPL thickness if an oil/water interface probe is not available.

- Open wells to the atmosphere and allow them to equilibrate prior to collecting LNAPL depth measurements.
- Slowly lower the water level meter until contact with fluid is indicated by the meter.
- Record the depth to fluid measurement.
- Lower a clear bailer into the well and slowly into the LNAPL. Do not submerge the bailer.
- Slowly raise the bailer out of the well and measure LNAPL thickness in the bailer using a ruler or tape measure.

Calculating Depth to Groundwater

The depth to water can be calculated as follows:

DTW = DTF + PT
DTW = Depth to Groundwater
DTF = Depth to Fluid
PT = Measured Product Thickness

Calculating Corrected Depth to Groundwater

Once the LNAPL thickness is known and the depth to groundwater is known, the corrected depth to groundwater can be calculated.

Corrected DTW = Static DTW – (PT x G)
DTW = Depth to Ground Water
PT = Measured Product Thickness
G = Specific Gravity (density of free product / density of water)

4.3 DNAPL Measurements Using Weighted Cotton String

A weighted cotton string may be used to estimate approximate DNAPL thickness.

- Secure cotton string.
- Secure clean steel nuts and/or washers.

- Tie the string to the nuts/washers, so that there is adequate weight.
- Lower the weighted string into the well slowly, until a firm bottom is sensed.
- Remove the weighed string and measure the DNAPL coated portion of the string.
- Record the thickness.
- Dispose of any NAPL-impacted debris properly. Check with the Project Manager if you are uncertain of the appropriate disposal method.

5. Health and Safety Considerations

The health and safety considerations for the work associated with this SOP, including both potential physical and chemical hazards, will be addressed in the site specific Health and Safety Plan (HASP). The collection and accumulation of NAPL presents the potential for significant hazards that need to be managed. A detailed job safety analysis (JSA) should be completed prior to the start of work.

6. Considerations

- Weak batteries in water level and oil/water interface meters frequently produce weak or gradual auditory and/or visual responses, making it difficult to accurately determine when the probe of the unit has come in contact with ground water or NAPL. As such, it is recommended that electronic ground water-level indicators be tested before they are brought out into the field.
- Electronic oil/water interface meters do not respond to distilled water. Do not use de-ionized water to test these units.
- Wells that are not vertical may result in probe contact with the side of the well casing providing a false measurement. Once the probe has come in contact with ground water in the well, water may be trapped by capillary action between the probe and the well casing. If this happens, the unit may continue to signal even after the probe has been raised above the ground water surface. The deeper the well, the more likely this problem may occur. To correct this, the cable should be raised several feet above the water and shaken to remove water from the probe. A new ground water-level measurement should then be collected. If the signals from the unit are not abrupt or reproducible, the probe and tape may need to be retrieved and dried off before trying again.
- Accumulation of sediment, organic material, or floating debris in the probe may also result in gradual or non-reproducible readings. Wells that are constructed with metal inner casings may lead to difficulties in collecting reproducible ground water-level measurements because the inner sides of the well casing are conductive.

- In some cases, a rubber grommet or metal centralizer may need to be placed on the probe so that it cannot contact the inner casing.
- Well gauging equipment should be properly decontaminated between wells and piezometers to avoid cross contamination.
- Water levels in wells may be influenced by changes in river stages, pumping of nearby wells, precipitation, tides, etc.
- Using a bailer to estimate LNAPL thickness can result in inaccuracies because successful use of the bailer is dependent upon the expertise of the operator and assumes the check valve does not leak upon retrieval.
- The optical sensor on interface probes may become damaged if solvents are used to clean NAPL from the probes.
- The optical sensor may become smeared when used to measure NAPL, rendering pinpoint accuracy to an estimate at best.
- Close attention to decontamination procedures will improve accuracy, operational life, and reduce the risk of cross contamination with other wells.
- LNAPL thickness can be affected by fluctuations in the water table. In some cases, an LNAPL's thickness may decrease when the water table rises, while its thickness increases as the water table drops. In other cases, fluctuating water tables may cause sudden appearances and disappearances of LNAPL layers.
- Monitoring points with LNAPL can pose a problem when measuring the level of groundwater. Floating LNAPL can depress the groundwater level in a monitoring well or piezometer and distort the measurement. Therefore, the Corrected Depth (CD) formula shown above should be applied to groundwater level measurements in monitoring points where LNAPL are present:
- Some interface probes are factory-calibrated based on an assumed conductivity of NAPL and water, both of which may vary. An interface probe that is functioning properly may not be able to discern different NAPLs at all sites.
- An interface probe may not successfully provide both LNAPL and DNAPL measurements in the same well because the probe is coated by LNAPL and loses its ability to detect DNAPL.
- DNAPL, in particular, may be only slightly heavier than water, or may be neutrally buoyant. As a result, it can be easily disturbed. Once it is disturbed, meaningful measurements can be difficult or impossible to obtain. As such, all tapes or probes used for measurements should be used slowly.

STANDARD OPERATING PROCEDURE

GW-003 Low Flow (Low Stress) Groundwater Sampling

1. Objective

Describe methods to collect groundwater samples most likely to produce results that represent aquifer conditions.

Low-flow purging is limited to wells that, with sustained pumping, exhibit no continuous drawdown.

2. Execution

- Prior to groundwater sampling consult with the project manager to confirm that the type of pump is appropriate and consistent with the approved work plan.
- Record activities in the field notebook (see SOP FD-001 Field Notebook) and on a Monitoring Well Sampling Record such as the examples in Attachment A. Use a separate form for each sampling location and event. You may forego the forms and record all information in the field notebook if the Project Manager approves.
- Calibrate pH, temperature, Specific Conductance (SC), turbidity, Dissolved Oxygen (DO), and Oxidation-Reduction Potential (ORP) on the meter(s). Use calibration methods provided by the manufacturer of the equipment. Note that appropriate calibration for dissolved oxygen requires a water saturated air environment, along with measured temperature and barometric pressure.
- Begin with the monitoring well believed to have the least contaminated groundwater and proceed systematically to the well with the most contaminated groundwater. Check the well, the lock, and the locking cap for damage or evidence of tampering.
- Slowly and gently measure the depth to water with a water level probe and/or oil-water interface probe. Do not measure depth to well bottom at this time (wait until sampling has been completed). Measure water level in accordance with SOP GW-001 Water Level Measurement.
- Attach new polyethylene or Teflon lined tubing to the sampling pump and the flow-through cell that contains the meter probes.
- Slowly and gently insert new polyethylene or Teflon lined tubing to the pump intake (or use dedicated tubing that remains in the well) and to the middle of the saturated screened interval or to the pre-determined sampling depth.
- The tubing intake should be kept at least two (2) feet above the bottom of the well to prevent disturbance or suspension of any sediment or Non-Aqueous Phase Liquid (NAPL) present in the bottom of the well. Record the depth of the pump intake.

- If possible, position your sampling equipment and tubing so that it is in the shade. The goal is to minimize the effect of sunlight raising the temperature of water being collected.
- Start the pump on the lowest setting and increase slowly until flow begins. Adjust the pumping rate so that drawdown in the well is minimal (0.3 feet or less, is desirable but not mandatory). Use a pumping rate between 100 to 1,000 milliliters per minute (mL/min) (or approximately 0.1 to 1 quarts per minute). Measure flow rate on the pump or using a graduated container every 3 to 5 minutes and record. The minimum purge volume will be twice the combined volumes of the sampling string (i.e. pump, tubing, and flow-through cell).
- While purging, record water levels every 3 to 5 minutes and monitor and record the water quality indicator parameters: pH, temperature, specific conductance (SC), dissolved oxygen (DO), and turbidity. If specified in the field sampling plan also include ORP.
- Purging is complete when, after three consecutive measurements, the water quality parameters have stabilized as follows:

    - pH (+/- 0.1 standard units)
    - temperature (+/- 3%)
    - SC (+/- 3%)
    - turbidity (+/- 10% if >5 NTU; if 3 values are <5 NTU, consider the values as stabilized)
    - DO (+/-10% if >0.5 mg/L; if 3 values are <0.5 mg/L, consider the values as stabilized)
    - ORP (+/- 10 mV)

- Dispose of purge water according to the field plan.

Sample Collection:

- Following purge, remove the discharge tubing from the flow-through cell. Do not disturb pump and tubing between stabilization and sample collection.
- Fill sample containers directly from the sampling device in order of decreasing volatility (i.e., Volatile Organic Compounds (VOC) samples are collected first; see SOP SC-002 Sampling Handling). Fill all containers from the discharge end of the tubing. Collect samples at a flow rate equal to the steady state purge rate.
- If not using a dedicated pump, remove sampling device and decontaminate (see SOP QA-001 Equipment Decontamination). Discard used tubing.
- Store samples in a cooler on ice for transport to the laboratory.
- Measure depth to bottom of well.

- Secure the well cap.

3. Limitations

- Prior to departure for the field, obtain available information on well construction for use in field investigation (i.e., screen and riser material, well diameter and depth, screened interval, optimum sampling depth, etc.).
- If possible, when using dedicated equipment, install equipment into well at least 24 hours before sample collection to minimize disturbance of the water column and/or suspension of sediments or NAPL on bottom.
- If water quality indicator parameters do not stabilize after removing 3 to 5 well volumes or 2 hours, contact the Project Manager. Three options will be available: 1) continue purging until stabilization; 2) discontinue purging and do not sample; or 3) discontinue purging and sample.
- The key indicator parameter for VOCs is DO. The key indicator parameter for all other samples is turbidity.
- Fill all sample containers with minimal turbulence by allowing the groundwater to flow from the tubing gently down the inside of the container.
- Consult with the project manager before field filtering samples for metals if using low-flow sampling.
- Be aware of any preservatives in the sample bottles and handle with care, in accordance with the Health and Safety Plan.

STANDARD OPERATING PROCEDURE

GW-004 pH and Temperature Measurement

1. Objective

Describe methods for measuring the pH and temperature of liquids using a combination pH/temperature meter.

2. Execution

Calibration

- Calibrate the meter according to the equipment manufacturer's instructions at the beginning of each day of use. Calibration for pH shall be performed using at least two buffer solutions. Solutions chosen should be similar to the expected pH of the liquids tested (pH 7 and 4 buffer solutions are preferred in most cases for groundwater or surface water measurements).
- Check calibration at the end of the day by reading the two solutions used in calibration. Also perform additional field checks as needed based on observed readings (i.e., inconsistent readings). Record measurements and time of measurement in the field book or sample sheet. If the readings are outside +/– 0.2 pH units, recalibrate the meter.

Sample Measurement

- Immediately prior to testing a sample, decontaminate testing container and probe assembly with one rinse of distilled water. Do not use methanol to rinse the probe. Methanol rinses could damage the probe.
- Gently dry the probe with a paper towel and shake beaker to remove excess solution. Visually inspect the bottom of the probe to ensure that liquid or sediment is not trapped between outer casing and probe.
- Pour the sample into the testing container and insert both temperature and pH probe. Stir sample for 30 seconds using both probes. Let the probes equilibrate in the sample solution for another 30 seconds. Measure and record the temperature. Measure and record pH reading after stabilization or 60 seconds, whichever is sooner. A reading has stabilized if pH units have not changed +/– 0.1 pH units during a 30 second period.
- Record pH to the nearest 0.1 unit and temperature to the nearest whole number.

3. Limitations

- Coatings and particulates may affect the response of the probe; more thorough cleaning using a weak alconox solution and distilled water rinse

and gently wiping the probe surface with a paper towel may be required to clean the surface of the probe.

- Temperature affects both the response of the instrument to pH and the actual pH of the sample. The Automatic Temperature Compensation (ATC) function compensates for the variation in the response of the meter only. Therefore, the pH must always be reported with temperature.
- The probe is a fragile thin glass bulb surrounded on three sides by a plastic casing. Care must be taken in handling the probe to avoid breakage.
- Do not use buffer solutions past their expiration date.

Saskia Oosting

STANDARD OPERATING PROCEDURE

GW-005 Turbidity Measurement

1. Objective

Describe calibration and use of a Hach nephelometer/turbidimeter.

The meter is used to measure turbidity of liquids by quantifying how much light passes through them. Turbidiity readings are required to be read using a portable (e.g Hach) instrument directly from the tubing before going through the flow-through cell.

This SOP is specific to a Hach turbidimeter. Follow manufacturer's recommendations for other meters.

2. Execution

i. Turn the meter "ON".
ii. Rinse the sample cell 3 times with distilled water.
iii. Fill the cell to the fill line with distilled water and then cap the cell.
iv. Wipe off excess water and streaks with a non-abrasive lint-free paper or cloth (preferably lens paper).
v. Open the cover and insert the cell (arrow to the front) into the unit and close the cover.
vi. Press "READ" and wait for the 'light bulb' icon to go off. Record the reading.
vii. Using the Gelex standards, repeat steps above. Record all measurements (note anomalies).
viii. Fill the cell with sample liquid to the fill line (about 15 mL) and replace the cap on the cell.
ix. Wipe off excess water and any streaks with a non-abrasive lint-free paper or cloth (lens paper).
x. Press "I/O" and the instrument will turn on. Place the meter on a flat, sturdy surface. Do not hold the instrument while making measurements.
xi. Insert the sample cell, arrow to the front, in the instrument. Close the lid.
xii. Select manual or automatic range selection by pressing the range key.
xiii. Use signal average mode if the sample causes a noisy signal (display changes constantly). Select signal averaging mode by pressing the "Signal Average" key.
xiv. Press Read. The display will show "---- NTU" and then the turbidity in NTU. Record the result after the lamp symbol turns off.
xv. Rinse the cell with distilled water.
xvi. Confirm the validity of the sample measurement by double-checking with one of the Gelex standards.

xvii. Periodically check the turbidity meter during the day by using the Gelex secondary standards provided.
xviii. Perform a post calibration at the end of the day and record all measurements.

3. Limitations

If the turbidity measurements are for National Pollutant Discharge Elimination System (NPDES) reporting purposes, all samples with values above 40 NTU must be diluted with turbidity free water (e.g. distilled water) and sample turbidity is calculated by multiplying the reading of the diluted sample by the dilution factor.

STANDARD OPERATING PROCEDURE

GW-006 Specific Conductance Measurement

1. Objective

Describe standard methods to measure conductivity of water using a field conductivity meter.

2. Execution

- Calibrate the meter according to equipment manufacturer's instructions at the beginning of each day of use. Calibration shall be performed using a standard KCl or other solution recommended by the manufacturer.
- Record the make, model, and serial or identification number of the instrument and calibration information in the field notebook.
- Check calibration at the end of the day by measuring the standard used in calibration and record in field book. Also perform additional field checks as needed based on observed readings (i.e., inconsistent readings). If the readings are outside +/- 0.02 mS/cm, the meter must be recalibrated. Initial calibration should be conducted under the same conditions (i.e., temperature, and location) of field testing.
- Immediately prior to testing a sample, decontaminate testing container and probe assembly with distilled water.
- Gently dry the probe with a paper towel and shake container to remove excess solution.
- Pour sample into the container and insert probe. Stir sample with the probe for approximately 10 seconds. Let the probe equilibrate in the sample solution for another 30 seconds. Measure conductivity and record in the field notebook.
- Record conductivity to the nearest whole number.

3. Limitations

- Oily coatings and particulates may affect the probe's response; more thorough cleaning using a weak alconox solution and distilled water rinse and gently wiping the probe surface may be required to clean the surface of the probe.
- If sample liquid is contaminated, (e.g. stained, conductance >0.75 mS/cm), rinse probe with distilled water immediately after measuring sample to minimize fouling of probe.
- Do not use calibration solutions past their expiration date.

4. References

Standard Methods for the Examination of Water and Wastewater, 18th Edition, Method 4500-H. American Public Health Association (1992).

5. Contact

Brian Conte
Saskia Oosting

STANDARD OPERATING PROCEDURE

GW-007 Dissolved Oxygen Measurement

1. Objective

Describe calibration and field use of dissolved oxygen meter.

2. Execution

- Place instrument in the intended operating position (vertical, tilted, or horizontal) before it is prepared for use and calibrated.
- Recalibration may be necessary when the instrument operating position is changed.
- Attach the prepared probe to the Probe connector of the instrument and adjust the retaining ring finger tight. Check that membrane is intact and check for presence of air bubbles under membrane. If bubbles are present or membrane is damaged, prepare probe again according to manufacturer's instruction.
- Place approximately 1/8 inch of water into the bottom of the calibration cup. Place the probe into the cup and engage only one thread of the calibration cup onto the probe to ensure that the DO probe is readily vented to the atmosphere. Make sure the DO and temperature probes are not in contact with the water. Wait approximately 10 minutes for the air in the calibration cup to become water saturated and for the temperature to equilibrate.
- Calibrate meter according to the procedures outline in the instrument manual. Calibrate probe to a zero oxygen solution provided by manufacturer, and water saturated air.
- The calibration procedure may require correction factors or input of site-specific barometric pressure and temperature. Correction factors can be found at:

  http://water.usgs.gov/owq/FieldManual/Chapter6/6.2_v2.1.pdf

- Otherwise, use appropriate instruments at the site to determine temperature and pressure.
- Perform Dissolved Oxygen Measurement using the following procedure:
  i. Submerge probe in flow-through chamber or water body.
  ii. Gently raise and lower probe in sample.
  iii. Allow sufficient time for probe to stabilize to sample temperature and dissolved oxygen.
  iv. Read and record the temperature and the value of the dissolved oxygen in mg/L.
  v. Document field analysis data and general observations in the field log book or groundwater sampling sheet.

3. Limitations

- Collect DO measurements in the field during sampling. Storing samples in containers will alter the DO concentration of the sample.
- Detection Limit (DL) = 0.1 mg/L for 0-10 mg/L range; do not record values less than Detection Limit: a zero reading is recorded < 0.1 mg/L.

STANDARD OPERATING PROCEDURE

GW-008 Temporary Groundwater Sampling Points

1. Objective

To define the procedures for installation of temporary groundwater sampling points (hereafter referred to as well point) for measuring depth to groundwater and collecting groundwater samples. Well points may aid in the placement of permanent monitoring wells.

A well point is a small diameter (1-2 inch) probe constructed of continuously wrapped stainless steel or wrapped stainless steel gauze screen over perforated carbon steel pipe. No filter or gravel pack is used in the installation.

Well point installations are not the only type of temporary monitoring wells. Alternative temporarily well constructions should be discussed with the project manager and may be more appropriate based on-site conditions.

2. Execution

2.1. Installation

- The well point can be placed with the use of a conventional hollow-stem auger rig, Geoprobe®, slide hammer, jack hammer, rotary hammer, or by hand.

- The well point may be driven through the unsaturated zone only in known "clean" soils. Driving the well point through contaminated soil may carry contamination downward with the point resulting in analytical sample results which are biased high. In areas with contamination above the desired screening zone, the well points should be installed with the aid of either hollow-stem augers or Geoprobe®, to “case off” contamination from the upper layer.

- If the well point is to be installed in an oversized (20% larger than the well point) pre-drilled hole, the hollow-stem augers or bull drive point must be advanced to a point which is just above the targeted sample zone. The well point is then placed in the hole and advanced beyond the bottom of the hole by hammering or pushing into place. The use of pre-drilled holes will reduce clogging of well point screens when driving.

- If the well point is used for piezometeric data, make a survey mark on top of the casing as a reference point for water level measurements.

- Caution must be used when using well points in areas of contaminated soil. Possible cross contamination may be introduced to the screen as it passes through the zone of contamination.

2.2. Sampling Procedures

Development of a well point is not required prior to sampling. Sampling of groundwater or collecting piezometric data must be performed by one of several recommended methods described in this manual.

After sample collection, (See Groundwater Sampling SOP) the well point is removed by back hammering or pulling the tool out with the rig hydraulics.

STANDARD OPERATING PROCEDURE

PM-001 Utility Markout and Clearance

1. Objective

Describe typical utility markout/clearance procedures prior to and during excavation. All markout procedures should be performed in accordance with local and state regulations.

Many states, by law, require that utility companies are notified before excavation begins. Actual procedures and requirements differ by state. City/state government may have additional requirements for utility markout procedures. Check the requirements in the locality before beginning. Also check with the GEI project manager to determine whether it is most appropriate for GEI or the drilling/excavation subcontractor to handle mark out and clearance.

2. Execution

Public Utility Markouts

- The drilling/excavation locations should be marked with white paint, stakes, or flags.
- The contractor should call the appropriate one call communication network for the state the work is being conducted in. Refer to the Reference section in this SOP for contact information. Contractors shall provide all necessary information to the one call system. Sample location maps may be provided to clarify sampling locations. The contractor shall provide GEI with the utility clearance ticket number.
- If necessary, contact the municipalities or other utility owners to mark their water, sewer, or other lines if they do not belong to the one call system. The contractor should keep a record of these calls.
- Utility plans, if available, should be obtained from the property owner or municipal offices.
- Prior to excavation, a visual check should be made that all utilities companies and municipalities have marked their locations. This includes looking for signs that a utility exists, and verifying that the markings agree with a visual check. If they do not, contact the appropriate utility to remark their locations.
- Utilities will generally only markout and clear utilities in roadways or other public property up to the property boundary. Owners of fiber optic cables, natural gas pipelines, and other high hazard utilities will often markout on private property if requested. The contractor should request this. See section on private utility clearance below.
- Public agencies, utilities, contractors, other associations, manufacturers and all others involved in excavation should adopt the American Public Works Association (APWA) Uniform Color Code using ANSI standard Z535.1 Safety Colors for temporary marking and utility identification, as follow:

The APWA Uniform Color Code

1. **White** – Proposed Excavation
2. **Pink** – Temporary Survey Markings
3. **Red** – Electric Power Lines, Cables, Conduit and Lighting Cables
4. **Yellow** – Gas, Oil, Steam, Petroleum & Gaseous Material
5. **Orange** – Communications, Alarm or Signal Lines, Cables or Conduit
6. **Blue** – Potable Water
7. **Purple** – Reclaimed Water, Irrigation and Slurry Lines
8. **Green** – Sewers and Drain Lines

However, not all organization do use these colors. Make sure the color scheme is understood.

- The excavator/contractor and consultant begins work on the scheduled work date and time (if all the facility operators have responded) taking care to find and preserve any markings that have been made.
- If markings may be disturbed during work, establish offset marks to create reference points for the underground utilities. Take photographs of the markings before starting work.
- When digging near a buried utility, the excavator/contractor and consultant should be aware of their proximity to the utility and use caution.
- If there is uncertainty about the accuracy of the markings or there are too many utilities in a given location to excavate or drill safely, consideration should be given to hand-digging the first few feet, vacuum excavation, or use of a utility location company as detailed below in Private Utility Markouts.
- Some clients may require hand or vacuum clearance to a minimum depth. Check with the GEI project manager.
- If exposing a utility, the excavator/contractor should provide proper support and protection for the utility to prevent damage. Contact the utility operator for support, guidance, or assistance.
- When the excavation is complete, the excavator/contractor should provide proper backfill for any utilities that have been exposed.

Private Utility Markouts

- Utility markouts on private property should follow the steps outlined above in public utility markouts with the additions below.
- If work is conducted on private property where public utilities may not provide markouts and the property owner cannot provide accurate utility plans, it is

recommended to use a company to determine the utility locations using one or more of the following technologies:

i. Electro-Magnetic (EM) device: This technology uses an electro-magnetic field in the subsurface to accurately locate metallic lines or non-metallic lines incorporating a metallic trace wire along their surface. The field is created either by direct contact to the pipe or tracewire, or by an induced current via radio waves.
ii. Sewer Sonde: For non-metallic lines where internal access is possible (such as clean-out ports in a sewer), a beacon or 'sonde' that emits a signal to the surface receiver as it is snaked through the pipe provides the same accuracy as the EM detector. If the internal condition of the pipe is desired, a camera can be deployed instead of a simple sonde.
iii. Ground Penetrating Radar (GPR): This technology involves radar waves reflecting to a surface receiver which provides a visual real-time map of the subsurface by which anomalies (such as pipes or tanks) may be detected. It has limitations in clay or wet soils and requires a skilled operator for interpretation. GPR should be considered for high risk utilities (e.g. PVC natural gas lines without trace wire) where line-of-sight project from site entry point to a kiosk or other building is uncertain.

- Utility markout on private property should include clearance for other types of underground structures such as underground storage tanks, septic systems, utility or access tunnels, and in-ground irrigation systems.

3. Limitations

- Markout notification time usually does not include holidays. Make sure holidays are considered and markout time is scheduled accordingly. Do not conduct excavation or drilling prior to the required wait time. Do not mark excavation locations using spray paint if it is raining or snowing enough so that the paint markings will be washed away. Consider using long stakes instead of paint if snow is predicted. Excavations within the tolerance zone should be performed with non-powered hand tools until the marked utility is exposed. The tolerance zone may be determined by the utilities, law or codes.
- When excavating close to an underground utility, it is good practice for the contractor/excavator to have a spotter assist and guide the machine operator.
- Take care not to damage the conduit or protective coating of a utility. If the excavator/contractor damages this, leave the damaged utility exposed and immediately call the utility owner.
- If contact to a gas utility occurs, notify police, fire, and emergency personnel, and evacuate employees and general public. No attempt should be made to tamper with or correct the damaged utility.

STANDARD OPERATING PROCEDURE

QA-001 Equipment Decontamination

1. Objective

This SOP describes methods used to decontaminate reusable sampling equipment for projects that require collection of organic and inorganic analytical samples. The goal is to minimize cross-contamination between samples. This maximizes confidence that field samples will be representative of specific locations and conditions.

Refer to the work plan or project manager to determine if different decontamination methods are acceptable.

2. Execution

- All contractor-provided equipment (augers, rods, spoons, backhoe buckets) should be decontaminated by steam cleaning or pressure washing prior to coming on site. If there is doubt about cleanliness of drilling tools, they should be decontaminated before use at the site.
- Sampling equipment decontamination is a sequential procedure consisting of the following steps:

    - Alconox-solution wash (or equivalent non-phosphate detergent)
    - Potable water rinse
    - A ten percent reagent grade nitric acid wash should be used to strip potential inorganic contaminants from sampling devices.
    - Laboratory grade 100 percent methanol, should be used to strip potential organic contaminants from sampling devices.
    - Three distilled/deionized water rinses.

- Alconox solution is a mixture of approximately 1 cup of Alconox per 1 gallon of potable water. Alconox solution wash requires scrubbing the equipment with a brush soaked in Alconox solution to remove visible contamination or dirt from sampling devices.
- Split-spoon samplers must be decontaminated prior to collecting each sample. The procedure follows:

    - Overall wash and scrub in a bucket of Alconox solution
    - Potable water rinse.
    - 10% nitric rinse
    - 100% laboratory grade methanol rinse
    - Three distilled-water rinses.

    The same procedure is applied to all devices that may contact soil or groundwater slated for analytical samples - spoons and knifes used to inspect or sample soils; water level indicators; oil/water interface probes.

Equipment used for well development of multiple wells must be decontaminated between wells.

Pumps and tubing should be flushed using a minimum of one gallon of Alconox-solution followed by a gallon of potable water. Some projects may require methanol (in much lower quantities) and distilled water instead of or in addition to the Alconox-solution and potable water.

For pumps and tubing, a final rinse of the sampling equipment may be performed with the water being sampled.

Equipment blanks measure the effectiveness of the decontamination procedures. Blanks should be collected per guidance provided in QA-002, Field Quality Control Samples.

3. Limitations

- Do not store the deionized/distilled water in polyethylene bottles, use Nalgene, glass, or Teflon. Polyethylene may leach phthalates.
- Do not attempt to decontaminate string or rope - replace it.
- Due to eye and skin absorption hazards, safety glasses and gloves must be worn when handling decontamination solvents.
- Decontamination procedures may also require modification based on state or federal requirements.
- Steam cleaning or pressure washing with potable water is generally an acceptable decontamination method for drilling equipment (i.e., augers). Check with the work plan.
- Dedicated equipment need not be decontaminated beyond initial decontamination prior to field use.

STANDARD OPERATING PROCEDURE

QA-002 Field Quality Control Samples

1. Objective

Field Quality Control (QC) samples are used to monitor the reproducibility and representativeness of field sampling. The QC samples are handled, transported, and analyzed in the same manner as the associated field samples. QC samples may include trip blanks, equipment blanks, and field duplicates.

2. Execution

2.1. Trip blanks

- Used to monitor possible sources of contamination from transport, storage, inadequate bottle cleaning, or laboratory methodologies.
- Sample containers filled at the laboratory with analyte-free water are transported to and from the site, and are not opened until time of analysis.
- Trip blanks are stored with the sample containers prior to and after field activities and remain with the collected samples until analyzed.
- Generally, one trip blank per volatiles analysis (e.g. volatile organic compounds) shipment.
- Consider submitting a trip blank when sample shipment is by Fed Ex or other large carrier, or laboratory courier.
- Trip blanks should be recorded in the field notebook and on the chain-of-custody that same as all other samples.

2.2. Equipment blanks

- Equipment blanks (also known as equipment rinsate blanks) are used to monitor possible sources of contamination associated with sample collection. Monitors on-site sampling environment, sampling equipment decontamination, sample container cleaning, the suitability of sample preservatives and analyte-free water, and sample transport and storage conditions
- Equipment blanks are collected by pouring laboratory supplied or distilled or deionized water over sampling tools that have been decontaminated per the work plan, into sample containers.
- Equipment blanks are stored with the associated field samples until submitted for analysis.
- Generally collected when site conditions indicate site related contamination is a concern. Check project-specific work plan and/or quality assurance project plan for required frequency.
- Prepare equipment blanks immediately after the equipment is cleaned in the field and before leaving the sampling site.
- Prepare equipment blanks by rinsing the decontaminated sampling equipment set with the appropriate type of analyte-free water and collecting the rinse water in appropriate sample containers.

- If a potable water rinse is the typical final step, collect the equipment blank with analyte-free water after the potable water rinse.
- Equipment blanks should be recorded in the field notebook and on the chain-of-custody that same as all other samples.

2.3. Field Duplicates

- Used to evaluate the precision and representativeness of the sampling procedures.
- Field duplicates are two samples collected from the same location using the same procedures. Both samples are submitted to the laboratory as individual samples with different sample identification.
- Field duplicates from groundwater sampling for all analyses except volatiles analysis are collected by alternating filling sample containers from the same sampling device. Field duplicates for volatiles analysis are filled sequentially.
- Soil or sediment field duplicates are collected by homogenizing the sample for all analyses except volatiles. The homogenized sample is then divided into two equal portions and placed in separate sample containers. Field duplicates for volatile analysis are collected at two adjacent sampling locations.
- Each sample is assigned different sample identifications.
- Field duplicates are generally collected at frequency of 1/20 samples. Check project-specific work plan and/or quality assurance project plan for required frequency.
- All field QC samples should be labeled in the field and submitted “blind” to the laboratory – as if they are separate, primary samples.
- Field duplicates should be recorded in the field notebook and on the chain-of-custody that same as all other samples.
-

2.4. Matrix-Spike samples (MS/MSD)

- Matrix spike and matrix spike duplicate samples (MS/MSDs) are environmental samples that are spiked in the laboratory or in the field with a known concentration of a target analyte(s) to verify percent recoveries.
- Matrix spike and matrix spike duplicate samples are primarily used to check sample matrix interferences. They can also be used to monitor error due to laboratory bias and poor precision. However, a data set of at least three or more results is necessary to statistically distinguish between laboratory performance and matrix interference.
- Generally, the laboratory is required to extract and analyze MS or MS / MSDs at a minimum frequency of 5% of samples being analyzed for the target analyte(s). If the project or client criteria require an MS or MS/MSD, collect sufficient volume in the appropriate containers, and designate the sample to be used as the MS or MS/MSD on the chain of custody.
- Calculate the percent recovery for all spiked analytes for both the MS and MSD. For MS/MSDs also calculate the relative percent difference (RPD). The

RPD for each spiked analyte is calculated using the amount detected not percent recovery. If your data will be subjected to validation, the % recovery and the RPD will generally be determined by the validator.

2.5. Typical QA/QC Frequency

- QA/QC frequency is determined by project, client or regulatory criteria and should be verified prior to sample collection. Generally, QA/QC samples are collected according to the frequency described below:

Duplicate Samples	One per sampling event, one per 10 samples collected, or one every two weeks, whichever comes first.
Equipment Blanks	For each equipment type that is not dedicated or disposable - one per sampling event, one per 20 samples collected, or one every two weeks, whichever comes first.
Trip Blanks	One per sample delivery group, or in each cooler containing VOC soil or aqueous samples, depending on project.
MS or MS / MSDs	One MS or MS/MSD per sampling event, one per 20 samples collected, or one every two weeks, whichever comes first.

3. Limitations

- Trip blanks must never be opened in the field.
- Trip blanks are usually for VOCs only because less volatile compounds are not likely to cross-contaminate other samples by simply being in close proximity.
- Laboratory-grade water must be used during the collection of equipment blanks.
- Field duplicates must have different sample identifications.

STANDARD OPERATING PROCEDURE

SC-001 Environmental Sample Types and Sampling Strategies

1. Objective

Describe types of samples and strategic approaches to sample locations.

Refer to Attachment A for guidance on compatible sampling materials.

2. Sample Types

Grab Samples

A grab (or discrete) sample is a single aliquot (part of the sampled media) collected from a single location at a specific time.

Surface soil samples are typically “grab” samples. Volatile organic samples are always grab samples because the least amount of sample disturbance is necessary.

Composite Samples

Composite samples are non-discrete samples composed of more than one aliquot collected from different sampling locations and/or at different points in time. Analysis of composite samples produces an average value.

Composite samples are frequently collected to characterize waste soil that has been stockpiled for eventual disposal. Several grab samples are collected from the stockpile and are blended together into a single sample.

Screening Samples

Screening samples may be grab or composite in nature. However, they offer potential advantages such as rapid results and low cost. The trade-off is that they may only provide results within a range and/or they may have elevated detection limits. Screening samples are most often used to evaluate presence/absence and/or indications of the potential magnitude of impacts.

3. Sampling Strategies

Generally, there are three sampling strategies: random, systematic, and judgmental sampling.

- Random sampling involves collection of samples in a non-systematic fashion from the entire site or a specific portion of a site.
- Systematic sampling involves collection of samples based on a grid or a pattern which has been previously established.
- Judgmental sampling is the collection of all other samples. This sampling might be from areas most likely to be contaminated, areas most likely to be clean, or areas where information is lacking.

Often, a combination of these strategies is the best approach depending on the type of the suspected/known contamination, the uniformity and size of the site, the level/type of information desired, etc.

4. Attachments

Attachment A - General Guidelines for selecting equipment

5. Contacts

Jerry Zak
Ryan Hoffman

General Guidelines for selecting equipment on the basis of construction material and target analyte(s)

[✔, generally appropriate for use shown; Si, silica; Cr, chromium; Ni, nickel; Fe, iron; Mn, manganese; Mo, molybdenum; CFC, chlorofluorocarbon; B, boron]

Construction material for sampling equipment		Target analyte(s)	
Material	**Description**	**Inorganic**	**Organic**
		Plastics[1]	
Fluorocarbon ploymers[2] (other varies available for differing applications)	Chemically inert for most analytes	✔ (potential source of fluoride)	✔ (Sorption of some organics)
Polypropylene	Relatively inert for inorganic analytes	✔ (not appropriate for Hg)	**Do not use**
Polypropylene (linear)	Relatively inert for inorganic analytes	✔ (not appropriate for Hg)	**Do not use**
Polyvinyl chloride (PVC)	Relatively inert for inorganic analytes	✔ (not appropriate for Hg)	**Do not use**
Silicone	Very porous. Relatively inert for most inorganic analytes	✔ (potential source of Si)	**Do not use**
		Metals	
Stainless steel 316 (SS 316)	SS-316-metal having the greatest corrosion resistance. Comes in various grades. Used for submersible pump casing.	✔ (Potential source of Cr, Ni, Fe, and possible Mn and Mo) **Do not use** for surface water unless encasted in plastic.	✔ Do not use if corroded[3]
Stainless steel 304	Similar to SS-316, but less corrosion resistant	**Do not use**	✔ Do not use if corroded[3]
Other metals: brass, iron, copper, aluminum, galvanized and carbon steels	Refrigeration-grade copper or aluminum tubing are used routinely for collection of CFC samples	**Do not use**	✔ Routinely used for CFCs Do not use if corroded[3]
		Glass	
Glass, borosilicate (laboratory grade)	Relatively inert. Potential sorption of analytes	✔ **Do not use** for trace element analyses. Potential source of B and Si	✔

[1]Plastic used in connection with inorganic trace-element sampling should be uncolored or white. Tubing used for trace metal sampling should be cleaned by soaking in 5-10 percent HCl solution for 8-24 hours, rinsing with reagent water (metals free) and allowed to air dry in mercury-free environment. After drying, the tubing is doubled-bagged in clear polyethylene bags, serialized with a unique number, and stored until used.

[2] Fluorocarbon polymers include materials such as Teflon™, Kynar™, and Tefzel™ that are relatively inert for sampling inorganic or organic analytes. Only fluoropolymer should be used for samples that will analyzed for mercury because mercury vapors can diffuse in or out of other materials, resulting in either contaminated or biased results.

[3] Corroded/weathered surfaces are active sorption sites for organic compounds.

STANDARD OPERATING PROCEDURE

SC-002 Environmental Sample Handling

1. Objective

Describe appropriate environmental sample handling procedures.

The procedures include collection and transport of environmental samples to a laboratory for chemical analysis. Appropriate sample handling should ensure that samples are properly:

- labeled and documented;
- preserved;
- packaged; and
- transported

2. Execution

- Prior to mobilizing to the field, select a shipper or arrange for a courier for sample delivery to the laboratory. If using a shipper (i.e., FedEx or UPS) determine the time constraints for pickup requests, the location and hours of the nearest shipping office, and any size/weight restrictions.
- A waterproof or permanent ink pen should be used for all labels. The label should have an adhesive backing and be placed on the jar or bottle, not on the cap. In addition, clear packing tape can be placed over the sample label to secure it to the bottle as moisture from the samples can loosen the label adhesive.
- Record the following information on the label and in the field notebook (See SOPs FD-001 and FD-003):
    - Project number
    - Sample identification (i.e. MW-201 or SS-2)
    - Date and time (military time) of collection
    - Sampler's initials
    - Analysis methods
    - Preservative, if present
- Pre-preserved laboratory jars are preferable and should be used whenever practicable. If sample jars are not pre-preserved, add preservative as appropriate.
- At each sampling location, samples should be collected in order of volatility, most volatile first. Samples collected for volatile analysis should be placed in sample containers immediately upon retrieval of the sample.
- Aqueous samples for volatile analysis should be collected without air bubbles.
- The collection and preservation method of soil samples for volatile analysis may depend on project, client, or state regulatory requirements. Check with your Project Manager and/or SOPs SM-001 and SM-002 where appropriate.

- Care must be taken to avoid getting soils on the threads of sample jars, which can cause a faulty seal.
- If compositing samples in the field, specify the basis for composite (i.e. volume, weight, spoon recovery, etc.) and record in the field book the procedure for compositing the sample.
- Once samples have been collected and labeled, place samples in a cooler with sufficient bagged ice or freezer packs (blue ice) (if allowed) to chill samples to 4°C. If using ice, use double-bagged ice.
- Complete the chain-of-custody (COC) (SOP FD-003).
- If transporting the samples by way of a shipper:
    i. The sample cooler should have water drains securely sealed with duct tape, both on the inside and outside of the cooler.
    ii. Place a layer of packing material on the bottom of the cooler as a cushion.
    iii. Individually wrap each sample bottle with bubble packing or suitable packing material and place the wrapped bottles upright in the cooler with sufficient packing material between samples to avoid breakage.
    iv. Methanol preserved samples for volatiles analysis should be packed so they remain upright with the soil completely covered by the methanol during transport.
    v. Place a layer of packing material on top of the sample bottles.
    vi. Place bagged ice or freezer packs on top of the packing material. Fill the remaining space in the cooler with packing material to eliminate the possibility of vertical movement of samples.
    vii. Place the completed and signed chain-of-custody form in a sealable plastic bag and place on top of the packing material in the cooler, or tape it to the inside lid of the cooler.
    viii. Fill out the appropriate shipping or courier forms and attach to the top or handle of the cooler. If necessary, place the proper shipping labels on the cooler. Have the courier sign the COC form (or write pickup by FEDEX, UPS, etc. with date and time). Place a signed and dated custody seal on the cooler.
- All samples should be submitted to the laboratory as soon as possible. In many cases, same day shipping will be required by the client or the project manager. Be clear on this before beginning the field work.
- A copy of the waybills should be kept by the field supervisor to track shipments if necessary.

3. Limitations

- If samples are shipped on a Friday, call the laboratory ahead of time to confirm that personnel will be at the laboratory to receive and log-in the samples.
- During warm weather, make sure to use plenty of ice in the shipping container.

- Field personnel should be aware of analyses which have short hold times and schedule sampling events and shipping accordingly. Shipment of samples for analyses with short hold times must be arranged for in advance. Refer to the project work plan, quality assurance project plan, or state/federal regulations for holding time and preservative information. Contact the laboratory ahead of time when shipping samples with short hold time to ensure the lab is prepared for these analyses.
- For glassware containing preservatives (e.g., HCl, HNO_3), take care not to overfill the container, thus flushing the preservative out of the bottle.
- Never composite samples for VOCs in the field. Collect individual aliquots and direct the laboratory to perform compositing, if needed.
- Collection of aqueous samples should not be performed over the opening of a monitoring well. Preservatives from overfilling, a marker pen or other objects could fall into the well.
- If the recharge volume for a monitoring well is low, completely fill all volatile vials and then collect the minimum sample volume required for each remaining analysis.
- During subsurface soil sampling, if the recovery from the split-spoon sample is inadequate, if appropriate, resample the bottom of the borehole to obtain proper sample volume.
- Laboratories will homogenize and test the contents of the sample container, unless directed otherwise. Samples should not contain rocks, twigs, leaves, etc… unless these materials are of interest.

STANDARD OPERATING PROCEDURE

SC-003 Investigation Derived Waste

1. Objective

Describe characterization and management of Investigation Derived Waste (IDW) resulting from site investigation activities.

IDW is solid and/or aqueous waste generated during environmental site investigations.

2. Execution

- Determine the suspected contamination type and impacted media based on previous investigations, available analytical data, and/or site history.
- Consider the following when selecting IDW management option(s):
    - Anticipated volume of IDW to be generated during on-site activities
    - Potential contaminants and their concentrations
    - Proximity to population centers and the potential for unauthorized site access
    - Potential exposures to workers
    - Potential for environmental impacts
    - Community concerns
    - Potential storage areas
    - Regulatory constraints
    - Potential on-site treatment options
    - Duration of storage
    - Client concerns or requirements
- Review IDW Management Options summarized in Attachment A for each media suspected of contamination.
- Select IDW Management Option(s) prior to the commencement of field activities that will generate waste materials.
- Include the selected IDW Management Option(s) in the Field Plan or other project documents.

Considerations and guidelines for IDW management for specific field tasks are provided below.

2.1. Test Pit Excavation

- Segregate contaminated soil from uncontaminated soil using visual and/or field screening methods.
- Use appropriate barrier (such as two layers of 6-ml plastic sheeting) for temporary stockpiling of contaminated soil adjacent to test pit.

- Backfill test pits with uncontaminated soil, unless otherwise directed by project manager.
- If directed by the Project Manager to return contaminated soil to the test pit, backfill soil in the same order as the soil was excavated from the test pit.

2.2. Boring/Monitoring Well Installation

- For auger borings, segregate contaminated soil (determined by visual and/or field screening methods) from uncontaminated soil during drilling. Segregate residual contaminated soil from split-spoon sampling.
- Auger cuttings or sediment generated by drive and wash may be spread around the ground surface at the boring location if it is acceptable to the client and the governing regulatory agency. If not, IDW may be placed in an appropriate area or container pending characterization and appropriate disposal. (A useful rule of thumb is to assume generation of one 55-gallon drum of cuttings for each 20 feet drilled with 7-¼-inch-I.D. augers).
- Segregate contaminated drilling fluid from uncontaminated fluid for rotary wash borings.
- Drilling fluid management options include pouring the drilling fluid on the ground near the boring location, if acceptable to the client and governing regulatory agency, or containerizing the fluid in drums or tanks.

2.3. Well Development/Sampling

Contaminated groundwater removed from wells by pumping or bailing for the purpose of well development and sampling may be poured on the ground near the well, if it is acceptable to the client and the governing regulatory agency. Otherwise, it should be containerized in drums or tanks.

2.4. Decontamination Fluids

Decontamination fluids may be poured on the ground in the vicinity of the well if approved by the project manager. Alternatively, the fluids may be containerized in drums or tanks.

2.5. Disposable Personal Protective Equipment

Disposable personal protective equipment (PPE) should be managed like any other IDW. However, with the clients' and project manager's approval, it may be removed from the site and disposed of as ordinary rubbish if it has not come into contact with contaminated materials.

3. Limitations

- The simplest IDW management option is to return the IDW to its source location.
- However, the selected IDW management options must meet state/federal regulations and have the client's approval. Consult with state/federal policies for IDW-related matters.

- The client is responsible for the disposal of IDW, should disposal be necessary.

Attachment A: - SUMMARY OF IDW MANAGEMENT OPTIONS
GEI Consultants, Inc. Standard Operating Procedures
Management of Investigation - Derived Waste

Type of IDW	Generation Processes	Management Options	Remarks
Soil	Boring/monitoring well installation Test pit excavation Soil sampling	Return to source location immediately after generation	Acceptable, if authorized by the client, the governing regulatory agency, and the project manager.
		Spread around boring, test pit, or original source location	Acceptable, if authorized by the client, the governing regulatory agency, and the project manager.
		Containerize and temporarily store on site	Can temporarily store in stockpiles or covered containers (i.e. drums, roll-off containers). Stockpiles must be underlain by plastic sheeting and covered with plastic sheeting. Plastic sheeting must be secure. Storage consistent with state/federal regulations.
		Send to off-site, treatment or disposal facility within appropriate timeframes	Requires proper shipping documents (i.e. manifest, Bill of Lading, etc.), analytical characterization
		Store for future treatment and/or disposal.	Storage consistent with state/federal regulations. If a RCRA hazardous waste, must meet RCRA Container/Waste Pile/Tank requirements (see notes)
		Store temporarily awaiting laboratory analysis.	Storage consistent with state/federal regulations. Can temporarily store in stockpiles or covered containers (i.e. drums, roll-off containers). Stockpiles must be underlain by plastic sheeting and covered with plastic sheeting. Plastic sheeting must be secure.
Sediment/Sludge	Sludge pit sampling Sediment sampling	Return to source immediately after generation	Acceptable, if authorized by the client, the governing regulatory agency, and the project manager.
		Store temporarily on site.	Storage consistent with state/federal regulations.
		Send to off-site facility within 90 days	Requires manifests, analytical characterization
		Store for future treatment and/or disposal.	Storage consistent with state/federal regulations. If a RCRA hazardous waste, must meet RCRA Container/Waste Pile/Tank requirements (see notes)

Attachment A: - SUMMARY OF IDW MANAGEMENT OPTIONS
GEI Consultants, Inc. Standard Operating Procedures
Management of Investigation - Derived Waste

Type of IDW	Generation Processes	Management Options	Remarks
Aqueous liquids (groundwater, surface water, drilling fluids, other wastewater)	Well installation/development Well purging during sampling Ground water discharge - pump tests Surface water sampling	Pour onto ground close to well	Non-hazardous liquids only. Should not exhibit a sheen or separate phase product. Do not discharge to the ground up-gradient of the source location. Ensure that it is permissible by local, state, and Federal regulations Is acceptable to the client, the governing regulatory agency, and the project manager.
		Store temporarily on site	If a RCRA hazardous waste, must meet RCRA Container/Waste Pile/Tank requirements (see notes)
		Send to off-site commercial treatment unit within appropriate timeframes	Refer to State regulations for appropriate timeframe. Requires appropriate shipping documents (i.e., manifest, Bill of Lading), analytical characterization
		Send to POTW	Obtain appropriate discharge permit(s)
		Store for future treatment and/or disposal.	Storage consistent with state/federal regulations. Consistent with final remedial action
		Discharge to surface water	OK if it complies with state and federal regulations. Obtain appropriate discharge permit(s).
Decontamination fluids	Decontamination of PPE and equipment	Store temporarily on site	If a RCRA hazardous waste, must meet RCRA Container/Waste Pile/Tank requirements (see notes)
		Send to off-site facility within appropriate timeframes	Requires manifests, analytical characterization
		Store for future treatment and/or disposal. Storage consistent with state/federal regulations.	Consistent with final remedial action
Disposable PPE	Sampling, drilling, and test pit excavation observation, other on-site activities	Store temporarily on site	Dispose of appropriately after characterization
		Place in on-site industrial dumpster	Project-specific determination required – must be acceptable to client and project manager
		Send to off-site facility within 90 days	Project-specific determination required
		Store for future treatment and disposal.	Storage consistent with state/federal regulations. Project-specific determination required

Notes:

1) PPE - personal protective equipment
2) POTW - publicly owned treatment works
3) Generation processes listed here are provided as examples.
   IDW may also be generated as a result of other site activities.
4) RCRA Container/Waste Pile/Tank requirements:
   Containers; 40 CFR 264 Subpart I and 265 Subpart I
   Waste Piles; 40 CFR 264 Subpart L and 265 Subpart L
   Tanks; 40 CFR 264 Subpart J and 265 Subpart J

STANDARD OPERATING PROCEDURE

SC-004 Headspace VOC Screening

1. Objective

Describe methods to obtain site-specific measurement of the total volatile organic compound (VOC) concentrations present in the headspace of a jar containing soil.

This information can be used for several purposes:

- Segregate soil based on degree of contamination.
- Identify samples for quantitative analysis of VOCs.
- Evaluate the presence or absence of VOCs in soil.

2. Execution

- A photoionization detector (PID) or flame ionization detector (FID) instrument is used to measure VOCs in jar headspace (JHS) screening.
- Select the appropriate instrument, lamp, and calibration gas for the site-specific contaminants. Calibrate the instrument in accordance with the manufacturer's instructions before JHS screening begins. Record the type of calibration gas, detector, lamp, and results of calibration in the field notebook.
- Note the highest VOC concentration that the instrument measures in air in the work area before performing JHS screening. Record this as the initial background concentration.
- Half-fill a clean, glass jar with the soil. Quickly cover the open top with one or two sheets of clean, aluminum foil and screw on the cap to tightly seal the jar. Label the jar with the sample location and sample depth.
- Allow headspace development for at least 10 minutes at an ambient temperature of 50°F or greater. Vigorously shake the jar for 15 seconds at the beginning and end of the headspace development period. When ambient temperatures are below 50°F, place the jar in a heated vehicle or building during the headspace development period.
- After headspace development, remove the screw cap to expose the foil seal. Quickly puncture the foil seal with the instrument's sampling probe and insert it to a point at about one-half of the headspace depth.
- Record the highest VOC concentration that the instrument displays as the JHS concentration. The highest concentration should occur between 2 and 5 seconds after probe insertion.

3. Limitations

- The instruments may work poorly in the rain and in freezing temperatures. Under such conditions, operate the instrument in a heated vehicle or building if possible.

- Prevent water and soil particles from entering the tip of the instrument probe. Use a filter on the instrument's probe.
- Measure background VOC conditions and perform JHS screening away from non-site-related VOC sources, such as vehicle and heavy equipment exhaust.
- The VOC concentration on the instrument's display may vary when the air contains high VOC concentrations or high moisture.
- JHS screening is a guide that helps the screener to segregate soils into broadly defined categories. JHS screening results may differ by orders of magnitude from laboratory testing results.
- Note that states may have specific procedures for field monitoring. In Massachusetts, the Massachusetts Department of Environmental Protection (DEP) requires that screening of gasoline-contaminated soil be performed in accordance with Attachment II of the DEP's policy #WSC-94-400 Interim Remediation Waste Management Policy for Petroleum Contaminated Soils. Consult this procedure or any relevant guidance documents for assistance.

STANDARD OPERATING PROCEDURE

SG-001 General Guidance on Soil Vapor Intrusion Evaluations

1. Objective

The goal of a soil vapor intrusion evaluation is to assess whether complete exposure pathways of soil vapor to indoor air exist. A complete exposure pathway exists if vapors from constituents are migrating through various pathways into residential or commercial buildings at concentrations that may result in an unacceptable human health risk. If a complete exposure pathway does not exist, then further assessment of soil vapor intrusion is not required.

Depending on the status of investigation performed at the site it may be appropriate to approach an evaluation of soil vapor intrusion at different tiers. If little work has been performed relative to the potential for contaminants to affect soil vapor near a structure, then a screening level assessment is an appropriate first step. However, if a plume is well delineated and the potential for groundwater impacts, or nearby source material, to affect soil vapor near a potential receptor structure is well understood, then it may be more appropriate to directly develop and implement a soil vapor and/or indoor air sampling plan. To accommodate the potential varied states of knowledge when a vapor intrusion evaluation is required, a flexible approach is needed that incorporates the following elements.

- SOP SG-002 Soil Vapor Sample Collection
- SOP SG-003 Sub-Slab Soil Vapor Collection
- Indoor Air Sampling
- SOP SG-004 Ambient Air Sample Collection

Soil vapor intrusion evaluations should be approached on a site-specific basis and depending on the site-specific setting and proximity to impacted groundwater or source material, it may be appropriate to proceed in a hierarchical fashion through each tier of evaluation or a variety of tiers may be combined and implemented simultaneously. The SOPs presented in this SOP address each of these sampling procedures.

2. Execution

2.1. Implementation Triggers

Soil vapor intrusion evaluations may be implemented at various times based on event triggers throughout the Site Characterization (SC), Remedial Investigation (RI), and site remedial action plan. The following event triggers would require the implementation of this soil vapor intrusion investigation.

- Identification of a potential complete exposure pathway
- Private property owner request for sampling

- State or Federal administrative order

2.2. Factors Affecting Soil Vapor Intrusion

Prior to conducting a soil vapor intrusion assessment at a private property, an analysis of the factors contributing to the migration of soil vapor to indoor air should be conducted. The completion of this analysis should take into account the two types of factors: environmental and building factors.

2.2.1. Environmental Factors

Environmental factors include site specific conditions in the subsurface and above the ground surface that may affect the rate and direction at which soil vapor may migrate.

The soil and groundwater conditions between the contamination and the residential/commercial building should be evaluated and recorded in any soil vapor intrusion investigation. If the SC/RI has been completed, then the data are available for this review. If the SC/RI has not been completed, then at a minimum the nature and extent of impacted soil and/or groundwater between the site and the residential/commercial building should be defined.

After compiling the necessary site-specific data, that information should be reviewed to determine groundwater conditions at the site. The potential for man-made or natural preferential pathways for vapor migration in the vadose zone and/or for groundwater migration in the saturated zone should also be determined at this time.

- The depth to groundwater below the residential or commercial building will be determined. For example, in cases where groundwater intersects the foundation there is no vadose zone to collect a sub-slab sample. In cases where the groundwater is close to the foundation, there is a risk of causing/exacerbating groundwater intrusion through the foundation during periods of high groundwater.

Additional Site Observations

- Direction of groundwater flow from the contaminant source to the residential or commercial building;
- The location, depth, extent, and concentration of potential constituents in unsaturated soil and groundwater on the property; and,
- Presence of an overlying water bearing zone that does not have impacts beneath the residential or commercial building. An un-impacted shallow water zone will significantly retard or completely prohibit the potential for deeper impacted groundwater to affect soil vapor.
- Potential “smear zones” (residual non-aqueous phase liquid (NAPL) present at depths over which the water table fluctuates) should also be identified as they may also affect the rate of soil vapor migration.
- Location, depth, extent of NAPL, if present.

Soils which are highly organic, wet, and/or of low permeability should be identified. If these soils are present beneath a structure and above impacted groundwater or soil, they may effectively shield the building from potential vapor intrusion. Conversely, dry and porous soils underlying a building may provide a less inhibited soil vapor intrusion pathway. The limits of backfill surrounding residential or commercial building should be also noted.

2.2.2. Building Factors

Building Factors include the physical characteristics, such as structure, floor layout, air flow, and physical conditions. These conditions will be documented during the evaluation. The New York State Department of Health (NYSDOH) Center for Environmental Health's Indoor Air Quality Questionnaire and Building Inventory form is presented in Attachment A. At a minimum, the following information should be recorded.

- Building foundation construction characteristics (basement, footers, crawl spaces, etc), including potential preferential vapor intrusion pathways such as foundations cracks and utility penetrations.
- Basement wall materials (hollow block, stone, or poured concrete, etc.)
- Presence of an attached garage.
- Recent renovations to the building such as new paint or new carpet.
- Mechanical heating/cooling equipment that may affect air flow.
- Use and storage of petroleum products such as home heating oil storage tanks, underground storage tanks (USTs), or kerosene heaters.
- Recent use of petroleum-based finish or other products containing volatile organic compounds (VOCs).
- Areas of pavement on the property should also be identified in the event sub slab vapor sampling is not feasible or appropriate due to a high groundwater table. Paved areas could serve as surrogate locations in lieu of sub slab soil vapor sampling if high water table conditions exist.

The construction materials and integrity of the floor of the structure closest to the potential point of entry for soil vapor (basement level or first floor for slab-on-grade constructions) should be identified. In addition to the foundation type and integrity, this survey should note any preferential pathways (utility lines/pipes, sumps, etc.) that may exist within the bottom-most level of the structure.

The operation and presence of heating systems, including fireplaces and clothes dryers, may create a pressure differential between the structure and the outside environment, causing an increase of migration of soil vapor into the building. The NYSDOH guidance document suggests limiting indoor air sampling to the heating season (with the exception of immediate inhalation hazard situations), which is roughly defined as November 15th to March 31st. However, sampling may be completed at any time during the year for any sampling completed in response to a request by a community member. In situations where non-heating season sampling

has taken place, consideration should be given to re-sampling the property within the heating season. The operation of HVAC systems should be noted on the building inventory form (Attachment A).

During the initial building assessment and visit, and again when sub-slab soil vapor and/or indoor air sampling are performed, differential pressure measurements between indoor air, ambient air, and soil vapor should be collected and recorded to document the potential effect building conditions have on soil vapor migration.

2.2.3. Property Visit

A property visit will be conducted prior to sampling. During the site visit, technical representatives will complete site visit observations, inventories and occupant questionnaire forms (Appendix A). During the course of the interview, observations will be made to identify any potential areas or issues of concern or the presence of any odors, and if sampling appears necessary, identify potential sampling points and general building characteristics. The questionnaire is also used to identify potential sources and activities that may interfere with sampling results. The questionnaire will specifically address the activities of the occupant's (e.g., smoking, work place activities) that may contribute to indoor air concentrations of volatile chemicals.

The responses to the questionnaire will be evaluated and a determination will be made as to whether additional investigation is required.

2.2.4. Chemical Inventory

The chemical inventory complements the identification of the building factors affecting soil vapor intrusion. The chemical inventory will identify the occurrence and use of chemicals and products throughout the building. These products can be used to develop an indoor environmental profile. A separate inventory should be prepared for each room on the floor being tested as well as any other indoor areas physically connected to the areas being tested. Inventories will include product names, chemical ingredients, or both. If possible, photographs of the products should be taken of the location and condition of the inventoried products and the photographic records should be indexed with the inventory records. The products inventory can also be used to document odors and if possible portable vapor monitoring equipment measurements should be taken and recorded. A product inventory will be repeated prior to each round of testing at the building. If available, the volatile ingredients should be recorded for each product. If the ingredients are not listed on the label, record the manufacturer's name and address or phone number if available. The product inventory form is presented in Attachment A.

2.2.5. Water Table Conditions and Vapor Intrusion Assessment Approach

Sub-slab soil vapor sampling is intended to evaluate the potential for vapor intrusion. However, there are circumstances where collection of sub-slab soil vapor samples may not be feasible if the water table is near, at, or above the elevation of a buildings foundation slab. An evaluation of the water table elevation relative to the

building slab should be made before attempting to install a sub-slab vapor sampling point.

If the water table is found to be sufficiently below the building slab and sub-slab vapor sampling can be performed, then the following Low Water Table Scenario should be followed.

2.2.5.1. Low Water Table Scenario

If the water table elevation is lower than the basement slab, then the following samples should be collected.

- Sub-slab soil vapor samples
- Indoor air samples from basement level
- Indoor air samples from main living space (First floor)
- Outdoor ambient air sample

If the water table is deemed to be at too high of an elevation to allow sub-slab vapor sampling, then alternate means of evaluating the potential for vapor intrusion must be employed. If a building has a groundwater sump, the sump should be evaluated to determine if there is water present in the sump and if that water is representative of groundwater or if the water is stagnant. If water in the sump represents groundwater, then a sample from the sump should be collected. The High Water Scenario below summarizes the methods to evaluate potential vapor intrusion if sub-slab vapor sampling cannot be conducted due to high groundwater conditions.

2.2.5.2. High Water Table Scenario

If the water table elevation is higher than the basement slab, then the following tasks should be performed.

- Determine if a sump pump is present and actively pumping water.
- If sump is actively pumping, collect a sample of groundwater from the sump.
- Collect an indoor air sample from basement level.
- Collect an indoor air sample from main living space (first floor).
- Identify exterior soil vapor sample location near foundation (outside of foundation backfill) and preferably beneath a surrogate vapor cap (e.g. paved driveway, patio).
- Collect soil vapor samples from exterior soil vapor location
- Collect an outdoor ambient air sample.

10. BULK PETROLEUM STORAGE

Aboveground storage tank on the property Yes ☐ No ☐

If yes, how old is tank? _____ Condition? _____

Last inspected? _____ Location: _____

Describe conduits to building (type, location, and entry portal condition): _____

_____

Underground storage tank on the property. Yes ☐ No ☐

If yes, how old is tank? _____ Condition? _____

Last inspected? _____ Location: _____

Describe conduits to building (type, location, and entry portal condition): _____

_____

11. WATER AND SEWAGE

Water Supply:

Public Water Drilled Well Driven Well Dug Well Other _____

Is there use of groundwater water for irrigation purposes? Yes ☐ No ☐

Sewage Disposal:

Public Sewer Septic Tank Leach Field Dry Well Other _____

12. FACTORS THAT MAY INFLUENCE INDOOR AIR QUALITY

a. Is there an attached garage? Yes ☐ No ☐

If not, is there a separate garage or carport? Yes ☐ No ☐

b. Does the garage have a separate heating unit? Yes ☐ No ☐ NA ☐

Property Location/Address: _____
Property: _____
Sampling Date: _____

c. Are petroleum-powered machines or vehicles stored in the garage (e.g., lawnmower, ATV, car)
Yes □ No □ NA □ Please specify_____

Is gasoline stored in the garage? Yes □ No □

Quantity? _____

d. Has the building ever had a fire? Yes □ No □

When?_____

e. Is a kerosene or unvented gas space heater present? Yes □ No □

Where? _____

f. Is there a workshop or hobby/craft area? Yes □ No □

Where & Type? _____

g. Is there smoking in the building? Yes □ No □

How frequently? _____

h. Have cleaning products been used recently? Yes □ No □

When & Type? _____

i. Have cosmetic products been used recently? Yes □ No □

When & Type? _____

j. Has painting/staining been done in the last 6 months? Yes □ No □

Where & When? _____

Is house paint stored inside? Yes □ No □

Where? _____

k. Is there new carpet, drapes or other textiles? Yes □ No □

Where & When? _____

l. Have air fresheners been used recently? Yes □ No □

When & Type? _____

m. Is there a kitchen exhaust fan? Yes □ No □

If yes, where vented?_____

n. Is there a bathroom exhaust fan? Yes □ No □

If yes, where vented?_____

o. Is there a clothes dryer? Yes □ No □

If yes, is it vented outside? Yes □ No □

p. Has there been a pesticide/chemical fertilizer application? Yes □ No □

Property Location/Address: _____
Property: _____
Sampling Date: _____

When & Type?_____

Conducted by Owner or Private Yard Service _____

Is yard waste/trash burned on-site? Yes □ No □

Do any of the building occupants use solvents at work? Yes □ No □

(e.g., chemical manufacturing or laboratory, auto mechanic or auto body shop, painting, fuel oil delivery, boiler mechanic, pesticide application, cosmetologist

If yes, what types of solvents are used? _____

If yes, are their clothes washed at work? Yes □ No □

Do any of the building occupants regularly use or work at a dry-cleaning service? (Circle appropriate response)

Yes, Use dry-cleaning regularly (weekly) No

Use dry-cleaning infrequently (monthly or less) Unknown

Yes, work at a dry-cleaning service

Is there a radon mitigation system for the building/structure? Yes □ No □

Date of Installation: _____

Is the system active or passive? Active □ Passive □

Are there any recent/past improvements to building? Yes □ No □

Interior painting? _____

Any landscaping improvements that involved bringing fill on site? Yes □ No □

Other _____

Approximately when (how long ago) did these improvements occur? _____

Does anyone living here engage in any of the following activities or hobbies?

a. Art projects (e.g. oil painting, ceramics, pottery, stained glass, metal sculpture)

Yes □ No □

Name: _____ Age: _____ Sex: _____

Name: _____ Age: _____ Sex: _____

Property Location/Address: _____

STANDARD OPERATING PROCEDURE

SG-002 Soil Vapor Sample Collection

1. Objective

This procedure outlines the general steps to collect soil vapor samples. The site-specific Sampling and Analysis Work Plan should be consulted for proposed sample locations, sample depths, and sampling duration.

2. Execution

Permanent and temporary soil vapor probes should be installed using the procedures outlined below. All soil vapor probes should be installed using a direct-push drill rig (e.g., Geoprobe® or similar), hand auger, or manually using a slide hammer.

2.1. Document Field Conditions

Document pertinent field conditions prior to installation of any probe points.

- Record weather information (precipitation, temperature, barometric pressure, relative humidity, wind speed, and wind direction) at the beginning of the sampling event. Record substantial changes to these conditions that may occur during the course of sampling. The information may be measured with on-site equipment or obtained from a reliable source of local measurements (e.g., a local airport). Data should be obtained for the past 24 to 48 hours.
- If sampling near a commercial or industrial building, uses of volatile chemicals during normal operations of the facility should be identified.
- Outdoor plot sketches should be drawn that include the site, area streets, neighboring commercial or industrial facilities (with estimated distance to the site), outdoor air sampling locations (if applicable), and compass orientation (North);
- Any pertinent observations should be recorded, such as odors and readings from field instrumentation.

2.2. Soil Vapor Point Installation Specifications

Each soil vapor point should be constructed as follows:

- Six-inch stainless steel Geoprobe® AT86 series Permanent Implants (soil vapor screens) or equivalent and threaded to an (expendable) stainless steel anchor point.
- The implants should be fitted with inert Teflon or stainless steel tubing of laboratory or food grade quality.
- The annular space surrounding the vapor screen interval and a minimum of 6-inches above the top of the screen should be filled with a porous backfill

material (e.g., glass beads or coarse silica sand) to create a sampling zone 1 foot in length.

For temporary points, a hydrated bentonite surface seal should be created at the surface to minimize infiltration. For permanent points, the additional measures described below should be included.

- The soil vapor points should be sealed above the sampling zone with a bentonite slurry for a minimum distance of 3 feet (or to grade, whichever is smaller) to prevent ambient air infiltration.
- If needed, the remainder of the borehole should be backfilled with clean material.
- A protective casing should be set around the top of the point tubing and grouted in place to the top of the bentonite to minimize infiltration of water or ambient air, as well as to prevent accidental damage to the soil vapor point.
- The tubing top should be fitted with a Swagelok® and cap to prevent moisture and foreign material from infiltrating the tubing.

2.3. Soil Vapor Sample Collection

Soil vapor samples should be collected as indicated in the work plan and in accordance with applicable state or federal guidance documents. Specifically, samples from the points should be collected as follows:

- Permanent soil vapor points should not be sampled or purged for a minimum of 24 hours after installation. Temporary points may be purged and sampled immediately following installation.
- Document pertinent field conditions prior to sampling as described above.
- A suction pump should be used to remove a minimum of three implant volumes from the soil vapor points prior to sampling. Include the volume of any additional tubing added to affix sampling equipment and the annular space between the probe and the native material if sand or glass beads were used.
- The purge rate shall not exceed 0.2 liters per minute.
- Samples should be collected for volatile organic compounds (VOCs) in an individually laboratory certified clean 1-liter SUMMA® canister (or equivalent) using a certified flow controller calibrated for the anticipated sample duration (4 minutes). The regulator flow rate should not exceed 0.2 liters per minute.
- A helium tracer gas should be used to identify any potential migration or short circuiting of ambient air during sampling as described below.
- Remove the protective brass plug from the canister. Connect the pre-calibrated flow controller to the canister.
- Record the identification numbers for the canister and flow controller.
- Record the initial canister pressure on the vacuum gauge (check equipment-specific instructions for taking this measurement). A canister with a significantly different pressure than originally recorded by the testing

laboratory should not be used for sampling. Record these numbers and values on the chain-of-custody form for each sample.

- Connect the tubing from the soil vapor probe to the flow controller.
- Open the valve on the canister. Record the time that the valve was opened (beginning of sampling) and the canister pressure on the vacuum gauge.
- Photograph the canister and the area surrounding the canister.
- Monitor the vacuum pressure in the canister routinely during sampling.
- Stop sample collection when the canister still has a minimum amount of vacuum remaining. Check with the laboratory supplying the canister and flow controller for the ideal final vacuum pressure. Typically, the minimum vacuum is between 2 and 5 inches of mercury, but not zero. If there is no vacuum remaining, the sample should be rejected and collected again in a new canister.
- Record the final vacuum pressure and close the canister valve. Record the date and time that sample collection was stopped.
- Remove the flow controller from the canister and replace the protective brass plug.
- Attach labels/tags (sample name, time/date of sampling, etc.) to the canister as directed by the laboratory.
- Place the canister and other laboratory-supplied equipment in the packaging provided by the laboratory.
- Enter the information required for each sample on the chain-of-custody form, making sure to include the identification numbers for the canister and flow controller, and the initial and final canister pressures on the vacuum gauge.
- Samples should be analyzed for VOCs and naphthalene via modified USEPA modified Method TO-15 and helium via ASTM D-1945.
- Include the required copies of the chain-of-custody form in the shipping packaging, as directed by the laboratory. Maintain a copy of the chain-of-custody for the project file.
- Deliver or ship the samples to the laboratory as soon as practical.
- All laboratory analytical data should be validated by a data validation professional in accordance with the USEPA Contract Laboratory Program National Functional Guidelines for Organic Data Review, January 2005 and the USEPA Region II Standard Operating Procedure (SOP) for the Validation of Organic Data modified to accommodate the USEPA Method TO-15 and natural gas analysis by ASTM D-1945.

2.4. Tracer Gas Evaluation

The tracer gas evaluation provides a means to evaluate the integrity of the soil vapor probe seal and assess the potential for introduction of ambient air into the soil vapor sample.

A tracer gas evaluation should be conducted on the each temporary soil vapor probe to be sampled in a sampling event. A tracer gas evaluation should be conducted on

the each permanent soil vapor probe during the initial sampling event and a minimum of 10% of the soil vapor probes during subsequent sampling events.

The following tracer gas evaluation procedure uses helium as a tracer gases which can be measured through laboratory analysis or by a portable detector.

Retain the tracer gas around the sample probe by filling an air-tight chamber (such as a plastic bucket) positioned over the sample location.

- Make sure the chamber is suitably sealed to the ground surface.
- Introduce the tracer gas into the chamber. The chamber should have tubing at the top of the chamber to introduce the tracer gas into the chamber and a valved fitting at the bottom to let the ambient air out while introducing tracer gas. Close the valve after the chamber has been enriched with tracer gas at concentrations >10%.
- The chamber should have a gas-tight fitting or sealable penetration to allow the soil vapor sample probe tubing to pass through and exit the chamber.
- After the chamber has been filled with tracer gas, attach the sample probe tubing to a pump that should be pre-calibrated to extract soil vapor at a rate of no more than 0.2 liters per minute. Purge the tubing using the pump. Calculate the volume of air in the tubing and probe and purge one to three tubing/probe volumes prior collecting an analytical sample or using a portable device to measuring the tracer gas concentration.
- Samples collected from vapor points during a tracer gas evaluation should be analyzed for VOCs and naphthalene via modified USEPA modified Method TO-15 and helium via ASTM D-1945.
- Alternately, a tracer gas detector may be used to verify the presence of the tracer gas in the chamber by affixing it to the valve fitting at the bottom of the chamber. The tracer gas detector may also be used to measure the tracer gas concentration in the pump exhaust during purging. If used, then record the tracer gas concentrations in the chamber and in the soil vapor sample.
- Based on the concentrations of the tracer gas detected during analysis or direct measurement, determine whether additional gas tracer evaluations are necessary.

If the evaluation on a probe indicates a high concentration of tracer gas in the sample (>10% of the concentration of the tracer gas in the chamber), then the surface seal is not sufficient and requires improvement via repair or replacement prior to commencement subsequent sample collection.

A non-detectable level of tracer gas is preferred, however, if the evaluation on a probe indicates a low potential for introduction of ambient air into the sample (<10% of the concentration of the tracer gas in the chamber), then proceed with the soil

vapor sampling. While lower concentrations of tracer gas are acceptable, the impact of the detectable leak on sample results should be evaluated in the sampling report.

Analysis of Parent and Alkylated Polynuclear Aromatic Hydrocarbons, Selected Heterocyclic Compounds, Steranes, Triterpanes and Triaromatic Steroids by GC / MS – SIM

References: Federal Register 2003, 40 CFR, Chapter I – EPA. Part 300: National Oil and Hazardous Substances Pollution Contingency Plan, Appendix C to Part 300, Chemical Analysis of Oil Composition, May 28, 2003.

EPA 8270E, SW-846, Test Methods for Evaluating Solid Waste: Physical/Chemical Methods, EPA SW-846, Revision VI (Phase II), June 2018.

ASTM, Method D7363 - 07 Standard Test Method for Determination of Parent and Alkyl Polycyclic Aromatics in Sediment Pore Water Using Solid-Phase Microextraction and Gas Chromatography/Mass Spectrometry in Selected Ion Monitoring Mode.

1. Scope and Application

Matrices: Extracts from water, soil, sediment, tissue, sludges and petroleum products.

Definitions: Refer to Alpha Analytical Quality Manual.

This method is applicable to the analysis of sample extracts for parent and alkylated polynuclear aromatic hydrocarbons (PAHs), selected heterocyclic compounds, steranes, triterpanes and triaromatic steroids by gas chromatography / mass spectrometry with selected ion monitoring (GC/MS-SIM). Target analytes listed in Tables IA and IB are determined and measured in the concentration range of 10 to 20,000 parts per trillion (ng/L) for water samples, 1 to 2,000 parts per billion (ug/Kg) for soil and sediment samples, 2 to 4,000 parts per billion (ug/Kg) for tissue samples, and 2 to 4,000 parts per million (mg/Kg) in petroleum product samples. Analytes detected over these ranges will be diluted and re-analyzed for accurate quantitation. Lower detection limits can be achieved if large volume injection (LVI, from 1uL to 50uL volume injections) techniques are employed. This technique requires client and project specific requests.

This method is intended to assist in the identification or “fingerprinting” of source material against a potentially contaminated site and can also provide information to assist in the identification of petrogenic or pyrogenic contamination.

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is required by one or more of the following laboratory personnel before performing the modification: Area Supervisor, Department Supervisor, Laboratory Director, or Quality Assurance Officer.

This method is restricted to use by or under the supervision of analysts experienced in the operation of the GC/MS and in the interpretation of GC/MS data. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

2. Summary of Method

An aliquot of a well mixed, homogeneous aqueous, solid, tissue or petroleum sample is accurately measured or weighed for sample preparation (Generally, 1L of water sample, 15-30g of soil, sediment or tissue sample, and 0.1g of petroleum sample). Please refer to the appropriate Alpha Analytical SOPs for extraction methods and sample preparation information:

- Method 3510C – *Extraction of Water Samples by Separatory Funnel* (SOP/2165),
- *Tissue Preparation and Homogenization* (SOP/2166) and *Tissue Extraction* (SOP/2264)
- *Shaker Table Extraction* (SOP/2261)
- *Organic Waste Dilution* (SOP/2265)

Water, soil/sediment, tissue and petroleum samples are spiked with surrogate compounds and extracted using methylene chloride. Sample extracts are concentrated and preliminarily screened for oil content following Alpha Analytical SOP *Gravimetric Determination* (SOP/2263). Gravimetric screening is essential at times to ensure the analytical equipment, as well as the cleanup columns, are not overloaded with oil laden samples. Samples may be cleaned by *Alumina Column Cleanup* (SOP/2260), or they may then be exchanged into hexane for optional cleanup and/or fractionation into saturated (F1) and aromatic (F2) fractions prior to analysis. See the SOP *Silica Fractionation and Cleanup* (SOP/2267) for additional sample cleanup information and details. After cleanup, the extracts are concentrated to an appropriate final volume based on oil content as determined by gravimetric weighing and spiked with internal standards for GC/MS-SIM analysis.

Analytes are introduced into the GC/MS by injecting a known volume of the calibration standards, quality control samples, and sample extracts into the GC equipped with a narrow-bore capillary column. The GC column is temperature programmed to separate the analytes, which are then detected with a mass spectrometer operating in the selective ion mode. Identification of target analytes is accomplished by comparing retention times and mass spectra with the retention times and electron impact spectra of the calibration standards. Concentrations are determined using mean relative response factors from a multi-level calibration curve. Response factors for target analytes and surrogate compounds are determined relative to the internal standards. Multi-component analytes (alkylated PAHs) are assigned the response factors of their unsubstituted, parent compounds. Sterane and Steroid compounds are assigned the response factor of the compound 5B(H)-Cholane. Triterpane compounds are assigned the response factor of the compound 17A(H), 21B(H)-Hopane-C30H52.

2.1 Method Modifications from Reference

The continuing calibration verification %D for each calibrated PAH must be below 25%, with no more than 10% of all compounds greater than 25% but less than 35%. Each CCV must be analyzed within 24 hours of the previous CCV.

The surrogate recovery limits are 50%-130%.

The duplicate RPD limit is 30%.

The PFTBA tuning is done once before each initial calibration.

The internal standard compounds used for this method are Acenaphthene-d10 and Chrysene-d12.

The confirmation ions listed in Table II are recommended and may be included or excluded based on project requirements.

3. Reporting Limits

Reporting limits for individual alkylated PAH and biomarker compounds are 2 mg/Kg (ppm) for petroleum products, 0.667and 1.0 µg/Kg (ppb) for soil/sediment samples per project requirements, 2.67 µg/Kg (ppb) for tissue samples, and 10ng/L (ppt) for water samples.

4. Interferences

Contaminants in solvents, reagents, glassware, and other sample processing hardware may cause interferences that lead to discrete artifacts and/or elevated baselines in the ion current profiles. Demonstrate that all of these materials are free from interferences under the conditions of the preparation and analysis by extracting and analyzing a laboratory method blank with each batch of up to 20 samples.

Contaminants coextracted from the sample may cause matrix interferences. The extent of matrix interferences will vary considerably from sample to sample, depending upon the nature of the environment being investigated. An interference which is unique to SIM techniques can arise from the presence of a coeluting compound which contains the quantification mass ion. This event results in a positive interference to the reported value for the compound of interest. Interferences are controlled to some degree by acquiring data for a confirmation ion. If the ion ratios between the quantification ion and the confirmation ion are not within the specified limits, then interferences may be present. Quantification and confirmation ions should agree within +/- 50% of the calibration standard ion ratios. However, the stability of confirmatory/primary ion abundance ratios may decrease as the IDL is approached. Analysts must apply judgment in evaluating apparent interferences as SIM provides less mass spectral information compared to a full-scan method. Recommended confirmation ions are listed in Table II.

The presence of a large amount of a single alkyl homolog group without the presence of the other related groups may be indicative of an interference. For example, the presence of an apparent C_2 - Naphthalenes in the absence of C_1 - Naphthalenes or C_3 - Naphthalenes may be an analytical interference. The analyst should use the retention times of major peaks and pattern recognition when determining whether to select a homolog group.

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material safety data sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

All relevant Material Safety Data Sheets (MSDSs) are kept alphabetically in the centrally located file storage.

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

Aqueous samples are collected in 1L or 500mL amber glass bottles with a Teflon lined cap.

Soil/sediment and tissue samples are collected in glass soil jars. For soil/sediment matrices the amount of sample needed is 5-30 grams, for tissues 5-15grams, and for petroleum products the amount of sample needed is 0.1 grams.

Additional sample is needed (approximately 3X the minimum amount) if MS/MSD analyses are to be performed.

6.2 Sample Preservation

Aqueous samples are stored without preservative at 4°C. Soil/sediment and tissue samples are stored at 4°C, or if desired, frozen.

6.3 Sample Shipping

Refer to the Sample Receipt and Login SOP/1559 for sample shipping requirements.

6.4 Sample Handling

The hold time for this method is 7 days for the extraction of aqueous samples and 14 days for the extraction of soil/sediment and tissue samples. There is no extraction holding time applied to petroleum product samples. If sediment or tissue samples are frozen, this suspends the holding time until removal from the freezer. All extracts must be analyzed within 40 days of the extraction date.

7. Equipment and Supplies

7.1 Gas Chromatograph: Model Agilent/HP6890 or equivalent. The instrumentation includes a temperature-programmable gas chromatograph and all required accessories including syringes, analytical columns, and gases. The injection port is designed for split or splitless injection onto a capillary column. The injection port includes a Phenomenex drilled uniliner with a hole on the top and contains a small plug of silanized glass wool. The injector port will require maintenance on an as needed basis if degradation or contamination is apparent.

7.2 Column: Restek or Phenomenex 60-m x 0.25 mm ID, 0.25 um film thickness, fused-silica capillary column with RTX-5 or ZB-5 bonded phase, or equivalent.

7.3 Mass Spectrometer – Agilent/HP5973, or equivalent. The mass spectrometer must operate at 70ev (nominal) electron energy in the electron impact ionization mode and be tuned to optimize the sensitivity of the instrument to the mass range being monitored (30 - 550 amu). The GC capillary column is fed directly into the ion source of the mass spectrometer. The source will require cleaning and/or filament replacement on an as needed basis. Please refer to the instrument hardware manual for detailed procedures, located in the laboratory next to the instrument.

7.4 Auto sampler: Agilent/HP 7683 series autosampler and tray, or equivalent.

7.5 Computer: with Windows NT version 4.0 operating software utilizing Agilent/HP Enviroquant G1701BA Version E.02.00 software, or equivalent/higher versions.

7.6 Helium: Ultra high purity grade (99.9999% pure).

8. Reagents and Standards

Use reagent grade chemicals for all reagents. Deionized (DI) water is ASTM Type II laboratory reagent grade water.

All stock standard solutions are purchased from commercial vendors as ampulated certified solutions or prepared in house from neat materials. Standards are stored according to the vendor recommendations. When an ampulated stock solution is opened, or prepared fresh from neat materials, it must be transferred into a PTFE-lined screw capped vial. All working standard solutions are stored at -10°C or less, away from light, when not in use. They are discarded after 1 year unless the vendor expiration date states otherwise or if breakdown is observed. Expired standards are prohibited from use.

8.1 Methylene Chloride, ACS approved, Pesticide grade, see Alpha Analytical SOP Reagent, Solvent and Standard Control (SOP/1816) for additional details regarding solvent purity.

8.2 Hexane, ACS approved, Pesticide grade, see Alpha Analytical SOP Reagent, Solvent and Standard Control (SOP/1816) for additional details regarding solvent purity.

8.3 Acetone, ACS approved, Pesticide grade, see Alpha Analytical SOP Reagent, Solvent and Standard Control (SOP/1816) for additional details regarding solvent purity.

8.4 Methanol, Purge and Trap grade, see Alpha Analytical SOP Reagent, Solvent and Standard Control (SOP/1816) for additional details regarding solvent purity.

8.5 Custom Mix Calibration Standard prepared by Supelco which contains the parent PAH and Heterocyclic compounds at 1000ug/mL.

8.6 5B(H)-Cholane (CAS# 80373-86-0) and 17A(H), 21B(H)-Hopane (CAS# 13849-96-2): Obtained from Chiron AS Norway at 1000ug/mL. These compounds are used for calibration and quantitation of all steranes, triterpanes and triaromatic steroids, and 5B(H)-Cholane is also used as a surrogate compound.

8.7 Surrogates:

8.7.1 **Surrogates:** Naphthalene-d8, Phenanthrene-d10, Benzo(b)fluoranthene-d12 and Benzo(a)pyrene-d12 from AccuStandard custom mix in Methylene Chloride with a concentration of 2000ug/mL. Take 500uL of stock solution into 100mL of Methylene Chloride for a spiking solution at 10ug/mL. This solution must be assayed for use by analysis before release to the preparation lab. All compounds must be within 10% of their true value. A manager's approval is needed for all surrogate spiking solutions prior to use. 100uL of solution is spiked into each QC and field sample. This amount may be adjusted to meet project specific requirements, or if a sample is suspected to contain high concentration PAHs or oil is observed.

8.7.2 **Alternate Surrogates:** This solution may be used for some programs. 2-Methylnaphthalene-d10, Pyrene-d10, and Benzo(b)fluoranthene-d12 from Restek, custom mix in Methylene Chloride with a concentration of 2000ug/mL. Take 500uL of stock solution into 100mL of Methylene Chloride for a spiking solution at 10ug/mL. This solution must be assayed for use by analysis before release to the preparation lab. All compounds must be within 10% of their true value. A manager's approval is needed for all surrogate spiking solutions prior to use. 100uL of solution is spiked into each QC and field sample. This amount may be adjusted to meet project specific requirements, or if a sample is suspected to contain high concentration PAHs or if oil is observed.

8.7.3 Biomarker surrogate: 5B(H)-Cholane from Chiron AS Norway solution at 1000ug/mL in iso-octane. Take 1,000uL of stock solution into 100mL of Methylene Chloride for a spiking solution at 10ug/mL. This solution must be assayed for use by analysis before release to the preparation lab. All compounds must be within 10% of their true value. A manager's approval is needed for all surrogate spiking solutions prior to use. 100uL of solution is spiked into each QC and field sample. This amount may be adjusted to meet project specific requirements, or if a sample is suspected to contain high concentration PAHs or oil is observed.

8.8 Internal Standards (IS): Acenaphthene-d10 and Chrysene-d12 from Restek, custom mix in Methylene Chloride with a concentration of 2000ug/mL. Prepare a 250ug/mL intermediate solution by spiking 3125uL into 25mL Methylene Chloride. Then prepare a working solution by adding 2000uL to 100mL for a 5ug/mL solution. 100uL is spiked into each 1mL of QC sample or field sample, for a concentration of 500ng/uL on column.

8.9 Laboratory Control Spike and Matrix Spike (LCS/LCSD/MS/MSD): A solution of 17 priority pollutant parent PAH's from Restek, or equivalent, at 1000ug/mL. This solution is from a separate source than the calibration solutions. Prepare the spike mix by adding 250uL of the solution to 25mL of Methylene Chloride for a 10ug/mL LCS/LCSD/MS/MSD spiking solution. The solution must be assayed for use by analysis before release to the preparation lab. All compounds must be within 10% of their true value. 100uL is spiked into the LCS/LCSD and each designated MS/MSD field sample. This amount may be adjusted to meet project specific concentrations, as needed.

8.10 Alaska North Slope Crude Oil (ANS): Weigh approximately 0.5g neat oil, add 10mL each PAH and biomarker surrogates, and 200uL internal standard stock solution into 100mL of Methylene Chloride for a working solution of approximately 5mg/mL (with surrogates at 1.0µg/mL and internals at 0.5µg/mL).

8.11 Independent Calibration Verification (ICV): Prepared as below in Section 8.13 at 0.5ug/mL, but from a different source, lot, or vendor. Independent Check analyses must agree within 20% of their true value.

8.12 SRM 1941b, 1944 – PAH's in sediment, SRM 1974a – PAH's in Tissue and SRM 1582 PAHs' in Crude Oil: From the National Institute of Standards & Technology (NIST). Please refer to the individual certifications for the assigned true values. These SRMs may be extracted and analyzed with sample batches as part of the overall QC evaluation if requested by the client. Other certified SRMs may be used on a project specific basis.

8.13 Working Stock Standard: Prepare the Working Stock Standard (all resulting concentrations at 5µg/mL) in 50mL of Methylene Chloride (CH_2Cl_2) as follows. (**Note:** The following is just one way an analyst may make up calibration standards. Limitations may exist that would cause the method to be adjusted. Problems with standard availability, solubility, or expiration may affect how the following 6 level calibration standards are prepared.)

Component	Volume Added	Final Volume in (CH_3Cl_2)
Custom Supelco Mix (PAH)	250 µL of 1000 µg/mL	50 mL
5B(H)-Cholane	250 µL of 1000 µg/mL	50 mL
Custom Deuterated Surr Mix	125 µL of 2000 µg/mL	50 mL

7 Level Curve Preparation for Individual Components

Calibration Level	Volume of Working Std. Added (5 ug/mL)	Volume of IS Stock added	Final Volume in (CH_3Cl_2)
Level 1 - 10 ng/mL	200 µL	200 uL	100 mL
Level 2 - 25 ng/mL	500 µL	200 uL	100 mL
Level 3 - 100 ng/mL	2000 µL	200 uL	100 mL

Calibration Level	Volume of Custom PAH mix Std. Added (1000 ug/mL)	Volume of IS Stock added	Final Volume in (CH_3Cl_2)
Level 4 – 500 ng/mL	25 µL	100 uL	50 mL
Level 5 - 5,000 ng/mL	125 uL	50 uL	25 mL
Level 6 - 10,000 ng/mL	250 uL	50 uL	25 mL
Level 7 - 20,000 ng/mL	500 uL	50 uL	25 mL

Note: A minimum of a 5-level curve must be analyzed, but more levels may be analyzed and evaluated.

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

Quality Control (QC) samples are necessary to monitor both the sample extraction and instrument analysis procedures. The Quality Control samples described below are considered the method defaults, and are the minimum requirements, except where noted. Client and Project specific Data Quality Objectives (DQOs) supersede the requirements in this section where applicable. Client or Project specified DQOs shall be included, or referenced, in the final report to the client.

9.1 Blank(s)

A method blank must be extracted (spiked with surrogates and internal standards) and analyzed once per every 20 samples or per extraction batch, whichever is more frequent.

Acceptance Criteria: Method Blanks must not contain any individual compound at or above the concentration of the reporting limit. If a blank does contain target compounds greater than the reporting limit, they should be less than 10% of any sample results for the same compound(s). Individual compounds may be detected in the blank below the reporting limit. Associated sample results are flagged with a “B” qualifier if the concentration of the analyte in the sample is less than 10x the concentration in the blank.

Corrective Action: If the blank does not meet the above criteria, all efforts must be made to identify and eliminate any source of contamination, and all samples associated with the

contaminated blank should be re-extracted and reanalyzed. Exceptions may be made with the approval of the Department Supervisor. Any exceedances are noted in the case narrative.

9.2 Laboratory Control Sample and Laboratory Control Sample Duplicate (LCS/LCSD)

The laboratory control samples (LCS/LCSD) contain 17 priority pollutant parent PAHs. The spiking solution is from a second/separate source, to verify the accuracy of the calibration curve. The LCS/LCSD are extracted along with the samples. An LCS/LCSD must be extracted and analyzed once per every 20 samples or per extraction batch, whichever is more frequent.

Acceptance Criteria: All LCS/LCSD compound recoveries must be between 50-130% of the true values, with <30%RPD.

Corrective Action: If the LCS/LCSD do not meet the QC limits, check to see if an analytical or spiking error has occurred. If the LCS/LCSD recoveries are still out of control, re-extraction of the entire extraction set may be necessary. If the samples are also associated with a matrix spike and matrix spike duplicate that are in control, re-extraction may not be necessary, as this demonstrates an isolated problem pertaining to the LCS/LCSD only. Exceptions may be made with the approval of the Department Supervisor. Any exceedances are noted in the case narrative.

9.3 Initial Calibration Verification (ICV)

The analysis of an ICV standard must follow the initial calibration curve.

After final processing, calculate the percent recovery of each PAH by using the following calculation:

% Recovery = Found Amount / True Value x 100

Acceptance Criteria: All recoveries must be +/- 20% of the true values.

Corrective Action: If the ICV fails, perform instrument maintenance and repeat the initial calibration..

9.4 Continuing Calibration Verification (CCV)

A continuing calibration verification (CCV) standard, at the concentration of a mid-level initial calibration standard, must be analyzed at the beginning and end of every analytical sequence, and every 24 hours within the sequence, to confirm instrument stability, via response factor, for each calibrated PAH. Only the parent PAH compounds are monitored for %D and the following acceptance criteria.

Acceptance Criteria: Compare the CCV response factor(RF) against the average RF for the initial calibration for each calibrated PAH. The %D for each calibrated PAH must be below 25%, with no more than 10% of all compounds greater than 25% but less than 35%. If multiple CCVs are analyzed within an analytical sequence, each CCV must be analyzed within 24 hours of the previous CCV. Each CCV, including the ending CCV must meet the acceptance criteria.

Corrective Action: If the CCV does not meet the acceptance criteria for each calibrated PAH, perform instrument maintenance and repeat the continuing calibration. Re-analyze all affected samples. Reported results for the failing CCV may be “J” qualified; including all alkylated compounds quantified using the suspect response. If the failure of the suspect response

appears related to a loss in MS sensitivity, instrument maintenance and repeat analysis of the continuing calibration, and all affected samples, must be performed. Exceptions may be made with the approval of the Department Supervisor. Any exceedances are noted in the case narrative.

9.5 Matrix Spike/Matrix Spike Duplicate (MS/MSD)

Matrix spike and matrix spike duplicate analyses are performed per client request and may only be performed if sufficient sample is supplied. It is preferable to extract samples that have been selected specifically by the client. If none have been assigned than the laboratory analyst must choose a representative sample.

Acceptance Criteria: All matrix spike/matrix spike duplicate compound recoveries must be between 50-150% of the true values, with <30%RPD.

Corrective Action: If the MS/MSD do not meet the QC limits, check to see if an analytical or spiking error has occurred. If the recovery still exceeds the control limits, re-extraction of the set may be necessary. If the associated LCS/LCSD is within control, re-extraction may not be necessary, as this demonstrates that there may be matrix effects on the accuracy of the affected results as evidenced by the matrix spike and matrix spike duplicate exceedance. Exceptions may be made with the approval of the Department Supervisor. Any exceedances are noted in the case narrative.

9.6 Sample Duplicate

A sample duplicate (DUP) is extracted per client request.

Acceptance Criteria: The QC limit is 30% RPD for target compounds found above 5 times the reporting limit.

Corrective Action: If the %RPD exceeds the 30% control limit, checkto see if an analytical or spiking error has occurred. Also check sample preparation notes for heterogeneity comments or for possible calculation errors. If the RPD still exceeds the control limits, re-extraction of the set may be necessary. If the associated LCS/LCSD is within control, re-extraction may not be necessary, as this demonstrates that there may be matrix effects on the precision of the affected results as evidenced by the sample and duplicate exceedance. Exceptions may be made with the approval of the Department Supervisor. Any exceedances are noted in the case narrative.

9.7 Method-specific Quality Control Samples

9.7.1 Surrogates

Acceptance Criteria: All surrogate recoveries must be between 50-130% of the true values.

Corrective Action: If the surrogate does not fall within the QC limits, check to see if an analytical or spiking error has occurred. If only one surrogate falls below the 50% recovery limit, but is above 10% recovery, re-extraction may not be necessary. If all surrogates are recovered below the 50% limit, re-extract the sample and report the re-extract results along with the original results, if re-extraction occurred beyond the holding time, and the re-extract surrogates are within the QC limits. If the surrogates are recovered below 50% in the re-extract, this confirms suspected matrix interference on the surrogates, and only the original analysis needs to be reported. If the chromatogram shows obvious matrix interference, no re-analysis or re-extraction is necessary.

9.7.2 Internal Standards

Internal standards are added to every field sample, QC sample, and method blank.

Acceptance Criteria: The acceptance limits are 50-200% of the internal standard response (or area) of the daily continuing calibration verification standard.

Corrective Action: If the internal standard areas fall outside the QC limits, check to see if an analytical, dilution or spiking error occurred.

- If internal standards are low and surrogate recoveries are acceptable reanalyze the extract.
- If internal standards are low and surrogate recoveries are high, there may have been a spiking error; re-spike a pre-internal standard extract with internals and re-analyze.
- If internal standards are high and surrogate recoveries are low, there may have been a spiking error; re-spike a pre-internal standard extract with internals and re-analyze.
- If internal standards are high and surrogate recoveries are acceptable, the extract may have concentrated while on the instrument, then:
    - If no obvious interference is present, re-analyze the extract. If internal standards are now within the acceptance limits, report only the re-analysis, as long as the re-analysis occurred within the 40-day analytical hold time. If the re-analysis occurred outside of the 40-day analytical hold time, both the original and re-analysis must be reported. If the internal standards again are outside the acceptance limits, and either within or outside of the 40-day hold time, try re-analyzing at a 1:5 or greater dilution (see below).
    - If the chromatogram shows obvious matrix interference that cannot be avoided when integrating, a re-analysis at a 1:5 or greater dilution may be helpful in minimizing the interference while ensuring better quantitation.

Exceptions may be made with the approval of the Department Supervisor. Any exceedances are noted in the case narrative.

9.7.3 Standard Reference Materials (SRMs)

Standard reference materials (SRM) are available from the National Institute of Standards and Technology (NIST) and are extracted and analyzed with samples on a project specific basis. These are not used as controls, but to evaluate potential matrix effects in associated samples for the target compounds being evaluated.

Acceptance Criteria: Acceptance criteria for SRM analysis will vary from project to project depending upon client data quality objectives (DQOs). Generally, ± 35% difference (%D) based on the true certified values of the target compounds of interest, or 65% - 135% recovery, serve as advisory acceptance criteria.

Corrective Action: Repeat analysis and/or check to see if an analytical error has occurred. If the % recovery or %D still exceeds the control limits, re-extraction of the set may be necessary. If the associated LCS/LCSD and/or MS/MSD are

within control, re–extraction may not be necessary as this may be isolated to this sample as evidenced by the LCS/LCSD and/or MS/MSD acceptance. Exceptions may be made with the approval of the Department Supervisor. Any exceedances are noted in the case narrative.

9.8 Method Sequence

Samples are prioritized for analysis by the Department Supervisor or GC/MS Team Leader based on client due date and sample analytical hold time. Samples are retrieved from the sample storage refrigerator.

The sequence is prepared and run using the Enviroquant software. Printouts of all sequences are kept in a three-ring binder for each instrument. The sequence printouts are used to document analytical runs; notations are manually added of any reruns or dilutions that will need to be performed.

10. Procedure

10.1 Equipment Set-up

Prior to the analysis of any standards or samples, the instrument acquisition and process methods must be set up. This includes the GC run parameters and the SIM mode acquisition ion entries into the different SIM acquisition retention time windows. The mass spectrometer must be tuned to the meet the abundance criteria for PFTBA (then DFTPP if required per client request or project specific DQOs) and an initial calibration must be analyzed to establish linearity of the instrument.

10.1.1 PFTBA Manual Tuning

10.1.1.1 Prior to initial calibration, tune the mass spectrometer using PFTBA (Perfluorotributylamine - calibration gas) to maximize the sensitivity of the instrument in the mass range of interest, 35-525 amu.

10.1.1.2 The following PFTBA mass intensity criteria must be met:

PFTBA Ion	Relative Abundance
m/e 69	Base Peak with > 200,000 counts
m/e 219	30% to 60% of Base Peak
m/e 502	5% to 11% of Base Peak

10.1.2 GC Instrumental Conditions

Inject an aliquot of 1uL into the capillary column of the gas chromatograph at the following conditions. Larger injection volumes (to 50uL using the Large Volume Injector, LVI) will be dictated by project specific DQOs.

GC Parameter	Setting
Injector Temp:	300 °C
Transfer Line Temp:	300 °C
Initial Oven Temp:	40 °C
Initial Hold Time:	1 minute
Ramp Rate:	6 °C / minute
Final Temperature:	315 °C
Final Hold Time:	30 minutes
Total runtime:	76 minutes
Mode:	Splitless / Constant Flow 1.0ml/min
Purge:	20 mL / minute – on at 1.0 minutes
MS Temperature	300

10.1.3 Mass Spectrometer Conditions

The effluent from the GC capillary column is fed directly into the ion source of the mass spectrometer. The MS is operated in the SIM mode using appropriate retention time windows to include the quantification and confirmation ions for each PAH and Biomarker compound as shown in Table II. For each retention time window the ions 191, 217, and 218 are included for sterane and triterpane quantification, if requested by the client.

10.1.4 Data Acquisition Parameters

10.1.4.1 SIM Windows must be set up that bracket the expected retention times for each target analyte. These windows include the quantitation (primary) and confirmation ions for each parent PAH and Alkyl homolog group. To establish the expected retention time window ranges, the mid-level calibration standard must be analyzed in full scan mode. The resulting full scan analysis will dictate the windows in which the selected ions will be monitored. Depending upon the length of the analytical GC column, the time each window is selectively monitored may vary. The retention time windows must be shifted accordingly, when instrument maintenance is performed, (*i.e.,* the column is clipped).

10.1.4.2 The “dwell” time for each window should be set to 18, and the resolution should be set to “high”. Each window must contain a total of 28 ions, and must contain the appropriate quantification ions, and if possible, confirmation ions, as determined by full scan analysis of the mid-level standard from 10.1.4.1, Specific projects may require the addition of ions to one or more SIM windows; in these instances it is acceptable to remove confirmation ions as necessary to keep the total number of ions in each window at 28 and the dwell time per ion at 18.

10.2 Initial Calibration

10.2.1 Before analysis of sample extracts, establish a multi-point response factor calibration curve showing the linear range of the analysis for all target analytes in Table IA and IB. Use standard concentrations of 10, 25, 100, 500, 5000, 10,000 and 20,000 ng/mL to construct the curve. See Section 8.13 for the preparation of the standard solutions for the initial calibration curve.

10.2.2 Run a sequence with the initial calibration standards and the retention time standard.

- Create a processing method from a previous method on that instrument. Set retention time windows using a mid level standard.

- Quantify and QEDIT the initial calibration standards. Update the response factors for each level of the method with these standards. Use each parent PAH compound response for any associated homolog group. Use hopane response for associated triterpane biomarkers and 5B(H)cholane response for associated sterane and triaromatic steroid biomarkers.

  Acceptance Criteria: 25% RSD for 90% of all target compounds, with the exception for 10% to be between 25%RSD and 35%RSD. All calibration standards must be analyzed within 24 hours. An alternative calculation may be employed by the use of linearity calibraton model as long as the correlation coefficient is >0.995 and orgin is NOT forced through 0.

10.2.3 Initial Calibration Verification (ICV)

- The analysis of an ICV standard must follow the initial calibration curve.

- After final processing, calculate the percent recovery of each PAH by using the following calculation:

  % Recovery = Found Amount / True Value x 100

- Acceptance Criteria: All recoveries must be +/- 20% of the true values.

10.2.4 If the initial calibration fails, perform instrument maintenance and repeat.

10.2.5 Alaska North Slope Crude Reference Oil (ANS)

- The ANS crude oil reference standard is analyzed following each initial calibration curve. Analysis of this reference oil is to establish the integration patterns of the Alkyl PAH homolog groups, and to establish the current instrument quantitation and confirmation ion ratios. Analysis of this standard following the initial calibration ensures the retention time windows in the SIM mode of acquisition have been set up properly.

- The analysis of the ANS standard is for reference. If instrument maintenance is performed, such as removing a significant section of the analytical column consisting of one “loop” or more, the ANS must be analyzed to update and/or confirm the SIM acquisition windows.

- The ANS reference standard is processed against the completed initial calibration curve method. See Section 11.1 for information regarding manual integration of the

Alkyl PAH homolog clusters. This standard will be used for reference when processing field samples for this method, until such a time that a new ANS standard needs to be analyzed. Other project/client specific source oils may be used. These specific oils will likely display patterns that differ from ANS, but will aid analysts in pattern identification of the related field samples.

10.2.6 ICALs are documented on the *Alkylated PAH ICAL Checklist (Form/11443)* . The initial calibration must be secondary reviewed before analyzing samples.

10.3 Equipment Operation and Sample Processing

10.3.1 Daily PFTBA Tuning is not required. See Section 10.1.1 for details.

10.3.2 If the on-column concentration of any single peak PAH compound exceeds the calibration range of 20,000 ng/mL, the sample must be diluted and re-analyzed.

10.4 Continuing Calibration

A continuing calibration verification (CCV) standard, at the concentration of a mid-level initial calibration standard, must be analyzed at the beginning and end of every analytical sequence, and every 24 hours within the sequence, to confirm instrument stability, via response factor, for each calibrated PAH.

10.4.1 Quantitate and QEDIT the continuing calibration standard. **Note:** The Alkyl homolog groups may be deleted from the report. Only the parent PAH compounds are monitored for %D and the following acceptance criteria.

10.4.2 Acceptance Criteria: Compare the CCV response factor(RF) against the average RF for the initial calibration for each calibrated PAH. The %D for each calibrated PAH must be below 25%, with no more than 10% of all compounds greater than 25% but less than 35%. If multiple CCVs are analyzed within an analytical sequence, each CCV must be analyzed within 24 hours of the previous CCV. Each CCV, including the ending CCV must meet the acceptance criteria.

10.4.3 If the CCV does not meet the criteria for each calibrated PAH, the following *corrective actions* are recommended:

- Perform instrument maintenance and repeat the continuing calibration, and re-analyze all affected samples, OR,
- Qualify all results reported for the failing CCV with an appropriate qualifier, including all alkylated compounds quantified using the suspect response, and any non-detects. If the failure of the suspect response appears related to a loss in MS sensitivity, instrument maintenance and repeat analysis of the continuing calibration, and all affected samples, must be performed.

The choice of corrective action must be made in consultation with the Department Manager, Project Manager and/or the client. The reasoning for choosing the second option must be documented in the project narrative to the client.

10.5 Preventive Maintenance

If performing any maintenance on any piece of equipment it must be documented in the *Instrument Maintenance Logbook* located in the laboratory specific to each instrument. Specific instrumentation service contracts or warranties differ from each instrument. See the Department Manager for specific instrument details.

Injection Port and Column Maintenance: Maintenance should be done when the daily CCV starts to demonstrate degradation. The type of samples analyzed will have an effect on how

soon maintenance should be performed. The injection port can be cleaned using cotton swabs and DCM until no contamination is observed. Generally maintenance is performed by trimming 6 cm off the front of the column. The column is then installed into the injection port liner and the inlet nut is tightened. After cleaning the instrument must be checked for any air leaks while cool. The first injection should be a primer to remove any active sites and to check if any of the windows need updating.

Merlin Maintenance: The Merlin High Pressure Microseal (Part #410 Phenomenex) should be replaced when it cannot hold back pressure. A septum may be used as a backup or for troubleshooting.

11. Data Evaluation, Calculations and Reporting

11.1 Identification of the priority pollutant PAH compounds is based on gas chromatographic relative retention times (RRTs) from the analysis of a mid-level initial calibration standard. For these compounds, manual quantitations may be performed, if necessary, by integrating the area of the quantitation ion or peak. For *alkylated* PAHs, the homolog groupings (*i.e.,* C_3-Naphthalenes) appear in the extracted ion current profiles (EICPs) as a cluster of isomers. Integrate peaks within the cluster by straight-line integration to the baseline, taking into account background noise in the EICPs. Reference the Alaska North Slope Crude Oil pattern book, for a cluster by cluster example of each integration for each alkylated PAH homolog group. Table II, in Section 16, lists the representative ion(s) used for quantitation and confirmation of each parent PAH and alkylated PAH homolog group.

> **Note:** Manual integration is not to be used solely to meet QC criteria, nor is it to be used as a substitute for corrective action on the chromatographic system.

11.2 From EICP of the quantification (primary) mass ions and the confirmatory mass ions, identify all target analytes according to the following criteria:

- The characteristic masses of each analyte of interest should maximize in the same, or within one scan of each other.
- The retention time should fall within ± 10 seconds of the retention time of the parent PAH from the preceding CCV. **Note:** When evaluating alkyl homolog groups, the retention time of the most intense peak within the group may not have the exact retention time of the most intense peak in the ANS reference standard. Analyst judgement and referral to each homolog groups' retention time window is essential for identification. Apply analyst judgment regarding corrective action when this criterion is not met.
- The relative peak heights of the primary ion compared to the confirmation or secondary ion masses for parent compounds should fall within ± 50 percent of the relative intensities of these masses in the reference mass spectrum (*i.e.,* the mid-level of the initial calibration curve and/or the Alaska North Slope Crude Oil).

Note: The relative intensities of the primary and secondary ions may vary widely within a given group of alkyl homologs (*i.e.,* C_3 - Naphthalenes). Thus, the pattern of each alkyl homolog cluster, and the retention time window for the cluster, will be the primary identification criteria for alkyl homologs. In some instances, a parent compound that does not meet secondary ion confirmation criteria may still be determined to be present in a sample after close inspection of the data by the experienced mass spectrometrist. Supportive data includes the presence of the secondary ion, but ratio value greater than ± 50 percent of the primary ion, may be caused by an interference of the secondary ion.

11.3 To calculate the ***Relative Standard Deviation*** (RSD) of all target analytes and surrogate compounds for the initial calibration use the formula below. The RSD of each target compound and surrogate must be below 25% with the exception for 10% to be between 25%RSD and 35%RSD. Additionally, use the initial seven-point calibration and determine ***Relative Response Factors*** (RRF_Is) at each concentration level. Average the RRF_Is, to generate mean RRF_Is, for quantification of all target analytes and surrogate compounds. The RRF_Is are based on the internal standard compounds, and are calculated using the formula below. (The relative response factors for the continuing calibration verifications (RRF_Cs) are calculated using the same formula). See Section 16, Table IA and Table IB, for the listing of target compounds and their associated internal standards for quantification.

$$\mathbf{RSD = SD / mean\ RRF_I \times 100}$$

where:

SD = Standard deviation between the five points, for that target analyte.

$$\mathbf{RRF_I = (A_c \times C_{IS}) / (A_{IS} \times C_c)}$$

where:

A_c = Area of the characteristic ion for the standard compound to be measured.
A_{IS} = Area of the characteristic ion for the representative internal standard compound.
C_{IS} = Concentration of the representative internal standard compound (ng/mL).
C_c = Concentration of the standard compound to be measured (ng/mL).

Note: Assign the response factor of the parent compound to the alkyl homolog cluster.

11.4 Based on the mean RRF_Is, calculate the ***Sample Extract Amount*** for each target analyte and surrogate in the extracts using the following formula:

$$\mathbf{Q_e = (A_a \times Q_{IS}) / (A_{IS} \times RRF_I)}$$

where:

Q_e = Sample extract amount (ng) of target analyte, from quantitation report.
A_a = Area of the characteristic ion for the target analyte.
A_{IS} = Area of the characteristic ion for the representative internal standard compound.
Q_{IS} = Amount of internal standard compound added to each extract (ng).

11.5 Calculate the ***Sample Concentration*** (C) for each compound by the following formula:

$$\mathbf{C = (Q_e / V_s) \times DF}$$

where:

C = Concentration in sample (ng/L water, ug/Kg sediment/tissue, or mg/Kg product).

V_s = Original volume or weight of sample extracted.

DF = Dilution factor or fraction of the original extract to which internal standard added.

11.6 If the response of any individual target compound in a sample exceeds the linear response range, as defined by the initial calibration standards in Section 10.2.1, dilute the extract so that the concentrations of all individual target compounds fall within the range of the calibration curve. If that compound is also part of an alkyl homolog group, the group is considered to exceed the calibration range and thus, would also require dilution. Reported concentrations that are above the highest standard concentration in the initial calibration are qualified with an "E". If the response of any target compound in a sample exceeds the MDL but is below the reporting limit (RL), qualify the reported concentration with a "J". If any target compound is found in the associated sample(s) at or below 10x the concentration of the method blank, qualify the reported concentration with a "B".

11.7 Compare response factors for each compound in the ***Continuing Calibration Verification*** (CCV), to those of the initial calibration curve by determining the percent difference.

$$\textbf{Percent Difference (\%D)} = ([RRF_I - RRF_C] / RRF_I) \times 100$$

where:

RRF_I = Mean response factor from initial calibration.

RRF_C = Response factor from CCV.

11.8 All results must be reported to three significant figures. All solids including soils, sediments, and sludges must be reported on a dry-weight basis. Tissue results may be reported in wet-weight depending upon client request. Petroleum results are reported "as received" or on a wet-weight basis.

11.9 The analyst does data entry, or upload of the data, into the LIMS system. The LIMS is linked to the instrument, so the analyst must choose the sample(s) to be reported from that instrument's analytical sequence. All associated preparation and instrumental QC samples and dilutions are also chosen. Once the data/samples have been selected and with the proper QC samples, the batched data set is reported.

11.10 The laboratory generates two types of data packages from the LIMS: "Standard" for routine projects and "CLP-like" for fully data validated projects. A standard package consists of sample results and the associated QC sample results. A CLP-like package includes all sample results, all preparation and instrumental QC results, and the associated supporting raw data. A secondary review is performed on all data.

11.11 Procedures for data and record management must adhere to the Quality Systems Manual, other subordinate documents covering record keeping, and the *Document Control* SOP (1729). All records shall be stored in such a manner as to be safe and accessible for at least 10 years.

11.12 Notebooks: Laboratory notebooks are designed to accommodate the specific analysis. Instrument printouts are used to document run sequences, and each sequence printout is filed in a three-ring binder. Each sequence notebook page is numbered. If a sample requires re-analysis or re-extraction for any reason, a notation is made next to the sample entry on the sequence log. The sequence run log is permanently bound, assigned an internal ID number, and filed accordingly. Such files shall be archived so as to remain available for at least 10 years. All laboratory notebooks must follow the specifications in the *Laboratory Notebook Usage* Work Instructions, WI 1556, and all record keeping and document control practices.

11.13 Electronic records: All data files from computers, attached to instruments, shall be backed up daily onto the proper directory on the server. The backups shall be stored so as to be accessible for 10 years. Movement of the data files to the server is the responsibility of the primary analyst. Server backup and storage is the responsibility of the IT department.

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

All Alkylated PAH-SIM results are reportable without qualification if analytical holding times are met, preservation requirements (including cooler temperatures) are met, and all QC criteria defined in the table below are met. If any of the below QC parameters are not met, all associated samples must be evaluated for re-analysis or re-extraction. See Sections 9, 10.2, 10.3 and 10.4 for additional QC discussion including corrective actions for any QC outliers.

QC Parameter	Acceptance Criteria
Initial Calibration Curve	≤ 25%D for all target analytes with exception for 10% of target analytes can be >25%, but ≤ 35%
Independent Calibration Verification	+/- 20% recovery of the true values
Continuing Calibration Verification	Analyzed every 10 samples or 24 hours, ≤ 25%D for all target analytes with exception for 10% of target analytes can be >25%, but ≤ 35%
Method Blank	No analyte at or above the RL, “B” qualify analyte if detected in the samples ≤ 10x the concentration in the blank
Laboratory Control Sample/Laboratory Control Sample Duplicate	50-130%R for all target analytes, <30%RPD between duplicates
Matrix Spike / Matrix Spike Duplicate	50-150%R for all target analytes, <30% RPD between the duplicates.
Sample / Sample Duplicate	<30% RPD between the duplicates, for compounds >5X RL.
Surrogates	50% - 130% recovery
Internal Standards	50% - 200% of the daily CCV area for the Internal Standards
SRM	+/- 35% D or 65% - 135% recovery

Section 9, Quality Control, defines the corrective actions that must be taken in instances where QC outliers exist.

If non-compliant Alkylated PAH-SIM results are to be reported, the Department Manager and/or the Laboratory Director must approve the reporting of these results. The laboratory Project Manager shall be notified, and may chose to relay the non-compliance to the client, for approval, or other corrective action, such as re-sampling and re-analysis. The analyst or Department Manager performing the secondary review initiates the project narrative, and the narrative must clearly document the non-compliance and provide a reason for acceptance of these results.

13. Method Performance

13.1 Method Detection Limit Study (MDL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the MDL, LOD, and/or LOQ as outlined in Alpha SOP/1732. These studies performed by the laboratory are maintained on file for review.

13.2 Demonstration of Capability Studies

Refer to Alpha SOP/1739 for further information regarding IDC/DOC Generation.

13.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

14. Pollution Prevention and Waste Management

Refer to Alpha's Chemical Hygiene Plan and Waste Management and Disposal SOP for further pollution prevention and waste management information.

1,4-Dioxane

By Gas Chromatography / Mass Spectrometry in Selected Ion Mode (GC/MS-SIM) with Isotope Dilution Modification

1,4-Dioxane Analytical Notes, Appendix II-B-4, WSC-CAM-II-B, Revision 1, July 2010, (Massachusetts Department of Environmental Protection Bureau of Waste Site Cleanup).

1. Scope and Application

Matrices: Aqueous, soil/sediment and non-aqueous waste matrices

Definitions: Refer to Alpha Analytical Quality Manual.

This method is applicable to the quantification of 1,4-Dioxane extracted from aqueous samples in methylene chloride and analyzed by GC/MS-SIM. The extraction method is listed below and should be referenced for more details. Detection limits will vary with instrument calibration range, and volume of sample analyzed. 1,4-Dioxane detected over the calibration ranges of the instrument it is being analyzed on will be diluted and re-analyzed for accurate quantification.

The following extraction method applies:

- *Extraction of Water Samples by Separatory Funnel* (SOP 2165)
- *Microscale Solvent Extraction (MSE)* (SOP 2172)
- *Organic Waste Dilution Extraction* (SOP 2265)

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one or more of the following laboratory personnel before performing the modification: Area Supervisor, Department Supervisor, Laboratory Director, or Quality Assurance Officer.

This method is restricted to use by or under the supervision of analysts experienced in the operation of the GC/MS-SIM and in the interpretation of GC/MS-SIM data. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

2. Summary of Method

250mL, 500mL or 1000mL of aqueous samples are serially extracted with methylene chloride in a 2 Liter Separatory Funnel (Method 3510) at a neutral pH. The extract is concentrated in MeCl2 to a 2.5mL to 10mL final volume respectively depending on the volume of sample extracted. Soil/sediment samples are extracted by Microscale Solvent Extraction (MSE Method 3570). Approximately 5g of sample is extracted and concentrated to a 4mL final volume. Non-aqueous waste samples are extracted by Organic Waste Dilution Extraction (Method 3580). Approximately 1g is diluted to 10mL

final volume.

Analytes are introduced into the GC/MS using a large volume injector and injecting 3ul of the calibration standards, quality control samples, and sample extracts into the GC equipped with a narrow-bore capillary column. The GC column is temperature programmed to separate the analytes, which are then detected with a mass spectrometer (MS) in selective ion mode. Identification of target analytes is accomplished by comparing their mass spectra with the electron impact spectra of the calibration standards. Concentrations are determined using mean relative response factors from a multi-level calibration curve. Response factors for target analytes and surrogate compounds are determined relative to the internal standards.

Isotope dilution quantification is achieved by spiking 1,4-Dioxane-d8 at extraction which is then in turn used as both an internal standard (IS) and surrogate. For quantification, the 1,4-Dioxane-d8 IS quantifies 1,4-Dioxane in samples. An additional IS added prior to analysis, 1,4-Dichlorobenzene-d4, quantifies 1,4-Dioxane-d8 as a surrogate.

2.1 Method Modifications from Reference

SIM option with Isotope dilution is utilized to increase sensitivity for this analyte. Note that while this method may be used for the evaluation of 1,4-Dioxane in soil/sediment samples, the MA DEP CAM does not approve of this method for determining presumptive certainty for MA DEP cleanup sites. Method 8260 should be employed in these cases.

3. Reporting Limits

Concentrations for 1,4-Dioxane can be detected in water samples in the range of 150ng/L to 100,000ng/L. Soil/sediment samples can be detected in the range of 8ug/Kg to 8,000ug/Kg. Standard reporting limits for aqueous samples are 150ng/L and for soil/sediment samples 8ug/kg respectively.

4. Interferences

4.1 Phthalate esters can be a major source of contamination if any material containing plasticizers (phthalates) comes in contact with the sample during the extraction process. Use of plastic or any material containing plasticizers (phthalates) should be avoided during extraction or analysis.

4.2 The injection port of the gas chromatograph can become contaminated with high boiling compounds resulting in the loss of sensitivity. It may be necessary to replace the injection port liner routinely to prevent this loss of sensitivity. Clipping off approximately four inches of the column at the injection end may also increase sensitivity. Low instrument response can be detected during the daily tuning procedure by including pentachlorophenol and benzidine in the daily tuning mix.

4.3 Raw GC/MS data from all blanks, samples, and spikes must be evaluated for interferences or carryover. Contamination by carryover can occur whenever high-concentration and low-concentration samples are sequentially analyzed.

4.4 Solvents, reagents and glassware may introduce interferences. These must be demonstrated to be free of interferences by the analysis of a method blank. See the SOP *Reagent, Solvent and Standard Control* (G-008) and *Laboratory Glassware Cleaning* (G-002), for additional details.

4.5 It should be noted that there are some chromatographic consequences observed due to the acetone used in the MSE extraction process. This is characterized by a shift in retention time

for 1,4-Dioxane and the 1,4-Dioxane-d8 surrogate (~0.4minutes), as well as the presence of a large peak (likely acetone) in all chromatograms.

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material safety data sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

Solid samples; A minimum of 100grams of sample must be collected in a glass jar with a Teflon lined screw cap.

Water samples: A minimum of 0.25 to 1 liters of sample must be collected in amber glass bottles.

6.2 Sample Preservation

Solid samples: The sample must be refrigerated and maintained at 4±2 °C until extraction and analysis. Sediment samples can be frozen at -20±5 °C until extraction to extend hold time. The extracts must be refrigerated and maintained at 4±2 °C until analysis.

Water samples: The samples must not be preserved except by refrigeration at 4±2 °C until extraction and analysis. The extracts must be refrigerated and maintained at 4±2 °C until analysis.

Non-aqueous waste samples: Concentrated sample extracts must be stored in contaminant-free containers and preserved in a refrigerator when not used for more than four hours.

6.3 Sample Shipping

No special shipping requirements.

6.4 Sample Handling

Solid samples: All solid samples must be extracted within 14 days from the date of collection. Frozen sample hold times are monitored up to 14 days from the date removed from freezer. The extracts must be refrigerated and maintained at 4±2 °C until analysis. Sample extracts must be analyzed within 40 days from date of extraction.

Water samples: All water samples must be extracted within 7 days from the date of collection. Sample extracts must be analyzed within 40 days from date of extraction.

Non-aqueous waste samples: Hold times do not apply to neat oils/NAPL/product samples.

7. Equipment and Supplies

7.1 Gas chromatograph – Programmable, heating range from 40C to 350C; splitless-type inlet system, (Hewlett Packard 6890N Series II or similar); mass selective detector (Hewlett Packard 5973, or similar); automatic injector (Hewlett Packard 7683B or similar).

7.2 Chromatography Column – Fused silica capillary column, 0.25mm ID x 60m length, 0.25um film thickness RTX-5, Restek Corporation, 5% diphenyl-95% dimethyl polysiloxane, Fused silica capillary column, 0.18mm ID x 60m length, 0.18um film thickness RTX-PCB, Restek Corporation, Fused silica capillary column, 0.25mm ID x 30m length, .25um film thickness (Zebron ZB-SemiVolatiles, Phenomenex Corporation, 5% Polysilarylene - 95% Polydimethylsiloxane) , or equivalent.

7.3 Gerstel Large Volume Injection System – Temperature programmable range from 0C to 350C; pressure programmable; capable of split or splitless injection; Injection volumes range from 1 to 50uL and Cryo cooling availability to allow for cold injections.

7.4 Agilent Split/Splitless injector System

7.5 Data Acquisition System - Computerized system for collecting, storing, and processing detector output (Hewlett Packard Enviroquant target software) or equivalent.

7.6 Gases - BIP Ultra high purity helium (99.9995%); Compressed nitrogen for N-Evap. Carbon dioxide (siphon type) for Gerstel.

7.7 Syringes – 10uL to 1.0mL

7.8 Vials- including 2ml, 4ml, 10ml, 40ml and other sizes as necessary.

7.9 Hamilton Gas tight Syringes - varying sizes

7.10 Gerstel Single baffle injection port liners- packed lightly with glass wool.

7.11 GC Injection Port Liner: Phenomenex Direct Connect Top Hole

7.12 Class A Volumetric flasks: Including 10ml, 20 ml, 50 ml, 100ml and other sizes as necessary

8. Reagents and Standards

Use reagent grade chemicals for all reagents. Deionized (DI) water is ASTM Type II laboratory reagent grade water.

8.1 Solvents: All solvent expirations determined as indicated by manufacturer guidelines

8.1.1 Methylene Chloride, ACS approved, Pesticide grade, see SOP *Reagent, Solvent and Standard Control* (SOP 1816) for additional details regarding solvent purity. Used to extract samples and prepare instrument/analytical standards.

8.1.2 Acetone, ACS approved, Pesticide grade, see SOP *Reagent, Solvent and Standard Control* (SOP 1816) for additional details regarding solvent purity. This water soluble solvent is used for surrogate and LCS/MS preparation.

8.1.3 Methanol, ACS approved, Pesticide grade, *Reagent, Solvent and Standard Control SOP* (SOP 1816) for additional details regarding solvent purity.

8.2 Analytical Standards: Standards should be stored at –10C or less, away from light when not in use. They should be discarded after 1 year unless the vendor expiration date states otherwise or, if degradation is observed. Stock standards are given a 1 year expiration from the preparation date or the expiration of the primary vendor solution, whichever occurs first. Working standards are given six month expiration from the preparation date or the expiration of the primary solution whichever occurs first. All analytical standards are made up in Methylene Chloride. All prep standards are made up in Acetone.

8.3 Surrogate/Internal Standard (IS):

8.3.1 A 1,4-Dioxane-d8 Primary neat standard is commercially obtained from Cambridge Isotope (Cat #DLM-28-10 or equivalent). A stock surrogate/internal standard solution is prepared by weighing 0.1 g of the primary neat standard and diluting volumetrically in 10 mls methylene chloride (or equivalent preparation) to obtain a concentration of ~10,000 ug/ml.

8.3.2 From this stock (Section 8.3.1), the Surrogate spiking solution is made by a serial dilution (1 ml diluted up in a 50 ml volumetric flask, followed by a 0.5 ml of this solution diluted up in a 20 ml volumetric flask or equivalent preparations) in Acetone to achieve a concentration of 5 ug/mL. Of this surrogate solution, 1 mL is spiked into each water sample, and 0.4 mL is spiked into each soil/sediment sample for a surrogate/IS concentration of 500 ng/mL in samples.

8.3.3 The initial stock solution (Section 8.3.1) is diluted volumetrically (250 uL diluted up in a 100 ml volumetric flask or equivalent preparation) in methylene chloride to obtain an IS solution at a concentration of 25 ug/ml for the spiking of only the analytical standards (i.e. calibration curve and continuing calibration).

8.4 Internal Standard: 1,4-Dichlorobenzene-d4 commercially obtained from Restek (Cat #31206 or equivalent). This primary solution is at 2000 ug/mL and contains other Semivolatile Internal standards, however this method only utilizes the 1,4-Dichlorobenzene-d4. This solution is diluted volumetrically (250 uL diluted up in a 50 ml volumetric flask or equivalent preparation) in methylene chloride to obtain a SIM-IS solution at a concentration of 25 ug/ml. All samples and standards are spiked with 20uL of internal standard before analysis. This IS is intended to be used for both quantitation (of the surrogate 1,4-Dioxane-d8) and the establishment of relative retention times.

8.5 Matrix Spike/Laboratory Control Spike Solutions (MS/LCS) – 1,4-Dioxane primary spike solution is commercially obtained from Restek at 2000 ug/mL (Cat #31853 or equivalent). To prepare the working spike solution, syringe measure 0.25 mL of stock and bring to 100 mL in acetone (or equivalent preparation) for a 5 ug/mL concentration. From this solution, 1 mL is spiked into each MS/LCS QC water sample and 0.4 mL is spiked into each soil/sediment sample. The final concentration in a 10 mL water extract and in a 4 mL soil/sediment sample will be 500 ng/mL.

8.6 Stock Calibration Standards are prepared from a primary standard commercially obtained from Restek at a concentration of 2000 ug/ml (Cat #31853 or equivalent). The primary standard is used to appropriately prepare a stock standard at a concentration of 10,000 ng/ml (125 uL diluted up in a 25 ml volumetric flask or equivalent preparation). The stock solution is generally made up in 25 ml increments. The stock solution then doubles as a high level standard for the calibration curve, as well as a stock solution by which to serially dilute to prepare the other calibration standards. Except for the high level standard, the calibration curve levels are generally each made at 10 ml. Refer to the table below for example calibration curve levels. All the calibration curve levels, once aliquoted at 1 ml increments for injection, have 20 ul of 1,4

Dichlorobenzene IS (SIM IS – Section 8.4) added as well as 20 uL of 1,4 Dioxane-d8 IS/Surrogate (Section 8.3.3) added.

8.7 Curve Preparation: The following 7 levels are the possible levels that can be analyzed for an ICAL.

Calibration Level	*Volume of Stock Std Added Into 10 ml of DCM*
Level 1 (10 ng/mL)	10 uL
Level 2 (50 ng/mL)	50 uL
Level 3 (100 ng/mL)	100 uL
Level 4 (500 ng/mL)	500 uL
Level 5 (1000 ng/mL) - CCV	1.0 mL
Level 6 (5000 ng/mL)	5.0 mL
Level 7 (10,000 ng/mL)	NA

8.8 The Independent Check Verification Standard is prepared from a Primary standard solution commercially obtained from Ultra (Cat NV-150-1 or equivalent) at a concentration of 100 ug/ml. The primary solution is diluted volumetrically (100 ul diluted up in a 10 ml volumetric flask or equivalent preparation) in methylene chloride to create a working ICV solution at a concentration of 1000 ng/ml. The working ICV solution is aliquoted into 1 ml increments as needed to inject with each calibration curve. Additionally, 20 ul of SIM IS (Section 8.4) and 20 ul of 1,4-Dioxane-d8 IS (Section 8.3.3) is added into the 1 ml aliquot.

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

9.1 Blank(s)

A method blank must be prepared once per every 20 samples or per extraction batch, whichever is more frequent.

Organic compounds of interest must not be detectable in the method blank at a concentration greater than the reporting limit.

Corrective Action: For contaminated blanks, all efforts must be made to identify and eliminate the source of contamination. The presence of analytes at concentrations at or above the reporting limit will warrant application of a “B” qualifier to that target compound(s) on all associated report forms, and perhaps re-extraction of all associated samples. Re-extraction of the method blank and all associated samples must be performed until the blank is in control. Surrogate recoveries must meet the QC limits for the method blank. Re-extraction must be initiated immediately so that minimum time is wasted before re-extraction can occur - if at all possible-this re-extraction should take place within holding time. Re-extraction *corrective action* that would exceed the sample holding time criteria should be discussed with the Organics Supervisor, Project Manager, client, and Operations Manager prior to implementation. Exceptions may be made with approval of the Organics Section Supervisor if the samples associated with an out of control method blank are non-detect for the affected compound(s) or if the concentration of the affected compound(s)in the sample is greater than 10x the blank level. In such cases, the sample results are accepted without corrective action for the high method blank result. The client must be notified, via the project narrative, of any method blank non-compliance associated with sample results

9.2 Laboratory Control Sample/Laboratory Control Sample Duplicate (LCS/LCSD)

Laboratory control samples (LCS/LCSD) must be prepared once per every 20 samples or per extraction batch, whichever is more frequent, and spiked with 1,4 Dioxane spike solution (Section 8.5) and surrogate (Section 8.3.2) before extraction. The IS (Section 8.4) is spiked after extraction and before the analysis.

Acceptable Recovery limits are 40% - 140%. The relative percent difference (RPD) between the LCS/LCSD is 30%. Limits are adapted from MCP protocol and are generally monitored and documented in-house through control charts.

Corrective Action: Analysis must be repeated if an analytical error is suspected. If the LCS/LCSD recoveries and/or %RPD are still out of control, re-extract and re-analyze the LCS/LCSD and all associated samples. Samples cannot be reported until an acceptable LCS is obtained.

9.3 Initial Calibration Verification (ICV)

Refer to Section 10.2.

9.4 Continuing Calibration Verification (CCV)

Refer to Section 10.4.

9.5 Matrix Spike / Matrix Spike Duplicate (MS/MSD)

Matrix spike / matrix spike duplicate (MS/MSD) samples are performed upon project specifications. They are performed per client request. The sample is spiked with 1,4-Dioxane spike solution (Section 8.5) and surrogate (Section 8.3.2) before extraction. The IS (Section 8.4) is spiked after extraction and before the analysis. The recovery limits are 40% - 140% and the RPD limit is 30%. Limits are adapted from MCP protocol and are generally monitored and documented in-house through control charts.

Corrective Action: Analysis must be repeated if an analytical error is suspected. If the % recovery and/or %RPD still exceeds the control limits and the LCS/LCSD is compliant; include a project narrative with the results to client noting that there may be potential matrix effects on the accuracy or precision of the reported results as evidenced by MS/MSD recoveries and/or %RPD outside of QC limits.

9.6 Laboratory Duplicate

Duplicate analyses are performed upon client and/or workplan request. *For Organic analyses, the matrix duplicate is usually in the form of the matrix spike duplicate, see Section 9.5.*

Acceptable relative percent difference (RPD) of duplicates is 30%. Acceptance criterion is not applicable to sample concentrations less than 5 times the reporting limit. Calculate the RPD as follows:

$$RPD = \frac{R1 - R2}{\frac{[R1 + R2]}{2}} \times 100$$

where:

R1 = sample Replicate #1
R2 = sample Replicate #2

The RPD limits should be monitored and documented in-house through control charts and updated as needed.

Corrective Action: Analysis must be repeated if an analytical error is suspected.. If the % RPD still exceeds the control limits; include a project narrative with the results to client noting that there may be potential matrix effects on the precision of the reported results as evidenced by the matrix duplicate % RPD exceedence.

9.7 Method-specific Quality Control Samples

9.7.1 Surrogates

Surrogate spikes (Section 8.3.2 and Section 8.3.3) must be added to QC and field samples to evaluate the extraction method performance.

The acceptable surrogate recovery limits are 15% - 110%. Limits are adapted from MCP protocol.

Corrective Action: Analysis must be repeated if an analytical error is suspected. If the % recovery still exceeds the control limits the sample must be re-extracted and re-analyzed to confirm the sample matrix. If *obvious* matrix interferences are noted, consultation with the Organic Supervisor or Operations Manager may be in order to confirm the need for sample re-extraction. If no re-extraction occurs, the surrogate results and reasons for the decision not to re-extract must be discussed in the project narrative to the client. Due to the isotope dilution nature of this method, the analyst must pay close attention to surrogate recoveries and areas as this recovery is then used to surrogate correct (as an Internal standard) the response of 1,4-Dioxane.

9.7.2 Internal Standards

Internal standards must be added to all sample extracts, QC samples and standards for quantitation purposes. For sample extracts, only the 1,4-Dichlorbenzene-d4 IS (SIM IS – Section 8.4) should be added since the extraction surrogate is then used as an Internal Standard upon analysis. However, all Calibration standards must be spiked with both 1,4-Dichlorobenzene-d4 as well as 1,4-Dioxane-d8 (Section 8.3.3). In the sample extracts the area counts for 1,4-Dioxane-d8 will vary based on the extraction, however the 1,4-Dichlorobenzene-d4 area counts should remain fairly constant. The 1,4-Dichlorobenzene-d4 internal standard should also remain constant with respect to the continuing calibration analyzed at the beginning of the run. Sample IS areas must be –50% to +100% of the Internal Standards in the Continuing Calibration – applies only to 1,4-Dichlorobenzene-d4. Additionally, the IS retention times should not differ more than 30 seconds from the Continuing Calibration.

Corrective Action: Analysis must be repeated once unless there are obvious samples matrix interferences, i.e., the sample extract was very colored and viscous, or there are obvious chromatographic interferences. If *obvious* matrix interferences are noted, consultation with the Organic Supervisor or Operations Manager may be in order to confirm the need for sample re-analysis or re-extraction.

10. Procedure

10.1 Equipment Set-up

10.1.1 The instrument used for the analysis is a HP 6890N Series gas chromatograph. The HP system is equipped with a Gerstel large volume injection system, and a 7683B-type autosampler or equivalent. The mass spectrometer is an HP 5973 or 5975 with the HP Enviroquant data system. The method is modified for selective ion monitoring. The table below lists the ions monitored in one SIM window. This method must only be set up and analyzed by an experienced mass spectrometrist.

Compound	*Primary Ion*	*Secondary Ion*
1,4-Dioxane	88	58, 43
1,4-Dioxane-d8	64	96
1,4-Dichlorobenzene-d4	152	115

10.1.2 The basic GC parameters are as follows for the Gerstel Large Volume Injection System:

Oven Equib Time: 0.10 min
Oven Max: 325
Initial Temp.: 45°C
Initial Time: 6.00 min

Level	Rate (°C/min)	Final Temp. (°C)	Final Time (min)
1	19.00	120	1.0
2	11.00	150	1.00
3	19.00	305	4.00

Final Time: 26.83

10.1.3 The basic injection port parameters are as follows for the Gerstel Large Volume Injection System:

"Splitless" mode
Initial Temp: 46 °C
Initial Time: 0.30 min
Ramp Rate: 300°/second
Final Temp: 300°C
Final Time: 30.0
Cryo: ON
Cryo Use temp: 25 °C
Cryo Timeout: 30.0 min
Cryo Fault: ON
Purge Flow: 25 ml/min

Purge Time: 2.50 min
Gas Saver: off
Gas: Helium

Mode: Constant Pressure
Average Velocity: 30cm/sec
Initial flow: 1.3 ml/min

10.1.4 The basic GC parameters are as follows for the Agilent Split/Splitless injector System:

Oven Equib Time: 0.20 min
Oven Max: 325°C
Initial Temp.: 30°C

Level	Rate (°C/min)	Final Temp. (°C)	Final Time (min)
1	0	30	2.00
2	5	50	0.00
3	50	300	2.00

Final Time: 13.00

10.1.5 The basic injection port parameters are as follows for the Agilent Split/Splitless injector System:

:

Mode: Splitless
Temperatuire: 200 °C
Flow: 1.0 mL/min
Velocity: 36.074 cm/sec
Septum Purge: 3mL/min
Purge Flow to Split Vent: 60 mL/min at 0.3 min

10.1.6 MS Acquisition Information:

Tune file: dftpp.u
Acquisition Mode: SIM
Solvent Delay: 7.70 min
MS Source temp: 280°C

10.1.7 Tuning

10.1.7.1 Before the analytical standards are analyzed the mass spectrometer must be adjusted to meet the proper ion criteria for DFTPP. This is demonstrated by injecting into the GC/MS system 1uL of a 50ug/mL DFTPP solution. After the analysis of the DFTPP, evaluate the tune as follows:

- Enter into the “Environmental Data Analysis” (off-line) screen.
- Go to “File” and select the tune data file.
- Go into “Tuner” and select “Eval DFTPP”, then select “AutoFind DFTPP to Screen,” to evaluate the tune file, based on the pre-set SW-846 criteria**.** The software will evaluate the tune by selecting three scans of the DFTPP peak

and will display the ion intensities on the screen. That is, one scan at the apex, one scan directly preceding the apex and one scan following the apex and averages them, then takes one background subtracted scan, 20 seconds before the beginning of the DFTPP peak. If the criteria below are met, repeat, select "AutoFind to Printer", for a hardcopy of the tune evaluation for the record.

If the "AutoFind" tune evaluation does not meet the criteria below, manual evaluation of the tune can be performed by attempting either of the options below:

- Blow up the DFTPP peak on the screen and select either one single scan at the apex of the peak, or a scan immediately preceding or following the apex. Go into "Tuner" and select "Evaluate DFTPP to Screen," or "Evaluate DFTPP to Printer," as described above, OR,
- Take the average of the scans across the entire peak. Go into "Tuner" and select "Evaluate DFTPP to Screen," or "Evaluate DFTPP to Printer," as described above.

10.1.7.2 The following DFTPP mass intensity criteria should be used.

DFTPP KEY MASSES AND ABUNDANCE CRITERIA

Mass	m/z Abundance criteria
51	10-80 percent of mass 198.
68	Less than 2 percent of mass 69.
70	Less than 2 percent of mass 69.
127	10-80 percent of mass 198.
197	Less than 2 percent of mass 198.
198	Base peak, or >50 percent of Mass 442.
199	5-9 percent of mass 198.
275	10-60 percent of mass 198.
365	Greater than 1 percent of mass 198.
441	Present but less than 24 percent of mass 442.
442	Base Peak, or > 50 percent of mass 198.
443	15-24 percent of mass 442.

10.1.8 Tune acceptance should be verified at the beginning of every 12 hour analytical shift. The DFTPP may be combined with the calibration verification standard as long as both tuning and calibration acceptance criteria are met.

10.2 Initial Calibration

10.2.1 After the DFTPP passes criteria, a set of multi-level calibration standards listed in Section 8.7 are analyzed, from low concentration to high. A minimum of five calibration levels are analyzed. The calibration standards are stored in amber vials in the standards freezer. The labeling convention allows each standard to have a unique identifier which distinguishes it from field samples. The naming convention used throughout the laboratory identifies the standard as semivolatile, hydrocarbon, pesticide/PCB or volatile. An example of this would be SW042407E, meaning it is a semivolatile (S) working (W) standard made on April 24, 2007 and that it was the fifth standard made that day. All certificates of analysis that are shipped with standards are filed with their receipt ID written on it to insure traceability.

10.2.2 Once the standards have been analyzed, they are reduced by the search software of the Enviroquant data system. Once all the components are identified, a linear curve is calculated for the components. The criteria for evaluation are as follows:

10.2.2.1 The average RF for each compound must be greater than 0.05.

10.2.2.2 The %RSD of each compound must not exceed 20%. If they do this may be an indication that the chromatographic system is too reactive for analysis to begin. This indicates the instrument may need maintenance.

10.2.2.3 Alternatively, a linear regression model may be employed, provided that the coefficient of determination (COD or r2) is ≥0.99. Otherwise, construct a nonlinear calibration of no more than a third order equation. Statistical considerations in developing a non-linear calibration model require more data than the more traditional linear approach. A quadratic (second order) model requires six standards, and a third order polynomial requires seven standards. In setting model parameters, do not force the line through the origin. The COD or r^2 must be greater than or equal to 0.99.

10.2.2.4 Once the calibration curve is reviewed, an Initial Calibration Checklist must be completed.

10.2.3 All samples and standards are spiked with Internal Standards (IS) before analysis. Refer to section 8.4 for specific internal standard spiking information. The IS is intended to be used for both quantitation and the establishment of relative retention times. Internal standard acceptance criteria can be found in Section 9.7.2.

10.2.4 Independent check standards (Section 8.8) from a separate source or different lot are analyzed after every initial calibration for evaluation against calibration standard solutions. The % Difference (%D) should not be greater than ±30%.

10.3 Equipment Operation and Sample Processing

10.3.1 Tuning

A DFTPP standard must be analyzed and pass criteria before a continuing calibration verification standard or any samples are analyzed. The DFTPP may be combined with the calibration verification standard as long as both tuning and calibration acceptance criteria are met. A DFTPP tune standard must be analyzed before each 12 hour analytical shift. Please refer to Section 10.1.5 for tuning criteria and other information.

10.3.2 Daily Calibration

On a daily basis after the DFTPP has passed, a mid-level (usually 1000 ng/mL) continuing calibration standard which contains all of the analytes of interest is analyzed. The criteria for acceptance are:

10.3.2.1 All analytes must have response factors greater than 0.05.

10.3.2.2 The % D must be ±20% D from the initial calibration.

10.3.3 Sample Analysis

10.3.3.1 The prep lab staff will transfer the samples to the instrument laboratory. The samples are generally brought to a 10 mL final volume for liquids or 4 ml for soil samples; 1 mL is transferred and the remaining sample volume is archived. One aliquot of each sample is then placed in the sample extract holding refrigerator located in the instrument laboratory.

10.3.3.2 All of the samples at 1 mL (including the batch QC samples) are spiked with 20 uL

internal standard (see section 8.4 for specifics regarding the internal standard). The samples are shaken briefly after the internal standard is added to ensure mixing. A sample will need a dilution for target analytes that are over calibration.

10.3.3.3 After the daily tune and CCAL have passed criteria, the analyst places the samples onto the autosampler tray. (Generally, the samples will be analyzed in order of color (lightest to darkest.) with QC samples being analyzed first. The instrument sequence is typed into the HP Chemstation Software. Next run "Simulate Sequence" (also under the "Sequence" dropdown list) without clicking the "Overwrite Files" box. Compare the order of the vials on the instrument versus the sequence to confirm all the samples and standards are in the right places. Next click "Run Sequence" also under the HP Chemstation "Sequence" dropdown list.

10.3.3.4 After the samples have been analyzed, the data files from the MS are quantitated versus the proper quantitation method. The QCPRN1.MAC macro creates a form with which to easily check internal standard and surrogate criteria are met. The following should be reviewed initially:

10.3.3.4.1 Are all the surrogates within QC criteria? Please see Section 9.7.1 for surrogate information.

10.3.3.4.2 Is the internal standard- 1,4 Dichlorobenzene-d4, within 50-200% of the daily CCAL? If not, the samples should be checked for matrix interferences that may be causing these issues. The IS peaks should also be evaluated for peak splitting or incorrect integration by the software. A sample may not need to be reanalyzed if it can be determined (with guidance from a supervisor) that the QC is exceeded due to matrix interference.

10.3.3.4.3 Are all target analytes within calibration range? If not, the sample(s) should be diluted and re-analyzed. If a dilution is performed after the internal standard has already been added, it will be necessary to add additional IS in order to make up for the impact of the original IS added also being diluted. Conversely, if a sample has been over-diluted, it may need to be analyzed at less of a dilution to detect target analytes that may have been diluted out. Note: for this method, due to the isotope dilution, it is necessary to refer to area counts to determine if dilution is required. The area response for 1,4-Dioxane should be compared to the area of the highest level of the ICAL standard for that target. If the area of 1,4-Dioxane in the extract is greater than the area of 1,4-Dioxane in the Highest level of the Calibration Curve, then a dilution is necessary. The analyst **CAN NOT** use the concentration of 1,4-Dioxane found in the extract to determine if dilution is required because the concentration of 1,4-Dioxane in the sample is surrogate corrected in Chemstation based on the use of the extraction surrogate as an Internal Standard. Once it is determined based on the peak area that a sample requires a dilution, the analyst must pay attention to the concentration of IS in the dilution. Although the analyst will adjust the 1,4-Dichlorobenzene-d4 concentration by adding the appropriate amount of additional IS to the dilution, there is no way for the analyst to make up for the dilution of the extraction surrogate 1,4 dioxane-d8 (also used as internal standard). To account for this the analyst must change the concentration of the 1,4-Dioxane-d8 within the calibration table to a value which accounts for the dilution. (Example: If the analyst performs a 10x dilution then the concentration of 1,4-Dioxane–d8 must be changed within the ICAL to 50.) The analyst must ensure that only the diluted sample is calculated against this

value and that the method is returned to the proper concentration once the analysis of the dilution is complete.

10.3.3.4.4 Are all analyses within 12 hour tune time? If a sample is analyzed outside tune time, it will need to be re-analyzed in another tune clock.

10.3.3.4.5 The sequence should also be printed out from Chemstation, initialed and dated, and placed in the logbook.

10.3.3.4.5.1 If anything in the initial review of the data indicates that there should be a re-analysis, the reason for re-analysis should be noted on the sequence.

10.3.3.4.5.2 Also, note the time the tune standard was analyzed, the time of the last sample analysis. If there are samples analyzed outside tune time, the time the last sample within tune time ran should be noted, as well as the last sample analyzed.

10.3.3.4.5.3 If a re-extract is required, the "Request for Repreparation/Reclean" book should be filled out and a photocopy of the appropriate page should be given to the Preparation Group leader or the Organics Section Head.

10.4 Continuing Calibration

Continuing Calibration Criteria is outlined in section 10.3.2

10.5 Preventive Maintenance

If performing any maintenance on any piece of equipment it must be documented in the *Instrument Maintenance Logbook* located in the laboratory specific to each instrument.

Daily

Injection port maintenance: Maintenance should be done when the daily CCAL starts to demonstrate degradation either by %D outliers or area responses <50% as compared to the ICAL areas. Several tune clocks may be injected before maintenance is needed. The type of samples analyzed will have an effect on how soon maintenance should be performed. Injection port maintenance should be done as needed. General maintenance includes replacing the single baffle liner packed lightly with glass wool, cutting about 2-4 inches off the head of the column, and replacing the septa. Refer to maintenance log for more specific information.

The Gerstel Injection port should be handled with care. The liners are quite thin. Do not force the Gerstel weldmen into place as the threads are soft metal and will cross thread. Always make sure the weldmen goes on straight. The Gerstel injection port does not require significant tightening of either the weldmen or column nut, tighten enough to seal but there is no need to crank down on it.

11. Data Evaluation, Calculations and Reporting

11.1 Qualitative Analysis

11.1.1 The qualitative identification of compounds determined by this method is based on retention time and on comparison of mass spectrum, after background correction, with

characteristic ions in a reference mass spectrum. The reference mass spectrum must be generated by the laboratory using the conditions of this method. The characteristic ions from the reference mass spectrum are defined as the two ions of greatest relative intensity, and are over 30% relative intensity. Compounds are identified when the following criteria are met.

11.1.2 The intensities of the characteristic ions of a compound must maximize in the same scan or within one scan of each other. A peak selected by the data system, based on the presence of target specific ions at a target specific retention time will be accepted as meeting these criteria.

11.1.3 The relative retention time of the sample component is within $\pm$ 0.06 RRT units of the RRT of the standard component.

11.1.4 The relative intensities of the characteristic ions agree within 30% of the relative intensities of these ions in the reference spectrum (Example: For an ion with an abundance of 50% in the reference spectrum, the corresponding abundance in a sample spectrum can range between 20% and 80%.) The relative intensities are monitored daily. The relative intensities will be updated when they exceed established values from the reference spectrum.

11.1.5 Structural isomers that produce very similar mass spectra should be identified as individual isomers if they have sufficiently different GC retention times. Sufficient GC resolution is achieved if the height of the valley between two isomer peaks is less than 25% of the sum of the two peak heights. Otherwise, structural isomers are identified as isomeric pairs.

11.1.6 Identification is hampered when sample components are not resolved chromatographically and produce mass spectra containing ions contributed by more than one analyte. When gas chromatographic peaks obviously represent more than one sample component (i.e. a broadened peak with shoulder(s) or a valley between two or more maxima), appropriate selection of analyte spectra and background spectra is important. Selective ion monitoring eliminates this potential.

11.2 Quantitative Analysis

11.2.1 Response factors and % RSD to evaluate Initial Calibration acceptability.

Calculate RF by:

$$RF = \frac{area_{cmp}}{area_{is}} \times \frac{conc_{is}}{conc_{cmp}}$$

where:

area cmp = Area of the characteristic ion for the compound being measured.
area is = Area of the characteristic ion for the specific internal standard.
conc is = Concentration of the specific internal standard.
conc cmp = Concentration of the compound being measured.

Calculate % RSD by:

$$\%RSD = \frac{SD}{\overline{x}} \times 100 \qquad SD = \sqrt{\sum_{i=1}^{N} \frac{(x_i - \overline{x})^2}{N-1}}$$

where:

% RSD = percent relative standard deviation
x = average of RF's
SD = standard deviation
xi = analytical results of each level in the final reporting units
N = number of results (levels)

11.2.2 Calculate % Difference (%D) by:

$$\%D = \frac{\overline{RF}_i - RF_c}{\overline{RF}_i} \times 100$$

where:

RFi - Initial Calibration average RF
RFc = Continuing Calibration RF

11.2.3 Results of Water Analysis - calculation as performed in report form:

$$\text{Concentration (ug/L)} = \frac{(\text{Conc})\ (\text{Vf})\ (\text{DF})}{(\text{Vi})} \times 1000$$

11.2.4 Results of Soil/Sediment Analysis – calculation as performed in report form:

$$\text{Concentration (ug/Kg)} = \frac{(\text{Conc})\ (\text{Vf})\ (\text{DF})}{(\text{Vi})\ \%S} \times 1000$$

where:
Conc = Raw on-column concentration obtained from the quantitation report using Initial Calibration results.
Vf = Final volume of extract (mL)
Vi = Volume of sample extracted (mL), or weight of sample extracted in grams (g)
DF = Dilution factor, for manually prepared dilutions, not instrumental "dilutions".
%S = percent solids, as a decimal

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

Section 9.0 outlines sample batch QC acceptance criteria. If non-compliant organic compound results are to be reported, the Organic Section Head and/or the Laboratory Director, and the Operations Manager must approve the reporting of these results. The laboratory Project Manager

shall be notified, and may chose to relay the non-compliance to the client, for approval, or other corrective action, such as re-sampling and re-analysis. The analyst, Data Reviewer, or Department Supervisor performing the secondary review initiates the project narrative, and the narrative must clearly document the non-compliance and provide a reason for acceptance of these results.

All results for the organic compounds of interest are reportable without qualification if extraction and analytical holding times are met, preservation requirements (including cooler temperatures) are met, all QC criteria defined in the table below are met, and matrix interference is not suspected during extraction or analysis of the samples. If any of the below QC parameters are not met, all associated samples must be evaluated for re-extraction and/or re-analysis.

QC Parameter	Acceptance Criteria
Method Blank	No analyte above the reporting limit The results are qualified with a "B" for any associated sample concentrations that are less than 10x the blank concentration for this analyte
Surrogate Recovery	15% - 110%
Laboratory Control Samples	40% - 140% and 30% RPD
Matrix Duplicate	30% RPD
Matrix Spike	40% - 140%
Matrix Spike Duplicate	40% - 140% and 30% RPD

13. Method Performance

13.1 Method Detection Limit Study (MDL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the MDL, LOD, and/or LOQ as outlined in Alpha SOP 1732. These studies performed by the laboratory are maintained on file for review.

13.2 Demonstration of Capability Studies

Refer to Alpha SOP 1739 for further information regarding IDC/DOC Generation.

13.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

14. Pollution Prevention and Waste Management

Refer to Alpha's Chemical Hygiene Plan and Waste Management and Disposal SOP for further pollution prevention and waste management information.

Acid Volatile Sulfides and Simultaneously Extracted Metals in Sediments

Reference: "Determination of acid-volatile sulfide and simultaneously-extracted metals in sediments using sulfide-specific electrode detection," Warren S. Boothman, USEPA Environmental Research Laboratory, Narragansett, RI, and Andrea Helmstetter, Science International Corp., Narragansett, RI. September 4, 1992. AVSSEM SOP v2.0.

EPA-821-R-91-100 – DRAFT Analytical Method of the Determination of Acid Volatile Sulfide in Sediment, US EPA Offices of Water, and Science and Technology, 1991.

1. Scope and Application

Matrices: Sediments

Definitions: Refer to Alpha Analytical Quality Manual.

Acid volatile sulfides (AVS) are amorphous or moderately crystalline metal monosulfides, primarily FeS. It has been demonstrated that AVS may be the most important factor controlling the availability of heavy metals to benthic organisms in anoxic sediments. The relative concentrations of AVS and simultaneously extractable metals (SEM) is postulated as an indicator of metal availability.

The classification of sulfides as "acid volatile" is an operational definition; i.e., the extent to which mineral sulfide phases are volatilized by the analysis will depend on the analytical conditions used (acid concentrations, time, etc.). For AVS data to be comparable, the reaction conditions used to volatilize sediment sulfides must be similar. Simultaneously extracted metals are operationally defined as the metals extracted from the sediment into solution by the acid volatilization procedure. Soluble metals are those passing through a 0.45 μm filter.

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one or more of the following laboratory personnel before performing the modification: Area Supervisor, Department Supervisor, Laboratory Director, or Quality Assurance Officer.

This method is restricted to use by or under the supervision of experienced analysts. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

2. Summary of Method

To determine AVS in sediments, an aliquot of wet sediment is acidified with HCl under nitrogen gas to produce gaseous hydrogen sulfide (H_2S). The H_2S is purged from the flask and trapped in buffer solution. The sulfide concentration is measured electrometrically using an ion-selective electrode against a sulfide standard solution curve.

Simultaneously extracted metals (SEM) are determined by filtration of the acid-sediment slurry and analysis of the extract by ICP, ICP-MS, or CVAF as per laboratory SOPs which describe analysis of dissolved metals in aqueous solutions.

2.1 Method Modifications from Reference

None.

3. Reporting Limits

Sulfide – 200 ug/L (0.624 µmol/g)

Cd – 2 µg/L (0.00178 µmol/g)

Cu – 10 µg/L (0.0157 µmol/g)

Pb – 20 µg/L (0.00965 µmol/g)

Ni – 20 µg/L (0.0341 µmol/g)

Zn – 20 µg/L (0.0306 µmol/g)

µmol/g values are based on 1 g wet weight.

4. Interferences

Volatilized sulfide will be lost if oxygen is present in apparatus or reagents. The apparatus used must be completely purged with oxygen-free nitrogen gas prior to beginning of analysis.

Volatilization of sulfides from sediments by acidification can be affected by sediment matrix which may consume the acid and increase the slurry pH. This may occur in sediments with high carbonate content. In such cases, the acid extracts should be tested periodically, especially if effervescence is observed during acidification with HCl, to insure that the pH < 2.

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material safety data sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

Because the sulfide ion is unstable in the presence of dissolved O_2, storage containers should minimize the air space above the sediment. Samples should be collected in soil jars with sealed caps to minimize volatile losses. Approximately 20 to 30 g are required (to allow for replicate and QC analyses, as required).

6.2 Sample Preservation

Samples should be stored at 4° ± 2° C following collection.

6.3 Sample Shipping

No special shipping requirements.

6.4 Sample Handling

Samples should be analyzed within 14 days of collection.

7. Equipment and Supplies

7.1 pH/Ion selective electrode meter

7.2 Sulfide selective electrode

7.3 Flow controller

7.4 Flasks (250 mL round-bottom; 100 mL volumetrics), beakers (150 mL), graduated cylinders (50 mL and 100 mL)

7.5 Filter holders with receivers (250 mL)

7.6 47 mm filters, 0.45 μm nominal pore size

7.7 Tygon tubing

7.8 Air sampling impingers and impinger bottles

7.9 20-30 ml polyethylene barrel syringes with needles

8. Reagents and Standards

8.1 Reagents

8.1.1 Nitrogen gas - oxygen-free. Ultra pure N_2 gas can be purchased and/or an oxygen trap attached to the N_2 gas tank in-line to remove the trace oxygen.

8.1.2 Hydrochloric Acid (HCl). Instra-Analyzed Grade. 6N HCl prepared by diluting 250 mLs HCl into 250 mLs DI water.

8.1.3 Sulfide Anti-Oxidant Buffer Reagent (SAOB). (2M NaOH, 0.2M EDTA, 0.2M ascorbic acid) (note - prepare in order indicated). Dissolve 80.00 g NaOH *slowly* in 700 mL DDI water. When cool, add 74.45 g EDTA (disodium form) and stir until dissolved. Add 35.23 g ascorbic acid and stir until dissolved. Pour solution into a 1000 mL beaker and dilute to volume with DDI water. For use in impinger.

8.1.3.1 Dilute SAOB. Mix 350 ml of SAOB with 350 ml DDI water. For use with standards only.

8.1.4 Sulfide Stock Solution

8.1.4.1 Primary Stock Preparation (Approx. 1650 ppm). Wash crystals of $Na_2S \bullet 9H_2O$ with deionized water and blot dry. Weigh approximately 12 g of $Na_2S \bullet 9H_2O$ and dissolve in 900 ml DDI water. Pour into a 1000 ml volumetric flask and dilute to volume with DDI water. Standardize daily.

8.1.4.2 PrimaryStock Standardization. Pipette 10.00 ml of standard iodine solution into each of two 125 ml Erlenmeyer flasks. Pipette 2.00 ml of sulfide stock into one flask. Pipette 2.00 ml of DDI water as a method blank into the other flask. Add 5.0 ml of 6M HCl into each flask, swirl lightly, then cover and place in the dark for 5 minutes. Titrate each with 0.025N thiosulfate solution, adding soluble starch indicator when the yellow iodine color fades. The end point is reached when the blue color disappears.

$$\text{sulfide } (\mu\text{mol/ml}) = \frac{(T_{bl}-T_s) \times N \times \frac{1 \text{ mole } S^{2-}}{2 \text{ equiv } S^{2-}} \times \frac{1000 \ \mu\text{moles}}{1 \text{ mole}}}{\text{ml sample}}$$

sulfide (ppm) = sulfide (Φmol/ml) x 32
where T = ml titrant used for blank and spike
where N = normality of thiosulfate titrant

8.1.5 Standard Iodine solution (0.025N). This solution is purchased commercially.

8.1.6 Thiosulfate titrant (0.025N). This solution is purchased commercially and diluted. The solution is then standardized against the 0.025N standard iodine solution.

8.1.7 Soluble starch indicator. Prepare by dissolving 1.0 g starch in 100 ml boiling deionized water.

8.2 Calibration and QC Solutions

8.2.1 Calibration standards are prepared by diluting primary sulfide stock solution to produce a working standard. The primary stock concentration *must* be standardized by iodometric titration before preparing the working standards. See section 8.1.4.2.

8.2.2 Working standard is made by 6.0 ml primary sulfide stock and diluting to a final volume of 200 ml with dilute DI WATER. The working standard exact concentration is determined by the following calculation:

$$\text{working standard (ppm)} = \frac{(6) \text{ (Primary stock conc. *)}}{}$$

200

* as determined by standardization

8.2.3 Calibration curve consists of the following aliquots of working standard diluted to 100 ml with dilute SAOB: 0.20, 0.50, 2.0, 5.0, 20.0, and 50.0 ml. Exact concentrations are determined daily by the following equation:

$$\text{ppm sulfide} = \frac{(\text{ml working standard}) \times (\text{conc. working standard})}{100}$$

8.2.4 Initial Calibration Verification (ICV) Continuing Calibration Verification (CCV). The mid point of the calibration curve must be analyzed at the beginning of an analytical sequence, after a minimum of every ten samples and at the end of each analytical sequence. The calibration curve need not be generated daily. If a calibration curve is used over more than a one day period then an acceptable CCV must be generated prior to continuing with the analysis.

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

9.1 Blank(s)

A preparation blank should be prepared with each batch. The concentration should be less than the reporting limit of the analysis. Corrective Action. Determine the cause of the contamination, reprepare batch if reporting limit can not be raised above the level of the blank.

9.2 Laboratory Control Sample (LCS)

A LCS or blank spike should be analyzed with every batch to verify the analytical system. Recovery should be within the range of 85-115%. Corrective Action: If LCS recovery is outside this range, determine source of error before analyzing samples. An acceptable LCS recovery must be obtained prior to the analysis of samples.

9.3 Initial Calibration Verification (ICV)

The ICV should be analyzed at the beginning of each run, after calibration, to verify the accuracy of the electrode. Acceptable recovery is ± 15% of true value. Corrective Action: Repeat the determination if recovery is still out determine cause. Re-calibrate electrode meter. Reanalyze ICV. Analysis cannot proceed until an acceptable ICV recovery is obtained.

9.4 Continuing Calibration Verification (CCV)

The CCV should be analyzed after a maximum of ten samples with a recovery of ± 15%. Corrective action. Repeat the determination if recovery is still out determine cause. Re-calibrate electrode meter. Reanalyze all samples from last passing QC standard.

9.5 Matrix Spike

Analyze a matrix spike (MS) for every ten environmental samples(10% or more frequent) using the working standard as a spiking solution. Add the sulfide metals spike with the 6N HCl through the sidearm. Acceptable recovery is 75-125%. Corrective Action: If blank spike is in-control and the MS is not; matrix interference is suspected. Include a narrative explanation to

client that there is evidence of a matrix effect on the accuracy of the results. If project-specific QC requires, the analysis of the MS could be repeated using a smaller sample aliquot to minimize matrix effects.

9.6 Laboratory Duplicate

Duplicate analyses (matrix duplicate) should be performed at a frequency of 5% or each analytical batch, whichever is more frequent. The RPD should not exceed 20%. Corrective Action: If the RPD exceeds 20%, include narrative to client that there is evidence of a matrix effect on the precision of the results.

10. Procedure

10.1 Equipment Set-up

10.1.1 **Extraction**.

10.1.1.1 Weigh 2-3 g sediment into an acid washed 250 ml round bottom flask with septum sidearm. Add 50 ml DDI water and an acid washed stir bar. It is important to try to extract enough sample to generate a positive Sulfide response in order to evaluate the SEM/AVS ratio. Some samples (such as clean sand) will not contain enough sulfide for detection.

10.1.1.2 To the impinger (trap) add 50 ml SAOB solution and 30 ml DDI water. Purge system with nitrogen for 10 minutes. Slowly add 10 ml of 6N HCl through sidearm. Turn on stir plate.

10.1.1.3 Purge system with nitrogen for 60 minutes.

10.1.1.4 Remove impinger. and pour solution into 100 ml volumetric flask while rinsing impinger trap with DI water. Dilute to 100 ml with DDI water.

10.1.2 Measurement of sulfide by ion-specific electrode.

10.1.2.1 Prepare calibration curve after standardizing primary stock to determine exact sulfide concentration. A 6-point curve is generated by regressing log sulfide concentration against mvolt reading from the probe. The blank is not used in the regression. The correlation coefficient r must be $\leq$ -0.995.

10.1.2.2 Pour standard or sample from flask into 150 ml beaker, add stir bar and stir with minimum agitation (to avoid oxidation of sample). Using DDI water, rinse electrodes and blot dry. Immerse electrode in sample solution.

10.1.2.3 Allow electrode response to stabilize. Record millivolt reading. Plot calibration curve of standards. Use standard curve to convert sample millivolt readings to log sulfide concentration of sample. The sample sulfide concentration is calculated as the antilog of the result generated from the calibration curve.

10.1.2.4 If the measured sulfide concentration exceeds the range of calibration standards, repeat the analysis using a smaller amount of sediment. If the measured concentration is less than the low standard of the calibration curve, repeat the analysis for that sample using more sediment.

10.2 Initial Calibration

Refer to Section 10.1.2.1 for sulfide calibration curve information.

10.3 Equipment Operation and Sample Processing

10.3.1 Simultaneously extracted metals.

10.3.1.1 Assemble the acid washed filtration unit with a 0.45μm pore size filter and apply pressure.

10.3.1.2 Pour the acid-sediment slurry of the round-bottom flask into the upper chamber of the filtration unit and apply pressure. Rinse the round bottom flask several times with DDI water and add the rinsed to the filtration unit. When all the solution has been filtered, wash the walls of the upper chamber of the filtration unit with DDI water.

10.3.1.3 Pour the filtrate into a clean 100 mL graduated cylinder. Bring to volume with DDI water. Mix the sample and pour into a labeled, acid-cleaned polyethylene bottle and cap. The sample is ready for metals analysis.

10.3.1.4 Weigh out aliquot and perform dry-weight (percent solids test) determination following laboratory SOP.

10.4 Continuing Calibration

CCVs must be 90-110% for SEM metals by ICPMS, sulfide must be 85-115%.

10.5 Preventive Maintenance

Clean impinge exterior with Kimwipes to remove sediment/residue. Clean interior with cotton swabs.

11. Data Evaluation, Calculations and Reporting

11.1 AVS concentration in sediments.

$$\text{Acid Volatile Sulfide (mg/Kg dry wt)} = \frac{\text{mg/L from curve x trap volume}}{\text{initial g sediment x dry wt conversion}}$$

11.2 SEM concentrations in sediments.

$$\text{SEM } (\mu\text{g/g dry wt}) = \frac{\text{concentration metal x final volume of 100 mL}}{\text{initial g sediment x dry wt conversion}}$$

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

Refer to Section 9.

13. Method Performance

13.1 Detection Limit Study (DL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the DL, LOD, and/or LOQ as outlined in Alpha SOP/08-05. These studies performed by the laboratory are maintained on file for review.

13.2 Demonstration of Capability Studies

Refer to Alpha SOP/08-12 for further information regarding IDC/DOC Generation.

13.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

14. Pollution Prevention and Waste Management

Refer to Alpha's Chemical Hygiene Plan and Waste Management and Disposal SOP for further pollution prevention and waste management information.

Chemical Oxygen Demand (COD)
Including: High (0-1500ppm) and Low (0-150ppm) Levels
Closed Reflux, Colorimetric Method (Total and Soluble in Liquid)

References: **SM 5220 D,** Standard Methods for the Examination of Water and Wastewater. APHA-AWWA-WEF. Standard Methods Online.

Method 410.4, Methods for the Determination of Inorganic Substances in Environmental Samples, August 1993.

1. Scope and Application

Matrices: This method is applicable to liquid samples.

Definitions: Refer to Alpha Analytical Quality Manual.

The Chemical Oxygen Demand (COD) is used as a measure of the oxygen equivalent of the organic matter content of a sample that is susceptible to oxidation by a strong chemical oxidant. For samples from a specific source, COD can be related empirically to BOD, organic carbon, or organic matter. The test is useful for monitoring and control after correlation has been established. The dichromate reflux method is preferred over procedures using other oxidants because of superior oxidizing ability, applicability to a wide variety of samples, and ease of manipulation. Oxidation of most organic compounds is 95 to 100% of the theoretical value. Pyridine and related compounds are oxidized only to the extent that they remain in contact with the oxidant. Ammonia, present either in the waste or liberated from nitrogen-containing organic matter, is not oxidized in the absence of significant concentration of free chloride ions.

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one or more of the following laboratory personnel before performing the modification: Area Supervisor, Department Supervisor, Laboratory Director, or Quality Assurance Officer.

. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

2. Summary of Method

Most types of organic matter are oxidized by a boiling mixture of chromic and sulfuric acids. A sample is refluxed in strongly acid solution with a known excess of potassium dichromate ($K_2Cr_2O_7$). After digestion, the remaining unreduced $K_2Cr_2O_7$ is determined colorimetrically and the oxidizable organic matter is calculated in terms of oxygen equivalent. Keep ratios of reagent weights, volumes, and strengths constant. The standard two-hour reflux time may be reduced if it has been shown that a shorter time yields the same results.

2.1 Method Modifications from Reference

2.1.1 Soluble COD (SCOD): Filter the sample through 0.45µm filter followed by preservation to pH $\leq$2 using 1:1 H_2SO_4.

2.1.2 Low Level COD: Analyze samples in low level range COD tubes for more precise results on lower concentrations of target analyte.

3. Reporting Limits

The reported detection limit for chemical oxygen demand, closed reflux, colorimetric method, is 20.0mg/L for (High) COD method, and 10.0mg/L for (Low) COD method.

4. Interferences

4.1 Instrumental

The Spectrophotometer and COD Reactors are subject to preventative maintenance, which will minimize instrumental interferences. (Refer to Section 10.6)

4.2 Parameters

4.2.1 **Volatile Straight-Chain Aliphatic Compounds:** These compounds are not oxidized to any appreciable extent. This failure occurs partly because volatile organics are present in the vapor space and do not come in contact with the oxidizing liquid. Straight-chain aliphatic compounds are oxidized more effectively when silver sulfate (Ag_2SO_4) is added as a catalyst. However, Ag_2SO_4 reacts with chloride, bromide, and iodide to produce precipitates that are oxidized only partially. The difficulties caused by the presence of the halides can be overcome largely, though not completely, by complexing with mercuric sulfate ($HgSO_4$) before the refluxing procedure. Although 1g $HgSO_4$ is specified for 50mL sample, a lesser amount may be used where sample chloride concentration is known to be less than 2000mg/L, as long as a 10:1 ratio of $HgSO_4$ is maintained. Do not use the test for samples containing more than 2000mg Cl/L. Techniques designed to measure COD in saline waters are available.

4.2.2 **Nitrite (NO_2^-)** exerts a COD of 1.1mg O_2/mg NO_2^- -N. Because concentrations of NO_2^- -N in waters rarely exceed 1 or 2mg NO_2^- -N/L, the interference is considered insignificant and usually is ignored. To eliminate a significant interference due to NO_2^-, add 10mg sulfamic acid for each mg NO_2^- -N present in the sample volume used; add the same amount of sulfamic acid to the reflux vessel containing the distilled water blank.

4.2.3 **Reduced Inorganic Species,** such as ferrous iron, sulfide, managanous manganese, etc., are oxidized quantitatively under the test conditions. For samples containing significant levels of these species, stoichiometric oxidation can be assumed from known initial concentration of the interfering species and corrections can be made to the COD value obtained.

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material safety data sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

NOTE: COD tubes contain Mercury, Dichromate and Sulfuric Acid. General laboratory safety practices must be observed

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

Preferably, collect samples in glass bottles. Blend samples containing settleable solids with a homogenizer to permit representative sampling.

6.2 Sample Preservation

If delay before analysis is unavoidable, preserve sample by acidification to pH ≤2 using 1:1 H_2SO_4. Preferably acidify any sample that cannot be analyzed the same day it is collected.

6.3 Sample Shipping

No specific requirements.

6.4 Sample Handling

Test unstable samples without delay. Preserved samples are analyzed within 28 days of sampling. Store samples under refrigeration at 4 ± 2°C.

7. Equipment and Supplies

7.1 COD Reactor: HACH Company, Environmental Express or equivalent, 150ºC

7.2 Spectrophotometer: For use at 620nm.

7.3 Computer and related accessories: with LIMS access and Excel

7.4 Automatic Pipettor: Capable of 2.0mL

7.5 Pipets: 10mL and 1mL, borosilicate glass.

7.6 Centrifuge.

7.7 Kim Wipes.

7.8 Volumetric flasks, assorted sizes (1000mL, 100mL)

8. Reagents and Standards

8.1 Stock Calibration Standard (for calibration curve generation): 5000ppm Potassium Hydrogen Phthalate (KHP) Stock Calibration Standard: 4.25g of dry KHP and 1ml H3PO4 brought up to 1L with DI. Prepare stock calibration standard every six months and generate a new calibration curve (Section 10.1). Store stock calibration standard under refrigeration at 4 ± 2 °C. Standard expires after six months.

8.1.1 Working Calibration Standards for High COD: Prepare fresh standards for each calibration curve. The following Potassium Hydrogen Phthalate (KHP) standards are prepared in volumetric flasks:

8.1.1.1 400ppm: 8ml of 5000ppm (Section 8.1) to 100ml with DI.

8.1.1.2 800ppm: 16ml of 5000ppm (Section 8.1) to 100ml with DI.

8.1.1.3 1000ppm: 20ml of 5000ppm (Section 8.1) to 100ml with DI.

8.1.1.4 1250ppm: 25ml of 5000ppm (Section 8.1) to 100ml with DI.

8.1.1.5 20ppm: 2ml of 1000ppm (Section 8.1.1.3) to 100ml with DI.

8.1.1.6 50ppm: 5ml of 1000ppm (Section 8.1.1.3) to 100ml with DI.

8.1.1.7 100ppm: 10ml of 1000ppm (Section 8.1.1.3) to 100ml with DI.

8.1.1.8 200ppm: 20ml of 1000ppm (Section 8.1.1.3) to 100ml with DI.

8.1.2 Working Calibration Standards for Low COD:

8.1.2.1 500ppm: 10ml of 5000ppm (Section 8.1) to 100ml DI.

8.1.2.2 5ppm: 1ml of 500ppm (Section 8.1.2.1) to 100ml DI.

8.1.2.3 10ppm: 2ml of 500ppm (Section 8.1.2.1) to 100ml DI.

8.1.2.4 20ppm: 4ml of 500ppm (Section 8.1.2.1) to 100ml DI.

8.1.2.5 50ppm: 10ml of 500ppm (Section 8.1.2.1) to 100ml DI.

8.1.2.6 100ppm: 20ml of 500ppm (Section 8.1.2.1) to 100ml DI.

8.1.2.7 125ppm: 25ml of 500ppm (Section 8.1.2.1) to 100ml DI.

8.2 Stock Verification Standard (for calibration curve verification): 5000ppm Potassium Hydrogen Phthalate (KHP) Stock Verification Standard: 4.25g of dry KHP and 1ml H3PO4 brought up to 1L with DI. Prepare stock verification standard every six months. Stock verification standard must be of a different source than that used for the stock calibration standard (Section 8.1). Store stock verification standard under refrigeration at 4 ± 2 °C. Standard expires after six months.

8.2.1 Working Verification Standards [Including LCS (Laboratory Control Standard), ICV (Initial Calibration Verification), and CCV (Continuing Calibration Standard), (Section 9.2)]: Prepare fresh standards monthly or as needed. Standards are stored at room temperature in complete darkness. Standards expire after one month. The following Potassium Hydrogen Phthalate (KHP) standards are prepared in volumetric flasks:

8.2.1.1 1000ppm: 20ml of 5000ppm (Section 8.2) to 100ml with DI. (Also Low Cod Spike Solution).

8.2.1.2 500ppm Hi LCS/ICV Solution: 10ml of 5000ppm (Section 8.2) to 100ml with DI.

8.2.1.3 200ppm CCV Solution: 4ml of 5000ppm (Section 8.2) to 100ml with DI.

8.2.1.4 400ppm CCV Solution: 8ml of 5000ppm (Section 8.2) to 100ml with DI.

8.2.1.5 50ppm Low LCS Solution: 5ml of 1000ppm (Section 8.2.1.1) to 100ml with DI.

8.2.1.6 60ppm CCV Solution: 6ml of 1000ppm (Section 8.2.1.1) to 100ml with DI.

8.2.1.7 20ppm ICV/CCV Solution for Low Cod: 4ml of 500ppm (Section 8.2.1.1) to 100ml DI.

8.3 COD Tubes: High Cod Range 0 – 1500 mg/L, Low Cod Range 0-150 mg/L. Follow the manufacturer's directions for use and date of expiration. Store at room temperature in a complete darkness. NOTE: A new calibration curve must be generated for each brand of COD tubes purchased. The same curve cannot be used for different brands.

8.3.1 High Level COD Tubes (0-1500ppm): Environmental Express, Catalog # B1015

8.3.2 High Level COD Tubes (0-1500ppm): CPI International, Catalog #4380-1500-150

8.3.3 Low Level COD Tubes (0-150ppm): Environmental Express, Catalog # B1010

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

9.1 Blank(s)

9.1.1 Method Blank/Initial Calibration Blank (ICB)

Add 2 mL DI to COD tube and digest. One Method Blank is analyzed per batch of 20 samples or less. The Method Blank result must be less than the RL. If the Method Blank fails acceptance criteria, the entire batch must be reset and reanalyzed. This Blank is used to zero the spectrometer before reading the cod batch samples and associated QC.

9.1.2 Continuing Calibration Blank (CCB)

The tube used the as the ICB is the same one used as the CCB. One CCB is analyzed every 10 samples. If the CCB fails acceptance criteria, the previous 10 samples need to be reread. If it fails a second time, then the entire batch must be reset and reanalyzed.

9.2 Laboratory Control Sample (LCS)

9.2.1 ICV / LCS

One Low LCS and one Hi LCS/ICV pair are analyzed per batch of 20 samples or less.

For method 5220, the LCS must be recovered within laboratory Control Limits.

For method 410.4, the results of the low LCS and Hi LCS/ICV must be within ± 10% of the true value.

If recovery is outside of acceptance criteria, the low LCS and Hi LCS/ICV are re-made and reanalyzed. If these criteria are still not met, a new calibration curve must be generated (Section 10.1), and the entire batch of samples is reset.

9.2.1.1 High COD:

9.2.1.1.1 Low LCS: 2.0mL of 50ppm standard (Section 8.2.1.5) is added to a COD tube.

9.2.1.1.2 High LCS/ICV: 2.0mL of 500ppm standard (Section 8.2.1.2) is added to a COD tube.

9.2.1.2 Low Cod:

9.2.1.2.1 Low LCS: 2.0mL of 20ppm standard (Section 8.2.1.7) is added to a COD tube.

9.2.1.2.2 High LCS/ICV: 2.0mL of 50ppm standard (Section 8.2.1.5) is added to a COD tube.

9.3 Initial Calibration Verification (ICV)

Refer to Section 9.2.

9.4 Continuing Calibration Verification (CCV) (Applies to High Cod only).

A CCV standard is analyzed after a Blank sample in the sample batch and after every 10 samples. The CCV is to verify that the calibration curve is valid over the range of use. The CCV concentration is rotated daily, with a different concentration each day.

To a COD tube, add 2.0mL from one of the CCV standards: 60ppm (Section 8.2.1.6), 200ppm (Section 8.2.1.3) or 400ppm (Section 8.2.1.4).

% Recovery must be within ± 10% of the true value. If % recovery is outside of these limits, the CCV Standard is re-made and reanalyzed. If these criteria are still not met, a new calibration curve must be generated (Section 10.1), and the entire batch of samples is reset.

9.5 Matrix Spike

One matrix spike is analyzed per batch of **20 samples** or less for method **5220**. One matrix spike is analyzed per batch **of 10 samples or less for method 410.4**. :

9.5.1 High COD: 100µL of 5000ppm KHP stock working standard (Section 8.2) is added to 2.0mL of sample in a COD tube. (Base value before dilutions = 238.1 mg/L).

9.5.2 Low COD: 100uL of 1000ppm KHP stock working standard (Section 8.2.1.1) is added to 2.0mL of sample in a COD tube. (Base value before dilutions = 47.6 mg/L).

% Recovery must be within **laboratory control limits** for method **5220** and be within **± 10%** of the true value for method **410.4.** If % recovery is outside of these limits, and the LCS recovery is acceptable, the matrix spike sample is reset. If failure continues, the matrix spike is reset on dilution. If recovery is acceptable, a narrative is submitted with the data indicating a dilution was necessary due to sample matrix. If failure still continues, and the LCS is acceptable, a narrative is submitted with the data indicating failure is due to sample matrix.

9.6 Laboratory Duplicate

One duplicate sample is analyzed per batch of 20 samples or less. The % RPD must be within laboratory control Limits for method 5220. The % RPD must be ≤ 20% for method 410.4. If % RPD is outside of these limits, the sample and its duplicate are reset. If failure continues, a narrative is submitted with the data indicating the sample is non-homogeneous.

9.7 Method-specific Quality Control Samples

Not applicable.

9.8 Method Sequence

- Blank (ICB)
- Low LCS
- Hi LCS (ICV)
- Samples/QC Samples (1-10 or less)
- CCV
- CCB

- Samples/QC Samples (11-20 or less)
- CCV
- CCB

10. Procedure

10.1 Equipment Set-up

10.1.1 Preparation of Calibration Curve: A Calibration Curve is generated every six months when new Stock Calibration Standard is prepared (Section 8.1), upon purchase of a new brand and **new lot** of COD tubes, or sooner if necessary for method 5220. A Calibration Curve must be in place prior to sample analysis. The curve is generated using the eight calibration standards included within Section 8.1.1. for High Cod, or Section 8.1.2 for Low Cod.

Note: New calibration curve must be generated with every new lot of tubes purchased for method 5220.

NOTE for Method 410.4: Calibration curve is generated daily using Blank and 4 calibration standards: 20 mg/l, 100 mg/l, 400 mg/l and 1250mg/l.

Correlation coefficient will be calculated. All calibration points are back calculated on excel and should be within 10% from true concentration, except lowest point of calibration curve. %recoveries for low range will be wider, but shouldn't exceed 100% and correlation coefficient must be > or = 0.995.

If calibration curve criteria failed, then new calibration standards have to be re-analyzed and new calibration curve has to be generated and all calibration points have to be recalculated to meet criteria.

If second calibration curve fails acceptance criteria, then analysis have to stopped, problem has to be identified; new calibration standards made and analyzed.

10.2 Initial Calibration

Analyze these standards according to Section 10.3.

Plot the absorbance values of the standards versus the corresponding COD concentrations. The correlation coefficient must be $\geq$ 0.995 for the curve to be considered valid.

10.3 Equipment Operation and Sample Processing

10.3.1 Preparation of COD tubes:

Preheat the COD reactor to 150°C.

Measure 2.0mL of sample or diluted sample into a COD tube. (NOTE: Use appropriate range level of tubes for High or Low COD analysis). In a similar manner, prepare the QC samples to be digested with the samples (refer to Sections 9.2 – 9.4 for High COD, and Sections 9.2 – 9.3 for Low Cod).

Tightly cap tubes and invert several times to mix completely. **CAUTION! Protect hands from heat produced when the contents of the vessel are mixed.** In order

to prevent local heating of vessel bottom and a possible explosive reaction, mix vessel contents thoroughly before placing in the COD reactor.

Place the prepared COD tubes into the heated COD reactor. Record the "Time in" and the reactor temperature on the batch sheet for later entry onto excel sheet. Reflux for 2 hours. Remove tubes from the COD reactor. Record the "Time out" and the reactor temperature on the batch sheet for later entry onto excel sheet. Allow tubes to cool to room temperature.

10.3.2 Measurement of Dichromate Reduction: If any liquid is visible on the walls of the cooled COD tubes, invert the tubes to incorporate this liquid. Allow solids to settle before measuring absorbance. If solids do not settle, the COD tubes must be centrifuged. Refer to section 10.3.3 for instructions on how to enter the data directly onto the Cod excel sheet.

10.3.3 Entering data onto the COD excel sheet

10.3.3.1 Turn on the computer and the spectrophotometer, at least 30 minutes prior to use.

10.3.3.2 On the computer desktop, double-click with the mouse to open the Gensys1 shortcut, hit "okay" when the box that says "device error" appears, then minimize the box which shows that the device has been activated.

10.3.3.3 Next, open the \\Fileserv\wetchem shortcut, followed by the cod_xlt file for High Cod, and cod_low_xlt file for Low Cod. Once these excel sheet opens, located at the top, right of the page, enter the WG batch number from the LIMS printout (done prior to Cod analysis). Enter the technician's initials in the appropriate area. Enter the date and time of the Cod preparation, then the date and time of the cod analysis.

10.3.3.4 Select which corresponding COD product is being analyzed: (ex. COD-5210), from the "buttons" area.

10.3.3.5 In the reagents/media information section of the excel sheet, enter the date of the preparation of the working standards (the High LCS/ICV, Low LCS, and CCV) used during the procedure (in order for the excel sheet to accept these dates, a " ' " must be typed first, followed by the date in an only numerical fashion, (for example: '091108 would express that the standards were made on 09-11-08 on the excel sheet) note that when this is typed, the " ' " will not be visible, but it is required to enter on the sheet).

10.3.3.6 On the MS line, enter the date of preparation of the original stock standard by typing it the same way.

10.3.3.7 On the COD Tubes line, enter the WC # which is the Wet Chemistry reagent log identifier, (for example: on the exterior of the cod box, a handwritten identifier saying WC-596 is visible).

10.3.3.8 Use the mouse to hit the "Get Samples" button on the screen. This will call up all the batch information and place it onto the excel sheet.

10.3.3.9 Below the column heading entitled Time, count down 10 samples; use the mouse to click on the far left, row numbers column, right-click on the mouse to activate the choice to insert another row. Do this process twice. In these newly added rows, type in (under column heading entitled Sample number), and the concentration of the (rotating for High Cod only) CCV standard, which was used

for the Cod batch to be read. If the batch is a full batch of 20 samples, this process of inserting extra rows will need to be repeated below the next 10 samples also. (Therefore, when reading the Cod tubes, the Blank, ICV, and first 10 samples will be read, then the CCV and CCB, followed by the next 10 samples, the CCV and CCB a second time, followed by the Duplicate and Spike, followed by the CCV and CCB a third time to finish the readings for that batch. If there are less than 20 samples, the rows are entered accordingly where necessary, allowing for the CCV and CCB to be read every 10 samples.)

10.3.3.10 Once all of the initial setup of the excel sheet has been accomplished, set the curser above the Time column and use the arrows to move the cursor down to the first box in the column. It is imperative that the box does NOT have a blinking cursor present in it when readings are begun.

10.3.3.11 Ensure that the spectrophotometer is set to the 620 wavelength and that all Cod tubes are ready for reading as described in section 10.3.1

10.3.4 Reading COD tubes (including Initial and Continuing Calibration requirements)

10.3.4.1 Wipe the exterior of the digested Method Blank COD tube with a Kim Wipe. Insert the Blank COD tube into the light path of the spectrophotometer set at 620nm. Set the absorbance to Zero.

10.3.4.2 Initial Calibration for the analysis requires that all initial QC (i.e. Blank, Low and High LCS) pass method requirements before proceeding on to read samples.

10.3.4.3 Read the absorbance of all samples and QC samples, wiping each tube with a Kim Wipe prior to reading.

10.3.4.4 On the lower right side of the face of the spectrophotometer, there is a print button. Once zeroing the Blank, and making sure to have the correct box highlighted on the excel sheet, hit the print button and it will beep as the date, time, and absorbance information are transferred to the excel sheet. The batch should be read in order as it occurs on the excel sheet, to enable the time sequence to be accurate.

10.3.4.5 Continuing Calibration requires that, following each 10 samples, the CCV (rotating value for High Cod only) is read, followed by the CCB, in order to demonstrate that the curve is valid. If the recovery result is valid according to the method criteria, then continue reading the next 10 samples. If the CCV and/or CCB fail, the previous 10 samples are no longer valid and must be reanalyzed as well as the CCV, CCB, and future unread samples in the batch.

10.3.4.6 When all readings have been taken, manually fill in the spike result based on the result shown in the above readings. Then hit the Save To LIMS button. Once this has been done, the data will be available in the LIMS, and a hardcopy will automatically print to review.

10.3.4.7 To repeat this process for a new COD batch, return to section 10.3.3.3.

10.4 Continuing Calibration

See Section 10.3.4.5

10.5 Preventive Maintenance

All spectrophotometers are calibrated on a semi-annual basis and an instrument service company calibrates the COD Reactors on an annual basis. Records are kept on file.

Perform routine preventative maintenance following manufacturer's specification. Record all maintenance in the instrument logbook.

11. Data Evaluation, Calculations and Reporting

$$\text{COD as mg } O_2 / L = \frac{\text{Absorbance - Y-intercept}}{\text{Slope}} \times \text{dilution factor}$$

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

Holding time exceedence and improper preservation are noted on the nonconformance report form.

Review of standards, blanks and standard response for acceptable performance occurs for each batch of samples. Record any trends or unusual performance on a nonconformance action form.

If the LCS recovery falls outside the designated acceptance range, the laboratory performance is judged to be out of control, and the problem must be immediately identified and corrected. Immediate corrective action includes reanalyzing all affected samples by using any retained sample before the expiration of the holding time.

If the Matrix Spike acceptance criteria is not met, the spiked sample is reanalyzed (if possible). If failure continues and if all other QC performance criteria are met, the data is reported and a narrative is included with the final report.

If the RPD for the Duplicate measurements falls outside the Laboratory defined control limits, the sample is reanalyzed (if possible). If failure continues, and if all other QC performance criteria are met, the data is reported and a narrative is included with the final report.

13. Method Performance

13.1 Method Detection Limit Study (MDL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the MDL, LOD, and/or LOQ as outlined in Alpha SOP/1732. These studies performed by the laboratory are maintained on file for review.

The quarterly method reporting limit (MRL) verification requirement is satisfied by the quarterly LOQ analysis, as per SOP/1732.

13.2 Demonstration of Capability Studies

Refer to Alpha SOP/1734 and 1739 for further information regarding IDC/DOC Generation.

13.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

14. Pollution Prevention and Waste Management

Refer to Alpha's Chemical Hygiene Plan and Waste Management and Disposal SOP for further pollution prevention and waste management information.

Chloride

References: **Method SM 4500Cl-E,** Standard Methods for the Examination of Water and Wastewater. APHA-AWWA-WEF. Standard Methods Online.

Method 9251, SW-846, Test Methods for Evaluating Solid Waste: Physical/Chemical Methods, EPA SW-846, Update III, 1997.

Method 10-117-07-1-B, Chloride in Water, Lachat Instruments, 6645 West Mill Road, Milwaukee, WI 53218 (1993).

1. Scope and Application

Matrices: The method is applicable to potable water, surface water, saline water, domestic and industrial wastewaters. The concentration range can be varied by using the colorimeter controls. Soil samples can be analyzed following water extraction.

Definitions: See Alpha Laboratories Quality Manual Appendix A.

Chloride, in the form of chloride (Cl-) ion, is one of the major inorganic anions in water and wastewater. In potable water, the salty taste produced by chloride concentrations is variable and dependent on the chemical composition of water. Some waters containing 250mg Cl-/L may have a detectable salty taste if the cation is sodium. On the other hand, the typical salty taste may be absent in waters containing as much as 1000mg/L when the predominant cations are calcium and magnesium. The chloride concentration is higher in wastewater than in raw water because sodium chloride (NaCl) is a common article of diet and passes unchanged through the digestive system. Along the seacoast, chloride may be present in high concentrations because of leakage of salt water into the sewerage system. It also may be increased by industrial processes. A high chloride content may harm metallic pipes and structures, as well as growing plants.

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one of the following laboratory personnel before performing the modification: Area Supervisor, Laboratory Director, or Quality Assurance Officer.

This method is restricted to use by or under the supervision of trained analysts. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

2. Summary of Method

Thiocyanate ion is liberated from mercuric thiocyanate by the formation of soluble mercuric chloride. In the presence of ferric iron, free thiocyanate ion forms the highly colored ferric thiocyanate, of which the absorbance is proportional to the chloride concentration. Samples are analyzed directly against a nonlinear calibration curve.

2.1 Method Modifications from Reference

None.

3. Detection Limits

The reported detection limit is 1.0mg Cl^-/L for water samples or 10.0 mg/kg for soils.

4. Interferences

4.1 Turbid samples and samples containing suspended solids are filtered through a 0.45µm filter.

4.2 Substances, which reduce iron (III) to iron (II) and mercury (II) to mercury (I), (e.g. sulfite, thiosulfate), will interfere.

4.3 Halides which also form strong complexes with mercuric ion (e.g. Br-, I-) give a positive interference.

4.4 Calcium and Magnesium ion may precipitate if present in sufficient concentration.

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material data handling sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

Samples are collected in clean, chemically resistant glass or plastic bottles. The maximum sample portion required is 100mL. Soil samples may be collected in glass or plastic containers.

6.2 Sample Preservation

Refrigerate at 4 ± 2 ºC until analysis.

6.3 Sample Shipping

No special shipping requirements.

6.4 Sample Handling

The maximum holding time is 28 days from collection.

7. Equipment and Supplies

7.1 Automated Ion Analyzer: Lachat Instruments.

7.2 Volumetric Flasks: Various volumes.

7.3 Volumetric Pipets: Various volumes.

7.4 Filtering Apparatus

7.5 0.45 µm Filters

7.6 Data Station

7.7 Analytical balances

7.8 Stirring plate

7.9 Plastic cups.

7.10 Ottawa sand.

7.11 10 ml syringes

8. Reagents and Standards

8.1 Stock Calibration Standard, 1000mg Cl^-/L: Commercially prepared. A Certificate of Analysis is kept on file. Stored at room temperatures and expires per manufacturer's expiration date.

8.1.1 Working Calibration Standards: Stable for period of six months. Store at room temperature.

8.1.1.1 100ppm Working Standard: To a 200mL volumetric flask, pipet 20.0mL of 1000ppm stock standard, (Section 8.1). Bring to volume with DI.

8.1.1.2 80ppm Working Standard: To a 100mL volumetric flask, pipet 8.0mL of 1000ppm stock standard, (Section 8.1). Bring to volume with DI.

8.1.1.3 20ppm Working Standard: To a 200mL volumetric flask, pipet 4.0mL of 1000ppm stock standard, (Section 8.1). Bring to volume with DI.

8.1.1.4 10ppm Working Standard: To a 200mL volumetric flask, pipet 2.0mL of 1000ppm stock standard, (Section 8.1). Bring to volume with DI.

8.1.1.5 5ppm Working Standard: To a 200mL volumetric flask, pipet 1.0mL of 1000ppm stock standard, (Section 8.1). Bring to volume with DI.

8.1.1.6 1ppm Working Standard: To a 200mL volumetric flask, pipet 2.0mL of 100ppm working standard, (Section 8.1.1.1). Bring to volume with DI.

8.1.1.7 Calibration Blank: DI water.

8.2 Stock Mercuric Thiocyanate Solution: In a 1L volumetric flask, dissolve 4.17g mercuric thiocyanate ($Hg(SCN)_2$) in about 500mL methanol. Dilute to the mark with methanol and stir for 20 minutes until dissolved. **CAUTION!** Mercury is a very toxic metal. Work under a hood and wear gloves! Solution is prepared every six months, and stored at room temperature.

8.2.1 Mercuric Thiocyanate, $Hg(SCN)_2$: Purchase ACS Grade. Store at room temperature. Expires upon manufacturer's expiration date.

8.2.2 Methanol: Reagent grade. Store at room temperature. Expires upon manufacturer's expiration date.

8.3 Stock Ferric Nitrate Reagent 0.5M: In a 1L volumetric flask, dissolve 202g ferric nitrate $Fe(NO_3)_3$ x $9H_2O$ in approximately 800mL water. Add 25mL concentrated nitric acid and dilute to the mark. Stir until dissolved. Reagent is prepared every 6 months, and stored at room temperature.

8.3.1 Ferric Nitrate, $Fe(NO_3)_3$ x $9H_2O$: Purchase ACS Grade. Store at room temperature. Expires upon manufacturer's expiration date.

8.3.2 Concentrated Nitric Acid, HNO_3: Reagent Grade. Store at room temperature. Expires upon manufacturer's expiration date.

8.4 Combined Color Reagent: In a 500mL volumetric flask, mix 75mL stock mercuric thiocyanate solution (Section 8.2) with 75mL stock ferric nitrate reagent (Section 8.3) and dilute to the mark with water. Invert three times to mix. Solution is prepared monthly, and stored at room temperature.

8.5 Stock LCS Standard, 1000mg Cl/L: Commercially prepared. A Certificate of Analysis is kept on file. The LCS Stock Standard must be from a different source than the Calibration Stock Standard. Store at room temperature, expires per manufacturer's expiration date.

8.5.1 5ppm (Low-level) LCS: Pipet 1mL of the 1000ppm stock LCS into a 200mL volumetric flask and bring to volume with DI. Standard is stable for six months. Store at room temperature.

8.5.2 30ppm (Mid-range) LCS: Pipet 3mL of the 1000ppm stock LCS into a 100mL volumetric flask and bring to volume with DI. Standard is stable for six months. Store at room temperature.

8.5.3 80ppm (High-level) LCS: Pipet 8mL of the 1000ppm stock LCS into a 100mL volumetric flask and bring to volume with DI. Standard is stable for six months. Store at room temperature.

8.5.4 Soil LCS: weigh 5 g(record exact weight) of Ottawa sand into plastic cup, pipet 2 ml of 1000 ppm stock LCS and add 48 ml of DI. Stir for 30 min, analyze water portion.

Final LCS concentration @ 400 mg/kg.

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

9.1 Blank(s)

9.1.1 Method Blank / ICB

Analyze one DI Blank per batch of 20 samples or less. An Initial Calibration Blank is analyzed at the start of each analytical sequence. The ICB consists of DI that has been filtered through a 0.45µm filter.
For soil samples: weigh 5 g of Ottawa sand (record exact weight in Log book), add 50 ml of DI, stir for 30 min, and filter. Analyze water portion.

Results must be less than the RL. If the ICB fails, re-run the ICB. If it passes criteria, the analysis can continue. If the ICB fails again, re-filter the ICB. If failure continues, analyze the ICB without filtering the DI, to determine if the contamination is coming from the filter or the water. If the ICB passes criteria, then check the filters. Any contaminated filters must be discarded; samples are only filtered through clean filters. Samples that don't have any trace of turbidity may be analyzed without filtering.

9.2 Laboratory Control Sample (LCS)

The calibration curve is verified at three concentrations at the start of each analytical run (ICV standards). Middle standard (30 mg/L) used for reportable LCS. The LCS for aqueous matrix must fall between 90-110% of the true value.

The LCS recovery criteria for the soil matrix is determined by calculating laboratory control limits, currently 89-109%.

If the LCS falls outside acceptance criteria, reprepare the solution and reanalyze. If the LCS falls outside for a second time, re-calibrate the system.

9.3 Initial Calibration Verification (ICV)

Refer to Section 9.2.

9.4 Continuing Calibration Verification (CCV)

The calibration curve is verified at 20 mg/l standard after every 10th sample, and at the end of the analytical run. Recovery for the CCV must be within ±10% of the true value.

If the CCV fails criteria, reanalyze the CCV. If it passes criteria, then continue with the analytical run. If the CCV fails for a second time, reprepare the CCV and reanalyze. If it passes criteria, reanalyze all samples that were analyzed since the last acceptable CCV.

9.5 Matrix Spike

Pipet 0.5mL of the 1000ppm Calibration Stock Standard (Section 8.1) into a 25mL volumetric flask and bring to volume with sample. The spike concentration will be 20ppm. Analyze one spike per batch of **20** samples or less for method **4500**. Analyze one matrix Spike sample for the batch of **10** or less samples for method **9251**.

For soil samples: weigh 5 g of sample (record exact weight), pipet 2 ml of 1000 ppm stock LCS and add 48 ml of DI. Stir for 30 min, analyze water portion. Final spike concentration is 400 mg/kg.

The MS recovery must fall within in-house control limits. If the MS falls outside of the recovery criteria, re-analyze both the MS and the associated sample. If the % recovery is still outside acceptance criteria, narrate the nonconformance due to sample matrix.

9.6 Laboratory Duplicate

Analyze one sample in duplicate per batch of **20** samples or less for method **4500**. Analyze one Duplicate sample for the batch of **10** or less samples for method **9251**.

The duplicate must be within in-house control limits. If the RPD falls outside acceptance limits, re-run both the duplicate and out of control sample. If the RPD is still outside acceptance criteria, narrate the nonconformance.

9.7 Method-specific Quality Control Samples

Not applicable.

9.8 Method Sequence

- Calibration of the instrument
- ICV/LCS analysis (5, 30, 80ppm standards)
- Curve verification (DI blank and 20ppm calibration standard)
- Auto dilutor check
- Sample analysis, up to ten samples
- Curve verification (DI blank and 20ppm calibration standard) after every tenth sample and at the end of the analytical run.

10. Procedure

10.1 Equipment Set-up

Turn on instrument and connect appropriate board.

10.2 Initial Calibration

10.2.1 Calibrate the Lachat flow injection analyzer according to the manufacturer's instructions.

10.2.2 Connect the chloride board in the appropriate channel position.

10.2.3 Using the six calibration standards and a DI blank (see Section 8.1.1.1 to 8.1.1.7), calibrate the instrument. A correlation coefficient ≥ 0.995 must be achieved using a second order quadratic calibration, otherwise recalibration will be necessary. This can be done by re-analyzing the standards used previously, or preparing the standards again. The calibration curve is prepared by plotting the peak areas of each standard processed through the manifold against the true chloride concentrations in each standard.

All calibration points are back calculated by Lachat software and should be within 10% from true concentration, except lowest point of calibration curve. %r recoveries for low range will be wider, but shouldn't exceed 100% and correlation coefficient will not be worse than 0.995.

10.2.4 **Initial Calibration Verification (ICV/LCS):** Prior to sample analysis, the calibration curve is checked at low, mid and high ends of the curve with 5ppm LCS, 30ppm LCS and 80ppm LCS respectively (Sections 8.5.1 through 8.5.3). Recovery for each standard must be within ±10% of their true value, otherwise recalibration is necessary.

10.2.5 **Auto dilutor check:** Prior to sample analysis, following ICV verification, auto dilutor check has to be performed (if dilutor will be used during analytical run). Analyze 100 mg/l calibration standard (8.1.1.1) using 10x auto dilution function. Recovery for

standard must be within ±10% of true value, otherwise repeat auto dilution. If recovery still will be outside of 10%, then recalibration is necessary. If after re-calibration recovery still will be outside of 10%, auto dilution function cannot be used and manual dilutions must be performed when needed.

10.3 Equipment Operation and Sample Processing

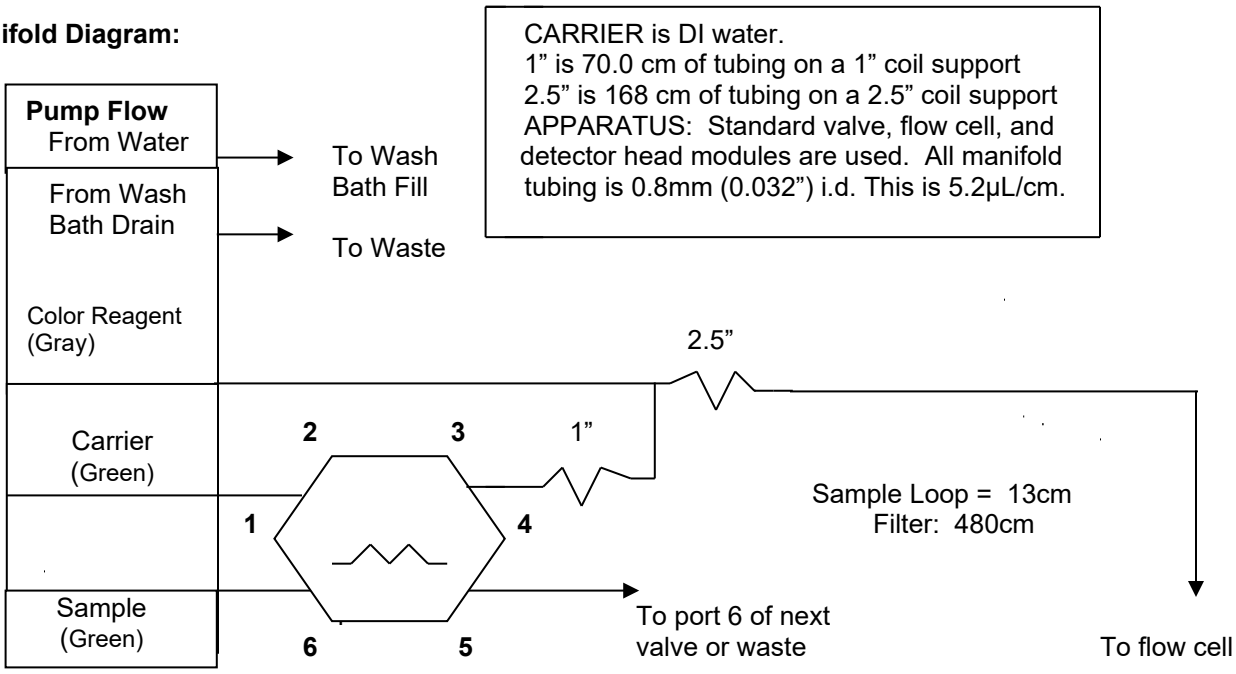
10.3.1 Follow the instrument manual for instrument operating instructions. Water samples should be poured in sample tubes for analysis. If sample is turbid or has sediment, sample has to be filtered prior analysis using 0.45 nm acrodisk filters. For soil samples: weigh 5 g of sample (record exact weight in log book), add 50 ml of Di stir for 30 min, filter and analyze water portion.

Note: 1:10 ratio should be used for soil:water extraction

10.3.2 The following are the specific parameters for this method:

Sample throughput:	120 samples/h; 30 s/sample
Pump speed:	35
Cycle period:	30 s
Inject to start of peak period:	8 s
Inject to end of peak period:	30 s
System IV Gain Setting	149 x 1
Presentation, Data Window	
Top Scale Response:	1.00
Bottom scale response:	0.00

Manifold Diagram:



10.3.3 A volumetric dilution is performed on any sample that has a result greater than 100ppm (the highest point on the calibration curve), so that the sample concentration is near the midpoint of the curve. All dilution factors are recorded.

10.3.4 Any sample with a result >1ppm, that follows a sample with a result of 100ppm or greater, should be considered suspect due to possible carry-over contamination and must be reanalyzed.

10.4 Continuing Calibration

Before sample analysis begins, after every 10 samples, and at the end of the sample run, the following must be analyzed:

- DI blank (Section 8.1.1.7)
- 20ppm calibration working standard (CCV) (Section 8.1.1.3)

The blank must yield a non-detectable result and the standard must be recovered within ±10% of its true value. If recoveries fall outside of this range, the cause for the failure is determined and corrected. When the CCV fails low, the CCV is re-made and re-analyzed. If failure continues, all samples analyzed since the last valid CCV, are considered invalid and must be re-analyzed. However, prior to re-analysis, a new calibration curve must be generated. If the CCV fails high, and all sample are considered ND, then the failure is narrated.

10.5 Preventative Maintenance

10.5.1 All lines are flushed with DI at the end of each run.

10.5.2 Tubing is replaced as necessary.

10.5.3 All equipment is kept clean.

10.5.4 All maintenance is recorded in the Instrument Maintenance Logbook.

11. Data Evaluation, Calculations and Reporting

Prepare standard curves by plotting peak heights of standards processed through the manifold against chloride concentrations in standards. The Lachat software will compute the sample chloride concentration by comparing the sample peak height with the standard curve.

The analyst has two options for final calculation: 1) Manually multiply the Lachat result times the dilution factor, if any, or 2) Input the dilution factor into the Lachat software and allow it to compute the corrected results.

Note: Chloride calibration curve is not linear; it's second order quadratic calibration. To ensure that result is accurate toward high end of the calibration curve, all samples with concentration over 90 mg/l, have to be re-analyzed with dilution.

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

Holding time exceedence and improper preservation are noted on the nonconformance report form.

Perform routine preventative maintenance following manufacturer's specification. Record all maintenance in the instrument logbook.

Review of standards, blanks and standard response for acceptable performance occurs for each batch of samples. Record any trends or unusual performance on a nonconformance action form.

If the CV or LCS recovery of any parameter falls outside the designated acceptance range, the laboratory performance for that parameter is judged to be out of control, and the problem must be immediately identified and corrected. The analytical result for that parameter in the unspiked samples is suspect and is only reported for regulatory compliance purposes with the appropriate nonconformance action form. Immediate corrective action includes reanalyzing all affected samples by using any retained sample before the expiration of the holding time.

13. Method Performance

13.1 Method Detection Limit Study (MDL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the MDL, LOD, and/or LOQ as outlined in Alpha SOP/1732. These studies performed by the laboratory are maintained on file for review.

The quarterly method reporting limit (MRL) verification requirement is satisfied by the quarterly LOQ analysis, as per SOP/1732.

13.2 Demonstration of Capability Studies

Refer to Alpha SOP/1734 and 1739 for further information regarding IDC/DOC Generation.

13.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

14. Pollution Prevention and Waste Management

Refer to Alpha's Chemical Hygiene Plan and Waste Management and Disposal SOP for further pollution prevention and waste management information.

None.

Technical Information

Reference Number:	ASTM D4318-17
Test Method Title:	Standard Test Method for Liquid Limit, Plastic Limit and Plasticity Index of Soils
Test Property:	Plasticity of soils
Test Specimen Size:	150-200 grams of material passing the #40 sieve 100 grams of as received soil for Moisture Content Determination
Number of Test Specimens:	1 (representative sample obtained by quartering, mixing or splitting)
Test Equipment:	Liquid limit device Flat grooving tool Drying containers Balance readable to 0.01 gram with 500 gram capacity Ground glass plate Spatula #40 sieve Wash bottle Distilled Water Drying oven capable of maintaining 110 $\pm$ 5 °C Drying Plate/vacuum pump apparatus Soil Blender with mixing cup

Standard Operating Procedure

The Atterberg Limit Test requires the As Received Moisture content determination to be reported. If no other assigned testing requires the As Received Moisture content determination, follow ASTM D 2216 and obtain the result for the sample.

GTX requires a daily IRM check of the equipment to include, but is not limited to: the wear of the grooving tool, the drop height of the Liquid Limit device cup and the wear spot on the base under the cup at the point of impact of the Liquid Limit device. Do not use equipment that is not comply with the IRM tolerances, found on the IRM log.

SAMPLE PREPARTION (wet method)

1. If sample has little or no material retained on the #40 sieve, prepare specimen of 150-200 g by mixing thoroughly with distilled water on glass plate or mixing dish using a spatula. If desired, soak the material in a mixing/storage dish with a small amount of water to soften the material before the start of mixing. Adjust the water content of the soil and mix again to bring to a consistency that would require between 25-35 blows. Remove >#40 sieve material by hand if small percentage is present. If water has been added to specimen place in a covered dish and allow to cure for a minimum of 16 hours.

2. If large percentage of >#40 sieve material is present, obtain a large enough specimen which will contain 150-200 g of material passing the #40 sieve. Place specimen in mixing cup and cover with distilled water. Mix into slurry, pass specimen through a #40 sieve and discard >#40 material. Reduce the amount of water using the drying plate/vacuum pump apparatus. Do not allow sample to over dry. Dry until sample is at a consistency that would require between 25-30 blows. Water has been added to the specimen so place in a covered dish and allow to cure for a minimum of 16 hours.

SAMPLE PREPARATION (dry method)

1. If sample is received dry, pass the material through a #40 sieve, and adjust the moisture content and mix thoroughly to bring the soil to a consistency that would require between 25-35 blows. Place specimen in a covered dish and allow to cure for a minimum of 16 hours.

LIQUID LIMIT DETERMINIATION (multipoint method)

1. Before starting test, remix thoroughly in its dish adjusting the water content slightly, as necessary.

2. Fill the liquid limit cup even with front rim, to a depth that allows a full height cut with grooving tool. Keep the unused material covered with a wet towel in the mixing dish.

3. Form a groove in the soil from the highest point to the lowest point on the rim of the cup using the beveled edge facing forward of the grooving tool. Keep the tool perpendicular to cup from back to front by using an arc type motion. If the groove cannot be made in one stroke without tearing the soil, cut the groove in layers a little deeper with each cut, without tearing the soil.

4. Inspect the underside of the Liquid Limit Device, making sure the underside of the cup and base are clean. Lift and drop the cup at a rate of 1.9-2.1 drops per second until the two halves of the soil pat come in contact at the bottom of the groove along a distance of 0.5 inch. The base of the machine shall not be held with a hand while the crank is being turned. Record number of blows required. Take approximately 10 g of material from the closed area, perpendicular to the groove and place into a pre-weighed drying container. Measure and record mass to nearest 0.01 g. Cover the container.

5. Remove balance of material from cup and remix with soil in dish. Clean the cup.

6. By wetting the remaining material, adjust the blow counts so a distribution of blow counts is obtained. One point between 35 and 25 blows, another point between 20 and 30 blows, and a third point between 25 and 15 blows. For each point repeat steps 1 through 6.

PLASTIC LIMIT DETERMINATION

1. Obtain about 20 grams of soil prepared for the Liquid Limit test and dry by blotting with paper towels until it can be rolled without sticking to the glass plate.

2. To determine plastic limit, roll three to four threads of 1.5-2.0 grams of material down to a 1/8 inch diameter for a total sample weight of at least 6 grams.

3. Roll the material on a glass plate with the palm of your hand until a thread of uniform diameter of 1/8 inch is obtained (80-90 strokes per minute). This should take no longer than 2 minutes.

4. Ball up and repeat step 3 again. Repeat until 1/8 inch diameter cannot be obtained (thread crumbles under the pressure required for rolling). The only requirement for continuing is that the threads are able to be reformed into a ball and rolled out again.

5. Gather portions of the crumbled thread together and place into a pre-weighed container. Measure and record mass to nearest 0.01 g.

6. Repeat steps 2 through 5 one more time.

7. Dry all materials to a constant mass in oven with the temperature required for the material type being tested. Weigh again to the nearest 0.01 g.

8. Calculate the plasticity index as follows:

   PI = LL-PL

   where:

   PI = Plasticity Index
   LL = Liquid Limit
   PL = Plastic Limit

9. If either the liquid limit or plastic limit could not be determined, or if the plastic limit is equal to or greater than the liquid limit, report the soil as non-plastic.

10. Report: sample identification, as received moisture content, sample preparation procedure, liquid limit, plastic limit and plasticity index to the nearest whole number, and non-plastic if applicable.

Determination of Inorganic Anions by Ion Chromatography

Reference: **EPA 300.0,** Methods for the Determination of Inorganic Substances in Environmental Samples, EPA/600/R-93/100, August, 1993.

Method 9056A, SW-846, Test Methods for Evaluating Solid Waste: Physical/Chemical Methods, EPA SW-846, Revision IV, February 2007

1. Scope and Application

Matrices: Drinking water, surface water, mixed domestic and industrial wastewaters, groundwater, reagent waters, solids (after extraction) leachates (when no acetic acid is used).

Definitions: Refer to Alpha Analytical Quality Manual.

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one or more of the following laboratory personnel before performing the modification: Area Supervisor, Department Supervisor, Laboratory Director, or Quality Assurance Officer.

This method is restricted to use by or under the supervision of analysts experienced in the operation of the ion chromatography and in the interpretation of ion chromatography data. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

Parameter	CAS
Bromide	24959-67-9
Chloride	16887-00-6
Fluoride	16984-48-8
Nitrate – N	14797-55-8
Sulfate	14808-79-8

2. Summary of Method

A small volume of sample is introduced into an ion chromatograph. The anions are separated and measured, using a system comprised of a guard column, analytical column, suppressor device, and conductivity detector.

2.1 Method Modifications from Reference

Use of other eluents that improve method performance are minor modifications of the method and are considered by the method to be acceptable.

3. Reporting Limits

The laboratory follows the procedure found in 40CFR Part 136 to determine the MDL on a semi-annual basis.

Parameter	RL
Bromide	.05 mg/L
Chloride	.5 mg/L
Fluoride	.05 mg/L
Nitrate – N	.05 mg/L
Sulfate	1 mg/L

4. Interferences

4.1 Interferences can be caused by substances with retention times that are similar to and overlap those of the anion of interest. Large amounts of an anion can interfere with the peak resolution of an adjacent anion. Sample dilution and/or fortification can be used to solve most interference problems associated with retention times.

4.2 Method interferences may be caused by contaminants in the reagent water, reagents, glassware, and other sample processing apparatus that lead to discrete artifacts or elevated baseline in ion chromatograms.

4.3 Samples that contain particles larger than 0.45 microns and reagent solutions that contain particles larger than 0.20 microns require filtration to prevent damage to instrument columns and flow systems.

4.4 Any anion that is not retained by the column or only slightly retained will elute in the area of fluoride and interfere. Known coelution is caused by carbonate and other small organic anions. At concentrations of fluoride above 1.5mg/L, this interference may not be significant, however, it is the responsibility of the user to generate precision and accuracy information in each sample matrix.

4.5 The acetate anion elutes early during the chromatographic run. The retention times of the anions also seem to differ when large amounts of acetate are present. Therefore, this method is not recommended for leachates of solid samples when acetic acid is used for pH adjustment.

4.6 The quantitation of unretained peaks should be avoided, such as low molecular weight organic acids (formate, acetate, propionate, etc.) which are conductive and coelute with or near fluoride and would bias the fluoride quantitation in some drinking and most waste waters.

4.7 Any residual chlorine dioxide present in the sample will result in the formation of additional chlorite prior to analysis. If any concentration of chlorine dioxide is suspected in the sample, purge the sample with an inert gas (argon or nitrogen) for about five minutes or until not chlorine dioxide remains.

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material safety data sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

Sulfuric acid used in this method has the potential to be highly toxic or hazardous.

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

Samples are collected in glass or plastic bottles of sufficient volume to allow replicate analyses of the anions of interest.

6.2 Sample Preservation

Samples are refrigerated at 4°C.

6.3 Sample Shipping

No specific requirement.

6.4 Sample Handling

The sample holding time is 48 hours for the following anions: Nitrate –N.

The sample holding time is 28 days for the following anions: Bromide, Chloride, Fluoride, and Sulfate

7. Equipment and Supplies

7.1 Balance: Analytical, capable of weighing to 0.0001g.

7.2 Ion Chromatograph: Analytical system (Dionex ICS-2000 or Dionex Integrion HPLC) complete with ion chromatograph and all required accessories including syringes, autosampler, analytical columns, compressed gasses and detectors.

7.2.1 Anion guard column: AG-18 (Dionex PN 060551) or AG-18-Fast (Dionex PN 076035) A protector of the separator column. If omitted from the system the retention times will be shorter. Usually packed with a substrate the same as that in the separator column.

7.2.2 Anion analytical column: AS-18 (Dionex PN 060549) or AS-18-FAST (Dionex PN 076034) . This column produces the separation shown in Figure 1.

7.2.3 Anion supressor: ASRS Ultra II 4mm (PN 061561). The supressor column is packed with a high capacity cation exchange resin that is capable of converting the eluent and separated anions to their respective acid forms.

7.2.4 Detector: DS6 (PN 057985) Temperature controlled, heated conductivity cell

7.2.5 Eluent Generator: EG40 (Dionex PN 058900) Prepares the eluent electronically, controlled by the software; equipped with KOH cartridge.

7.3 Software: The Dionex IC Instrument uses Chromeleon Software.

7.4 0.45µm Membrane Filter Syringes.

7.5 Volumetric Flasks: Various volumes.

7.6 Volumetric Pipets: Various volumes.

7.7 0.5mL Vials with Caps: Dionex PN 038142

7.8 Vial kit: 30 ml PP w/Slit septum (Dionex PN 055428)

8. Reagents and Standards

Note: All analytical standards used for calibration and calibration verification must be traceable to NIST. Each standard is recorded in a Logbook and unique ID is assigned to each standard. The unique IDs must also be included in all analytical sequences.

8.1 Reagent Water: Deionized water, free of the anions of interest. Water should contain particles no larger than 0.20 microns.

8.2 Eluent Solution: 32mM KOH, Prepared by the Eluent Generator.

8.3 Stock Calibration / ICV Standard Solutions, 1000mg/L (1mg/mL): Stock standards for all analytes are usually purchased as certified solutions. Certificates of analysis are kept on file.

However, if it is necessary, the Stock Solutions may be prepared from ACS reagent grade materials (dried at 105°C for 30 minutes) as listed below. The ICV Standards must be prepared from a different source than the calibration standards.

NOTE: Stock calibration/ ICV standards are stable for at least six months when stored at 4°C. Dilute working standards are prepared weekly.

8.3.1 Standard 1: Fluoride Stock Standard, 1000mg F^-/L

In a 250mL volumetric flask, dissolve 0.5526g of sodium fluoride (NaF, CASRN 7681-49-4) in about 200mL reagent water. Dilute to the mark with reagent water, and invert to mix.

8.3.2 Standard 2: Fluoride Stock Standard, 100mg F^-/L

In a 250mL volumetric flask, pipet 25mL of Standard 1, dilute to the mark with reagent water, and invert to mix.

8.3.3 Standard 3: Chloride Stock Standard, 1000mg Cl^-/L

In a 250mL volumetric flask, dissolve 0.4121g of sodium chloride (NaCl, CASRN 7647-14-5) in about 200mL reagent water. Dilute to the mark with reagent water, and invert to mix.

8.3.4 Standard 4: Bromide Stock Standard, 1000mg Br^-/L

In a 250mL volumetric flask, dissolve 0.3219g of sodium bromide (NaBr, CASRN 7647-15-6) in about 200mL reagent water. Dilute to the mark with reagent water, and invert to mix.

8.3.5 Standard 5: Bromide Stock Standard, 100mg Br^-/L

In a 250mL volumetric flask, pipet 25mL of Standard 4, dilute to the mark with reagent water, and invert to mix.

8.3.6 Standard 8: Nitrate Stock Standard, 1000mg NO_3^--N /L

In a 250mL volumetric flask, dissolve 1.5170 g of sodium nitrate ($NaNO_3$, CASRN 7631-99-4) in about 200mL reagent water. Dilute to the mark with reagent water, and invert to mix.

8.3.7 Standard 9: Nitrate Stock Standard, 100mg NO_3^--N /L

In a 250mL volumetric flask, pipet 25mL of Standard 8, dilute to the mark with reagent water, and invert to mix.

8.3.8 Standard 12: Sulfate Stock Standard, 1000mg SO_4^{2-} /L

In a 250mL volumetric flask, dissolve 0.4535 g of anhydrous dibasic, potassium sulfate (K_2SO_4, CASRN 7778-80-5) in about 200mL reagent water. Dilute to the mark with reagent water, and invert to mix.

8.3.9 Stock Bromide Standard, 1000ppm

Commercially available. Certificate of analysis required and kept on file. Use separate sources for the ICV and Calibration standards listed below.

8.3.9.1 ICV Bromide Standard, 100ppm

In a 100mL volumetric flask, add 1mL of Stock 1000ppm Bromide standard (Section 8.4.13). Bring to volume with reagent water.

8.4 Working Mixed Stock Standard A (Calibration Stock)

In a 200mL volumetric flask, transfer using volumetric pipets, 2mL each of Standards Bromide 1000ppm and Nitrate 1000ppm; 20mL of Chloride 1000ppm and Fluoride 100ppm (Section 8.3). Dilute to the mark with reagent water and invert to mix. Store at 4 ± 2°C for up to one month.

This makes Standard A containing F^-, Cl^-, NO_2^- -N, Br^-, NO_3^- -N and SO_4^{2-} at the concentrations of 10, 100, 10, 10 and 200ppm respectively.

8.4.1 Analyte Matrix Spike Solution

Volumetrically prepare the spike solution by bringing 1.0 mL of the calibration stock standard (Section 8.4) up to a 25mL final volume with the sample.

8.5 Working Mixed Standards B through G (Calibration Curve)

Working mixed standards B through F are prepared by diluting Standard A as summarized in the following Table. These are prepared fresh as needed for calibration.

Std.	Std. A (mL)	Final Vol. (mL)	F^-	Cl^-	Br	NO_3^- -N	SO_4^{2-}
B	5	10	5.0	50.0	5.0	5.0	100.0
C	5.0	25	2.0	20.0	2.0	2.0	40.0
D	1.25	25	0.5	5.0	0.5	0.5	10.0
E	0.5	25	0.2	2.0	0.2	0.2	4.0
F	1 of Std D	10	0.05	0.5	0.05	0.05	1.0
G	0.5 of Std D	10	0.025	0.25	0.025	0.025	0.5

Example: To make up Standard B, take 25mL of Standard A in a 10mL volumetric flask and dilute to the mark with reagent water.

Note: The dynamic range for the method is two orders of magnitude. The concentrations for the standards could be changed to bracket the concentrations of the samples to be analyzed.

8.6 ICV Stock Standard (Second Source Verification)

To a 200mL volumetric flask add 20mL of the following standards: Chloride 1000ppm and Sulfate 1000ppm, and 2mL of Fluoride 1000ppm, Bromide 1000ppm and Nitrate 1000ppm (Section 8.3). Dilute to volume with reagent water.

8.6.1 ICV Working Standard / LCS Solution

In a 25mL volumetric flask, add 2mL of the ICV Stock Standard. Bring to volume with reagent water. Store at 4 ± 2°C. Prepare weekly.

ICV working standard will have the following concentrations: 0.8 mg/L for Fluoride, Nitrate and Bromide; 8.0 mg/L for Chloride and Sulfate.

8.7 CCV Working Solution

The CCV Working Solution is made by diluting 2.5 ml of Mixed Stock Standard A up to 25 ml of DI Section 8.4. Final concentrations are: 1.0 mg/L for Fluoride, Nitrate and Bromide; 10.0 mg/L for Chloride and 20.0mg/l for Sulfate. Store at 4 ± 2°C. Prepare weekly.

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

9.1 Blank

One Method Blank consisting of an aliquot of reagent water is analyzed with each batch of 20 samples or less. Data produced are used to assess contamination from the laboratory environment. Method Blank results must be less than the Reporting Limit (RL) for the analyte.

Note: If samples have to be filtered prior to analysis, all associated batch QC must also be filtered.

9.2 Laboratory Control Sample (LCS)

The ICV/LCS is analyzed at the beginning of each run, but after the CCV standard. This standard is prepared from a different source than that used to prepare the calibration standards (Section 8.6). The % Recovery of this standard must be within ± 10% of the calibration standard.

9.3 Initial Calibration Verification (ICV)

See Section 9.2.

9.4 Continuing Calibration Verification (CCV)

The CCV Standard is the equivalent of Standard D in Section 8.5. Store at 4 ± 2°C. Prepare weekly. The CCV is analyzed at the beginning of each run, after every tenth sample, and at the end of the sample run. The % Recovery of this standard must be within ± 10% of the calibration standard. If the Continuing Calibration cannot be verified within the specified limits, reanalyze the CCV solution. Record the reason for re-injection. If the second analysis of the CCV solution confirms calibration to be outside the limits, sample analysis must be discontinued, the cause determined and/or in the case of drift, the instrument recalibrated. All samples following the last acceptable CCV solution must be reanalyzed. The analysis data of the calibration blank and CCV solution must be kept on file with the sample analyses data

9.5 Matrix Spike

Prepare and analyze one spiked sample per batch of 10 samples or less (Section 8.4.1). Recovery of the Matrix Spike must be within +/-10% of the true value for method 300 and +/-20% for method 9056.

9.6 Laboratory Duplicate

Prepare and analyze one duplicate sample per batch of 20 samples or less. The RPD for the duplicate measurements must be ≤ 15%.

9.7 Method-specific Quality Control Samples

None.

9.8 Method Sequence

- Instrument calibration
- Rinse
- CCV
- CCB
- ICV
- ICB
- Blank
- LCS
- Six samples
- CCV
- CCB
- Ten samples
- CCV
- CCB
- Shut-down

10. Procedure

10.1 Equipment Set-up

10.1.1 Determination of Linear Calibration Range (LCR)

The LCR must be determined initially and verified every six months or whenever a significant change in instrument response is observed or expected. The initial demonstration of linearity must use sufficient standards to ensure that the resulting curve is linear. The verification of linearity must use a minimum of a blank and three standards. If any verification data exceeds the initial values by ± 10%, linearity must be

reestablished. If any portion of the range is shown to be nonlinear, sufficient standards must be used to clearly define the nonlinear portion.

10.1.2 Prime Pump: The pump must be primed prior to analysis, to ensure that there is no gas entering the column.

10.1.3 Monitor Baseline: From the main Panel screen, press the "Startup" Button. This will turn on, in order, the pump, the eluent generator, and the conductance cell. Allow the instrument to warm up for 10 – 20 minutes to ensure the baseline is stable and flat.

10.1.4 While the baseline stabilizes, the sample sequence can be written and the autosampler may be loaded.

10.1.5 When the baseline is stabilized, the sample sequence may be loaded into the analytical run, and started from the Chromeleon software.

10.1.6 Operating Conditions: Dionex IC Instrument

Eluent Concentration: 32mM KOH

Flow rate: 1.0mL / minute

Injection volume: 100µL

ASRS: ON

Conductivity Cell Temperature: 30 °C

10.1.7 Monitor instrument stability: Prior to QC sample and sample analysis, analyze a DI water blank to ensure the instrument is stable.

10.1.8 Sample filtration: Autosampler vials are equipped with a filter. If additional filtration is necessary, samples may be filtered through a 0.45µm membrane filter attached to a syringe. **NOTE:** If samples require filtration, all associated batch QC samples must also be filtered.

10.1.9 Extraction of solid materials: Add a volume of reagent water equal to 10 times the weight of dry solid material taken as a sample. This slurry is mixed for 10 minutes using a magnetic stirring device. Filter the resulting slurry before injecting using a 0.45µ membrane filter attached to a syringe. Care should be taken to show that good recovery and identification of peaks is obtained with the user's matrix through the use of matrix spikes (Section 9.5).

10.2 Initial Calibration

For each analyte of interest, prepare calibration standards at a minimum of three concentration levels and a blank by adding accurately measured volumes of one or more stock standards (Section 8.5) to a volumetric flask and diluting to volume with reagent water. If a sample analyte concentration exceeds the calibration range, the sample may be diluted to fall within the range.

Using injections of 100µL of each calibration standard, tabulate peak height or area responses against the concentration. The results are used to prepare a calibration curve for each analyte. During this procedure, retention times must be recorded.

The calibration curve for each analyte is prepared by plotting instrument response against the standard concentration. A correlation coefficient of 0.995 or greater is considered acceptable for all analytes.

All calibration points are back calculated by Dionex software and should be within 10% from true concentration, except 2 lowest points of calibration curve. %recoveries for low range will be wider, but shouldn't exceed 50% and correlation coefficient will not be worse than 0.995.

If calibration curve criteria failed, then new calibration standards have to be re-analyzed and new calibration curve has to be generated and all calibration points have to be recalculated to meet criteria.

If second calibration curve fails acceptance criteria, then analysis have to stopped, problem has to be identified; new calibration standards made and analyzed.

10.2.1 Initial Calibration Verification (ICV/LCS): The calibration curve must be verified on each working day, and after every 20 samples. The ICV/LCS sample is prepared from a different source than that used for the calibration standards (Section 8.6). If the response or retention time for any analyte varies from the expected values by more than ± 10%, the analysis must be repeated, using fresh calibration standards. If the results are still more than ± 10%, a new calibration curve must be prepared for that analyte.

10.3 Equipment Operation and Sample Processing

10.3.1 An automated constant volume injection system is used. Load and inject a fixed amount of well-mixed sample. Flush injection loop thoroughly, using each new sample. Use the same size loop for standards and samples. Record the resulting peak size in area or peak height units.

10.3.2 The width of the retention time window used to make identifications should be based upon measurements of actual retention time variations of standards over the course of a day. Three times the standard deviation of a retention time can be used to calculate a suggested window size for each analyte. However, the experience of the analyst should weigh heavily in the interpretation of chromatograms.

10.3.3 If the response for the peak exceeds the working range of the system, dilute the sample with an appropriate amount of reagent water and reanalyze.

10.3.4 If the resulting chromatogram fails to produce adequate resolution, or if identification of specific anions is questionable, fortify the sample with an appropriate amount of standard and reanalyze.

Note: Retention time is inversely proportional to concentration. Nitrate and sulfate exhibit the greatest amount of change, although all anions are affected to some degree. In some cases this peak migration may produce poor resolution or identification.

10.4 Continuing Calibration

This standard (Standard D: Section 8.5) is prepared weekly. The CCV is analyzed at the beginning of each run, after every tenth sample, and at the end of the sample run. The % Recovery of this standard must be within ± 10% of the calibration standard. Refer to Section 9.4 if % Recovery falls outside of the acceptance range.

10.5 Preventive Maintenance

Follow the Preventative Maintenance Schedule as outlined on the Dionex ICS-2000 CDROM.

As Needed

- Check the eluent reservoir to see if it needs to be refilled.

Daily

- Check the ICS-2000 component mounting panel for leaks or spills. Wipe up spills. Isolate and repair leaks. Rinse off any dried eluent with reagent water.

- Check the waste container daily and empty when needed.

Weekly

- Once a week, check fluid lines for crimping or discoloration. Relocate any pinched lines. Replace damaged lines.
- Check the junctions between the pump heads and the pump casting for evidence of liquid leaks. If piston seal wash tubing is not connected, check the drain tubes at the rear of the pump heads for evidence of moisture. Normal friction and wear may gradually result in small liquid leaks around the piston seal. If unchecked, these leaks can gradually contaminate the piston housing, causing the pump to operate poorly. If leaks occur, replace the piston seals.

- Check the end-line filter (PN 045987) and change if needed. When new, end-lline filters are pure white. If the system is in continuous operation, change the end-line filter weekly, or whenever it becomes discolored. Replace the filter more often if bacterial buildup is visible or if the eluent does not contain solvent.

> **NOTE:** It is especially important to regularly replace end-line filters when using aqueous eluents, which may contaminate the filter with bacteria or algae. The bacterial buildup may not be visible.

Yearly (performed by Dionex technician)

- Calibrate the cell.
- Calibrate the vacuum degas assembly
- Replace the pump piston rinse seals and piston seals

11. Data Evaluation, Calculations and Reporting

11.1 Compute the sample concentration by comparing sample response with the standard curve. Multiply the result by the appropriate dilution factor.

11.2 Report only those values that fall between the lowest and the highest calibration standards. Samples exceeding the highest standard should be diluted and reanalyzed.

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

If the Method Blank result exceeds the Reporting Limit (RL) for the analyte, the Blank is reanalyzed. If the second result remains > RL, notify the Laboratory Manager to ensure maintenance is performed on the water filtration system and seek an alternate reagent water source within the laboratory. If the alternate reagent water source is acceptable, this source must be utilized for all blanks, standards and sample dilutions for the sample batch. If the second source reagent water also fails, the Laboratory Manager is notified.

If the Continuing Calibration cannot be verified within the specified limits, reanalyze the CCV solution. Record the reason for re-injection. If the second analysis of the CCV solution confirms calibration to be outside the limits, sample analysis must be discontinued, the cause determined and/or in the case of drift, the instrument recalibrated. All samples following the last acceptable CCV solution must be reanalyzed. The analysis data of the calibration blank and CCV solution must be kept on file with the sample analyses data.

If the ICV/LCS acceptance criterion cannot be met, reanalyze the standard. If failure continues, the instrument is recalibrated.

If the Matrix Spike acceptance criteria is not met, the spiked sample is reanalyzed (if possible). If failure continues and if all other QC performance criteria are met, the data is reported and a narrative is included with the final report.

If the RPD for the Duplicate measurements falls outside the Laboratory defined control limits, the sample is reanalyzed (if possible). If failure continues, and if all other QC performance criteria are met, the data is reported and a narrative is included with the final report.

Holding time exceedance and improper preservation are noted on the nonconformance report form.

Perform routine preventative maintenance following manufacturer's specification. Record all maintenance in the instrument logbook.

Review of standards, blanks and standard response for acceptable performance occurs for each batch of samples. Record any trends or unusual performance on a nonconformance action form.

If the CCV or LCS recovery of any parameter falls outside the designated acceptance range, the laboratory performance for that parameter is judged to be out of control, and the problem must be immediately identified and corrected. The analytical result for that parameter in the unspiked samples is suspect and is only reported for regulatory compliance purposes with the appropriate nonconformance action form. Immediate corrective action includes reanalyzing all affected samples by using any retained sample before the expiration of the holding time.

13. Method Performance

13.1 Detection Limit Study (DL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the DL, LOD, and/or LOQ as outlined in Alpha SOP ID 1732. These studies performed by the laboratory are maintained on file for review.

13.2 Demonstration of Capability Studies

Refer to Alpha SOP ID 1739 for further information regarding IDC/DOC Generation.

13.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

14. Pollution Prevention and Waste Management

Refer to Alpha's Chemical Hygiene Plan and Hazardous Waste Management and Disposal SOP for further pollution prevention and waste management information.

Determination of Organochlorine Pesticides By Gas Chromatography/Electron Capture Detection (GC/ECD)

References: Method 8081B Rev. 2, Update IV, Feb 2007, and Method 8000C Test Methods for Evaluating Solid Waste, SW-846, Third Edition, Final Update III, December 1996 (USEPA, Office of Solid Waste and Emergency Response, Washington, DC).

USEPA Contract Laboratory Program Statement of Work for Organics Analysis Multi-Media, Multi-Concentration" August 1991. Document Number OLM03.1 and OLM04.2.

Massachusetts Contingency Plan (MCP) WSC-CAM for SW846 Method 8081 Pesticides by GC/ECD. Section VB Rev4. August 2004 (Massachusetts Department of Environmental Protection Bureau of Waste site cleanup)

1. Scope and Application

Matrices: This method is applicable to the quantification of Organochlorine Pesticides in water, soil, sediment, sludge, product, and tissue (either animal or vegetative).

Definitions: Refer to Alpha Analytical Quality Manual.

This method is applicable to the analysis and quantification of sample extracts for Organochlorine Pesticides by gas chromatography/electron capture detector. Target analytes include a wide range of pesticides, a basic list of which is included below. The sensitivity of the method usually depends on the concentration of interferences as well as instrumental limitations. If interferences prevent detection of the analytes, the method may also be performed on samples that have undergone cleanup. Typical reporting limits are based on the lowest level of the initial calibration curve and generally correspond to limits derived from quarterly LOQ studies to verify our MDLs.. Detection limits will vary with the individual sample matrix, sample preparation procedures, instrument calibration range, and volume of sample analyzed.

This method is in substantial conformance with the guidelines established in SW-846 for performing chromatographic analysis as defined in the Method 8000B ("Gas Chromatography), Method 8081B ("Organochlorine Pesticides"), Method 3510C ("Separatory Funnel Liquid - Liquid Extraction"), and Method 3570 Microscale Extraction. The data quality objectives of these methods are met or exceeded by this SOP. The following extraction and cleanup methods may also apply, depending on project specifications:

- Extraction of Water Samples by Separatory Funnel (2156)
- Tissue Preparation and Homogenization (2166)
- Shaker Table Extraction (2261)
- Sulfur Cleanup (2168)
- Microscale Solvent Extraction - 3570 (2172)
- Silica cleanup (2170)
- GPC Cleanup by HPLC (2167)

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one or more of the following laboratory

personnel before performing the modification: Area Supervisor, Department Supervisor, Laboratory Director, or Quality Assurance Officer.

This method is restricted to use by or under the supervision of analysts experienced in the operation of the GC/ECD and in the interpretation of GC/ECD data. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

Table 2: Target Analytes for Pesticides by GC/ECD

Parameter	CAS
alpha-BHC	319-84-6
beta-BHC	319-85-7
gamma-BHC (Lindane)	58-89-9
delta-BHC	319-86-8
Heptachlor	76-44-8
Aldrin	309-00-2
alpha-Chlordane	5103-71-9
gamma-Chlordane	5103-74-2
Heptachlor epoxide	1024-57-3
Oxychlordane	27304-13-8
Dieldrin	60-57-1
Endrin	72-20-8
Endrin aldehyde	7421-93-4
Endrin ketone	53494-70-5
4,4'-DDD	72-54-8
4,4'-DDE	72-55-9
4,4'-DDT	50-29-3
2,4'-DDD	53-19-0
2,4'-DDE	3424-82-6
2,4'-DDT	789-02-6
Endosulfan I	959-98-8
Endosulfan II	33213-65-9
Endosulfan sulfate	1031-07-8
Methoxychlor	72-43-5
Mirex	2385-85-5
Cis-Nonachlor	5103-73-1
Trans-Chlordane	5103-74-2
Hexachlorobenzene	118-74-1
Toxaphene	72-43-5
Chlordane	57-74-9

2. Summary of Method

An aliquot of a well mixed, homogeneous aqueous, solid, or tissue sample is accurately measured or weighed for sample preparation. Generally, 500mL or 1000mL of water sample, 1-5g of tissue sample, or 5g to 30g of sediment/soil sample is extracted. Water, soil/sediment, and tissue samples are spiked with surrogate compounds and then extracted using methylene chloride or a methylene chloride/acetone mixture. The extract is dried and exchanged into hexane during sample concentration. After extraction, cleanup techniques are applied. Generally extracts are cleaned by GPC (for hydrocarbon or lipid removal) and silica cartridge or automated silica column followed by copper (for sulfur removal). The extract is exchanged into hexane and concentrated to the appropriate volume, generally 5mL or 10mL, for analysis. Alternatively, this method can be employed for lower detection limits by decreasing the final volume to 1-5 mL.

After cleanup and re-concentration, the extracts are spiked with internal standards, and analyzed on a gas chromatograph, which is fitted with two capillary columns of differing polarities each employing a separate detector. The target analytes are resolved on each column and detected using an electron capture detector (ECD). Analytes are introduced into the GC/ECD by injecting a known volume of the calibration standards, quality control samples, and sample extracts into the GC that is temperature and flow programmed to separate the compounds of interest. Identification of target analytes is accomplished by confirming a target hit on two dissimilar columns using Retention Time and Pattern Recognition. Concentrations are calculated from the ECD response using internal standard techniques, additionally external standard techniques can also be utilized circumstantially. Concentrations are determined using Mean Relative Response Factor from a multi-level calibration curve. Response factors for target analytes and surrogate compounds are determined relative to the internal standards.

2.1 Method Modifications from Reference

This method exhibits some modification from the reference method. Method 8081B discusses the allowed shelf life for stock solutions as one year and working solutions as six months. The standard expiration protocol for the lab is the same however, if there is a significant amount of working spike or surrogate solution expired after the six-month period the lab will re-QC the solution. If the QC of the solution still passes the lab will extend the expiration date by another month. The method also indicates that a mid level multi-component standard is analyzed with the initial calibration for multi component compounds such as Toxaphene and Chlordane. The current lab procedure is to run the lowest possible level of the multi-component standard and include it with the Initial Calibration so the analyst can determine the lowest level at which the multi-component targets can be detected. If the multi-component analyte is then detected in a sample extract the analyst will then analyze a mid level standard for a single-point quantitation.

3. Reporting Limits

Table 1 lists the routine reporting limits.

4. Interferences

4.1 Contaminants in solvents, reagents, glassware, syringes, and other sample processing hardware may cause inferences that lead to discrete artifacts, biases, and/or elevated baselines. Demonstrate that all of these materials are free from interferences under the conditions of the preparation and analysis by extracting and analyzing a laboratory method blank with each batch of up to 20 samples. Also new solvent lots are to be prescreened and approved by GC/ECD analyst prior to use. All glassware and equipment should be

properly cleaned and solvent rinsed prior to use. Never use any glassware, or other implements such as syringes, on multiple samples within the batch unless there has been thorough cleaning and decontamination between samples.

4.2 Contaminants co-extracted from the sample may cause matrix interferences. The extent of matrix interferences will vary considerably from sample to sample, depending upon the nature of the environment and matrix being investigated. In some cases depending on the severity of the observed interferences, a target hit on one column may be biased high when interfered with. Skilled analyst judgment is imperative in determining if a chromatographic peak appears interfered with. In these cases the non-interfered, non-biased hit can be forced for reporting purposes providing a more suitable value. In extreme cases of interference additional cleanups can be employed, or it may be necessary to analytically re-run the sample at a dilution.

4.3 The ECD is theoretically a halogen specific detector. However, phthalate esters can be a major source of contamination in that they do respond to the ECD and can interfere with accurate determination of the compounds of interest. No forms of plastic or any material containing plasticizers (phthalates) should be used in conjunction with any part of this analysis.

4.4 Elemental sulfur is readily extracted from soil and sediment samples and may cause chromatographic interferences in the determination of pesticides. Sulfur can be removed through the use of Method 3660B.

4.5 Care must be taken to ensure a complete hexane exchange is performed on the extract, because residual methylene chloride would be an interferent in the analysis. Residual methylene chloride can also damage the electron capture detectors.

4.6 The injector system of the gas chromatograph can become contaminated with non-volatile components from samples. This can act to decrease the resolution and responsiveness of the system. The analysis of a DDT/Endrin breakdown standard is the best indicator of the condition of the injector system and the condition of the column. As the percent breakdown increases gradually the system should undergo general maintenance (liner changes, injection port cleaning, etc.) to avoid prolonged down time.

4.7 Aldol condensation products (4-methyl-4-hydroxy-2-pentanone and 4-methyl-3-pentene-2-one) can arise during soil extraction when using methylene chloride: acetone. These products may interfere with detection of analytes and should be monitored.

4.8 Raw GC/ECD data from all blanks, samples, and spikes must be evaluated for interferences or carryover. Contamination by carryover can occur whenever high-concentration and low-concentration samples are sequentially analyzed.

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material safety data sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

Aqueous samples should be collected in 500mL, 1L or 2L amber glass bottles and stored without preservative at 4°C. The minimum amount of sample needed to reach the reporting limits on Table 1 in Section 16 for this method for aqueous samples is 500mL. Additional sample is needed (approximately 3X the minimum amount) if MS/MSD analyses are to be performed.

Soil/sediment and Tissue samples should be collected in glass soil jars and stored at 4°C, or if desired, frozen. The minimum amount of sample needed to reach the reporting limits on Table 1 in Section 16 for solid and tissue matrices is 50g. Additional sample is needed (approximately 3X the minimum amount) if MS/MSD analyses are to be performed.

6.2 Sample Preservation

Aqueous samples should be stored without preservative at 4°C.

Soil/sediment and Tissue samples should be stored at 4°C, or if desired, frozen.

6.3 Sample Shipping

Sample Receipt & Login SOP 1559 describes how samples are normally shipped or obtained by the laboratory, precautions to be used in opening sample shipments, and sample storage conditions.

6.4 Sample Handling

The hold time for this method is 7 days for the extraction of aqueous samples and 14 days for the extraction of solid and tissue samples. If a sediment or tissue samples are frozen, this suspends the holding time until removal from the freezer. All extracts must be analyzed within 40 days of the extraction date. Extracts are stored in a refrigerator at 2-6ºC.

7. Equipment and Supplies

7.1 Gas Chromatograph: The instrumentation is a temperature-programmable gas chromatograph with heating range from 40ºC to 325ºC and splitless-type inlet system with electron capture detectors (Hewlett-Packard HP 5890 Series II GC, HP 6890 Plus, or similar).

7.2 Injection Port: Designed for splitless injection onto a capillary column. The injection port utilizes a uniliner for direct injection, to decrease the potential for breakdown of compounds in the injection port and to increase sensitivity. These uniliners are used in place of the standard splitless liners. The 6890 model requires a drilled uniliner due to Electronic Pressure Control (EPC). The injection port will require maintenance on an as needed basis if degradation or contamination is apparent. Please refer to the front of the *Instrument Maintenance Logbook, which* outlines the routine maintenance procedures

7.3 Columns and supplies

7.3.1 Restek's proprietary "RTX-5" Stationary Phase, 60m length x 0.25mm ID, 0.25□m film thickness - Restek Corporation, PN 10226, or equivalent.

7.3.2 Restek's proprietary "RTX-CLPesticide II" Stationary Phase, 60m length x 0.25mm ID, 0.2□m film thickness - Restek Corporation, PN 11326, or equivalent.

7.3.3 Guard column, deactivated fuse silica phenyl-methyl, 5 m x 0.32 mm ID. Restek PN 10027 or equivalent.

7.3.4 flow from the guard column can be split between the two analytical columns using a Siltek MXT-Y connecter Restek PN 20396

7.4 Guard Column: The GC/ECD utilizes one injector with guard column sealed to the uniliner inside the injection port. The guard column is split by connector into the two dissimilar columns listed above. Each column is then attached to a separate detector. The Rtx-5 is always the front detector column and the CLP II is the back detector column.

7.5 Auto sampler: Adapted onto the Gas Chromatograph. Model is HP 6890 series autosampler with a GC autosampler controller and HP 5890 series autosampler with controller, or equivalent.

7.6 Computer: with Windows XP operating software utilizing HP Enviroquant G1701DA Version D.03.00 software, or equivalent.

7.7 Gases: Hydrogen, ultra high purity grade (99.9999% pure) and Nitrogen of equivalent purity. Hydrogen is generally supplied by a Proton Hogen GC 600 Hydrogen generator.

7.8 Syringes: Hamilton Gas tight, various sizes.

7.9 Glass Pasteur Pipettes

7.10 Volumetric Flasks: Class A, various sizes

7.11 Vials: 2ml, 4ml, 10ml

8. Reagents and Standards

Reagent grade or pesticide grade chemicals are used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. See SOP *Reagent, Solvent, and Standard Control* (1816) for additional details regarding solvent purity. All solvent expirations determined as indicated by manufacturer guidelines

Analytical Standards are stored at 2-6ºC, according to manufacturer's recommended procedure. Primary standards are discarded as indicated by the vendor expiration. Stock standards are given 1 year expiration from the preparation date or the expiration of the primary vendor solution, whichever occurs first. Working standards are given a six month expiration from the preparation date or the expiration of the primary solution whichever occurs first. If breakdown of a solution is observed the solution will be discarded. All analytical standards are prepared in Hexane. All prep standards are prepared in Acetone or Hexane.

8.1 Methylene Chloride: ACS approved, Pesticide grade.

8.2 Acetone: ACS approved, Pesticide grade.

8.3 Hexane: ACS approved, Pesticide grade.

8.4 Methanol: Purge and Trap grade.

8.5 Surrogate Spiking Solution: Two surrogates are used for this method, 2,4,5,6-tetrachloro-m-xylene (TMX) and Decachlorobiphenyl (DCB). Alternate surrogates may be employed to avoid co-elutions or when DCB is a target analyte. Example alternate

surrogates would be DBOB (4,4'-Dibromooctafluorobiphenyl) BZ-198 (2,2',3,3',4,5,5',6 Octachlorobiphenyl). Surrogate Spiking solutions are stored in 40ml pre-cleaned amber VOA vials and placed in a standards freezer in the preparatory lab. The Pest/PCB Surrogate is made from the *Pesticides Surrogate Standard Spiking Solution* (catalog # ISM-320) commercially obtained from Ultra at a concentration of 200ug/mL. The spiking solution is the "Pest/PCB Surrogate" spike, which is made by diluting the primary standard appropriately to achieve a concentration of 1000ug/L. All solutions are made volumetrically in Acetone at desired final volume. Generally 200ml of standard is made but this can vary depending on use, need, and preference. The solution must be assayed by analysis before release to the preparation lab. Generally 1ml of surrogate spiking solution is spiked into the samples and QC. Alternative solution concentration and spiking amount can be used.

8.6 LCS and Matrix spiking solution: Two Pest LCS Spiking solutions are generally used in this method. Alternatively, solutions with project specific targets may be used. The LCS spiking solutions are stored in the same manner as surrogate solutions. The Pest LCS solutions are made from a combination of Restek Pest Mix 8081AB#1 cat#32291 at concentration 200ug/ml and Hexachlorobenzene and Additional Pesticide Mix (Quote#041310-632 from Ultra at a concentration of 100ug/ml. The spiking solution is labeled "Pest LCS" spike and is prepared by diluting the appropriate aliquot of each of the two primary solutions to obtain a spike solution concentration of 1000ug/L. All solutions are made volumetrically in Acetone at desired final volume. Generally 100ml of spiking solution standard is made but this amount can vary depending on use, need and preference. Generally 1 mL of LCS spiking solution is added into each laboratory control spike, matrix spike, and spike duplicate QC samples. Alternative solution concentration and spiking amount can be used.

8.7 Internal Standards (IS): PCB congener BZ 192 (2,2',3,4,4',5,6,6'-octachlorobiphenyl This solution is commercially obtained from Ultra at 100ug/mL. The IS solution is prepped by making a volumetric dilution of the primary standard in hexane to achieve a concentration of 2.5ug/ml. For method quantification by internal standard 20ul of internal standard is added into 1ml extracts, to produce a mid-calibration range response on column at 50ng/mL in final sample extract.

8.8 Breakdown Mix: This solution is commercially obtained from Ultra (PN ISM-450) containing Endrin at 1 μg/mL and 4,4'-DDT at 2ug/ml. The primary solution is volumetrically diluted to achieve a working standard concentration of 100ug/L for Endrin and 200 ug/L for 4,4'-DDT.

8.9 Toxaphene Calibration solution: Toxaphene solution is commercially obtained from Ultra (PP-270) at a concentration of 100ug/ml. The stock solution at the concentration of 10,000ug/L is prepared as an intermediate solution. The stock solution is diluted volumetrically to obtain a mixture at the concentration of 25ug/L. The 25ug/L solution is injected as a low standard and run with the calibration curve. If Toxaphene is detected an additional mid level Toxaphene standard is used for the one point quantitation of this compound. The stock solution is appropriately diluted volumetrically to obtain a concentration of 1000 ug/L for the Toxaphene and includes TMX/DCB at 100ug/L.

Toxaphene ICV solution is commercially obtained from NST (111-M) at a concentration of 2000ug/ml. The stock solution at the concentration of 20,000ug/L is prepared as an intermediate solution. The stock solution is appropriately diluted volumetrically to obtain a concentration of 1000 ug/L for the Toxaphene ICV working standard.

8.10 Chlordane Calibration solution: Chlordane solution is commercially obtained from Ultra (PP-151) at a concentration of 100ug/ml. The stock solution at the concentration of 10,000ug/L is prepared as an intermediate solution. The stock solution is diluted

volumetrically in hexane to obtain a mixture at the concentration of 25ug/L. The 25ug/L solution is injected as a low standard and run with the calibration curve. If Chlordane is detected and additional mid level Chlordane standard is utilized for the one point quantitation of this compound. The stock solution is appropriately diluted volumetrically to obtain a concentration of 500ug/L for Chlordane and includes TMX/DCB at 100ug/L

Chlordane ICV solution is commercially obtained from Restek (32021) at a concentration of 1000ug/ml. The stock solution at the concentration of 20,000ug/L is prepared as an intermediate solution. The solution is appropriately diluted volumetrically to obtain a concentration of 500 ug/L for the Toxaphene ICV working standard.

8.11 Independent Calibration Verification (ICV) standard: This is a secondary source standard separate from the calibration curve standards containing target pesticides compounds. The ICV can be made two ways as a combination of "Custom Standard – Pesticide Mix" (Quote#041310-631) and "Custom Standard – Additional Pesticide Mix" (Quote#041310-632) both commercially obtained from Ultra at a concentration of 100ug/ml. Alternatively, use Restek Pest Mix 8081AB#1 cat#32291 at concentration 200ug/ml and Hexachlorobenzene and Additional Pesticide Mix (Quote#041310-632) from Ultra at a concentration of 100ug/ml. Cis-Nonachlor obtained from Ultra at (PP-490) concentration 100ug/ml and Chlorpyriphos obtained from Restek (32212) at concentration 1000ug/ml are added to both mixtures to obtain all targets compounds. The ICV is prepared by diluting the appropriate aliquot of each of the two primary solutions to obtain a spike solution at the concentration of 50ug/L. This standard must be spiked with 20uL of the internal standard as referenced in section 8.7.

8.12 SRM: *1944 – New York/New Jersey Waterway Sediment, and SRM 2974a – Organics in Freeze Dried Mussel Tissue*, from National Institute of Standards & Technology (NIST). Please refer to the individual certifications for the assigned true values. These SRMs may be extracted and analyzed with sample batches as part of the overall QC evaluation, if requested by the client. Other certified SRMs may be used on a project specific basis.

8.13 Pesticide Calibration Standard: Commercially obtained primary solutions are used to volumetrically create stock solutions. All stock solutions are made by adding the appropriate amount of primary standard to a 25 mL volumetric flask to obtain the concentration of 5000 ug/L. The stock solutions are then used in various combinations and serial dilutions to make calibration curve standards (see Table 3).

Calibration standards are always prepared in hexane. The basic calibration curve is made from MCP Pest Stock, Additional Pest Stock, Chloropyrifos/Cis-nonachlor Stock and DBOB/BZ198 Surrogate Stock. MCP Pest Stock is derived from primary *Custom Pesticide Standard (PN # S-9553-SS)* commercially obtained from Accustandard, Additional Pest Stock is made from primary *Custom Pesticide Standard (PN#S-14378-R1)* commercially obtained from Accustandard, and DBOB/BZ198 Surrogate Stock is prepared from primary surrogate solutions commercially obtained from Ultra: *DBOB* – at a concentration of 5000 ug/mL *(catalog # PPS-172) and BZ#198* – at a concentration of 100 ug/mL *(catalog # RPC-075S).* Chloropyrifos/Cis-nonachlor Stock is prepared from primary solutions commercially obtained from Accustandard at a concentration of 100 ug/mL: Chloropyrifos (Dursban) *(catalog # P-094S) and Cis-nonachlor (catalog # P-297S).*

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

9.1 Blank

9.1.1 Method Blank

9.1.1.1 A method blank must be extracted (spiked with surrogates) and analyzed once per every 20 samples or per extraction batch, whichever is more frequent.

9.1.1.2 Because the analysis of a method blank is used to determine background contamination, an *acceptable* method blank should not contain any individual compound at the concentration of reporting limit, or above. For contaminated blanks all efforts must be made to identify and eliminate the source of contamination. The presence of analytes at concentrations at or above the reporting limit will warrant application of a “B” qualifier to that target compound(s) on all associated report forms, and perhaps re-extraction of all associated samples. The results are qualified with a “B” for any associated sample concentrations that are less then 10x the blank concentration for the analyte. Surrogate and internal standard recoveries must meet the QC limits for the method blank, see Sections 9.7.1 and 9.7.2. Re-extraction must be initiated immediately so that minimum time is wasted before re-extraction can occur - if at all possible, this re-extraction should take place within holding time. Re-extraction *corrective action* that would exceed the sample holding time criteria should be discussed with the client, Laboratory Director, QA Manager, and/or Section Supervisor prior to implementation. Exceptions may be made with approval of the Section Supervisor if the samples associated with an out of control method blank are non-detect for the affected compound(s) or if the concentration of the affected compound(s)in the sample is greater than 10x the blank level. In such cases, the sample results are accepted without corrective action for the high method blank result. The client must be notified, via the project narrative, of any method blank non-compliance associated with the sample results.

9.2 Laboratory Control Sample (LCS)

9.2.1 The laboratory control sample (LCS/LCSD) generally contains all Pesticides listed in Table 1, Section 16 except for Toxaphene & Chlordane. The number of Pesticide compounds in the LCS may vary with client specific requests. The Pesticide list reported to the client on the recovery form depends on the target list requested by the client and may also vary between different projects. The LCS/LCSD is extracted along with the samples and must be extracted and analyzed once per every 20 samples or per extraction batch, whichever is more frequent.

9.2.2 The acceptable recovery QC limits as well as RPD limits are found in Table 2 Section 16 for an aqueous, solid, and tissue LCS/LCSD. All recovery limits should

be monitored and documented in-house through control charts and updated as needed.

9.2.3 Corrective Action: Repeat analysis or check to see if an analytical or spiking error has occurred. If the LCS/LCSD recoveries are still out of control, re-extract and re-analyze the LCS/LCSD and all associated samples. Samples cannot be approved until an acceptable LCS is obtained. Exceptions may be made with approval of the Section Supervisor if the samples associated with the out of control LCS are also associated with a matrix spike and matrix spike duplicate that is in control which demonstrates an isolated problem pertaining to the LCS only. An explanation of this out of control LCS/LCSD recovery must be included in the project narrative to the client and the sample data reported with the acceptable MS/MSD results as batch QC. For specific work plans the project requirements may supersede existing acceptance criteria. E.g., if the LCS/LCSD do not meet quality control criteria for recovery of some of the spike and surrogate compounds, the results for the other samples and quality control samples within the batch must be evaluated to determine if this is an isolated problem for the LCS/LCSD and whether the data should be reported with the affected LCS/LCSD.

9.3 Initial Calibration Verification (ICV)

Refer to Section 10.2.4

9.4 Continuing Calibration Verification (CCV)

Refer to Section 10.4

9.5 Matrix Spike

9.5.1 Matrix spike and matrix spike duplicate analyses are performed on a project specific basis. If a project calls for a MS/MSD one is performed per 20 samples and per matrix.

9.5.2 The acceptable recovery and RPD QC limits are found in Table 2 for an aqueous, solid, tissue, and product MS/MSDs. All recovery limits should be monitored and documented in-house through control charts and updated as needed.

9.5.3 Corrective Action: Repeat analysis or check to see if an analytical error has occurred. If the % recovery or %RPD still exceeds the control limits and the associated LCS is within control, include a project narrative with the results to client noting that there may be potential matrix effects on the accuracy or precision of the affected results as evidenced by the matrix spike and matrix spike duplicate exceedance.

9.6 Laboratory Duplicate

9.6.1 Laboratory matrix or sample duplicates are analyzed if requested by the client. The QC limit is 50% RPD for target compounds.

9.6.2 Corrective Action: If the %RPD exceeds the 50% control limit and the associated LCS/LCSD %RPD is within 50%, include a project narrative with the results to client noting that there may be potential matrix effects on the precision of the results isolated to this sample, as evidenced by the matrix duplicate exceedance and the LCS/LCSD acceptance. If an MS/MSD was also extracted with the batch and the sample/duplicate as well as the MS/MSD exceed the control limits, include a project narrative with the results to client noting that there may be potential matrix effects on the precision of the results as evidenced by the sample/duplicate and the MS/MSD exceedences.

9.7 Method-specific Quality Control Samples

9.7.1 Surrogate

9.7.1.1 Surrogates are monitored for recovery for all matrices. Two surrogates are used, one that elutes at the beginning and one at the end of GC run. Every sample, blank, and quality control sample (LCS, LCSD, MS, MSD, Dup) must be spiked with the surrogates prior to extraction. The recovery limits are found in Table 2. The recovery limits should be monitored and documented in-house through control charts and updated as necessary.

9.7.1.2 Corrective Action: Check to see if an analytical, spiking, or dilution error occurred and re-calculate. If only one surrogate falls below the recovery limit and all QC samples have acceptable recovery indicating a matrix effect isolated to the sample, the exceedance is noted, with approval of the Section Supervisor, and the results are reported to the client with a notation in the case narrative. If all surrogates are recovered below the limit or there are outliers in any QC, re-extract the sample. If re-extraction occurred beyond the holding time and the re-extract surrogates are within the QC limits, report the re-extract results along with the original results. If the surrogates are recovered below the limit in the re-extract, this confirms suspected matrix interference on the surrogates, and only the original analysis needs to be reported unless a specific QAPP requires otherwise. If the chromatogram shows obvious matrix interference, no re-analysis or re-extraction is necessary. *This decision must be made with approval of the Section Supervisor and/or Data reviewer.* Surrogate outliers and sample re-extracts must be noted in the case narrative to the client.

9.7.2 Internal Standards

9.7.2.1 Internal standards are added to every field sample, QC sample, standard, and method blank. The Daily opening CCV IS areas are compared to the ICAL; for subsequent samples analyzed following CCVs – the IS areas are compared to the nearest opening CCV for each sample. The acceptance limits are -50% to +200% of the internal standard response (or area) of the daily continuing calibration verification standard.

9.7.2.2 Corrective Action: Check to see if an analytical, dilution or spiking error occurred. If the chromatogram shows obvious matrix interference, no re-analysis is necessary. *This decision must be made with approval of the Section Supervisor.* Note the exceedance in the case narrative to the client. If no obvious interference is present, re-analyze the extract. If internal standards are now within the acceptance limits, report only the re-analysis, as long as the re-analysis occurred within the 40-day analytical hold time. If the re-analysis occurred outside of the 40-day analytical hold time, both the original and re-analysis must be reported. If the internal standards again are outside the acceptance limits, after re-analysis, either within or outside of the 40-day hold time, report only the original analysis, and include a narrative to the client that the suspected matrix interference on the internal standards was confirmed by sample re-analysis.

9.7.3 SRMs

9.7.3.1 Standard reference materials (SRMs) are available from the National Institute of Standards and Technology (NIST) and are extracted and analyzed with samples on a project specific basis. These are not used as controls, but to evaluate potential matrix effects in associated samples for the target compounds being evaluated.

9.7.3.2 Acceptance criteria for SRM analysis will vary from project to project depending upon client data quality objectives (DQOs). Generally, 40% - 140% recovery based on the true certified values of the target compounds of interest, serve as advisory acceptance criteria.

9.7.3.3 Corrective Action: Repeat analysis and/or check to see if an analytical error has occurred. If the % recovery still exceeds the control limits and the associated LCS and/or MS/MSD are within control, include a project narrative with the results to client noting that the observed recovered of the SRM are isolated to this sample as evidenced by the LCS and/or MS/MSD acceptance.

9.7.4 Evaluate the percent degradation of 4,4'-DDT (to 4,4'-DDE and 4,4'-DDD) and Endrin (to Endrin Aldehyde and Endrin Ketone) in the Performance evaluation mixture (PEM) to monitor the integrity of the injection system (see section 11.10 for calculation). The breakdown mixture must be analyzed daily to verify that degradation in the system is not excessive. Degradation is not considered to be a problem if the percent degradation of 4,4'-DDT and Endrin are ≤15%. If either compound does exceed 15% breakdown, the analysis must be stopped, the injection port serviced and other maintenance may need to be performed.

9.8 Method Sequence

PEM3060501	(PEM)
C3060501	(CCV at 50ug/L)
Prep Blank ID	Method Blank
LCD ID	LCS
LCSD ID	LCSD
Sample ID	about 10 samples
PEM3060502	(PEM)
C3060502	(CCV at 50ug/L)
Sample ID	about 10 samples
PEM3060503	(PEM)
C3060503	(CCV at 50ug/L)
Sample ID	about 10 samples
C3060504	(Closing CCV at 50ug/L)

10. Procedure

10.1 Equipment Set-up

10.1.1 Prior to the analysis of any standards or samples, the instrument acquisition and process methods must be set up. This includes the GC run parameters and retention time windows. An initial calibration must be analyzed to establish linearity of the instrument. The target analytes are resolved on each column and detected using an electron capture detector (ECD). Calibration standards, quality control samples, and sample extracts are injected into the GC which is temperature and flow programmed to separate the compounds of interest. Identification of target analytes is accomplished by confirming a target hit on two dissimilar columns using Retention time and pattern recognition. Concentrations are calculated from the ECD response using internal standard techniques. Concentrations are determined using Average Response Factor from a multi-level calibration curve. The calibration curves are generated during initial

calibration through the analysis of standards which define the working range of the method. The integrity of the chromatography system must be maintained throughout a run sequence. The chromatographer should ensure that all aspects of the system, from injection through data generation is done in a consistent manner across each batch.

10.1.2 PEM Evaluation

10.1.2.1 Prior to initial calibration and at the start of each run a PEM must be analyzed and evaluated as mentioned above in the quality control section 9.7.4.

10.1.3 GC/ECD Instrumental Conditions

10.1.3.1 Generally a 1 to 3uL aliquot is injected into a uniliner and onto the capillary column of the gas chromatograph at the conditions listed below. Once injected the aliquot moves through the Siltek guard column and into a MXT-Y connector allowing one injection to split onto the two dissimilar columns connected to two separate ECD detectors

GC Parameter	Setting	GC Parameter	Setting
Injector Temp:	250°C	Ramp Rate 3:	5 °C / minute
Initial Oven Temp	125°C	Final Temperature 3:	260 °C
Flow:	33.6 mL/min	Final Hold Time 3:	0 minutes
Initial Hold Time:	0 minutes	Ramp Rate 4:	25 °C / minute
Ramp Rate 1:	25 °C / minute	Final Temperature 4:	280 °C
Final Temperature 1:	197 °C	Final Hold Time 4:	9 minutes
Final Hold Time 1:	2 minutes	Total runtime:	37.68 minutes
Ramp Rate 2:	1 °C / minute	Mode:	Splitless / Ramped Flow
Final Temperature 2:	210 °C	Purge:	25mL / minute – on at 1 minute
Final Hold Time 2:	0 minutes	Detector temp:	300 °C

The settings listed may vary if situation arises requiring an adjustment to the chromatography. *Injection temperature, hold time, flow rate, purge time, and injection volume can affect chromatographic resolution and detection limits.* Only a trained and experienced GC analyst has the authority to change any setting. All standards and samples must be acquired using the same set of parameters. If any parameters are changed, a new initial calibration must be analyzed and accepted before any samples can be analyzed.

10.2 Initial Calibration

10.2.1 Before analysis of sample extracts, establish a multi-point response factor calibration curve showing the linear range of the analysis for all target analytes. At least 5 levels of standards must be analyzed generally the concentrations run are 0.5, 1, 10, 20, 50, 100 and 200. See Section 8.11 for the preparation of the standard solutions for the initial calibration curve.

10.2.2 Construct an analytical sequence using the HP Enviroquant software. ICAL standards are identified in a sequence with an “I” designation followed by the instrument number, the

date, and the sequential number assignment. In the comment section beside each level of the curve add the assigned calibration standard ID. In sequence editor construct a sequence similar to the example listed below:

An example initial calibration sequence, created on 06/05, follows:

Primer1	
PEM3060501	(PEM)
Hexane	
I3060501STD.5	(0.5ng/mL standard)
I3060502STD1	(1ng/mL standard)
I3060504STD10	(10ng/mL standard)
I3060505STD20	(20ng/mL standard)
I3060506STD50	(50ng/mL standard)
I3060507STD100	(100ng/mL standard)
I3060509STD200	(200ng/mL standard)
Hexane	
CQ3060510STD50	ICV@50ng/mL Initial Calibration Verification
Hexane	
I3060511STD25	(Toxaphene @ 25 ng/mL)
I3060512STD25	(Chlordane @ 25 ng/mL)

10.2.3 When the sequence has finished running, the Enviroquant software will generate "Not Reviewed" quantitation reports. All reports must be "Quant Reviewed" before they can become part of the initial calibration acquisition method for sample analysis.

- Enter into the "Environmental Data Analysis"
- Go to "File" and under method, select the appropriate quant method and then select the first data file.
- Go into "Quant" and select "QEdit Quant Results" to process the data files. See Section 11.0 for manual integration details and processing guidelines.
- When processing, peak identification, and retention update is complete for the first standard, "Save" the changes and "Exit." Re-print the re-processed data file by "Generating Quant Report," and save the hard copy for each level of the initial calibration.
- Repeat these steps for all initial calibration standards analyzed within the sequence.
- When all levels have been processed, go into "InitCal," and select "Update Levels," and enter all levels for the initial calibration at the proper concentrations.
- After all responses are entered, "Save" the completed method and print the resulting response factor summary by selecting "Response Factors to Printer" as well as "Response Factors to Forms File".

10.2.3.1 Acceptance Criteria: 20% RSD for all target compounds. All calibration standards must be analyzed within 12 hours.

10.2.3.2 The following *corrective actions* are recommended for failing initial calibrations:

- If a curve has outliers and greater than five calibration solutions were utilized in the initial calibration, standards can be excluded from either extreme to generate a passing calibration. That is, the low-level standard or the high-level standard may be dropped to generate a five-level initial calibration. However the analyst needs to be aware that dropping the low standard can affect the RLs for the project being analyzed. An intermediate-level calibration standard must not be dropped to convert a failing initial calibration curve into a passing five-level initial calibration curve. Reduction in the number of calibration standards must also reduce the linear dynamic range used to quantify analytes in the samples. The resulting average response factor for each target analyte in the initial calibration curve will be used by the computer software to calculate actual sample concentrations. See Section 11.0 for additional calculation details.
- Perform instrument maintenance and repeat the initial calibration

The choice of corrective action must be made in consultation with the Section Supervisor, QA Manager, Project Manager, and/or the client.

10.2.3.3 Alternately, a linear regression model may be employed, provided that the correlation factor (r) is $\geq$0.99. Otherwise, construct a non-linear calibration of no more than a third order equation. Statistical considerations in developing a non-linear calibration model require more data than the more traditional linear approach. A quadratic (second order) model requires six standards, and a third order polynomial requires seven standards. In setting model parameters, do not force the line through the origin. The COD (coefficient of determination) or r^2 must be greater than or equal to 0.99. The experienced analyst must select the regression order, which introduces the least calibration error into the quantitation.

10.2.3.4 Complete the initial calibration by filling out the *Initial Calibration Checklist*. The initial calibration, along with any corresponding continuing calibration data and sample data, is then forwarded for secondary review.

10.2.4 Initial Calibration Verification - ICV (separate source)

10.2.4.1 The analysis of separate source standard must follow the initial calibration curve. All target analytes in this verification standard are at the mid-point concentration. Note: This standard must be re-"Calculated and Generated" in the "QEdit" field, against the completed initial calibration curve method and processed, before it can be reviewed for acceptability.

After final processing, calculate the percent recovery of each target by using the following calculation:

% Recovery = (Found Amount / True Value) x 100

Acceptance Criteria: All recoveries must be +/- 20% of the true values.

10.3 Equipment Operation and Sample Processing

10.3.1 Evaluate the PEM as described in Sections 9.7.4

10.3.2 After successful analysis of the PEM, "Edit" the "Sample Table Log" to include the 50 ug/L CCV standard (C3060501, where "C" is for CCV, "3" is for instrument number 3,

followed by the date, and "01" for the first CCV analyzed this day), and acquire the CCV against the correct initial calibration method. "Save," then "Load and Run" the sequence.

10.3.3 When the sequence has finished running, the Enviroquant software will generate a "Not Reviewed" quantitation report. All reports must be "Quant Reviewed" against the acquisition method for sample analysis.

10.3.4 Samples are processed from "Not Reviewed" data files, to "Quant Reviewed" data files in a similar way the standards were previously processed. See Section 11.0 for details on sample processing. If a CCV fails the criteria outlined in Section 10.4.2, all samples since the last acceptable CCV must be re-analyzed.

10.3.5 If the on-column concentration of any compound exceeds the calibration range of 200 ug/L, the sample must be diluted, re-spiked with the appropriate amount of internal standard and re-analyzed. Assuming all samples are at a 1mL final volume, the following example dilutions would apply. Adjust the volumes accordingly for other sample final volume amounts and other desired dilutions.

1:2 dilution = 500uL of sample: 500uL Hexane and 10uL of IS
1:4 dilution = 250uL of sample: 750uL Hexane and 15uL of IS
1:5 dilution = 200uL of sample: 800uL Hexane and 16uL of IS
1:10 dilution = 100uL of sample: 900uL Hexane and 18uL of IS, etc

10.4 Continuing Calibration

10.4.1 A continuing calibration verification (CCV) standard, at the concentration of the mid-level of the initial calibration curve, must be analyzed at the beginning of every analytical sequence, and every 12 hours within the sequence, to confirm instrument stability, via response factor, for each calibrated pesticide.

10.4.2 Acceptance Criteria: Compare the CCV resulting concentration against the concentration of the compound in the injected solution for each calibrated pesticide, and calculate the % difference (%D). See Section 11.0 for the calculations. The %D for each calibrated pesticide must be below 20%D. Due to the nature of the dual column method, this criterion is applied to each set of column results. If multiple CCVs are analyzed within an analytical sequence, each CCV must be analyzed within 12 hours of the previous CCV and must meet the acceptance criteria. Note: closing CCV is not required as long as all samples are analyzed within 12h and the IS meets the acceptance criteria in section 9.7.2.1.

10.4.3 If the CCV does not meet the criteria for each calibrated analyte, the following *corrective actions* are recommended:

- Perform instrument maintenance and repeat the CCV. If the CCV fails again the initial calibration may need to be repeated
- If CCV is biased high and samples are non-detect the data may be usable
- If there is a CCV outlier for a target compound on one column, the analyst can make a judgment to force hits for that target in associated samples from the opposing acceptable column.
- If within 12 hours and no maintenance or adjustments have been made to the instrument the closing CCV can be re-injected once in case of mis-inject etc.

The choice of corrective action must be made in consultation with the Section Supervisor, QA Manager, Project Manager, and/or the client. The reasoning for choosing the second **option must be documented in the project narrative to the client.**

10.5 Preventive Maintenance

10.5.1 Preventive maintenance may or may not include the following: replacing system uniliner, o-ring, merlin septum, MXTY connector or clipping a length of guard column.

10.5.2 Additionally, preventive or routine maintenance for GC/ECD systems may involve baking out the ECD detector's, replacing guard, RTX-5 or CLPII columns.

11. Data Evaluation, Calculations and Reporting

11.1 Analyze extracts using the same conditions used for the analysis of the calibration standards. After sample analysis, “Not Reviewed” quantitation reports are generated by the software system. It is expected that situations will arise when the automated quantitation procedures of the chromatographic software provide inappropriate quantitations or integrations. Those situations will warrant the analyst perform manual integrations. Due to the especially low levels of the calibration curve, limitations of the software, and nature of the ECD, low level standards may require considerable manual integration. Because of this, a detailed report of both the low level standard and mid level standard will be submitted to QC for integration review and comparison.

11.2 Identification of the Pesticide compounds are based on gas chromatographic relative retention times (RRTs) and pattern recognition from the analysis of initial calibration standards. For these compounds, manual quantitations are performed, if necessary, by integrating the area of the peak. Qualitative identification for pesticides is made when a discrete peak in a sample is observed within the retention time window for a calibrated analyte on both columns. A pesticide hit can only be acceptable if confirmed by identification on the second column. If a Pesticide hit is not accurate on one of the two columns, i.e. outside of the retention window or absent, then the hit should not be quantitated. If manual integration of a candidate peak is necessary a straight-line integration to the baseline, taking into account background noise should be made. Area measurements should all be to baseline unless an unresolved complex mixture (UCM) is observed, in which case, the areas measured should skim the top of the UCM. Manual integrations may also be necessary when there are interferences or co-eluting peaks. Please refer to the manual integration SOP for further information.

Note: Manual integration is not to be used solely to meet QC criteria, nor is it to be used as a substitute for corrective action on the chromatographic system.

11.3 Due to the nature of this method requiring confirmation on two dissimilar columns, two quantitations are acquired. Calculate the relative percent difference (RPD) between compound concentrations between both columns. If the calculated RPD is >40%, check the chromatograms to see if an overlapping peak is causing an erroneously high result. If no overlapping peaks are noted, examine baseline parameters established by the data system (or operator) during peak integration.

- If no anomalies are noted, review the chromatographic conditions. If there is no evidence of chromatographic problems, report the higher result. This approach is conservative relative to the protection of the environment. The disparity between the two columns should be flagged with a “P” on the report.
- If the high RPD is clearly the result of an interference on one of the columns, the lower result is reported with an “IP” qualifier on the report.

11.4 Evaluate all samples according to the following criteria:

- Surrogates and internal standards should meet the acceptance criteria in Table 2.
- Examine the chromatograms for evidence of saturated targets. Re-analyze the sample(s) at the appropriate dilution(s), see Section 10.3.5, as needed for reference.
- Establish daily retention time windows as the retention time of the component in the opening verification standard ± 0.05. It has been found that this window works well, being wide enough to eliminate false-negatives while being tight enough to eliminate false-positives. Windows that are calculated using the procedure recommended in Method 8000 tend to be very narrow, creating the risk of false negative results. The window listed above is used as guidance; however the experience of the analyst weighs heavily in the interpretation of the chromatograms.
- If one of the two results for a target appears to have a biased response due to interference the analyst can force the quantitation from the column providing the more accurate value. Any target hit forced off of the compliant column due to interference on the alternate column will be flagged with an "I" on the report only if the RPD between the two columns is greater than 40%.
- In the instance that a Pesticide co-elutes with another Pesticide or other target compound on one column, the compound will be "C" flagged and reported off the unbiased conformant column (i.e.: on the RTX-5 column Heptachlor Epoxide/oxychlordane co-elute). Studies of independent targets have been conducted for reference of co-eluting pesticides and congeners.

11.5 In instances where manual integrations have been performed, the analyst must identify/acknowledge such edits or manual procedures by initialing and dating the raw quantitation report. The initialed hard copy/printed report, will display a "m" qualifier next to any modified or manually integrated compound(s) and shall be included in the raw data for secondary review. These requirements apply to all QC samples, field samples and blanks. For all samples the signed hard copy will be a detailed report submitted for secondary review. As mentioned above there are guidelines for appropriate manual integrations and analyst initials indicate that they accept the "m" flagged changes as appropriate.

11.6 Qualitative identification of multicomponent pesticides requires pattern matching between the calibration standards and the response observed in the sample on both columns. Retention time windows should be used as a gauge, however, pattern recognition for the multicomponent analytes is most important for samples with Toxaphene or chlordane positively identified on both columns, inject an analytical standard at the mid-level or at a concentration estimated to be similar to the sample amount, and re-inject the sample. Quantitation is generally performed using 3 to 5 major representative peaks.

11.6.1 Multi-component analytes are quantitated on the basis of 3 to 5 major peaks using an internal standard approach to calculate individual response factors for each peak. Separate calibration standards are necessary for each multi-component target analyte (e.g., toxaphene and chlordane). Analysts should evaluate the specific toxaphene standard carefully. Some toxaphene components, particularly the more heavily chlorinated components, are subject to dechlorination reactions. As a result, standards from different vendors may exhibit marked differences which could lead to possible false negative results or to large differences in quantitative results. The relative peaks and number of peaks in the sample should be similar to that observed in the standard; however,

degradation, weathering and interferences may cause the sample pattern to differ from that observed from the standard.

11.7 To calculate the ***Relative Standard Deviation*** (RSD) of all Pesticide targets and surrogate compounds for the initial calibration, use the formula below. See Section 10.2.3 for initial calibration acceptance criteria. Additionally, use the initial multi-point calibration to determine ***Relative Response Factors*** (RRF_Is) at each concentration level, for each Pesticide. Average the RRF_Is from the initial multi-point calibration, to generate mean RRF_Is, for quantification of each Pesticide. Follow the same calculations for each surrogate compound. The RRF_Is are based on the internal standard compounds, and are calculated using the formula below. See Table I, for the listing of target compounds, RLs, and their associated internal standards for quantification.

$$\mathbf{RSD = SD / mean\ RRF_I \times 100}$$

where:

SD = Standard deviation between the five points, for that target analyte.

$$\mathbf{RRF_I = (A_c \times C_{IS}) / (A_{IS} \times C_c)}$$

where:

A_c = Area of the characteristic ion for the standard compound to be measured.
A_{IS} = Area of the characteristic ion for the representative internal standard compound.
C_{IS} = Concentration of the representative internal standard compound (ng/mL).
C_c = Concentration of the standard compound to be measured (ng/mL).

11.8 Based on the mean RRF_Is, calculate the ***Raw Concentration*** (C_a) for each target analyte and surrogate in the sample extracts using the following formula:

$$\mathbf{C_a = (A_a \times C_{IS}) / (A_{IS} \times RRF_I)}$$

where:

C_a = Calculated concentration of the target analyte, from quantitation report (ug/L).
A_a = Area of the target analyte.
A_{IS} = Area of the representative internal standard compound.
C_{IS} =Concentration of the internal standard compound added to each extract (ug/L).

11.9 Calculate the ***Sample Concentration*** (C) for each Pesticide by the following formula:

$$\mathbf{C = (C_a / V_s) \times FV \times DF}$$

where:

C = Concentration in the sample (ug/L liquid or ug/Kg solid).
V_s = Original volume or weight of sample extracted, corrected for % solids, if applicable. (To correct for % solids, multiply the sample weight by the % solid as expressed as a decimal. For example: 15.24g x 0.843 = 12.85, for a sample size of 15.24g at 84.3% solid).
DF = Dilution factor or fraction of the original extract to which internal standard is added.
FV = Sample Final Volume

If the response of any analyte in a sample exceeds the linear response range, as defined by the initial calibration standards in Section 10.2, dilute the extract so that the concentrations of all target compounds fall within the range of the calibration curve.

11.10 The calculation for percentage breakdown for DDT and Endrin are:

$$\%\text{Breakdown DDT} = \frac{(\text{Area DDD} + \text{Area DDE})}{(\text{Area DDD} + \text{Area DDT} + \text{Area DDE})} \times 100$$

$$\%\text{Breakdown Endrin} = \frac{(\text{Area Endrin Ketone} + \text{Area Endrin Aldehyde})}{(\text{Area Endrin} + \text{Area Endrin Ketone} + \text{Area Endrin Aldehyde})} \times 100$$

11.11 Calculate the ***Surrogate Recoveries*** (%R) relative to the internal standards by the following formula:

$$\%R = \frac{C_S \times DF}{C_{Strue}} \times 100$$

where:

C_{Strue} = Actual concentration of the surrogate in the extract (ug/L).
C_S = Calculated concentration of the surrogate, from quantitation report (ug/L).
DF = Dilution factor or fraction of the original extract

11.12 Compare results for each analyte in the ***Continuing Calibration Verification*** (CCV), to the true value by determining the percent difference.

$$\textbf{Percent Difference (\%D)} = ([C_{Ctrue} - C_C] / C_{true}) \times 100$$

where:

C_{Ctrue} = Actual concentration of the compound in the CCV (ug/L).
C_C = Calculated concentration of the compound in the CCV, from quantitation report

11.13 All results must be reported to three significant figures. All solids including soils, sediments, and sludges must be reported on a dry-weight basis. Tissue results may be reported in wet-weight, or "as received," depending upon client request.

11.14 The primary analyst does data entry, or upload of the data, into the LIMS system. The LIMS is "linked" to the instrument, so the analyst must choose the sample(s) to be reported from that instrument's analytical sequence. All associated preparation and instrumental QC samples and dilutions are also chosen. Once the data/samples have been selected and "associated" with the proper QC samples, the batched data set is sent to print.

11.15 The laboratory generates two types of data packages from the LIMS: "Commercial" for routine projects, and "Full Deliverable" or "CLP-like" for fully data validated projects. A Commercial package consists of sample results and the associated method blank and LCS results. A Full Deliverable package includes all sample results, all preparation and instrumental QC results and the associated supporting raw data. Check the "Report Type"

on the project folder to ensure all required deliverables are included. A secondary review is performed on all data.

11.16 Procedures for data and record management must adhere to the Quality Systems Manual, other subordinate documents covering record keeping, and the *Document Control* SOP, 08-01. All records shall be stored in such a manner as to be safe and accessible for at least 10 years.

11.17 Notebooks: Laboratory notebooks are designed to accommodate the specific analysis. Instrument printouts are used to document run sequences, and each sequence printouts are filed in a three-ring notebook. If a sample requires re-analysis or re-extraction for any reason, a notation is made next to the sample entry on the sequence log. Requests for re-extraction are further documented in the "Request for Re-extraction" logbook. Once a sequence binder if full, the sequence run log is permanently bound, given page numbers and filed accordingly. Such files shall be archived so as to remain available for at least 10 years. All laboratory notebooks must follow the specifications in the *Laboratory Notebook Usage* SOP, G-009, and all record keeping and document control practices.

11.18 Electronic records: All data files from computers, attached to instruments, shall be backed up onto the proper directory on the server. The backups shall be stored so as to be accessible for 10 years. Movement of the data files to the server is the responsibility of the primary analyst. Server backup and storage is the responsibility of the IT department.

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

12.1 Section 9, Quality Control defines the corrective actions that must be taken in instances where QC outliers exist. If the corrective actions have been followed and the data is still unacceptable.

12.2 Table 2 outlines sample batch QC acceptance criteria. If non-compliant Pesticide results are to be reported, the Section Supervisor and/or the Laboratory Director, and the QA Manager must approve the reporting of these results. The laboratory Project Manager shall be notified, and may choose to relay the non-compliance to the client, for approval, or other corrective action, such as re-sampling and re-analysis. The analyst or Section Supervisor performing the secondary review initiates the project narrative, and the narrative must clearly document the non-compliance and provide a reason for acceptance of these results.

13. Method Performance

13.1 Method Detection Limit Study (MDL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the MDL, LOD, and/or LOQ as outlined in Alpha SOP 1732. These studies performed by the laboratory are maintained on file for review.

13.2 Demonstration of Capability Studies

Refer to Alpha SOP 1739 for further information regarding IDC/DOC Generation.

13.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

14. Pollution Prevention and Waste Management

Refer to Alpha's Chemical Hygiene Plan and Waste Management and Disposal SOP for further pollution prevention and waste management information.

15. Referenced Documents

Table 1: Reporting Limits

Table 2: QC Acceptance Criteria

Table 3: 5-8 Level Curve Preparation for Individual Components

Table 1: Reporting Limits (RLs) for Pesticides by GC/ECD

Parameter	Solid Samples (ug/Kg)	Aqueous Samples (ug/L)
alpha-BHC	0.0333	0.0005
beta-BHC	0.0333	0.0005
gamma-BHC (Lindane)	0.0333	0.0005
delta-BHC	0.0333	0.0005
Heptachlor	0.0333	0.0005
Aldrin	0.0333	0.001
Hexachlorobenzene	0.0666	0.001
alpha-Chlordane	0.0333	0.0005
gamma-Chlordane	0.0333	0.0005
Heptachlor epoxide	0.0333	0.0005
Oxychlordane	0.0666	0.001
Cis-Nonachlor	0.0333	0.0005
Trans-Nonachlor	0.0333	0.0005
Dieldrin	0.0333	0.0005
Endrin	0.0333	0.0005
Endrin aldehyde	0.1	0.0005
Endrin ketone	0.0333	0.0005
4,4'-DDD	0.0333	0.0005
4,4'-DDE	0.0333	0.0005
4,4'-DDT	0.0333	0.0005
2,4'-DDD	0.0333	0.0005
2,4'-DDE	0.0333	0.0005
2,4'-DDT	0.0333	0.0005
Endosulfan I	0.0333	0.0005
Endosulfan II	0.0333	0.0005
Endosulfan sulfate	0.0333	0.0005
Methoxychlor	0.333	0.005
Mirex	0.0333	0.0005
Toxaphene	1.67	0.025
Chlordane	1.67	0.025

Note: The reporting limits used for "Solid" refer to the matrices of soil, sediment, tissue, and any other possible non-aqueous matrix. The table above represents an example of the range of reporting limits generally used in this analysis. The RLs for this analysis can vary based on sample matrix, amount extracted, final volume and cleanup schemes. Adjustments to these limits can be made to satisfy specific workplan or data quality objective requirements and specialty matrices.

The quantitation Internal Standard for all the targets is BZ 192.

Table 2: QC Acceptance Criteria

QC Parameter	Acceptance Criteria
Initial Calibration Curve	20% RSD for all target analytes, r is ≥0.99, the COD (coefficient of determination) or r^2 ≥0.99
Independent Check Verification	+/- 20% recovery of the true values
Continuing Calibration Verification	Analyzed every 12 hours, 20% D
Method Blank	No analyte at or above the reporting limit, "B" qualify analyte if detected
Laboratory Control Sample	40-140% (Sporadic Marginal Failure Criteria allowed)
Matrix Spike / Matrix Spike Duplicate	Same as for LCS; 50% RPD between the duplicates.
Sample / Sample Duplicate	50% RPD between the duplicates.
Surrogates	30-150%
Internal Standards	50% - 200% of the daily CCV area for the Internal Standards
SRM	40-140%
%RPD between dual column	+/- 40%, "P" qualify analyste

Table 3: 5-8 Level Curve Preparation for Individual Components

Calibration Level	Volume of Pesticide/Surrogate Stocks added*	Aliquot of High Calibration level** added	Volume of Hexane added
Level 1 – 0.5 ug/L	NA	0.025 ml	10 mL final volume
Level 2 – 1.0 ug/L	NA	0.05 ml	10 mL final volume
Level 3 – 5.0 ug/L	NA	0.25 ml	10 mL final volume
Level 4 – 10 ug/L	NA	0.5 ml	10 mL final volume
Level 5 – 20 ug/L	NA	1.0 ml	10 mL final volume
Level 6 – 50 ug/L	0.25 mL	NA	25 mL final volume
Level 7 – 100ug/L	0.2 mL	NA	10 mL final volume
Level 8 – 150ug/L	0.3 mL	NA	10 mL final volume
Level 9 – 200ug/L	0.4 mL	NA	10 mL final volume

Up to 10 levels may be analyzed. Standards chosen should bracket the linear range of the instrument. A minimum of a 5-level curve must be analyzed, but 6-levels, or more, may be analyzed and evaluated depending upon client specific project detection limits. This is an example of possible curve levels, the curve used may vary based on project and instrument performance.
* Each calibration level is a combination of four stock solutions prepared at the concentration of 5000ug/L added at the indicated amount.
**High calibration level is 200ug/L.

Note: 20uL of the 2.5ug/mL chosen Internal Standard mix is added to each calibration level.

Determination of PCB Homologs and 209 Individual Congeners by GC/MS - SIM

NOAA Technical Memorandum NMFS-NWFSC-59, Extraction, Cleanup, and Gas Chromatography/Mass Spectrometry Analysis of Sediment and Tissue for Organic Contaminants, March 2004, U.S. of Department of Commerce, National Oceanic and Atmospheric Administration

1. Scope and Application

Matrices: This method is applicable to the quantification of Polychlorinated Biphenyls (PCBs) as Homologs and/ individual Congeners in water, soil, sediment, tissue (either animal or vegetable) and in ambient air using PUF sampling followed by Gas Chromatography/Mass Spectrometry with Selected Ion Monitoring (GC/MS-SIM).

Definitions: Refer to Alpha Analytical Quality Manual.

This method is applicable to the analysis and quantification of sample extracts for PCBs as single Congeners and Homologs (isomer groups by the level of chlorination) by Gas Chromatography/Mass Spectrometry with Selected Ion Monitoring (GC/MS-SIM). Additionally, this method can provide a "total" PCB result for a given sample extract. Target analytes include selected PCB congeners from BZ1 to BZ209 and the Homolog groups listed below. Individual congeners and homolog groups are determined and measured in the concentration range of 0.5 to 500 parts per trillion (ng/L) for water samples, 0.033 to 200 parts per billion (ug/Kg) for soil/sediment and tissue samples, and 5-5000 ng/puf for PUF cartridges. These ranges are determined based on the lowest and highest levels of the calibration curve, extracted amount and final volume therefore detection limits will vary with the individual sample matrix, sample preparation procedures, instrument calibration range, and volume of sample analyzed. Detection limits for Homolog groups are equal to the lowest detection limit of the individual congeners detected within that group. In general, analytes detected over these concentration ranges will be diluted and re-analyzed for accurate quantitation.

The following extraction and cleanup methods may apply, prior to sample analysis:

- *Extraction of Water Samples by Separatory Funnel-Method 3510C* (SOP 2165),
- *Tissue Preparation and Homogenization* (SOP 2166),
- *Shaker Table Extraction* (SOP 2261),
- *Sulfur Cleanup with Copper-Method 3660B* (SOP 2168),
- *Gel Permeation Chromatography-GPC (SOP 2167)*

- *Sulfuric Acid Cleanup-Method 3665A* (SOP 2169),
- *Silica Gel Cleanup* (SOP 2170),
- *Microscale Solvent Extraction – Method 3570* (SOP 2172)
- *Soxhlet Extraction – Method 3540C (SOP 2173),*
- *Soxhlet Extraction of PUF Cartridges (SOP 2174)*

The existence of 209 possible PCB congeners makes it impractical to list each potential method analyte and Chemical Abstract Service (CAS) number. Because in some cases, depending upon client request, PCBs are identified and measured as isomer groups, the non-specific CAS number for each level of chlorination is used to describe the method analytes. See below for this listing.

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one or more of the following laboratory personnel before performing the modification: Department Supervisor, Laboratory Director, or Quality Assurance Officer.

This method is restricted to use by or under the supervision of analysts experienced in the operation of the GC/MS and in the interpretation of GC/MS data. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

PCB Homolog Group	Formula	CAS #
Monochlorobiphenyl	$C_{12}H_9Cl$	27323-18-8
Dichlorobiphenyl	$C_{12}H_8Cl_2$	25512-42-9
Trichlorobiphenyl	$C_{12}H_7Cl_3$	25323-68-6
Tetrachlorobiphenyl	$C_{12}H_6Cl_4$	26914-33-0
Pentachlorobiphenyl	$C_{12}H_5Cl_5$	25429-29-2
Hexachlorobiphenyl	$C_{12}H_4Cl_6$	26601-64-9
Heptachlorobiphenyl	$C_{12}H_3Cl_7$	28655-71-2
Octachlorobiphenyl	$C_{12}H_2Cl_8$	31472-83-0
Nonachlorobiphenyl	$C_{12}H_1Cl_9$	53742-07-7
Decachlorobiphenyl	$C_{12}Cl_{10}$	2051-24-3

2. Summary of Method

An aliquot of a well mixed, homogeneous aqueous, solid, or tissue sample is accurately measured or weighed for sample preparation. Generally, 1L of water sample, 1-10g of tissue sample, 5-30g of sediment/soil sample for *Microscale Solvent Extraction - 3570 (*SOP 2172*) and 15-30g* of sediment/soil sample *for Soxhlet Extraction (SOP 2173)*. The PUF cartridge is extracted via Soxhlet, with the appropriate solvent. Water, soil/sediment, and tissue samples as well as PUF cartridges are spiked with surrogate compounds and extracted using methylene chloride,methylene chloride/acetone mixture, or hexane/ether mixture. The extract is dried and exchanged to hexane during sample concentration to a 1-10mL final volume. If necessary, the sample may be copper cleaned to remove sulfur, and/or GPC, silica or acid cleaned to lessen sample matrix interferences, prior to sample analysis.

After cleanup, the extracts are spiked with internal standards, and analyzed by GC/MS-SIM. Analytes are introduced into the GC/MS by injecting a known volume of the calibration standards, quality control samples, and sample extracts into the GC equipped with a narrow-bore capillary column. The GC column is temperature programmed to separate the analytes, which are then detected with a mass spectrometer operating in the selective ion mode (SIM). Identification of target analytes is accomplished by comparing their mass spectra with the electron impact spectra of the calibration standards. Concentrations are determined using mean relative response factors from a multi-level calibration curve. Response factors for target analytes and surrogate compounds are determined relative to the internal standards.

2.1 Method Modifications from Reference

This method exhibits some modification from the reference methods.

SIM data acquisition parameters, GC separation/operating conditions and MS sensitivity/calibration ratios for ions, and column type differ from the one described in Method 680 due to changes in technology since 1985.

Different compounds are utilized as Internal Standards and Surrogates then those specified in Method 680.

Different Calibration Congeners are used for Homologs group than the ones specified in Method 680.

Corrections are not made to any data for Homolog groups Cl2 – Cl8 for interferences resulting from M+35 or M+70 ions.

Acceptance criteria for ICAL, ICV, CCV, Method Blank, Surrogates and Internal Standards have been adopted from the guidance in Method 8270D.

The sample preservation procedure has been adopted from Method 8270D.

Different DFTPP criteria then specified in method 8270D. Maximum Sensitivity Criteria are used.

Method Modifications from NOAA Technical Memorandum:

- Different extraction method then specified, MSE versus ASE
- Different requirements for batch quality control samples: method blank and LCS/LCSD versus method blank and SRM
- Different cleanup techniques: silica columns only versus silica/alumina columns and size-exclusion high-performance liquid chromatography
- Different GC settings: PTV/splitless injection versus COC (cool on-column) injection; oven temperature program differs, no guard column
- Different MS settings: electron ionization versus chemical ionization
- Different Calibration model: Average Response Factor obtain from Multi Level Calibration versus Point-to-Point Calibration
- Different Quality Controls and Measurements

3. Reporting Limits

Analytes are determined and measured in the concentration range of 0.5 to 500 parts per trillion (ng/L) for water samples, 0.033 to 200 parts per billion (ug/Kg) for soil/sediment and tissue samples, and 5-5000 ng/puf for PUF cartridges. The detection limit for Homolog groups is equal to the lowest detection limit of the individual congener detected within that group. Detection limits will vary with the individual sample matrix, sample preparation procedures, instrument calibration range, and volume of sample analyzed.

4. Interferences

4.1 Contaminants in solvents, reagents, glassware, and other sample processing hardware may cause interferences that lead to discrete artifacts and/or elevated baselines in the ion current profiles. Demonstrate that all of these materials are free from interferences under the conditions of the preparation and analysis by extracting and analyzing a laboratory method blank with each batch of up to 20 samples.

4.2 Contaminants co-extracted from the sample may cause matrix interferences. The extent of matrix interferences will vary considerably from sample to sample, depending upon the nature of the environment being investigated. An interference, which is unique to SIM techniques, can arise from the presence of co-eluting compounds, which contain the same quantification mass ion, or the same number of chlorine atoms. This event results in a positive interference to the reported value for the compound of interest. This interference is controlled to some degree by acquiring data for a confirmation ion. If the ion ratios between the quantification ion and the confirmation ion are not within the specified limits, then interferences may be present. Quantification and confirmation ion criteria can be found in Table II.

4.3 With the isomer, or Homolog group quantification approach, co-eluting PCBs that contain the same number of chlorines, are identified and measured together. Therefore, co-eluting PCBs are only a problem if they contain a *different* number of chlorine atoms.

4.4 An interference can arise from the presence of co-eluting congeners containing one or two additional chlorines, which will contribute to the quant ion due to the fragmentation that occurs during the analysis. This event results in a positive interference to the reported value for the compound of interest. PCBs listed below are co-eluting with other congeners containing two additional chlorines:
- when analyzed on BNA2/5 for 209 Congeners – BZ#37, BZ#60, BZ#78, BZ#81, BZ#107/123, BZ#105, BZ#127, BZ#126, BZ#167,
The interference from another PCB containing one additional chlorine is small and can be neglected except when measuring the area of a small amount of the congener co-eluting with a large amount of another congener containing one more chlorine.

4.5 Raw GC/MS data from all blanks, samples, and spikes must be evaluated for interferences or carryover. Contamination by carryover can occur whenever high-concentration and low-concentration samples are sequentially analyzed.

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by

whatever means available. A reference file of material safety data sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

***Aqueous* samples:** Collect in 1L or 2L amber glass bottles. The minimum amount of sample needed to reach the reporting limits in Section 3.0 for this method for aqueous samples is 1L. Additional sample is needed (approximately 3X the minimum amount) if MS/MSD analyses are to be performed.

***Soil/sediment* samples:** Collect in glass soil jars. The minimum amount of sample needed to reach the reporting limits in Section 3.0 for this method for solid and tissue matrices is 5g or 30g. Additional sample is needed (approximately 3X the minimum amount) if MS/MSD analyses are to be performed.

***Air Samples*:** Collected with appropriate air sampling techniques described in the Reference Method for collecting PUF cartridge air samples.

6.2 Sample Preservation

***Aqueous* samples:** Store without preservative at 4°C.

***Soil/sediment* samples:** Stored at 4°C, or if desired, frozen.

Air Samples: Stored at 4°C without preservation.

6.3 Sample Shipping

No special shipping requirements.

6.4 Sample Handling

The hold time for this method is 7 days for the extraction of aqueous samples and 14 days for the extraction of solid and tissue samples. If sediment or tissue samples are frozen, this suspends the holding time until removal from the freezer. Air PUF cartridges must be extracted within 7 days of collection.

All extracts must be analyzed within 40 days of the extraction date.

7. Equipment and Supplies

7.1 Gas Chromatograph: The instrumentation includes a temperature-programmable gas chromatograph and all required accessories including syringes, analytical columns, and gases. The injection port is designed for splitless injection onto a capillary column. The injection port includes a silanized glass liner containing a plug of silanized glass wool to reduce high-molecular-weight mass discrimination. The model is HP6890 or equivalent. The injection port will require maintenance on an as needed basis if degradation or contamination is apparent.

7.2 Large volume injector, PTV - Gerstel, or equivalent: Temperature and flow programmable and capable of injecting 1 to 50 uL of standards and sample extracts onto the GC column in a split or splitless mode.

7.3 Column: For 209 Congener and Homolog Analysis - Restek 60-m x 0.18 mm ID, 0.18 um film thickness, fused-silica capillary column with Crossbond phase, or equivalent.

7.4 Mass Spectrometer: The mass spectrometer must operate at 70ev (nominal) electron energy in the electron impact ionization mode and be tuned to optimize the sensitivity of the instrument to the maximum in the mass range being monitored (45 - 525 amu). The GC capillary column is fed directly into the ion source of the mass spectrometer. The model is HP5973, or equivalent. The source will require cleaning and/or filament replacement on an as needed basis. Please refer to the instrument hardware manual, located in the laboratory, for detailed procedures.

7.5 Auto sampler: Adapted onto the Gas Chromatograph. The model is HP 6890 series autosampler with a GC autosampler controller, or equivalent.

7.6 Computer: With Windows XP operating software utilizing HP Enviroquant G1701DA Version D.01.02 software; Audit Trail: audit.txt function is used for audit trail purposes.

7.7 Helium: Ultra high purity grade (99.9999% pure) or hydrogen of equivalent purity.

8. Reagents and Standards

Reagent grade or pesticide grade chemicals are used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to specification of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. See SOP Reagent, Solvent, and Standard Control (SOP 1816) for additional details regarding solvent purity. All solvent expirations determined as indicated by manufacturer guidelines

Analytical Standards are stored according to manufacturer's recommended procedure. Stock standards, and calibration curve standards are stored in either 10mL or 40mL glass vials and kept in a standards freezer at -10^0 — -20^0C in the GC Instrumentation Lab. Primary standards are discarded as indicated by the vendor expiration. Stock standards are given one year expiration from the preparation date or the expiration of the primary vendor solution, whichever occurs first. Working standards are given six month expiration from the preparation date or the expiration of the primary solution whichever occurs first. If breakdown of a solution is observed the solution will be discarded. All analytical standards are prepared in Hexane. All extraction standards (surrogates, laboratory control spikes and matrix spikes) are prepared in acetone or hexane for Soxhlet extraction - *Method 3540C*. All spiking solutions must be assayed for use by analysis before release to the preparation lab If there is a significant amount of spiking solution remaining after the six-month period, the lab will re-QC the solution. If the QC of the solution still passes the lab will extend the expiration date by another month.

8.1 Methylene Chloride: ACS approved, Pesticide grade, see SOP *Reagent, Solvent, and Standard Control* (SOP 1816) for additional details regarding solvent purity.

8.2 Acetone: ACS approved, Pesticide grade, see SOP *Reagent, Solvent, and Standard Control* (SOP 1816) for additional details regarding solvent purity.

8.3 Hexane: ACS approved, Pesticide grade, see SOP *Reagent, Solvent, and Standard Control* (SOP 1816) for additional details regarding solvent purity.

8.4 Methanol: Purge and Trap grade, see SOP *Reagent, Solvent, and Standard Control* (SOP 1816) for additional details regarding solvent purity.

8.5 Ether, see SOP *Reagent, Solvent, and Standard Control* (SOP 1816) for additional details regarding solvent purity.

8.6 DFTPP (decafluorotriphenylphosphene) tuning solution: Prepare by diluting 0.025mLs of a 2000 ug/mL standard into 10mL of Methylene Chloride for a 5 ug/mL tuning standard. Working solution is further diluted 1:10 prior to analysis.

8.7 Individual Analytes (BZ-1 to BZ-209): Obtained from AccuStandard or equivalent at a concentration of 100 ug/mL.

8.8 209 Congeners Custom Calibration Set: Obtained from Accustandard as 9 separate mixes at the concentration of 10 ug/mL each. The solution consists of 209 Congeners. Prepare the Stock Solution by diluting the calibration mixes to a stock concentration of 1000 ng/mL. See Section 8.16 for calibration preparation information.

8.9 Custom 136 PCB Congeners Set/ Homolog Custom Mix, Retention Time Window / ICV Standard: Obtained from Accustandard as 7 separate mixes at the concentration of 4 ug/mL each. The solution consists of at least one representative PCB congener used for quantitation from each Homolog group and the first and last eluting congener of each Homolog group used to identify the start and stop time of each SIM window. Prepare the Stock Solution by diluting the calibration mixes and the Carbon-labeled Surrogate Stock solution to a 136 Cong/Surr Stock concentration of 400 ng/mL. See Section 8.16 for standard preparation information.

8.10 Surrogates: 4,4'-Dibromooctafluorobiphenyl (DBOB) and BZ 198, obtained from Ultra Scientific or equivalent.

8.10.1 DBOB/BZ198 stock solution: Add 25 uL of the 5000 ug/mL DBOB primary solution and 1250 uL of the 100 ug/mL BZ 198 primary solution to 25 mL volumetric flask and dilute with hexane for 5000 ug/L stock solution.

8.10.2 Pest/Cong Surrogate spiking solution: add 4 mL of DBOB/BZ198 stock solution to 200 mL volumetric flask and dilute with acetone, for a 100 ug/L final concentration. The solution must be assayed for use by analysis before release to the preparation lab. All compounds must be within 20% of their true value. 1mL is spiked into each QC and field sample. The concentrations may be adjusted to meet project specific needs.

8.11 Carbon-labeled Surrogates: BZ 19 and BZ 202, obtained from Cambridge Isotope or equivalent, at a concentration of 40 ug/mL and BZ 101 and BZ 153, obtained from Wellington Labs or equivalent, at a concentration of 50 ug/mL.

8.11.1 Carbon-labeled Surrogates Stock Solution: Prepare a separate solution by taking 1.25mL of each of the 40 ug/mL surrogate solutions and 1.00mL or each

of the 50 ug/mL surrogate solutions, and add to 10mL of hexane for a stock concentration of 5 ug/mL or 5000 ng/mL.

8.11.2 Homolog Surrogate spiking solution: Add 250 uL of each surrogate (BZ 19 and BZ 202) and 200 uL of each surrogate (BZ 101 and BZ 153) to 100 mL volumetric flask and dilute with acetone, for a 100 ug/L final concentration. All compounds must be within 20% of their true value. 1mL is spiked into each QC and field sample. The concentrations and the spiking amount may be adjusted to meet project specific needs.

8.11.3 High Homolog Surrogate spiking solution: Add 1.25 mL of each surrogate (BZ 19 and BZ 202) and 1.00 mL of each surrogate (BZ 101 and BZ 153) to 50 mL volumetric flask and dilute with hexane, for a 1000 ug/L final concentration. The solution must be assayed for use by analysis before release to the preparation lab. All compounds must be within 20% of their true value. 1mL is spiked into each QC and field sample. The concentrations and the spiking amount may be adjusted to meet project specific needs.

NOTE: PCB High Homolog Surrogate spiking solution is prepared in hexane and used for Soxhlet extraction only.

8.12 Carbon-labeled Internal Standards (IS): BZ 15 and BZ 180, obtained from Cambridge Isotope or equivalent, at a concentration of 40 ug/mL. Add 2.5mL of each internal standard to 10mL volumetric flask and dilute with hexane, for a final concentration of 10 ug/mL. 20uL is spiked into each standard, QC sample, and field sample. The resulting on-column concentration is 200 ug/L in a 1mL sample aliquot. The concentrations may be adjusted to meet project specific needs.

8.13 Laboratory Control Sample, Matrix Spike, and Matrix Spike Duplicate (LCS/MS/MSD) Preparation:

8.13.1 Homolog LCS spiking solution: Prepared using Accustandard C-CSQ-SET. Nine ampules containing all 209 congeners at 10ug/mL. Add 1.0 mL of each mix to 100mL volumetric flask and dilute with *acetone,* for a 100 ug/L final concentration. The solution must be assayed for use by analysis before release to the preparation lab. Recoveries of 90% of the analytes must be +/- 20% of the true values.

8.13.2 High Homolog LCS spiking solution: Prepared using Accustandard C-CSQ-SET. Nine ampules containing all 209 congeners at 10ug/mL. Add 1.0 mL of each mix to 25 mL volumetric flask and dilute with hexane, for a 400 ug/L final concentration. The solution must be assayed for use by analysis before release to the preparation lab. Recoveries of 90% of the analytes must be +/- 20% of the true values.

NOTE: HIGH Homolog LCS/MS/MSD spiking solution is prepared in hexane and used for Soxhlet extraction only

8.14 Independent Calibration Verification (ICV) standard:

8.14.1 209 Congener ICV Standard: For the 209 Congener Calibration Curve, a level 5 from the 136 Congeners standard serves as ICV (Accustandard or equivalent)

8.15 SRM 1944/1941b – New York/New Jersey Waterway Sediment, and SRM 1974b – Organics in Mussel Tissue: From National Institute of Standards & Technology (NIST). Please refer to the individual certifications for the assigned true values. These SRMs may be extracted and analyzed with sample batches as part of the overall QC evaluation, if requested by the client. Other certified SRMs may be used on a project specific basis.

8.16 Calibration Preparation Information

Homolog Calibration Congener	**Isomer Group**	**Stock Concentration ng/mL 209Congeners**
BZ 1 (1st Mono)	Cl1	400 1000 ng/mL
BZ 8, BZ 5/8	Cl2	400 1000 ng/mL
BZ 29	Cl3	400 1000 ng/mL
BZ 50	Cl4	400 1000 ng/mL
BZ 87, BZ 87/111	Cl5	400 1000 ng/mL
BZ 154	Cl6	400 1000 ng/mL
BZ 188 (1st Hepta)	Cl7	400 1000 ng/mL
BZ 200, BZ 200/204	Cl8	400 1000 ng/mL
BZ 206 (last Nona)	Cl9	400 1000 ng/mL
BZ 209 (Deca)	Cl10	400 1000 ng/mL
Add'l Ret. Window PCB Congeners	**Isomer Group**	**Stock Conc. ng/mL 209Congeners**
BZ 3 (last Mono)	Cl1	400 1000 ng/mL
BZ 10 (1st Di)	Cl2	400 1000 ng/mL
BZ 15 (last Di)	Cl2	400 1000 ng/mL
BZ 19 (1st Tri)	Cl3	400 1000 ng/mL
BZ 37 (last Tri)	Cl3	400 1000 ng/mL
BZ 54 (1st Tetra)	Cl4	400 1000 ng/mL
BZ 77 (last Tetra)	Cl4	400 1000 ng/mL
BZ 104 (1st Penta)	Cl5	400 1000 ng/mL
BZ 126 (last Penta)	Cl5	400 1000 ng/mL
BZ 155 (1st Hexa)	Cl6	400 1000 ng/mL
BZ 169 (last Hexa)	Cl6	400 1000 ng/mL
BZ 189 (last Hepta)	Cl7	400 1000 ng/mL
BZ 202 (1st Octa)	Cl8	400 1000 ng/mL
BZ 205 (last Octa)	Cl8	400 1000 ng/mL
BZ 208 (1st Nona)	Cl9	400 1000 ng/mL
Surrogates		
DBOB	N/A	5000 ng/mL
BZ 198	Cl8	5000 ng/mL
Carbon-labeled Surrogates		
BZ 19	Cl3	5000 ng/mL
BZ 202	Cl8	5000 ng/mL

Note: Any of the above congeners may be reported as individual congeners, as well as within a Homolog group, as this method is not limited to this congener list. Additional congeners may be analyzed via this method by utilizing the MDL and PQL from a congener of the same Homolog class that has been previously established. Parentheses indicate the first and last eluting PCB congener in each chlorination level, used to establish the selective ion monitoring (SIM) retention time windows.

Suggested ICV Preparation for 209 Congeners

Calibration Level	136 Cong. /Surr Stock 400ng/mL	Final Volume
ICV – 50 ug/L	1.25mL	10 mL

Suggested Curve Preparation for Individual Components (Minimum 5 Levels) for 209 Congeners

Calibration Level	Surr. Stock 5000ng/mL	209 Cong. Stock 1000ng/mL	Calibration L6 (200ug/L)	Final Volume
L1 – 0.5 ug/L	-	-	0.025mL	10 mL
L2 – 1.0 ug/L	-	-	0.05mL	10 mL
L3 – 10 ug/L	-	-	0.5mL	10 mL
L4 – 20 ug/L	-	-	1mL	10 mL
L5 – 50 ug/L	0.1mL	0.5mL	-	10 mL
L6 – 200ug/L	0.4mL	2mL	-	10 mL
L7 – 500 ug/L	1ml	5ml	-	10 mL

Curve Preparation for Individual Components

Up to 10 levels may be analyzed. Standards chosen should bracket the linear range of the instrument. A minimum of a 5-level curve must be analyzed, but 6-levels, or more, may be analyzed and evaluated depending upon client specific project detection limits. This is an example of possible curve levels, the curve used may vary based on project and instrument performance.
* Each calibration level is a combination of three stock solutions prepared at the concentration of 5000ug/L added at the indicated amount.
**High calibration level is 200ug/L.

Note: 20 uL of the 10 ug/mL chosen Internal Standard mix is added to each calibration level for a concentration of 200 ng/mL. *A minimum of a 5-level curve must be analyzed, but 6-levels, or more, may be analyzed and evaluated depending upon client specific project detection limits.*

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

Quality Control (QC) samples are necessary to monitor both the sample extraction and instrument analysis procedures. The Quality Control samples described below are considered the method

defaults, and are the minimum requirements, except where noted. Client and Project specific Data Quality Objectives (DQOs) supersede the requirements in this section where applicable. Client or Project specified DQOs shall be included, or referenced, in the final report to the client.

9.1 Blank(s)

A method blank must be extracted (spiked with surrogates and internal standards) and analyzed once per every 20 samples or per extraction batch, whichever is more frequent.

An *acceptable* method blank should not contain any individual compound at the concentration of reporting limit, or above. All efforts must be made to identify and eliminate the source of contamination. The presence of analytes at concentrations at or above the reporting limit will warrant application of a “B” qualifier to that target compound(s) on all associated report forms, and perhaps re-extraction of all associated samples. The results are qualified with a “B” for any associated sample concentrations that are less then 10x the blank concentration for the analyte. Surrogate and internal standard recoveries must meet the QC limits for the method blank, see Sections 9.7.1 and 9.7.2. Re-extraction *corrective action* that would exceed the sample holding time criteria should be discussed with the client, Laboratory Director, QA Manager, and/or Section Supervisor prior to implementation. Exceptions may be made with approval of the Section Supervisor if the samples associated with an out of control method blank are non-detect for the affected compound(s) or if the concentrations of the affected compound(s) are greater than 10x the blank level in the samples. In such cases, the sample results are accepted without corrective action for the high method blank result. The client must be notified, via the project narrative, of any method blank non-compliance associated with the sample results.

9.2 Laboratory Control Sample / Laboratory Control Sample Duplicate (LCS/LCSD)

The laboratory control sample/laboratory control sample duplicate (LCS/LCSD) contains at least 10 PCB congeners that represent each Homolog group. If only PCB Congeners are being evaluated, and if the list includes more than 20 congeners, at least 16 individual congeners will be spiked. The LCS/LCSD is extracted along with the samples. An LCS/LCSD pair must be extracted and analyzed once per every 20 samples or per extraction batch, whichever is more frequent. The number of PCB congeners in this sample may vary with client specific requests.

The acceptable recovery QC limits are found in Section 12 for an aqueous, solid, tissue and PUF LCS/LCSD.

Corrective Action: Repeat analysis or check to see if an analytical error has occurred. If the LCS recovery is still out of control, re-extract and re-analyze the LCS/LCSD and all associated samples. Samples cannot be analyzed until an acceptable LCS/LCSD is obtained. Exceptions may be made with approval of the Section Supervisor if the samples associated with the out of control LCS/LCSD are also associated with a matrix spike and matrix spike duplicate that is in control which demonstrates an isolated problem pertaining to the LCS and/or LCSD only. An explanation of this out of control LCS and/or LCSD recovery must be included in the project narrative to the client and the sample data reported with the acceptable MS/MSD results as batch QC.

9.3 Initial Calibration Verification (ICV)

Refer to section 10.2.8

9.4 Continuing Calibration Verification (CCV)

Refer to section 10.4

9.5 Matrix Spike / Matrix Spike Duplicate (MS/MSD)

Matrix spike and matrix spike duplicate analyses are performed at the client's request.
The acceptable recovery and RPD QC limits are found in Section 12 for an aqueous, solid, tissue, and PUF MS/MSDs.

Corrective Action: Repeat analysis or check to see if an analytical error has occurred. If the % recovery or %RPD still exceeds the control limits and the associated LCS/LCSD is within control, include a project narrative with the results to client noting that there may be potential matrix effects on the accuracy or precision of the affected results as evidenced by the matrix spike and matrix spike duplicate exceedance.

9.6 Laboratory Duplicate

Laboratory matrix or sample duplicates are analyzed if requested by the client. The QC limit is 30% RPD for target compounds found above 5 times the reporting limit.

Corrective Action: If the %RPD exceeds the 30% control limit and the associated MS/MSD %RPD is within 30%, include a project narrative with the results to client noting that there may be potential matrix effects on the precision of the results isolated to this sample, as evidenced by the matrix duplicate exceedance and the MS/MSD acceptance. If both the sample/duplicate and the MS/MSD exceed the control limits, include a project narrative with the results to client noting that there may be potential matrix effects on the precision of the results as evidenced by the sample/duplicate and the MS/MSD exceedences.

9.7 Method-specific Quality Control Samples

9.7.1 Surrogates

Surrogates are monitored for recovery for all matrices. The recovery limits are found in Section 12.

Corrective Action: Check to see if an analytical or dilution error occurred and re-calculate. If only one surrogate falls below the recovery limit, but is above 10% recovery, the exceedance is noted, with approval of the Section Supervisor, and the results are reported to the client with a notation in the case narrative. If all surrogates are recovered below the limit, re-extract the sample and report the re-extract results along with the original results, if re-extraction occurred beyond the holding time, and the re-extract surrogates are within the QC limits. If the surrogates are recovered below the limit in the re-extract, this confirms a suspected matrix interference on the surrogates, and only the original analysis needs to be reported. If the chromatogram shows obvious matrix interference, no re-analysis or re-extraction is necessary. *This decision must be made with approval of the Section Supervisor.* Surrogate outliers and sample re-extracts must be noted in the case narrative to the client.

9.7.2 Internal Standards

Internal standards are added to every field sample, QC sample, standard, and method blank. The acceptance limits are -50% to +100% of the internal standard response (or area) of the daily continuing calibration verification standard.

Corrective Action: Check to see if an analytical, dilution, or spiking error occurred. If the chromatogram shows obvious matrix interference, no re-analysis is necessary. *This decision must be made with approval of the Department Manager.* Note the exceedance in the case narrative to the client. If no obvious interference is present, re-analyze the extract. If internal standards are now within the

acceptance limits, report only the re-analysis, as long as the re-analysis occurred within the 40-day analytical hold time. If the re-analysis occurred outside of the 40-day analytical hold time, both the original and re-analysis must be reported. If the internal standards again are outside the acceptance limits, after re-analysis, either within or outside of the 40-day hold time, report only the original analysis, and include a narrative to the client that the suspected matrix interference on the internal standards was confirmed by sample re-analysis.

9.7.3 Standard Reference Materials

Standard reference materials (SRMs) are available from the National Institute of Standards and Technology (NIST) and are extracted and analyzed with samples on a project specific basis. These are not used as controls, but to evaluate potential matrix effects in associated samples for the target compounds being evaluated.

Acceptance criteria for SRM analysis will vary from project to project depending upon client data quality objectives (DQOs). Generally, 40% - 140% recovery of the true certified values of the target compounds of interest, serves as advisory acceptance criteria.

Corrective Action: Repeat analysis and/or check to see if an analytical error has occurred. If the % recovery or %D still exceeds the control limits and the associated LCS/LCSD and/or MS/MSD are within control, include a project narrative with the results to the client noting that the observed recovery exceedences of the SRM are isolated to this sample as evidenced by the LCS/LCSD and/or MS/MSD acceptance.

9.8 Method Sequence

Tune – (5 ug/mL) full scan using DFTPPBNA2/5
CCV – (50 ng/mL) using PCB209BNA2/5.m
Method Blank – (ID from sample preparation batch)
LCS – (ID from sample preparation batch)
LCSD – (ID from sample preparation batch)
Samples (up to 12-18 hours of analytical time)
Tune – (5 ug/mL) full scan using DFTPPBNA2/5
CCV – (50 ng/mL) using PCB209BNA2/5.m
Samples (up to 12-18 hours of analytical time)
CCV – (50 ng/mL) using PCB209BNA2/5.m

10. Procedure

10.1 Equipment Set-up

Prior to the analysis of any standards or samples, the instrument acquisition and processing methods must be set up. This includes the GC run parameters and the SIM mode acquisition ion entries into the different SIM acquisition retention time windows. An initial calibration must be analyzed to establish linearity of the instrument. First, the mass spectrometer must be tuned to the meet the abundance criteria for PFTBA when using maximum sensitivity tuning.

10.1.1 PFTBA Manual Tuning

10.1.1.1 Prior to initial calibration tune the mass spectrometer using PFTBA (Perfluorotributylamine - calibration gas) to maximize the sensitivity of the instrument in the mass range of interest, 45-525 amu. The use of PFTBA for MS tuning maximizes the sensitivity of the analysis within the mass/charge (m/e) range being monitored. *If only the PTFBA tune is required, per client request or project specific DQOs, the DFTPP tune in Section 10.1.2 does not need to be evaluated.*

10.1.1.2 To acquire the PFTBA Tune:

- Click on the “Instrument” icon to open the ChemStation.
- Go into “Instrument Control” in the “GC/MS Top Environmental” screen.
- Go to “View” and select “Manual Tune”.
- Go to “File” and select “Load Tune Values”. Select the ATUNE.U file.
- Go back into “File” and select “Generate Report”. The calibration gas will automatically turn ON, equilibrate for approximately 20 seconds, and generate a report. Evaluate the PFTBA tune against the parameters below.

PFTBA Ion	Relative Abundance
m/e 69	Base Peak with > 150,000 counts
m/e 219	40% to 90% of Base Peak
m/e 502	4% to 10% of Base Peak

If the PFTBA tune meets the criteria, “Save” the tune values, and exit the program.

10.1.1.3 If the PFTBA does not meet the criteria above, an experienced mass spectrometrist may attempt the following corrective actions:

- Adjust the ion focus value up or down while the calibration gas valve is open and continue to scan until the desired abundances are achieved.
- Adjust the entrance lens value up or down while the calibration gas valve is open and continue to scan until the desired abundances are achieved.
- Save the tune parameters under PCBTUNE.U.

10.1.2 DFTPP Tuning: If only DFTPP is required, per client request or project DQOs, PFTBA does not need to be evaluated.

10.1.2.1 Before the analytical standards are analyzed, the mass spectrometer must be evaluated for the proper ion criteria for DFTPP (decafluorotriphenylphosphene), if specifically requested by the client or included in a project specific QAPP. Generally, 1-4uL of a 10x dilution of 50 ug/mL solution is evaluated. A larger volume or lesser concentration may be evaluated if using large volume injections. If the instrument has been adjusted for the maximum sensitivity PFTBA, then the

criteria in Section 10.1.2.5 applies. *DFTPP must be injected under full scan mode.*

10.1.2.2 To acquire the DFTPP tune:

- Click on the "Instrument" icon to open the Chem Station, if not already open.
- *Go into the "GC/MS Top Environmental" screen.*
- *Go into "Sequence."*
- Edit the "Sample Table Log" by entering the "Vial" number starting at position 1, the "Data File ID" the acquisition method, DFTPPBNA2/5., and finally the "Sample Name" (*i.e*., "DFTPP 5 ug/mL") When complete, click "OK".
- Go back into "Sequence" and "Save" the sequence as the date, such as, S2060501.s. The ending "01" indicates the first sequence created on 06/05. The first number comes from instrument ID, i.e. BNA2.
- Go back into "Sequence" and "Load and Run" the sequence that was just saved.

10.1.2.3 After the analysis of the DFTPP, evaluate the tune as follows:

- Enter into the "Environmental Data Analysis" (off-line) screen.
- Go to "File" and select the tune data file.
- Go into "Tuner" and select "Eval DFTPP", then select "AutoFind DFTPP to Screen," to evaluate the tune file, based on the pre-set SW-846 criteria**.** The software will evaluate the tune by selecting three scans of the DFTPP peak and will display the ion intensities on the screen. That is, one scan at the apex, one scan directly preceding the apex and one scan following the apex and averages them, then takes one background subtracted scan, 20 seconds before the beginning of the DFTPP peak. If the criteria below are met, repeat, but select "AutoFind to Printer", for a hardcopy of the tune evaluation for the record.

  Note: the Maximum Sensitivity tune must be evaluated using the correct method to ensure the criteria in Section 10.1.2.5 are met.

10.1.2.4 If the "AutoFind" tune evaluation does not meet the criteria below, manual evaluation of the tune can be performed by attempting either of the options below:

- Blow up the DFTPP peak on the screen and select either one single scan at the apex of the peak, or a scan immediately preceding or following the apex. Go into "Tuner" and select "Evaluate DFTPP to Screen," or "Evaluate DFTPP to Printer," as described above, OR,
- Take the average of the scans across the entire peak. Go into "Tuner" and select "Evaluate DFTPP to Screen," or "Evaluate DFTPP to Printer," as described above.

10.1.2.5 "Maximum Sensitivity" DFTPP is used for the analysis of PCB Congeners by GC/MS. It shows high-end sensitivity for the higher molecular weight ions that are present in, and evaluated for PCBs.

DFTPP KEY MASSES AND ABUNDANCE CRITERIA
(Maximum Sensitivity)

Mass	m/e Abundance criteria
51	N/A
68	N/A
70	N/A
127	30-80 percent of mass 198.
197	Less than 3 percent of mass 198.
198	Greater than 40 percent of mass 442.
199	5-15 percent of mass 198.
275	15-50 percent of mass 198.
365	Greater than 3 percent of mass 198.
441	Present but less than mass 443.
442	Base peak, 100 percent relative abundance.
443	18-30 percent of mass 442.

10.1.2.6 Tune acceptance must be verified at the beginning of every analytical shift, and prior to the analysis of any standards, and again at the beginning of each 12-18 hour tune clock as defined by the injection time of each DFTPP analysis. If the DFTPP tune does not meet the criteria above, the PFTBA must be re-evaluated, and adjustments made by an experienced mass spectrometrist, to obtain an acceptable DFTPP tune, before continuing with any analysis.

10.1.3 GC Instrumental Conditions

10.1.3.1 For 209 Congener and Homolog Analysis inject an aliquot of 1uL to 50uL into the capillary column of the gas chromatograph at the following conditions. Injection volume (using the Large Volume Injector, LVI) amount will be dictated by project specific DQOs.

GC Parameter	*Setting*
Injector Temp:	*70 - 300 °C*
Transfer Line Temp:	*300 °C*
Initial Oven Temp:	*65°C*
Initial Hold Time:	*2.1 minutes*
Ramp Rate 1:	*25 °C / minute*
Final Temperature 1:	*170 °C*
Final Hold Time 1:	*0 minute*
Ramp Rate 2:	*3 °C / minute*
Final Temperature 2:	*290 °C*
Final Hold Time 2:	*15 minutes*
Total runtime:	*61.3 minutes*
Mode:	*Splitless / Constant Pressure or Solvent vent for LVI*
Purge:	*25 mL / minute – on at 2.00 minutes*
MS Temperature:	*250 °C, MS Source, 170 °C, MS Quad*

10.1.4 Mass Spectrometer Conditions

The effluent from the GC capillary column is fed directly into the ion source of the mass spectrometer. The MS is operated in the SIM mode using appropriate retention time windows to include the quantification and confirmation ions for each congener and the interference ions as shown in Table II.

10.1.5 Large Volume Injection (LVI) Parameters

*Gerstel **	*Settings**
Injector Temp:	*70 - 300 °C*
Initial Hold Time:	*30 sec. - 3 minutes*
Flow Rate:	*0.5 - 5.0 mL / minute*
Purge:	*25 mL / minute – on at 2.00 minutes*

Injection Volume:	*1uL - 50uL*

***** = The settings listed may vary from project to project, based on client specific DQOs. *Injection temperature, hold time, flow rate, purge time, and injection volume can affect chromatographic resolution and detection limits.* All parameters listed above can be set within the above setting ranges. Only a trained and experienced mass spectrometrist has the authority to change any setting. All standards and samples must be acquired using the same set of parameters. If any parameters are changed, a new initial calibration must be analyzed and accepted before any samples can be analyzed.

10.1.6 Data Acquisition Parameters

10.1.6.1 SIM Windows must be set up that bracket the expected retention times for each target analyte. These windows include the quantitation (primary) and confirmation ions for each congener Homolog group. To establish the expected retention time window ranges, the mid-level retention time window standard containing the first and last eluting congener in each Homolog group, must be analyzed in full scan mode. The resulting full scan analysis will dictate the windows in which the selected ions will be monitored. Depending upon the length of the analytical GC column, the time each window is selectively monitored may vary. The retention time windows must be shifted accordingly, when instrument maintenance is performed, (*i.e.,* the column is clipped).

10.1.6.2 The “dwell” time for each window should be set close to 20 and the resolution should be set to “high.”

10.2 Initial Calibration

10.2.1 Before analysis of sample extracts, establish a multi-point response factor calibration curve showing the linear range of the analysis for all target analytes in Table II. Use at least 5 levels of standard concentrations at 0.5, 1.0, 10, 20, 50, 200, and 500 or 400 ng/mL to construct the curve. See Section 8.16 for the preparation of the standard solutions for the initial calibration curve.

10.2.2 Construct an analytical sequence using the HP Enviroquant software:

- Click on the “Instrument” icon to open the ChemStation
- *Go into the “GC/MS Top Environmental” screen into “Sequence”*
- Edit the “Sample Table Log” by entering the “Vial” number starting at position 1, the “Data File ID” ,the acquisition method (such as, 209CONGBNA2.m, which indicates the type of method and the instrument ID), and finally the “Sample Name” (such as, “I206051001STD0.5”, for the first standard concentration level, etc.).
- Go back into “Sequence” and “Save” the sequence as the date, such as, S2060501.s. The ending “01” indicates the first sequence created on 06/05. The first number comes from instrument ID, i.e. BNA2.
- Go back in to “Sequence” and “Print” the sequence that was just saved. This will become part of the instrument run log. See Section 11.0 for additional instrument run log details.
- Go back into “Sequence” and “Load and Run” the sequence that was just saved.

10.2.3 When the sequence has finished running, the Enviroquant software will generate “Not Reviewed” quantitation reports. All reports must be “Quant Reviewed” before they can become part of the initial calibration processing method for sample analysis.

- Enter into the “Environmental Data Analysis” (off-line) screen.

- Go to "File" and under method, select the processing method (209Cong0605BNA2.m) that the initial calibration standards will be quantitated with.
- Go into "Quant" and select "QEdit Quant Results" to process the data files. See SOP Manual Integration 08-03 for manual integration details and Section 11.0 for processing of PCB Congener standards.
- When processing is complete for the first standard, "Save" the changes and "Exit." Re-print the re-processed data file by "Generating Quant Report," and save the hard copy for each level of the initial calibration.
- Repeat these steps for all initial calibration standards analyzed within the sequence.
- When the appropriate levels have been processed, go into "IntiCal," and select "Update Levels," and enter all levels for the initial calibration at the proper concentrations. Note: The PCB Homolog *group* responses *must be hand entered* into the calibration curve, or utilizing the RF macro, (*i.e.,* for Mono-, Dichlorobiphenyl, etc.) using the response of the appropriate calibration congener (*i.e.,* BZ1, BZ8, etc.).
- After all responses are entered, "Save" the completed method and print the resulting response factor summary by selecting "Response Factors to Printer."
- Acceptance Criteria: 20% RSD for all target compounds, except 10% of the analytes may be >20% RSD but ≤ 30% RSD. All calibration standards must be analyzed within 12-18 hours.
- Replace the Qion ratio values from the mid-point concentration level of the ICAL, by checking off the appropriate box, then update and "Save" the new method.
- Replace the reference spectra for the method from the spectra in the mid-point concentration level of the ICAL by going into "ConCal" and select "Update Reference Spectrum." Again, "Save" the method.
- Establish retention time window ranges from the first and last eluting congener within each chlorination level. Set the integration window ranges for each Homolog group (*i.e.,* Monochlorobiphenyl, Dichlorobiphenyl, etc.) by using the Easy ID function in the Enviroquant software.

10.2.4 If using greater than five calibration levels in the initial calibration, standards must only be excluded from either extreme. That is, the low-level standard or the high-level standard may be dropped to generate a five-level initial calibration. However, an intermediate-level calibration standard must not be dropped to convert a failing six-level initial calibration curve into a passing five-level initial calibration curve. Reduction in the number of calibration standards must also reduce the linear dynamic range used to quantify analytes in samples. The resulting average response factor for each target analyte in the initial calibration curve will be used by the computer software to calculate actual sample concentrations. See Section 11.0 for additional calculation details.

10.2.5 The following *corrective actions* are recommended for failing initial calibrations:

- Perform instrument maintenance and repeat the initial calibration, OR,
- Qualify all results reported for the analyte failing in the initial calibration, including all Homolog chlorination range(s) quantified using the suspect average response, and any non-detects. If the failure of the suspect average response appears related to a loss in MS sensitivity, instrument maintenance and repeat of the initial calibration curve must be performed.

The choice of corrective action must be made in consultation with the Section Supervisor, QA Manager, Project Manager, and/or the client. The reasoning for choosing the second option must be documented in the project narrative to the client.

10.2.6 Alternately, a linear regression model may be employed, provided that the coefficient of determination (COD or r^2) is ≥0.99. Otherwise, construct a nonlinear calibration of no more than a third order equation. Statistical considerations in developing a non-linear calibration model require more data than the more traditional linear approach. A

quadratic (second order) model requires six standards, and a third order polynomial requires seven standards. In setting model parameters, do not force the line through the origin. The COD or r^2 must be greater than or equal to 0.99. The experienced analyst must select the regression order, which introduces the least calibration error into the quantitation.

10.2.7 Complete the initial calibration by filling out the *Initial Calibration Checklist*. The initial calibration, along with any corresponding continuing calibration data and sample data, is then forwarded for secondary review.

10.2.8 Initial Calibration Verification - ICV (separate source)

The analysis of separate source standard must follow the initial calibration curve.
After final processing, calculate the percent recovery of each congener by using the following calculation:

% Recovery = Found Amount / True Value x 100

Acceptance Criteria: All compounds must agree within +/-30%D with the exception of the partially or fully coeluting congeners that are identified, measured and calibrated together and at least one of the coeluting compounds is not present in the ICV solution. The Compounds listed in section 4.4 should also be excluded from the evaluation due to the described interference.

10.3 Equipment Operation and Sample Processing

10.3.1 Evaluate the PFTBA tune and/or DFTPP tune as described in Sections 10.1.1 and 10.1.2. *The type of tune required will depend upon the client/project DQOs.*

10.3.2 Samples are prioritized for analysis by the Organic Section Supervisor or GC/MS Group Leader based on client due date and sample analytical hold time. Samples are retrieved from the sample storage refrigerator, spiked with 20uL of the chosen internal standard solution per 1mL extract from either Section 8.11 or 8.12, and loaded into the instrument autosampler trays following the generalized sequence below.

- Tune – (5 ug/mL) full scan using DFTPPBNA2/5.m
- CCV – (50 ng/mL) using PCB209BNA2/5.m
- Method Blank – (ID from sample preparation batch)
- LCS – (ID from sample preparation batch)
- SRM – (ID from sample preparation batch) if required
- Samples (up to 12-18 hours of analytical time)
- Tune – (5 ug/mL) full scan using DFTPPBNA2/5.m
- CCV – (50 ng/mL) using PCB209BNA2/5.m
- Samples (up to 12-18 hours of analytical time)
- CCV – (50 ng/mL) using PCB209BNA2/5.m

10.3.3 Samples are processed from “Not Reviewed” data files, to “Quant Reviewed” data files in a similar way the standards were previously processed. See Section 11.0 for details on sample processing. If a CCV fails the criteria outlined in Section 10.4.3, all samples since the last acceptable CCV must be re-analyzed.

10.3.4 If the on-column concentration of any compound exceeds the concentration of the highest calibration standard, the sample must be diluted, re-spiked with the appropriate amount of internal standard and re-analyzed. Assuming all samples are at a 1mL final volume, the following example dilutions would apply. Adjust the volumes accordingly for other sample final volume amounts and other desired dilutions.

- 1:2 dilution = 500uL of sample : 500uL Hexane and 10uL of IS
- 1:4 dilution = 250uL of sample : 750uL Hexane and 15uL of IS
- 1:5 dilution = 200uL of sample : 800uL Hexane and 16uL of IS
- 1:10 dilution = 100uL of sample : 900uL Hexane and 18uL of IS, etc.

10.4 Continuing Calibration

A continuing calibration verification (CCV) standard, at the concentration of the mid-level of the initial calibration curve, must be analyzed at the beginning and end of every analytical sequence, and every 12-18 hours within the sequence, to confirm instrument stability, via response factor, for each calibrated congener.

10.4.1 After successful analysis of the PFTBA or DFTPP tune (Section 10.1.1 or 10.1.2), "Edit" the "Sample Table Log" to include the 50 ng/mL CCV standard and acquire the CCV against the correct initial calibration method. "Save," then "Load and Run" the sequence, as in Section 10.2.3.

10.4.2 When the sequence has finished running, the Enviroquant software will generate a "Not Reviewed" quantitation report. All reports must be "Quant Reviewed" against the processing method for sample analysis.

- Enter into the "Environmental Data Analysis" (off-line) screen.
- Go to "File" and under method, select the method that the CCV was analyzed under, then select the CCV data file.
- Go into "Quant" and select "QEdit Quant Results" to process the CCV file. See SOP Manual Integration 08-03 for manual integration details and Section 11.0 for processing of PCB congener standards.

When processing is complete, go into "ConCal," and select "Evaluate Data File as Continuing Calibration." **Note:** The PCB Homolog group CCV responses may be omitted since the calibration congener associated with the Homolog group, is the quantitation congener for that same Homolog group.

10.4.3 Acceptance Criteria: Compare the CCV resulting response against the average response for the initial calibration for each calibrated congener, and calculate the % difference (%D). See Section 11.0 for the calculations. The %D for each calibrated congener must be below 20%D, except up to 20% of the analytes may be > 20%D but ≤ 30%D. If multiple CCVs are analyzed within an analytical sequence, each CCV must be analyzed within 12-18 hours of the previous CCV, and each CCV, including the ending CCV, must meet the acceptance criteria.

Additional Criteria:

1) The area counts of the internal standards must be within 50-200%of the mid-point standard level from the most recent initial calibration.
2) The retention time of the internal standards must be within 30 seconds of the previous daily standard.

If the CCV meets the acceptance criteria, save the hard copy for each CCV standard and include it with the *Continuing Calibration Checklist*.

Go back into "ConCal" and select "Update Continuing Calibration" and "Save" the method updated to the opening CCV of the day.

10.4.4 If the CCV does not meet the criteria for each calibrated analyte, the following *corrective actions* are recommended:

- Perform instrument maintenance and re-analyze the continuing calibration standard and all affected samples, OR,
- Perform instrument maintenance and repeat the initial calibration, and re-analyze all affected samples, OR,
- If the closing CCV does not meet the criteria and the sample chromatograms show obvious matrix interference, no re-analysis is necessary. *This decision must be made with approval of the Section Supervisor.* CCV outliers and affected samples must be noted in the case narrative to the client.
- If the failure of the suspect response appears related to a loss in MS sensitivity or other instrument related issues, instrument maintenance and repeat analysis of all affected samples and/or the initial calibration curve must be performed.

The choice of corrective action must be made in consultation with the Department Manager, QA Manager, Project Manager, and/or the client. The reasoning for choosing the third option must be documented in the project narrative to the client.

10.5 Preventive Maintenance

10.5.1 Preventive maintenance may include the following: replacing glass liner, ferrules, PTV injection port bottom adapter and/or clipping a length of the analytical column.

10.5.2 Additionally, preventive maintenance for GC-MS system may involve baking out the injection port and the oven, cleaning the ion source, and/or replacing the analytical column.

11. Data Evaluation, Calculations and Reporting

11.1 After sample analysis, "Not Reviewed" quantitation reports are generated by the software system. It is expected that situations will arise when the automated quantitation procedures of the chromatographic software provide inappropriate quantitations or integrations. This normally occurs when there is compound co-elution, baseline noise or matrix interference with the PCB congener compounds. However, with PCB Homolog groups, a range or cluster of peaks is evaluated and manual integration must be performed for each PCB Homolog group or chlorination level cluster. See SOP Manual Integration 08-03 for manual integration details.

11.2 Identification of the PCB congener compounds are based on gas chromatographic relative retention times (RRTs) from the analysis of the mid-level initial calibration standard. For these compounds, manual quantitations are performed, if necessary, by integrating the area of the quantitation ion or peak. For the ten *PCB Homolog groups*, the Homolog groupings (*i.e.,* Dichlorobiphenyl) appear in the extracted ion current profiles (EICPs) as a cluster of congeners with the same degree of chlorination. Establish the pattern of each Homolog group by comparing the primary and secondary ion profiles. Refer to the Manual Integration SOP 1731 for details on Manual Integration. Manually integrate candidate peaks by straight-line integration to the baseline, taking into account background noise in the EICPs for each Homolog group within each determined Homolog-specific retention time window. If a discrete peak, either target or non-target, does not have a confirmation ion, or the experienced analyst judges that the confirmation ion does not meet the ratio criteria, the area for that discrete peak can be measured and subtracted from the total area used to calculate the concentration for that Homolog group. The experienced analyst can also choose not to include the interference in the

manual integration even if the interference appears within the retention time window established by retention time markers for specific Homolog group. If there is interference observed within Homolog-specific retention time window that cannot be excluded or subtracted out, the results for the affected Homolog group will be qualified with the G flag and narrated in the case narrative to the client. See the most recently generated "detailed" PCB reference spectrum hardcopy that is based on the most recent analysis mid-point standard of the ICAL. Table II, in Section 16.0, lists the representative ion(s) used for quantitation and confirmation of each parent congener and PCB Homolog group.

Note: Manual integration is not to be used solely to meet QC criteria, nor is it to be used as a substitute for corrective action on the chromatographic system.

11.3 From EICP of the quantification (primary) mass ions and the confirmatory mass ions, identify all target analytes according to the following criteria:

- Surrogates and internal standards should meet the acceptance criteria in Section 12.0.
- Examine the chromatograms for evidence of saturated ions in mass spectra. Re-analyze the sample(s) at the appropriate dilution(s), see Section 10.3.4, as needed.
- The characteristic ions (primary and secondary) of each congener and/or Homolog group of interest should maximize at the same scan, or within one scan of each other.
- The retention time should fall within ± 10 seconds of the retention time of the authentic target compound or PCB Homolog grouping. *Note*: For PCB Homolog groups, the most intense peak within the group may not have the exact retention time of a calibration congener. Analyst judgment and referral to each Homolog groups' retention time window and group-specific pattern is essential for identification. Apply analyst judgment regarding corrective action, as needed, when these criteria are not met.
- The relative peak height of the quantitation ion compared to the confirmation ion for parent analyte should fall within ± 50 percent of the relative intensities of these ions in the reference mass spectrum (*i.e.,* the mid-level standard of the initial calibration curve).

Note: The relative intensities of the quantitation and confirmation ions may vary widely within a given group of PCB Homologs. Thus, the pattern of each PCB Homolog cluster, and the retention time window for the cluster, will be the primary identification criteria for PCB Homologs. In some instances, a parent congener that does not meet secondary ion confirmation criteria may still be determined to be present in a sample after close inspection of the data by the experienced mass spectrometrist. Supportive data includes the presence of the secondary ion, but ratio value greater than ± 50 percent of the primary ion, which may be caused by an interference of the secondary ion. See Section 11.6 for interferences.

11.4 In instances where manual integrations have been performed, they are assigned one of the Manual Integration codes, (Refer to Manual Integration SOP 1731) and can be found on the raw data provided within the data deliverable package The "detailed" report, displaying the manual integration, including an "m" qualifier(s) next to the modified or manually integrated compound(s), shall be provided to the LIMS for secondary review. These requirements apply to all standards, QC samples, field samples and blanks.

11.5 To calculate the ***Relative Standard Deviation*** (RSD) of all PCB congeners, Homolog groups, and surrogate compounds for the initial calibration, use the formula below. See Section 10.2 for initial calibration acceptance criteria. Additionally, use the initial multi-point calibration to determine ***Relative Response Factors*** (RRF_Is) at each concentration level, for each PCB congener. Average the RRF_Is from the initial multi-point calibration, to generate mean RRF_Is, for quantification of each PCB congener. Follow the same calculations for each surrogate

compound. The RRF_I for the quantification of each Homolog group is the RRF_I of the PCB calibration congener assigned to that Homolog group (*i.e.,* Tricholorbiphenyls are quantified using the RRF_I of the PCB calibration congener BZ29, which is associated with the Trichlorobiphenyl group). The RRF_Is are based on the internal standard compounds, and are calculated using the formula below. (The relative response factors for the continuing calibration verifications (RRF_Cs) are calculated using the same formula). See Section 16.0, Table II, for the listing of target compounds and their associated internal standards for quantification.

$$\textbf{RSD} = \textbf{SD / mean } RRF_I \textbf{ x 100}$$

where:

SD = Standard deviation between the five points, for that target analyte.

$$RRF_I = (A_c \times C_{IS}) / (A_{IS} \times C_c)$$

where:

A_c = Area of the characteristic ion for the standard compound to be measured.

A_{IS} = Area of the characteristic ion for the representative internal standard compound.

C_{IS} = Concentration of the representative internal standard compound (ng/mL).

C_c = Concentration of the standard compound to be measured (ng/mL).

Note: Assign the response factor of the calibration congener compound to the Homolog group, (*i.e.,* use BZ 5/8 for the Dichlorobiphenyl group).

11.6 Based on the mean RRF_Is, calculate the ***Sample Extract Amount*** for each PCB congener or Homolog group and surrogate in the sample extracts using the following formula:

$$Q_e = (A_a \times Q_{IS}) / (A_{IS} \times RRF_I)$$

where:

Q_e = Sample extract concentration (ng/mL) of target analyte, from quantitation report.

A_a = Area of the characteristic ion for the target analyte.

A_{IS} = Area of the characteristic ion for the representative internal standard compound.

Q_{IS} = Concentration (ng/mL) of representative internal standard compound, from quantitation report.t.

11.7 Calculate the ***Sample Concentration*** (C) for each PCB congener or Homolog group by the following formula:

$$C = (Q_e / V_s) \times FV \times DF$$

where:

C = Concentration in sample (ng/L water, ug/Kg sediment/tissue or ng/cert for PUF).

V_s = Original volume or weight of sample extracted, corrected for % solids, if applicable. (To correct for % solids, multiply the sample weight by the % solid as expressed as a decimal. For example: 15.24g x 0.843 = 12.85, for a sample size of 15.24g at 84.3% solid).

DF = Dilution factor

FV = Sample Final Volume or Final Effective.

If the response of any analyte in a sample exceeds the linear response range, as defined by the initial calibration standards in Section 10.2, dilute the extract so that the concentration of that analyte falls within the range of the calibration curve.

Note: Homolog groups exceed the calibration level if one single peak in the integration group exceeds the linear response range. If no single peak exceeds the range the total integration range may result above the calibration range. If the target compound in a sample is detected below the reporting limit (RL) but above half of the RL, qualify the reported concentration with a "J". If any target compound is found in the method blank and in the associated sample(s), qualify the reported concentration with a "B" if detected less than 10x the blank concentration for this analyte.

11.8 To calculate ***Total PCBs*** when analyzing for *less than 209 PCB Congeners* use the following:

- Each Homolog group will be identified and final concentration will be calculated using the formulas above.
- Sum all Homolog group concentrations.
- If a Homolog group is non-detect, zero is used in the summation. This minimizes the potential for a high bias result.

To calculate ***Total PCBs*** when analyzing for *all 209 PCB Congeners*, sum all identified congeners.

11.9 Calculate the ***Surrogate Recoveries*** relative to the internal standards by the following formula:

$$\%R_{sc} = (A_{sc} / A_{is}) \times (Q_{is} / Q_{sc}) \times (100 / RRF_{sc}) \times DF$$

where:

Q_{is} = Amount of the representative internal standard (ng).

DF = Dilution factor or fraction of the original extract.

11.10 Compare response factors for each PCB congener in the ***Continuing Calibration Verification*** (CCV), to those of the initial calibration curve by determining the percent difference.

$$\text{Percent Difference (\%D)} = ([RRF_I - RRF_C] / RRF_I) \times 100$$

where:

RRF_I = Mean response factor from initial calibration.

RRF_C = Response factor from CCV.

11.11 All results must be reported to three significant figures. All solids including soils, sediments, and sludge must be reported on a dry-weight basis. Tissue results may be reported on a dry-weight, or "as received," basis depending upon client request. PUF samples are reported "as received".

11.12 The primary analyst does data entry, or upload of the data, into the LIMS system. The LIMS is "linked" to the instrument, so the analyst must choose the sample(s) to be reported from that instrument's analytical sequence. All associated preparation and instrumental QC samples and dilutions are also chosen. Once the data/samples have been selected and "associated" with the proper QC samples, the batched data set is sent to print. In addition to the concentration of each selected PCB congener and Homolog group on the report, the Total PCB concentration is also reported.

11.13 The laboratory generates two types of data packages from the LIMS: "Commercial" or "Standard" for routine projects, and "Full Deliverable" or "CLP-like" for fully data validated projects. A Commercial/Standard package consists of sample results and the associated method blank and LCS/LCSD results. A Full Deliverable/CLP-Like package includes all sample results, all preparation and instrumental QC results and the associated supporting raw data. Check the "Report Type" on the project folder to ensure all required deliverables are included. A secondary review is performed on all data.

11.14 Procedures for data and record management must adhere to the Quality Systems Manual, other subordinate documents covering record keeping, and the *Document Control* SOP 1729. All records shall be stored in such a manner as to be safe and accessible for at least 10 years.

11.15 Notebooks: Laboratory notebooks are designed to accommodate the specific analysis. Instrument printouts are used to document run sequences, and each daily sequence printout is filed in a three-ring notebook. If a sample requires re-analysis or re-extraction for any reason, a notation is made next to the sample entry on the sequence log. Requests for re-extraction are further documented in the "Request for Re-extraction, Re-clean" logbook. At regular intervals the sequence run log is permanently bound, assigned an internal ID number, and filed accordingly. Such files shall be archived so as to remain available for at least 10 years. All laboratory notebooks must follow the specifications in the *Laboratory Notebook Usage* Work Instructions, WI 108-01, and all record keeping and document control practices.

11.16 Electronic records: All data files from computers, attached to instruments, shall be backed up daily onto the proper directory on the server. The backups shall be stored so as to be accessible for 10 years. Movement of the data files to the server is the responsibility of the primary analyst. Server backup and storage is the responsibility of the IT department.

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

All PCB congener and Homolog results are reportable without qualification if analytical holding times are met, preservation requirements (including cooler temperatures) are met, and all QC criteria defined in the table below are met. If any of the below QC parameters are not met, all associated samples must be evaluated for re-analysis. See Sections 9.0 and 10.0 for additional QC discussion including corrective actions for any QC outliers.

QC Parameter	Acceptance Criteria
Initial Calibration Curve	20% RSD for all target analytes with exception for 10% of target analytes to be >20%, but ≤ 30%
Independent Check Verification	+/- 30% recovery of the true values
Continuing Calibration Verification	Analyzed every 12-18 hours, 20% D for all target analytes with exception for 20% of target analytes to be >20%, but ≤ 30%
Method Blank	No analyte at or above the reporting limit, The results are qualified with a "B" for any associated sample concentrations that are less than 10x the blank concentration for this analyte.
Laboratory Control Samples (LCS/LCSD)	40-140%; 30% RPD (sporadic marginal failure criteria applies)
Matrix Spike / Matrix Spike Duplicate	Same as for LCS; 30% RPD between the duplicates.
Sample / Sample Duplicate	30% RPD between the duplicates.
Surrogates	50-125%
Internal Standards	50% - 200% of the daily CCV area for the Internal Standards
SRM	40% - 140% recovery

Section 9.0, Quality Control, defines the corrective actions that must be taken in instances where QC outliers exist.

If non-compliant PCB congener or Homolog results are to be reported, the Department Manager, the Laboratory Director, and/or the QA Manager must approve the reporting of these results. The laboratory Project Manager shall be notified, and may chose to relay the non-compliance to the client, for approval, or other corrective action, such as re-sampling and re-analysis. The analyst or Department Manager performing the secondary review initiates the project narrative, and the narrative must clearly document the non-compliance and provide a reason for acceptance of these results.

13. Method Performance

13.1 Method Detection Limit Study (MDL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the MDL, LOD, and/or LOQ as outlined in Alpha SOP 1732. These studies performed by the laboratory are maintained on file for review.

13.2 Demonstration of Capability Studies

Refer to Alpha SOP/08-12 for further information regarding IDC/DOC Generation.

13.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

14. Pollution Prevention and Waste Management

Refer to Alpha's Chemical Hygiene Plan and Waste Management and Disposal SOP for further pollution prevention and waste management information.

15. Referenced Documents

Table I: PCB Homolog Groups

Table II: PCB Homolog Quantification, Confirmation Ions

Table I: PCB Homolog Groups

Compound	Surrogate and IS Reference 209Cong	Compound	Surrogate and IS Reference
Monochlorobiphenyls	A	Surrogate Compounds	
Dichlorobiphenyls	A	DBOB	A
Trichlorobiphenyls	A	BZ 198	B
Tetrachlorobiphenyls	A	Carbon-labeled Surrogates	
Pentachlorobiphenyls	A	BZ 19	A
Hexachlorobiphenyls	A	BZ 202	B
Heptachlorobiphenyls	B		
Octachlorobiphenyls	B	Carbon-labeled ISs	
Nonachlorobiphenyls	B	BZ 15	A
Decachlorobiphenyl	B	BZ180	B

Note: Individual congeners may also be reported, as needed, depending upon client/project specific DQOs. Each congener depends on the level of chlorination would use the surrogates and internal standards similar to its chlorination grouping.

Table II: PCB Homolog Quantification, Confirmation Ions

Parameter	1^0 Ion	2^0 Ion	CASRN	Acceptance Ratio
Monochlorobiphenyls	188	190	27323-18-8	2.5-3.5
Dichlorobiphenyls	222	224	25512-42-9	1.3-1.7
Trichlorobiphenyls	256	258	25323-68-6	0.8-1.2
Tetrachlorobiphenyls	292	290	26914-33-0	1.1-1.5
Pentachlorobiphenyls	326	324	25429-29-2	1.4-1.8
Hexachlorobiphenyls	360	362	26601-64-9	1.0-1.4

Pace ANALYTICAL SERVICES	**ENV-SOP-ASHE-0009 v03_Sulfur by ASTM D4239**
	Effective Date: 04/10/2023

Management Approval:
Daniel Naylon Approved on 4/10/2023 10:33:17 AM
Eric Setzer Approved on 3/31/2023 9:14:55 AM
Felicia Grogan Approved on 3/30/2023 4:50:33 PM
Michael Washington Approved on 4/4/2023 4:43:58 PM
Jacob Cottrell Approved on 4/10/2023 10:36:02 AM

1.0 SCOPE AND APPLICATION

This SOP documents the procedure used by PASI – Asheville This adaptation of ASTM Method 4239 describes the determination of sulfur in waste materials using the LECO SC632 Sulfur Analyzer.

1.1 Target Analyte List and Limits of Quantitation (LOQ)

The PRL is 0.02%

1.2 Parameters:

1.2.1 Every sample is subjected to an oxidative-reduction process that first breaks down all sulfur bearing compounds, and then converts all sulfur to sulfur dioxides, which is detected by an infrared detector. These instruments are effective in the analysis of a wide variety of organic or inorganic waste materials.

1.2.2 Test results from this method are used primarily to show compliance with various EPA and State Environmental Regulations. These results may also be used by various manufacturing and service divisions to assist in process improvement.

1.2.3 This method is not included under the Laboratory NELAC Accreditation

1.3 Applicable Matrices

1.3.1 The results of this analysis are used to establish suitability and feed rates for burning of waste materials.

2.0 SUMMARY OF METHOD

2.1 The LECO Sulfur Analyzers are non-dispersive infrared instruments, which is software controlled and is calibrated to measure both high levels (>3%), and low levels (0 to 3%) of sulfur. Samples are weighed and placed in a sample boat, then pushed into a pure oxygen combustion chamber maintained at a temperature of 1350°C. All sulfur in the sample is then converted to SO2 gas in the high heat and swept through a series of filtering and drying tubes filled with anhydrous magnesium perchlorate, through a flow controller, which sets the sample gas flow to 3.5 L/min, and finally through one of the two IR detection cells. The detection cells are set at the wavelength specific to SO2. The detector measures the absorption in the cell, which is directly proportional to the concentration of sulfur in the sample. The instruments have a long cell for low concentrations and a short cell for high concentrations. A three coal standard series, at a sulfur concentration at the upper end of the detector cell range, with weights varying from 0.1 to 0.35 grams, is used to produce a calibration curve.

3.0 INTERFERENCES

The distribution of printed or electronic copies of this document outside of the PAS electronic document management system (eDMS) is not controlled or tracked. PAS employees must ensure any copy used for daily work, if not accessed directly from PAS eDMS, is the current version of the document.

3.1 Special Environmental Operating Conditions: The Sulfur Analyzers are computer controlled and may experience data system problems at ambient temperatures above 85°F.

3.2 Standard Contamination: If calibration standards are contaminated when an attempt is made to calibrate the instrument, it can affect the linearity of the calibration curve. Always discard a standard when 5 grams or less remain in the bottom of the bottle. Standards tend to become contaminated when they reach this level in the container.

3.3 For an extensive list of additional sources of error for this method and suggestions for eliminating them, refer to the troubleshooting matrix in Appendix 3.

4.0 DEFINITIONS

Refer to the Laboratory Quality Manual for a glossary of common lab terms and definitions.

5.0 HEALTH AND SAFETY

The toxicity or carcinogenicity of each chemical material used in the laboratory has not been fully established. Each chemical should be regarded as a potential health hazard and exposure to these compounds should be as low as reasonably achievable.

The laboratory maintains documentation of hazard assessments and OSHA regulations regarding the safe handling of the chemicals specified in each method. Safety data sheets for all hazardous chemicals are available to all personnel. Employees must abide by the health, safety and environmental (HSE) policies and procedures specified in this SOP and in the Pace Chemical Hygiene / Safety Manual.

Personal protective equipment (PPE) such as safety glasses, gloves, and a laboratory coat must be worn in designated areas and while handling samples and chemical materials to protect against physical contact with samples that contain potentially hazardous chemicals and exposure to chemical materials used in the procedure.

Concentrated corrosives present additional hazards and are damaging to skin and mucus membranes. Use these acids in a fume hood whenever possible with additional PPE designed for handing these materials. If eye or skin contact occurs, flush with large volumes of water. When working with acids, always add acid to water to prevent violent reactions. Any processes that emit large volumes of solvents (evaporation/concentration processes) must be in a hood or apparatus that prevents employee exposure.

Contact your supervisor or local HSE coordinator with questions or concerns regarding safety protocol or safe handling procedures for this procedure.

Samples: Take precautions when handling samples. Samples are always to be treated as potentially hazardous “unknowns”. The use of personal protective equipment (gloves, lab coats and safety glasses) is required when handling samples. In the event a sample container must be opened, it is recommended to perform this in a hood whenever possible.

The Sulfur Analyzers operate at very high temperatures. Handle sample boats with extreme caution when moving them in and out of the combustion chamber. Avoid contact with skin, clothing or other combustible materials.

The distribution of printed or electronic copies of this document outside of the PAS electronic document management system (eDMS) is not controlled or tracked. PAS employees must ensure any copy used for daily work, if not accessed directly from PAS eDMS, is the current version of the document.

Infrared can be damaging to the eyes. Do not look into the combustion chamber when the door is open. Keep the analyzer shut until a sample is to be analyzed.

Magnesium perchlorate is a strong oxidizer. Do not dispose of it with other chemicals. Consult the Safety Data Sheet for full hazard details.

Must be disposed of in water to neutralize. Do not throw in garbage.

Use adequate ventilation when working with glass wool. It is a respiratory hazard.

6.0 SAMPLE COLLECTION, PRESERVATION, HOLDING TIME, AND STORAGE

The laboratory does not perform sample collection for this test method. To assure sample collection and field checks and treatment are performed in accordance with applicable regulations Pace project managers will inform the client of these requirements at the time of request for analytical services when the request for testing is received prior to sample collection. If samples were already collected, the laboratory will record any nonconformance to these requirements in the laboratory's sample receipt record when sufficient information about sample collection is provided with the samples.

The laboratory will provide containers for the collection of samples upon client request for analytical services. Bottle kits are prepared in accordance with laboratory, *Bottle Preparation* (most current revision or replacement).

Requirements for container type, preservation, and field quality control (QC) for the common list of test methods offered by Pace are included in the laboratory's quality manual.

General Requirements

Matrix	Routine Container	Minimum Sample Amount[1]	Preservation	Holding Time
Solids	Glass bottle – cleaned and rinsed with reagent water	4/8 oz	Above zero to 6.0 ºC	There are no holding time requirements for this method.

Thermal preservation is checked and recorded on receipt in the laboratory in accordance with laboratory SOP, *Sample Management* (most current revision or replacement).

After receipt, samples are stored at ≤6°C until sample preparation (but not allowed to freeze).

After analysis, unless otherwise specified in the analytical services contract, samples are retained for 45 days from receipt and then disposed of in accordance with Federal, State, and Local regulations.

Note: Samples are to be stored separately from all standards, reagents, and highly contaminated samples. To avoid contamination, no food or drink products can be located near samples.

The distribution of printed or electronic copies of this document outside of the PAS electronic document management system (eDMS) is not controlled or tracked. PAS employees must ensure any copy used for daily work, if not accessed directly from PAS eDMS, is the current version of the document.

7.0 EQUIPMENT AND SUPPLIES

7.1 Equipment and Supplies

Supplies*	Manufacturer* / Vendor	Model/ Version	Description /Catalog #/Comments*
Analyzer	Leco	SC 632	
Analyzer	Leco	SC S832DR	
Drying Oven	Precision	9606-003	103-105°C
	Thermo Fisher	41729011	≤100°C
Disposable Pipette	Fisher or equivalent	N/A	N/A
Balance	Sartorius	SECURA 124-1S	Analytical
Sample boats	N/A	N/A	N/A

*Or Equivalent

8.0 REAGENTS AND STANDARDS

8.1 Reagents

Reagent	Concentration/ Description	Requirements
Coal Calibration Check Standards	LECO, approximately 2 %. LECO part number 501-437	Reagents and standards are stored in desiccator.
Coal QC Check Standard	LECO, approximately 1 %. LECO part number 501-435	Reagents and standards are stored in desiccator.
Magnesium Perchlorate	(LECO Anhydrone, part number 501-171	Reagents and standards are stored in desiccator.
Magnesium Sulfate, 26.64% sulfur	26.64% sulfur, Aldrich, part number 24697-2	Reagents and standards are stored at room temperature.
Sulfur, 100%	Aldrich, part number 21392-2	

The distribution of printed or electronic copies of this document outside of the PAS electronic document management system (eDMS) is not controlled or tracked. PAS employees must ensure any copy used for daily work, if not accessed directly from PAS eDMS, is the current version of the document.

Zinc Sulfide, 32.84% sulfur, or any certified standard at the 20-30% level for the high calibration standard.		Reagents and standards are stored at room temperature.
Compressed oxygen	medical grade	Reagents and standards are stored at room temperature.

9.0 PROCEDURE

9.1 Calibration and Standardization

Calibration Metric	Parameter / Frequency	Criteria	Comments
Initial Calibration Verification (ICV) (~1%)	Immediately after each initial calibration	% Diff ±10%	Second source single standard. Reanalyze once. If it still fails, recalibrate.
Continuing Calibration Verification (CCV) (~2%)	After every 10 samples and at the end of the analytical sequence.	% Diff ±10%	Second source single standard. Reanalyze once. If it still fails, recalibrate and reanalyze all samples after last passing CCV.

9.1.1.1 **NOTE: Calibration is typically done monthly unless the instrument fails standardization.**

9.1.2 All calibration standards that are to be used must be moisture free. To accomplish this, place standards in a drying oven at 104°C to 110°C for two hours prior to use, and then store them in desiccators.

9.1.3 The instrument remains on at all times, therefore the correct method settings and calibration is always loaded and ready for analysis.

9.1.4 Ensure that the instrument has been optimized and is functioning properly by clicking on diagnostics. Refer to attachment 1and 2.

9.1.5 Ensure that the appropriate method has been loaded. To change, click on cell in the “Methods” column to bring up the methods box.

9.1.6 On a balance that has been checked with reference weights, weigh the standard and analyze quickly to avoid moisture accumulation.

9.1.7 The instrument may need to be conditioned before attempting to calibrate by using a sample that has approximately 2 to 3% sulfur, labeled as “COND” in the sample file.

9.1.8 To enter “COND” standard to be analyzed, click “Add Sample” and put the cursor on the down pointing arrow at the bottom of the list of samples that have been run, and left click the mouse. Highlight “COND” standard that is to be run and hit enter.

9.1.9 Obtain a sample boat and place it on the balance and tare it. Add 0.25 g – 0.30 g of 2 3% sulfur.

The distribution of printed or electronic copies of this document outside of the PAS electronic document management system (eDMS) is not controlled or tracked. PAS employees must ensure any copy used for daily work, if not accessed directly from PAS eDMS, is the current version of the document.

9.1.10 Ensure that there is not another sample boat already in the combustion tube.

9.1.11 Click on the “Analyze” button on the tool bar. The SC632 system will only respond with the "Push boat into furnace" message.

9.1.12 After the "Push boat into furnace" message, open the oven door and gently push the boat into the furnace and all the way to the back of the tube with the boat puller. Immediately close the door and hit “OK”. Specific to 632

9.1.13 Repeat steps 9.1.7 -9.1.11 three times to properly condition the instrument.

9.1.14 The instrument has two sulfur cells that must be calibrated individually. The low cell which includes values below approximately 3.0% sulfur, and the high cell which includes values from 3.0% to 100%. However, it is not necessary to have a high-level calibration in place in order to use the low-level cell. The low-level cell is adequate for most samples. A low cell calibration is accomplished by analyzing an appropriate standard, at a concentration as close as possible to the top of the cell range, at 3 different weights (0.1 g - 0.3 g), creating a calibration for 0 to 3.0% sulfur. It is not necessary to calibrate the high cell unless it is needed for concentrations above 3% sulfur.

9.1.15 To ensure that the appropriate standards are entered into the software, click on “Standards” on the tool bar to bring up the standards dialogue box. Check to see that the standards being used are listed. If they are, click “OK” and exit. If they are not, click “New”. Enter the name of the standard and known sulfur percentage and hit “enter”.

9.1.16 When using the SC632 instrument, simply click on the next open box at the end of the column and enter the sample name.

9.1.17 To enter the correct standard to be analyzed, put the cursor on the down pointing arrow at the bottom of the list of samples that have been run, and left click the mouse. Highlight the standard that is to be run and hit “enter”. This will list that standard as the next one to be run, and automatically move the cursor to the sample “Weight” column.

9.1.18 Obtain a sample boat and place it on the balance and tare it.

9.1.18.1 For the 632 – for the first calibration point Weigh the appropriate amount of the NIST calibration coal standard (weighed to the nearest mg)(0.10-0.15g) and enter the weight in the weight column.

9.1.19 Note: The system operates better, and thus produces a better calibration, if the sample is distributed evenly in the sample boat before being placed into the combustion tube.

9.1.20 Ensure that there is not another sample boat already in the combustion tube.

9.1.21 Click on the “Analyze” button on the tool bar. The SC 632 system will only respond with the "Push boat into furnace" message.

9.1.22 After the "Push boat into furnace" message on the SC 632, open the oven door and gently push the boat into the furnace and all the way to the back of the tube with the boat puller. Immediately close the door and hit “OK”.

9.1.23 Repeat this process with approximate weights of 0.1 g, 0.2 g, and 0.3g to complete a run of three standards for the low-level cell calibration.

9.1.24 This calibration run data can now be used to calibrate the system.

The distribution of printed or electronic copies of this document outside of the PAS electronic document management system (eDMS) is not controlled or tracked. PAS employees must ensure any copy used for daily work, if not accessed directly from PAS eDMS, is the current version of the document.

9.1.25 Select the three low concentration standards, all the way left on the number column, by putting the cursor on the first one and clicking and dragging all the way down until all five standards are highlighted.

9.1.26 Click on the “Calibrate” button. The system will display a graph representing the low sulfur calibration curve and below the graph will be a table that indicates which samples it used on the graph and information about each point. Ensure that “Low Sulfur” is displayed and highlighted in the cell window. The curve type window displays “Linear, Fixed at Origin”, and the weighted window display “normal”.

9.1.27 Click on the “OK” button and a “save calibration” window will be displayed with “low sulfur” highlighted. Click “OK”.

9.1.28 The low concentration cell is now calibrated.

9.1.29 These calibrations can then be verified daily by analyzing the appropriate level of sulfur QC check standards (low level sulfur) or another appropriate level standard certified to be in the necessary range for a high-level calibration check.

9.1.30 A calibration check standard must also be analyzed prior to running any samples to verify the calibration.

9.1.31 To calibrate the high-level concentration cell, use a high-level sulfur standard (magnesium sulfate, zinc sulfide, cystene, or any other certified compound at the 20 to 30% sulfur range) following the same sequence as the low-level but highlight “High Sulfur” in the calibration dialog box. It is not necessary to calibrate the high-level cell to 100% sulfur unless a sample is expected to run higher than the set calibration will accommodate.

9.1.32 If a 100% sulfur calibration is required, use a standard certified to be 100% sulfur, and follow the procedure described above using weights in the range of 0.01 to 0.05 g. The weights must be smaller because the detector cell will saturate if larger weights are used.

9.2 Sample Procedure

9.2.1 Prior to the analysis of any samples on a given day, it may be necessary to condition the instrument. Analyze three “warm up” samples made from any other standard in the 2% to 3% sulfur range. Title these samples as “COND” so that they can be identified as conditioning samples.

9.2.2 Analysis of Daily Quality Check Standards - Use a certified standard at a percent sulfur level that is between zero and the calibration level. A quality check standard must be analyzed at the beginning and end of every set of ten samples.

9.2.3 The established limits of the certified coal standards are taken from the manufacturer’s stated precision limits printed on the bottle label. The ± number on the label is equal to 2 standard deviations. The limits of the daily standard are found by first dividing the label standard deviation by 2 then multiplying that number by 3. Plus or minus this number are the limits of that standard.

9.2.4 If a final quality check standard of a sample series is out of established limits, then the sample results, prior to that standard, back to the last check standard, are suspect and must be repeated.

The distribution of printed or electronic copies of this document outside of the PAS electronic document management system (eDMS) is not controlled or tracked. PAS employees must ensure any copy used for daily work, if not accessed directly from PAS eDMS, is the current version of the document.

9.2.5 Troubleshoot and service the system to correct the problem. See attachment 2 and 3. A couple of conditioning runs may be required afterwards.

9.2.6 Reanalyze the quality check standard. If the result is within limits, proceed to reanalyze the samples. Analyze final quality check standard after the last waste sample.

9.2.7 If the standard result still does not fall within limits, even after servicing, check the parameters in Appendix 1.

9.2.8 If all systems check out and are within limits, recalibrate the instrument.

9.2.9 Analysis of a Waste Sample - Place a sample boat on the analytical balance and tare it. Add 0.25 to 0.30 grams of the waste sample. On the data terminal click on the next open cell in the column for the SC 632. Then click again in the “Sample” box to type in sample identification. Click “enter.”

9.2.10 Click on “Weight” and type in the sample weight or use the weight transfer key on the balance to electronically transfer the weight.

9.2.11 At this point, ensure that there is not another boat already in the furnace.

9.2.12 Click on “Analyze.” The SC632 system will only respond with the "Push boat into furnace" message. When the "Push boat into furnace" prompt appears, open the oven door and gently push the boat into the furnace and all the way to the back of the tube with the boat puller. Immediately close the door and hit OK on the screen.

9.2.13 It will take approximately two minutes for the sample to be analyzed and the results will be displayed in the “Low Sulfur” column, in the “Sulfur, (%S)” column, and on the graph that appears at the bottom of the screen.

9.2.14 Most samples that are analyzed on the SC 632 will be low level samples and the result can be taken directly from the % sulfur column on the main screen, which will match the result in the low-level sulfur column. However, some samples will cause the low-level cell to become saturated and will be analyzed using the high-level cell. The result in the % sulfur column will then match the result found in the high sulfur column only if the high cell has been calibrated. It is necessary to view and evaluate the individual cell data confirm or rule out saturation.

9.2.15 To view and evaluate individual cell data, click on “sample” at the top of the screen, and then click on “properties.”

9.2.16 Check the name and weight to ensure it is the sample of interest.

9.2.17 If not, exit that window, and highlight the appropriate sample in the sample column to the left side of the screen then reenter the cell information window.

9.2.18 If the sample is correct, click on the “Low sulfur” tab. The low cell has saturated when the saturation indicator has a check mark in it. The sample weight can be reduced to 0.10 g to prevent low-level cell saturation and the need to calibrate the high-level cell.

9.2.19 If the sample cannot be analyzed at 0.10 g without saturating the low-level cell, then the high-level cell must be calibrated, and the sample must be reanalyzed and bracketed with high-level standards.

The distribution of printed or electronic copies of this document outside of the PAS electronic document management system (eDMS) is not controlled or tracked. PAS employees must ensure any copy used for daily work, if not accessed directly from PAS eDMS, is the current version of the document.

9.2.20 To ensure that the high-level cell is not saturated, hit the “High sulfur” tab and observe the saturation indicator for a highlight.

9.2.21 If a sample saturates the high-level cell, then the sample weight must be reduced, the high-level cell will have to be calibrated and the sample will have to be bracketed by high-level standards.

9.2.22 If the level of sulfur is so high that a 100% sulfur calibration must be used, use sample weights in the 0.01 to 0.05-gram range, just like the calibration weights.

9.2.23 When all samples have been analyzed (10 or fewer), analyze the final quality check standard.

9.2.24 If the final quality check standard is within limits, report the percent sulfur on the LIMS worksheet, then enter the results into LIMS.

9.2.25 For SC632 samples are manually posted at this time.

9.2.26 If a final quality check standard is out of limits, the sample data must be reanalyzed back to the last valid quality check standard.

9.2.27 Troubleshoot and service the instrument, including the reagent tubes. It may be necessary to analyze a couple of conditioning samples afterwards. Troubleshooting and service activity must be recorded in the instrument maintenance logbook including the problem, corrective action and results from recalibration or quality checks as well as the date and signature or initials of the analyst making the entry.

9.2.28 Reanalyze the quality check standard. If it meets acceptance criteria, reanalyze the remaining samples. If it still does not meet the acceptance criteria, then the system will have to be recalibrated.

9.2.29 Periodic Instrument Stabilization and Calibration – On a periodic basis (daily if the instrument is used daily), the stability of the instrument and its calibration must be verified by analyzing a sample of the certified coal standard that was used for calibration. The value determined for this standard must be within three standard deviations of the certified value.

9.2.30 The standard will be listed in the standards dialog box. Highlight “Verification” then follow steps 9.2.26-9.2.29.

9.2.31 If the system fails to meet this criterion, the system must be recalibrated and a verification check and quality check standard must meet requirements before analysis can proceed.

9.3 Data Reduction

9.3.1 Evaluate the calibration curve by plotting the instrument response against the standard concentration. Compute sample concentration by comparing sample response with the standard curve. Multiply answer by appropriate dilution factor.

9.3.2 Report only those values that fall between the lowest and the highest calibration standards. Samples that exceed the highest standard must be diluted and reanalyzed.

9.4 Instrument / Equipment Maintenance

9.4.1 Refer to instrument manual.

The distribution of printed or electronic copies of this document outside of the PAS electronic document management system (eDMS) is not controlled or tracked. PAS employees must ensure any copy used for daily work, if not accessed directly from PAS eDMS, is the current version of the document.

9.4.2 The analyst is responsible for performing daily and routine maintenance on all instrumentation and recording all information.

9.5 Troubleshooting

9.5.1 Refer to instrument manual as needed.

10.0 DATA ANALYSIS AND CALCULATIONS

See the Laboratory Quality Assurance Manual for equations for common calculations.

10.1 All calculations are completed by the data system for reportable data.

10.2 Data is rounded to two significant figures.

10.3 The established limits of the certified coal standards are taken from the manufacturer's stated precision limits printed on the bottle label. The ± number on the label is equal to 2 standard deviations. The limits of the daily standard are found by first dividing the label standard deviation by 2 then multiplying that number by 3. Plus or minus this number are the limits of that standard. Acceptable standards must fall in this range.

11.0 QUALITY CONTROL

The following QC samples are prepared and analyzed with each batch of samples.

Calibration Metric	Parameter / Frequency	Criteria	Comments
Initial Calibration Verification (ICV) (~1%)	Daily before any samples have been analyzed. Immediately after each initial calibration	% Diff ±10%	Second source single standard. Reanalyze once. If it still fails, recalibrate.
Continuing Calibration Verification (CCV) (~2%)	After every 10 samples and at the end of the analytical sequence.	% Diff ±10%	Second source single standard. Reanalyze once. If it still fails, recalibrate and reanalyze all samples after last passing CCV.

11.1 Batch:

11.1.1 Environmental samples that are prepared and/or analyzed together with the same process and personnel, using the same lot(s) of reagents. A preparation batch is composed of one to 20 environmental samples of the same NELAC-defined matrix, meeting the above-mentioned criteria and with a maximum time between the start of processing of the first and last sample in the batch to be 24 hours. An analytical batch is composed of prepared environmental samples (extracts, digestates or concentrates), which are analyzed together as a group.

11.2 Method Performance

11.2.1 Method Validation

The distribution of printed or electronic copies of this document outside of the PAS electronic document management system (eDMS) is not controlled or tracked. PAS employees must ensure any copy used for daily work, if not accessed directly from PAS eDMS, is the current version of the document.

11.2.1.1 **Detection Limits Not applicable**

11.2.2 Analyst Qualifications and Training

11.2.2.1 Employees that perform any step of this procedure must have a completed Read and Acknowledgment Statement for this version of the SOP in their training record. In addition, prior to unsupervised (independent) work on any client sample, analysts that prepare or analyze samples must have successful initial demonstration of capability (IDOC) and must successfully demonstrate on-going proficiency on an annual basis. Successful means the initial and on-going DOC met criteria, documentation of the DOC is complete, and the DOC record is in the employee's training file. Refer to laboratory SOP *Orientation and Training Procedures* (most current revision or replacement) for more information.

12.0 DATA REVIEW AND CORRECTIVE ACTION

12.1 Data Review

Pace's data review process includes a series of checks performed at different stages of the analytical process by different people to ensure that SOPs were followed, the analytical record is complete and properly documented, proper corrective actions were taken for QC failure and other nonconformance(s), and that test results are reported with proper qualification.

The review steps and checks that occur as employee's complete tasks and review their own work is called primary review.

All data and results are also reviewed by an experienced peer or supervisor. Secondary review is performed to verify SOPs were followed, that calibration, instrument performance, and QC criteria were met and/or proper corrective actions were taken, qualitative ID and quantitative measurement is accurate, all manual integrations are justified and documented in accordance with the Pace ENV's SOP for manual integration, calculations are correct, the analytical record is complete and traceable, and that results are properly qualified.

A third-level review, called a completeness check, is performed by reporting or project management staff to verify the data report is not missing information and project specifications were met.

Refer to laboratory SOP *Data Review Process* (most current revision or replacement) for specific instructions and requirements for each step of the data review process.

12.2 Corrective Action

Corrective action is expected any time QC or sample results are not within acceptance criteria. If corrective action is not taken or was not successful, the decision/outcome must be documented in the analytical record. The primary analyst has primary responsibility for taking corrective action when QA/QC criteria are not met. Secondary data reviewers must verify that appropriate action was taken and/or that results reported with QC failure are properly qualified.

Corrective action is also required when carryover is suspected and when results are over range.

Samples analyzed after a high concentration sample must be checked for carryover and reanalyzed if carryover is suspected. Carryover is usually indicated by low concentration detects of the analyte in successive samples analyzed after the high concentration sample.

The distribution of printed or electronic copies of this document outside of the PAS electronic document management system (eDMS) is not controlled or tracked. PAS employees must ensure any copy used for daily work, if not accessed directly from PAS eDMS, is the current version of the document.

Sample results at concentrations above the upper limit of quantitation must be diluted and reanalyzed. The result in the diluted samples should be within the upper half of the calibration range. Results less than the mid-range of the calibration indicate the sample was over diluted and analysis should be repeated with a lower level of dilution. If dilution is not performed, any result reported above the upper range is considered a qualitative measurement and must be qualified as an estimated value.

13.0 POLLUTION PREVENTION AND WASTE MANAGEMENT

Pace proactively seeks ways to minimize waste generated during our work processes. Some examples of pollution prevention include but are not limited to reduced solvent extraction, solvent capture, use of reusable cycletainers for solvent management, and real-time purchasing.

The EPA requires that laboratory waste management practice to be conducted consistent with all applicable federal and state laws and regulations. Excess reagents, samples and method process wastes must be characterized and disposed of in an acceptable manner in accordance with Pace's SOP *Waste Handling and Management* (most current revision or replacement).

14.0 MODIFICATIONS

A modification is a change to a reference test method made by the laboratory. For example, changes in stoichiometry, technology, quantitation ions, reagent or solvent volumes, reducing digestion or extraction times, instrument runtimes, etc. are all examples of modifications. Refer to Pace ENV corporate SOP ENV-SOP-CORQ-0011 *Method Validation and Instrument Verification* for the conditions under which the procedures in test method SOPs may be modified and for the procedure and document requirements.

Not applicable to this SOP.

15.0 RESPONSIBILITIES

Pace ENV employees that perform any part this procedure in their work activities must have a signed Read and Acknowledgement Statement in their training file for this version of the SOP. The employee is responsible for following the procedures in this SOP and handling temporary departures from this SOP in accordance with Pace's policy for temporary departure.

Pace supervisors/managers are responsible for training employees on the procedures in this SOP and monitoring the implementation of this SOP in their work area.

16.0 ATTACHMENTS

16.1 Attachment I - Maintenance for Leco Analyzer

16.2 Attachment II - Troubleshooting Matrix for Leco Analyzer

18.0 REVISION HISTORY

18.1 This Version: ENV-SOP-ASHE-0009-Rev.02

Section	Description of Change
7.0	Added new analyzer, LECO SC832DR
9.1	Reworded balance check process
11.0	Added ICV requirement "Daily before samples are analyzed."
All	Updated to newer formatting

This Document Supersedes the following documents(s):

Document Number	Title	Version
ENV-SOP-ASHE-0009	Determination of Sulfur in Waste Materials	02

The distribution of printed or electronic copies of this document outside of the PAS electronic document management system (eDMS) is not controlled or tracked. PAS employees must ensure any copy used for daily work, if not accessed directly from PAS eDMS, is the current version of the document.

Attachment 1

Maintenance for LECO Analyzer

1. If the reagent tubes material becomes moist during analysis, it will form a cake or crust on the surface, causing the gas flow through them to become severely hampered, causing poor instrument performance. A typical symptom of this is when the low concentration cell begins to saturate at concentration levels that previously did not saturate. The material in the tube needs to be changed. Also, if the reagent tube packing has become severely blackened and fouled by high carbon samples, the system response can be affected.

    1.1. Procedure: Slightly lift the reagent tube and remove it by pulling it out to the side. If the magnesium perchlorate packing material has moisture, caking or black soot accumulation, dump it out in an appropriate waste container.

    1.2. Inspect the O-rings on their metal seats for any obvious signs of damage.

    1.3. Use a small screwdriver or other tool to gently remove the O-rings from their seats. Do not damage them.

    1.4. Inspect for cuts or gouges. If they have no damage, they can be cleaned and reused. If they are damaged, they must be discarded and replaced.

    1.5. Use acetone and a cotton swab to clean the metal seats. Also use acetone and a cloth to clean the O-rings.

    1.6. Apply a thin coat of vacuum grease to the O-rings before placing them back in their seats.

    1.7. Remove the glass wool at the bottom of the reagent tube. Proceed to clean the reagent tube with acetone and a cloth.

    1.8. Replace the glass wool with approximately 0.5 inches of glass wool. Fill the space but do not pack it tightly. (The glass wool is at the bottom of the reagent tube)

    1.9. Refill the reagent tube with anhydrous magnesium perchlorate and reinstall the reagent tube, being careful not to get reagent dust under the O-ring and cause a gas leak.

2. A fouled disposable filter can become clogged, causing poor gas flow. Replace the filter when it turns gray, or the flow has become restricted.

    2.1. A fouled disposable filter can cause restricted flow.

    2.2. Unscrew the adapter.

    2.3. Ream out the adapter with the adapter brush and reinstall the reagent tube.

If a detector cell is not functioning properly, or a temperature is not at its set point, poor instrument performance can result. Ensure that the following parameters are at their set points by entering, “Tools” and “Diagnostics”. See Appendix 1 for Parameters.

The distribution of printed or electronic copies of this document outside of the PAS electronic document management system (eDMS) is not controlled or tracked. PAS employees must ensure any copy used for daily work, if not accessed directly from PAS eDMS, is the current version of the document.

Attachment:2

Troubleshooting Matrix for LECO Analyzer

Error	Source	Problem	1.1. Action
Gas flow	Parameters	Low gas flow	Check flow rates and adjust if necessary.
	Tanks	No gas flow	Check gauges and replace tanks (PSI 60).
	Adaptor	Low gas flow	Remove and clean with adapter brush.
	Reagent Tube	Low gas flow: Moisture	Replace reagent tube materials.
	Disposable filter	Low gas flow	Check filter, if clogged (gray) replace.
Low Recovery Broad Tail	Outer Combustion Tube (OCT)	Leak: cracked tube Front O-ring	Replace Outer Combustion Tube. Reconnect or Replace.
	Inner Combustion Tube (ICT)	Leak: cracked tube ICT O-ring	Replace Inner Combustion Tube. Reconnect or Replace.
	Reagent Tubes	Leak	Replace 0-rings.
	Parameters	Poor Performance	Check Diagnostics reset if needed.
	Saturated IR Cell	Loss of Sulfur Dioxide	Reduce sample weight and reanalyze.
	Balance	Improper technique	Calibrations of scales.
High Recovery	Operator	Improper technique Contamination Concentrated samples	Proper use of scales. Use clean boat and clean standards. Run quality check standards frequently.
	Reagent Tube	Contamination	Clean reagent tubes and replace reagent tube materials.

The distribution of printed or electronic copies of this document outside of the PAS electronic document management system (eDMS) is not controlled or tracked. PAS employees must ensure any copy used for daily work, if not accessed directly from PAS eDMS, is the current version of the document.

Attachment: 3

Instrument Parameters for LECO SC Analyzer

1. Oxygen inlet pressure: 35 psi
2. Oxygen flow: 3.5 lpm
3. Analyze flow: 2.5 lpm
4. Lance flow: 1.0 lpm
5. Low IR cell (gain): >1.5 V
6. High IR Cell (gain): >1.5 V
7. Furnace temperature: 1350° C (±25)
8. Oven temperature: 48° C (±2)

Note: Do not attempt to obtain a calibration if one or more of these voltages have drifted out of range. The check standards will not meet limits. The instrument software will alarm if these voltages drift out of tolerable range.

The distribution of printed or electronic copies of this document outside of the PAS electronic document management system (eDMS) is not controlled or tracked. PAS employees must ensure any copy used for daily work, if not accessed directly from PAS eDMS, is the current version of the document.

TEST METHOD STANDARD OPERATING PROCEDURE

TITLE:	DETERMINATION OF CALORIFIC VALUE (BTU/LB) OF WASTE MATERIALS USING A PARR 6300/6400 OXYGEN BOMB CALORIMETER
TEST METHOD	ASTM Method D 5468-95, Standard Test Method for Gross Calorific and Ash Value of Waste Materials.
ISSUER:	Pace ENV – Asheville– ASHE

COPYRIGHT © 2020 Pace Analytical Services, LLC

1.0 SCOPE AND APPLICATION

1.1 Target Analyte List and Limits of Quantitation (LOQ)

No Method Detection Limit (MDL) is performed for this test.

LOQ are established in accordance with Pace policy and SOPs for method validation and for the determination of detection limits (DL) and quantitation limits (LOQ). DL and LOQ are routinely verified and updated when needed.

The reporting limit (RL) is the value to which analytes are reported as detected or not detected in the final report. When the RL is less than the lower limit of quantitation (LLOQ), all detects and non-detects at the RL are qualitative. The LLOQ is the lowest point of the calibration curve used for each target analyte.

DL, LOQ, and RL are always adjusted to account for actual amounts used and for dilution.

Practical Quantitation Limit (PQL) = 50 BTU/lb (British Thermal Units)

1.2 The purpose of this method is to determine calorific value of waste materials.

1.2.1 Personnel: The policies and procedures contained in this SOP are applicable to all personnel involved in the analytical method.

1.2.2 Parameters: This adaptation of ASTM Method D 5468-95 describes the determination of the gross calorific value of waste materials by isoperibol (isothermal jacket) bomb calorimetry using the Parr 6300 /6400 bomb calorimeter.

1.2.3 The results from this analysis are used to establish suitability and feed rates for burning waste materials.

1.2.4 This method is not included under the Laboratory NELAC Accreditation

1.3 Applicable Matrices

1.3.1 The purpose of this method is to determine calorific value of waste materials.

2.0 SUMMARY OF METHOD

2.1 Calorific value is determined in this method by burning a weighed sample in oxygen under controlled conditions, in a calibrated calorimeter. The calorimeter is the isoperibol type and is calibrated by burning a specified amount of benzoic acid. The calorific value of the test sample is computed from temperature observations made before, during and after combustion and making proper allowances for heat contributions from other processes.

3.0 INTERFERENCES

Any printed copy of this SOP and all copies of this SOP outside of Pace are uncontrolled copies.
Uncontrolled copies are not tracked or replaced when new versions are released, or the SOP is made obsolete.
Users of the SOP should verify the copy in possession is the current version of the SOP before use.

COPYRIGHT © 2020 Pace Analytical Services, LLC

3.1 The balance must be capable of weighing to the nearest 0.0001 g and must be checked for accuracy at the beginning of each day that calorimetric tests are to be conducted.

3.2 Weight determination in this analysis is critical. All crucibles must be clean and dry before weighing the sample(s).

3.3 Contamination by residual materials on the crucible, or within the bomb, can cause error in the Btu value.

3.4 For reproducibility of results, the sample needs to be homogeneous.

3.5 Ensure that the correct heat of combustion is used for all combustion aid spikes.

3.6 Any standard that is used must not absorb water, or it is stored with a desiccant. Error can occur from weight fluctuations and/or varying BTU values.

3.7 All fusing must be sized according to manufacturer specifications and have the correct Btu value for its length and weight. This correction factor is permanently set into the instrument, and any deviation from that amount of fuse will cause error in the BTU result.

3.8 The formation of nitric acid during an analysis produces an appreciable amount of heat, which can cause error. This heat is produced in every analysis because of the nitrogen present. The corresponding Btu can be set as a correction factor in the instrument and is consistent in every analysis.

3.9 Care must be taken to ensure that complete combustion has occurred. If not, large error can occur in the BTU value. This analysis will tolerate as much as 20% moisture in a sample and still permit complete combustion. If the sample does not burn completely, it will require a catalyst to aid in combustion.

3.10 All instrument sensors, if not functioning properly, can cause error, particularly the temperature sensors. If the water temperature in the reservoir is not maintained properly then error will occur. The instrument software is designed to monitor these parameters and flag them if an error occurs.

3.11 First, check the oxygen supply pressure (see that the regulator is set to appropriate pressure of 450 psi.) and replace a cylinder if required. Check your oxygen supply pressure is ok.

3.12 Some samples can be corrosive to the rubber seals in the bomb, so check the condition of, and replace if necessary, the quad-ring or the bomb release piston and seal O-rings.

3.13 If the daily calibration verification benzoic acid standard fails to meet limits, the most common reason is a bad seal at the bomb lid quad ring. Accumulation of residual waste at this seal can create a leak that will not show as a low oxygen error message, but it will prevent the instrument from passing the daily calibration verification standard analysis limits.

3.13.1 Remove the bomb lid and remove the rubber quad ring seal from its polished brass seat at the top of the bomb.

3.13.2 Replace the ring with a new one.

3.13.3 Clean the brass surface at the top of the open bomb, with acetone to remove the heavy residual accumulation. Use Crocus cloth to polish the brass surface. Scrub the entire surface with the cloth until the entire surface has a shiny luster.

COPYRIGHT © 2020 Pace Analytical Services, LLC

3.14 All water needs to be wiped off the firing wire and electrodes before every analysis. If not, the cotton fuse will fail to ignite, and the analysis will fail. Also, for consistent results, the bomb and lid need to be dried before each analysis.

3.15 The bomb calorimeter is intended for use indoors between 20 – 30℃ with relative humidity between 20%-80%.

3.16 Avoid making any changes to the oxygen supply pressure after the instrument has been calibrated. This will change the pressure of the oxygen in the bomb during analysis, and will void the calibration. The pressure of the oxygen will not exceed 450 psi.

3.17 "Fuse misfire" error message is given in the display when the firing did not occur during analysis. Some main causes of this error are:

3.18 Sample has water in it (This will require a catalyst to aid in combustion).

3.19 Fuse thread has become unattached (replace with new one).

3.20 Fuse thread has moisture on it (replace with new one).

3.21 Fuse wire is burnt in two & needs to be replaced.

3.22 The "water diffuser screw" located underneath the bracket holder is loose and will need to be tightened.

4.0 DEFINITIONS

Refer to the Laboratory Quality Manual for a glossary of common lab terms and definitions.

5.0 HEALTH AND SAFETY

Standards and Reagents: The toxicity and carcinogenicity of standards and reagents used in this method have not been fully defined. Each chemical compound is treated as a potential health hazard. Reduce exposure by the use of gloves, lab coats and safety glasses. Safety Data Sheets (SDSs) are on file in the laboratory and available to all personnel. Standard solutions are prepared in a hood whenever possible.

Samples: Take precautions when handling samples. Samples are always treated as potentially hazardous "unknowns". The use of personal protective equipment (gloves, lab coats and safety glasses) is required when handling samples. In the event a sample container must be opened, it is recommended to perform this in a hood whenever possible.

Manufacturer operating instructions and guidelines for the Parr calorimeter shall be followed at all times.

The maximum mass of sample allowed for combustion is 1.5 grams. The bomb chamber could possibly explode if this mass is exceeded.

The pressure of the oxygen supply shall not exceed 450 psi. This pressure allows for a consistent oxygen pressure in the bomb chamber of 30 atm per analysis.

COPYRIGHT © 2020 Pace Analytical Services, LLC

Exercise caution when working with and around the oxygen supply line. It is made of plastic and could pose a hazard when pinched or cut. (The line is rated to 1000 psi.).

Inspect the bomb parts carefully after each use. All O-rings are to be replaced according to manufacturer specifications after 500 firings. After 500 firings the instrument software will give an alarm of "Exceeds bomb firing Count". Once routine maintenance is performed you will need to reset bomb firing counter.

Oxygen supply cylinders are to be equipped with approved regulators (300 to 500 psi discharge pressure).

To avoid damage to the instrument or bodily injury, do not fire loose fluffy material, or powdered samples unless thoroughly mixed with a combustion aid (mineral oil).

During ignition of a sample, the operator must not permit any portion of the operator's body to extend over the calorimeter.

Use extreme caution not to exceed the bomb manufacturer's recommended calorie limit of 8000 calories when using combustion aids, to avoid damage to the instrument or bodily injury.

Normal laboratory safety practices are to be observed at all times. Always wear proper PPE.

The Parr 6400/6300 is equipped with a bomb washings reservoir, which has to be emptied. This waste and all other sample waste are to be disposed of in accordance with laboratory policy.

6.0 SAMPLE COLLECTION, PRESERVATION, HOLDING TIME, AND STORAGE

6.1 The laboratory does not perform sample collection for this test method. To assure sample collection and field checks and treatment are performed in accordance with applicable regulations Pace project managers will inform the client of these requirements at the time of request for analytical services when the request for testing is received prior to sample collection. If samples were already collected, the laboratory will record any nonconformance to these requirements in the laboratory's sample receipt record when sufficient information about sample collection is provided with the samples.

6.2 The laboratory will provide containers for the collection of samples upon client request for analytical services. Bottle kits are prepared in accordance with laboratory, *Bottle Preparation* (most current revision or replacement).

6.3 Requirements for container type, preservation, and field quality control (QC) for the common list of test methods offered by Pace are included in the laboratory's quality manual.

General Requirements

Matrix	Routine Container	Minimum Sample Amount	Preservation	Holding Time
Solids	Glass bottle – cleaned and rinsed with reagent water	4/8 oz	above zero to 6.0 ºC	There are no holding time requirements for this method.

6.3.1 Thermal preservation is checked and recorded on receipt in the laboratory in accordance with laboratory SOP, *Sample Management* (most current revision or replacement).

COPYRIGHT © 2020 Pace Analytical Services, LLC

6.3.2 After receipt, samples are stored at ≤6°C until sample preparation (but not allowed to freeze).

6.3.3 After analysis, unless otherwise specified in the analytical services contract, samples are retained for 45 days from receipt and then disposed of in accordance with Federal, State, and Local regulations.

6.3.4 Note: Samples are to be stored separately from all standards, reagents, and highly contaminated samples. To avoid contamination, no food or drink products can be located near samples.

6.3.5 Care must be taken to eliminate the possibility of contamination during collection, transport, storage and analysis of samples. Samples stored in the lab must be kept separate from standards.

6.3.6 Sample Storage – Before transferring the portion of the sample to be ashed, to the evaporating crucible, take particular care to ensure that the portion taken is truly representative of the larger portion. Vigorous shaking could be necessary.

7.0 EQUIPMENT AND SUPPLIES

7.1 Equipment and Supplies

Supplies*	Manufacturer*/Vendor	Model/Version	Catalog#	Description/Comments*
Isoperibol (Isothermal-Jacket) Bomb Calorimeter	Parr	Parr 6400 and 6300	N/A	meets all criteria in ASTM Method D5468- 95

9.0 PROCEDURE

9.1 Calibration and Standardization – N/A

9.1.1 NOTE: The "Clear Entry" key can be used to clear error messages due to incorrect operations; do not press "Reset" with a sample loaded in the bomb calorimeter. This procedure is used in the setup of a new instrument or if a major change has been made to the instrument. Use "Parr benzoic acid tablets" to calibrate.

9.1.2 To "calibrate" the bomb calorimeter is to determine the heat capacity of the bomb and its components by burning a standard material with a known heat of combustion. This "heat capacity" or "energy equivalent" of the instrument is used in the calculation of the heat of combustion of all samples. Benzoic acid is used for this purpose.

9.1.2.1 Determine the initial heat capacity of a new bomb as the average of a minimum of 6 individual runs made over a period of not less than 3 days or more than 5 days. To be acceptable for high precision work, the relative standard deviation of the series shall be 0.15% or less. Any individual test may be discarded only if there is evidence of incomplete combustion. If this limit is not met, the entire series shall be repeated until a series is obtained with a relative standard deviation below the acceptable limit.

9.1.3 All crucibles made of base-metal alloys must be thoroughly heat treated before using for analysis, by baking in an oven for 4 hours at 500oC. If metal crucibles are not thoroughly oxidized, error in BTU measurement can occur.

9.1.4 The Parr cotton fuse must be prepared before any calorimeter analyses can be carried out.

9.1.4.1 Use precut thread.

COPYRIGHT © 2020 Pace Analytical Services, LLC

9.1.5 Each tablet of benzoic acid is to be weighed, to the nearest 0.0001 g, in the crucible in which it will be burned, on each day of use.

9.1.6 The calorimeter is the isoperibol type, which means that the calorimeter jacket temperature is maintained constant throughout the analysis. The instrument software calculates a temperature correction for the system to allow for any heat lost by the jacket.

9.1.6.1 The calculation for the corrected temperature rise is as follows:

$$t = t_c - t_a + C_r$$

Where: t = corrected temperature rise, °C

ta = initial temperature reading at time of firing

tc = final temperature reading

Cr = temperature correction

9.1.6.2 The calculations and Thermochemical corrections used by the instrument software, for the heat capacity of the bomb, are as follows:

$$E = [(H_c m) + e_1 + e_2] / t$$

Where: E = calorimeter heat capacity or energy equivalent

Hc = known heat of combustion of benzoic acid, cal/g.

M = mass of benzoic acid, g.

e1 = correction for heat of formation of nitric acid, 10 cal.

e2 = correction for heat of combustion for the fuse, 50 cal.

T = corrected temperature rise, °C.

9.1.7 The software keeps 10 heat capacity values in memory and uses the average of them in the calculation.

9.1.7.1 From “Main Menu”, arrow to “Calorimeter Operation” and press “Enter”. “Bomb Installed/EE”, is the current bomb configuration and current energy equivalent average being used by the calorimeter. The bomb configuration (#1) stays the same all the time since the instrument is recalibrated if a change is made with the bomb. The minimum number of average values that may be used is 10.

9.1.8 It is necessary to have all Thermochemical corrections in place before attempting to calibrate the instrument. The heats of combustion for the fuse (50 cal/g) and the formation of nitric acid (10 cal/g) must be entered in the system; however, a correction for the formation of sulfuric acid is not required here. Benzoic acid has no sulfur. This may be required later for a sample that has been found to contain a significant amount of sulfur.

9.1.8.1 To enter the Thermochemical corrections into the instrument, observe the instrument command screen.

COPYRIGHT © 2020 Pace Analytical Services, LLC

9.1.8.1.1 At "Main Menu", arrow down to "Thermochemical Corrections" and press "Enter".

9.1.8.1.2 All selections on this page are to be set "ON", except "Calculate Net Heat of Combustion". This selection is turned "OFF".

9.1.8.1.3 Enter the values for "Fixed Fuse Correction" and "Fixed Acid Correction" (50 cal/g and 10 cal/g, respectively) for both Standardization and Determination sections. Use the arrow keys to move through the table. When the value to be changed is highlighted, press "Skip". Type in the new value and press "Enter". Once these values have been entered into the system, they will default and won't need to be entered again.

9.1.9 "Escape" back to "Main Menu.

9.1.10 Arrow to "Calorimeter Operations" and press "Enter".

9.1.11 Operation Mode is set on "STD" by pressing the "Yes" button.

9.1.12 Arrow to "Heater and Pump". Turn "On" by pressing "Yes".

9.1.13 Allow instrument to warm up approximately 10-15 min. The Jacket temperature will be 30°C ± 1.05.

9.1.14 Press "Start the pretest." This initiates an instrument self-test, in which the instrument will go through the entire analysis process with the exception of actually firing. This ensures that all parameters are correct, and that the system is ready for use. When "Idle" is displayed analysis can proceed.

9.1.15 Place bomb head on rack.

9.1.16 Remove crucible from balance and place in crucible holder of the bomb head.

9.1.17 Attach a fuse thread to the firing wire. Using tweezers, lift benzoic acid tablet and place thread underneath to insure proper ignition.

9.1.18 Place the bomb head in the bucket turning clockwise.

9.1.19 Close lid.

9.1.20 When the analysis has finished the software will generate a heat capacity for the bomb (EE).

9.1.21 Press "Start"

9.1.22 "Bomb ID" will appear on screen this defaults to 1 or 2 depending on the bomb you are using, press "Enter".

9.1.23 "Sample ID" will appear on screen. This defaults to the next sequence number. You may press "Enter" at this point or type in your own 4-digit ID.

9.1.24 The instrument will prompt for sample weight. At this point, place a clean, dry sample crucible on scales. Zero. Add a Parr benzoic acid tablet

9.1.25 Press "Enter" to automatically enter weight or press "Skip" to enter weight manually.

9.1.26 The instrument will prompt to enter a spike weight. Press "Skip" to bypass this option and "Enter"

9.1.27 Open instrument lid. Remove bomb head by turning counterclockwise and lifting.

COPYRIGHT © 2020 Pace Analytical Services, LLC

9.1.28 A total of ten benzoic acid tablet analysis runs must be done within a 3-5-day period. These runs will be averaged by the instrument software. The RSD for the runs must not exceed 0.15% difference. If this limit is not met, the cause of the high standard deviation in the calibration series must be found and corrected and the calibration procedure repeated.

9.1.29 If a major component of the bomb or calorimeter is changed, the above process will need to be repeated to ensure appropriate calibration.

9.1.30 The calibration is checked once per month by running a second source benzoic acid tablet (Parr). This check must be within 1% of true value.

9.1.31 To clear Memory:

9.1.31.1 Press “CLEAR MEM.” Key

9.1.31.2 At the “From ID” prompt, enter the beginning ID number of the data to be cleared and press “Enter”.

9.1.31.3 At the “To ID” prompt, enter the ending ID number of the data to be cleared and press “Enter”. (To clear only one data point ID, enter the same number at both prompts.)

9.1.31.4 Instrument will indicate the data has been cleared.

9.1.32 After a proper calibration is in place, a study must be conducted to establish heat combustion for all spiking materials.

9.1.33 Analyze mineral oil as a sample, using 0.5-0.7g. Ensure that at least 6000 calories are generated. If the total calorie count is less than 6000, increase the sample size and repeat the analysis until the 6000-calorie minimum is achieved.

9.1.34 Analyze a total of 10 and average the Btu/lb values to obtain the heat of combustion for the spike.

9.2 Sample Preparation

9.2.1 Batch samples in groups of 20 or less using the associated A-code in EpicPro.

9.2.2 After selecting the samples, click the “Build Batch” button. This will put the sample in a unique Batch with its own Batch number and default QC samples with their own QC number IDs. If necessary, add QC by using the “Add QC” button. The cursor must be on a particular sample to add a DUP.

9.2.3 Deleting QC or samples is done by putting the cursor on what you want to delete and clicking the red “Delete Record” button in the Toolbar Menu. Press “F10” (save) when all is done. Print the newly created Batch Work list report using the Print button in the EpicPro toolbar. Select “All” for all pages to print.

9.2.4 Print the Batch Compound report for the analyst by going “System” > “Submit Job” > “F9” > “Batch Compound List” > “Enter” or “OK” > Select “WETA” as Queue and enter the Batch number > “F10”. Print using the Print command in the EpicPro toolbar, select “All” > “OK”. This will give the analyst a report of analytes to report per sample.

9.2.5 Pull samples from storage refrigerator.

9.3 Sample Procedure

COPYRIGHT © 2020 Pace Analytical Services, LLC

9.3.1 A daily Benzoic acid standard must be analyzed as a calibration verification at the beginning and end of each run. Calibration verification must also be run every 10 runs.

9.3.1.1 Use a Parr tablet for the daily calibration

9.3.1.2 Use a LECO table for the monthly calibration

9.3.2 The following procedure can be used to run the daily calibration verification as well as samples.

9.3.2.1 Arrow to “Calorimeter Operations” and press “Enter.

9.3.2.2 Operation Mode is set on “DETR” by pressing the “Yes” or “No” buttons.

9.3.2.3 Arrow to “Heater and Pump”. Turn “On” by pressing “Yes”.

9.3.2.4 Allow instrument to warm up approximately 10-15 min. The Jacket temperature is 30 °C ± 1.05.

9.3.3 Press “Start the pretest”.

9.3.3.1 This initiates an instrument self-test, in which the instrument will go through the entire analysis process with the exception of actually firing. This ensures that all parameters are correct, and that the system is ready for use. When “Idle” is displayed, analysis can proceed.

9.3.4 Analysis

9.3.4.1 Press “Start”.

9.3.4.2 Enter the Spike weight

9.3.4.3 Weight the sample and place it in the bomb head.

9.3.4.4 Enter the information into the instrument and follow the steps below

9.3.4.5 Press "Enter” to automatically enter weight or press “Skip” to enter weight manually.

9.3.4.6 The instrument will prompt for a spike weight. Press “Skip” to bypass this option or, if adding a spike, zero the balance. Add appropriate amount of spike to the sample and press “Enter”.

9.3.4.7 Open instrument lid. Remove bomb head by turning counterclockwise and lifting.

9.3.4.8 Place bomb head on rack.

9.3.4.9 Remove crucible from balance and place in crucible holder of the bomb head.

9.3.4.10 Attach a fuse thread to the firing wire. Make sure fuse thread is touching the sample to ensure proper ignition.

9.3.4.11 Place the bomb head in the bucket turning clockwise.

9.3.4.12 Close lid. The analysis will start automatically.

9.3.4.13 When analysis has finished, the software will generate a heat of capacity for the bomb (EE).

9.3.5 Two criteria determine whether the results of an analysis can be accepted.

COPYRIGHT © 2020 Pace Analytical Services, LLC

9.3.5.1 The sample must have completely combusted, leaving nothing but moisture and in some cases, a small amount of dark ash.

9.3.5.2 The sample must also have produced a temperature rise of at so that the calorie count is in the acceptable range of the instrument calibration.

9.3.5.2.1 Temp rise limits

9.3.5.2.1.1 6300 is 7.5-11°C

9.3.5.2.1.2 6400 is 5.1-8.5°C

9.3.5.3 If the above criteria are met, then the Btu/lb value of the sample can be reported as valid.

9.3.5.4 If not, either the sample must be reanalyzed using a larger sample size or the sample must be spiked. Use the following equations to evaluate the next analysis procedure.

9.3.6 Once you are finished using the instrument for the day, press the “No” key to turn off the heater and pump.

9.3.7 Check the waste reservoir underneath the cabinet and if it needs to be emptied, do so at this time.

9.4 Instrument / Equipment Maintenance

9.4.1 Refer to instrument manual.

9.4.2 The analyst is responsible for performing daily and routine maintenance on all instrumentation and recording all information.

9.4.3 Daily

9.4.3.1 Clean Small Quad Ring

9.4.3.2 Clean Electrode pins

9.4.3.3 Clean Bomb head seal

9.4.3.4 Verify glycerin correction factor and record on bench sheet.

9.4.4 Monthly

9.4.4.1 Clean, remove, and inspect Cylinder, and Sealing area in Cylinder

9.4.4.2 Wet the hole in the center of the head

9.4.4.3 Refill rinse tank

9.4.4.4 Clean electrode contact points

9.4.4.5 Inspect critical bomb head O-rings

9.4.4.6 ICV monthly QC Check (LECO -Benzoic Acid Tablet)

9.4.4.7 Inspect all tubing and wiring

9.4.4.8 Replace ignition wire

9.4.4.9 500 Count Maintenance

9.5 Troubleshooting

COPYRIGHT © 2020 Pace Analytical Services, LLC

9.5.1 Refer to instrument manual as needed and attachment II.

10.0 DATA ANALYSIS AND CALCULATIONS

10.1 See the Laboratory Quality Assurance Manual for equations for common calculations.

10.2 The following calculation can be used to help in determining the amount of spike needed for spiking a sample.

10.2.1 Calculate Calories/gram = (BTU/lb) x (0.56).

10.2.2 Calculate Total Calories = (Calories/gram) x (g sample).

10.2.3 Estimate the calorie output if the sample size was increased to the limit of 1.1 grams: Calories = (Calories/gram) x (1.1 g sample).

10.2.4 If it is estimated that this weight would give 6000 calories or more, proceed to prepare another sample at this weight and reanalyze.

10.2.5 If increasing the sample size is not expected to produce the necessary calorie count, the sample will have to be spiked with a combustion aid (mineral oil).

10.2.6 After determining the total calories from 0.7 g of sample, estimate the amount of mineral oil spike, which will have to be added to the sample to obtain the necessary 6000 calories using the following equations.

10.2.6.1 Calories required from spike = 6000 – Total Calories from sample.

10.2.6.2 Spike weight = 0.00009 x Calories required from spike.

10.2.6.3 Use caution when calculating the spike weight. Do not exceed 1.1g total weight limit or the calorie limit of 8000 calories.

10.2.7 Repeat the analysis procedure starting at Section 9.3.4.

10.2.8 If the acceptance criteria stated in Section 9.3.5 are met, the Btu/lb value can be reported. If not, repeat the analysis with a slightly higher spike weight until the criteria is met, being careful not to exceed the 1.1g total weight!

10.2.8.1 Calculation Example: 8842.1074 (BTU value) x 0.56 = 4912 x 0.7052 (sample weight) = 3464 (number of calories produced).

10.2.8.2 6000 (calories needed) – 3464 (calories produced) = 2536 (how many more calories are needed). 2536 x 0.00009 = (gram of spike needed).

10.3 The calculation used by the instrument software to obtain the heat of combustion of a sample is as follows:

10.3.1 Qg = Gross calorific value (heat of combustion) in BTU/lb.

10.3.2 Corrected temperature change in calorimeter degrees C.

10.3.3 Heat capacity or energy equivalent of the calorimeter in cal / degrees C.

10.3.4 Thermochemical correction for the formation of nitric acid, (10 cal/g) x (g HNO3); this correction is considered a constant value for every analysis.

COPYRIGHT © 2020 Pace Analytical Services, LLC

10.3.5 Thermochemical correction for the combustion of the fuse thread, (50 cal/g) x (g fuse thread); this correction is considered a constant value for every analysis.

10.3.6 Thermochemical correction for use of spiking material, (heat of combustion of spiking material) x (g spiking material).

11.0 QUALITY CONTROL

11.1 QC sample, components, frequency, acceptance criteria and corrective action.

QC Sample	Components	Frequency	Acceptance Criteria	Corrective Action
Sample Duplicate	Sample	Two per batch of 20 samples.	RPD ≤10%	Report results with appropriate footnote.
Continuing Calibration Verification (CCV)	Benzoic Acid Tablet	At start of run, every 10 runs (excluding misfires), and after last sample.	99% to 101% of True Value. TV = 11373	Rerun once. If rerun does not pass. Perform maintenance and recalibrate.
Initial Calibration Verification (ICV)	Benzoic acid table from second source.	Monthly	99% to 101% of True Value. TV = 11373	Rerun once. If rerun does not pass. Perform maintenance and recalibrate.

11.2 Batch:

11.2.1 Environmental samples that are prepared and/or analyzed together with the same process and personnel, using the same lot(s) of reagents. A preparation batch is composed of one to 20 environmental samples of the same NELAC-defined matrix, meeting the above-mentioned criteria and with a maximum time between the start of processing of the first and last sample in the batch to be 24 hours. An analytical batch is composed of prepared environmental samples (extracts, digestates or concentrates), which are analyzed together as a group.

11.3 Sample Concentration:

11.3.1 Not applicable

11.4 Method Performance

11.4.1 Method Validation

11.4.1.1 **Detection Limits Not applicable**

11.4.2 Analyst Qualifications and Training

COPYRIGHT © 2020 Pace Analytical Services, LLC

Employees that perform any step of this procedure must have a completed Read and Acknowledgment Statement for this version of the SOP in their training record. In addition, prior to unsupervised (independent) work on any client sample, analysts that prepare or analyze samples must have successful initial demonstration of capability (IDOC) and must successfully demonstrate on-going proficiency on an annual basis. Successful means the initial and on-going DOC met criteria, documentation of the DOC is complete, and the DOC record is in the employee's training file. Refer to laboratory SOP *Orientation and Training Procedures* (most current revision or replacement) for more information.

12.0 DATA REVIEW AND CORRECTIVE ACTION

12.1 Data Review

Pace's data review process includes a series of checks performed at different stages of the analytical process by different people to ensure that SOPs were followed, the analytical record is complete and properly documented, proper corrective actions were taken for QC failure and other nonconformance(s), and that test results are reported with proper qualification.

The review steps and checks that occur as employee's complete tasks and review their own work is called primary review.

All data and results are also reviewed by an experienced peer or supervisor. Secondary review is performed to verify SOPs were followed, that calibration, instrument performance, and QC criteria were met and/or proper corrective actions were taken, qualitative ID and quantitative measurement is accurate, all manual integrations are justified and documented in accordance with the Pace ENV's SOP for manual integration, calculations are correct, the analytical record is complete and traceable, and that results are properly qualified.

A third-level review, called a completeness check, is performed by reporting or project management staff to verify the data report is not missing information and project specifications were met.

Refer to laboratory SOP *Data Review Process* (most current revision or replacement) for specific instructions and requirements for each step of the data review process.

12.2 Corrective Action

Corrective action is expected any time QC or sample results are not within acceptance criteria. If corrective action is not taken or was not successful, the decision/outcome must be documented in the analytical record. The primary analyst has primary responsibility for taking corrective action when QA/QC criteria are not met. Secondary data reviewers must verify that appropriate action was taken and/or that results reported with QC failure are properly qualified.

Corrective action is also required when carryover is suspected and when results are over range.

Samples analyzed after a high concentration sample must be checked for carryover and reanalyzed if carryover is suspected. Carryover is usually indicated by low concentration detects of the analyte in successive samples analyzed after the high concentration sample.

Sample results at concentrations above the upper limit of quantitation must be diluted and reanalyzed. The result in the diluted samples should be within the upper half of the calibration range. Results less than the mid-range of the calibration indicate the sample was over diluted and analysis should be repeated with a lower level of dilution. If dilution is not performed, any

COPYRIGHT © 2020 Pace Analytical Services, LLC

result reported above the upper range is considered a qualitative measurement and must be qualified as an estimated value.

13.0 POLLUTION PREVENTION AND WASTE MANAGEMENT

13.1 Pace proactively seeks ways to minimize waste generated during our work processes. Some examples of pollution prevention include but are not limited to reduced solvent extraction, solvent capture, use of reusable cycletainers for solvent management, and real-time purchasing.

13.2 The EPA requires that laboratory waste management practice to be conducted consistent with all applicable federal and state laws and regulations. Excess reagents, samples and method process wastes must be characterized and disposed of in an acceptable manner in accordance with Pace's SOP *Waste Handling and Management* (most current revision or replacement).

14.0 MODIFICATIONS

14.1 A modification is a change to a reference test method made by the laboratory. For example, changes in stoichiometry, technology, quantitation ions, reagent or solvent volumes, reducing digestion or extraction times, instrument runtimes, etc. are all examples of modifications. Refer to Pace ENV corporate SOP ENV-SOP-CORQ-0011 *Method Validation and Instrument Verification* for the conditions under which the procedures in test method SOPs may be modified and for the procedure and document requirements.

14.2 Not applicable to this SOP.

15.0 RESPONSIBILITIES

15.1 Pace ENV employees that perform any part this procedure in their work activities must have a signed Read and Acknowledgement Statement in their training file for this version of the SOP. The employee is responsible for following the procedures in this SOP and handling temporary departures from this SOP in accordance with Pace's policy for temporary departure.

15.2 Pace supervisors/managers are responsible for training employees on the procedures in this SOP and monitoring the implementation of this SOP in their work area.

18.0 REVISION HISTORY

18.1 This Version: ENV-SOP-ASHE-0015-Rev.03

Section	Description of Change
3.5 and 9.1.41	Removed Reference to Cellulose Tape
3.13	Subordinated Steps following this.
7.1	Clarified crucible composition
8.1	Adjusted formatting
9.1.30-35	Removed calibration and calibration check that did not follow current practice.
9.3.1	Added statement that calibration verification must be run every 10 runs.
11.1	Added QC table
Attachment I	Removed Attachment I: Running Volatile Samples

18.2 This document supersedes the following document(s):

Attachment I

Routine Alarms and Troubleshooting

1. Temperature Rise must be 7.5-11°C for 6300 and 5.1-8.5°C for 6400

2. If the Temperature Rise exceeds 8.5 the instrument software will give an "Exceeds Temperature Rise" error. The analysis is to be repeated using a smaller sample weight or if the sample was spiked, use a smaller spike weight.

3. For analyzing glass: crush the glass into small pieces. Weigh up around 0.7g of glass and spike with 0.6g mineral oil. NOTE: a negative value will always print for the analysis of glass.

4. Never let your spike weight be greater than your sample weight. This is an invalid result and analysis should be repeated.

5. For samples that ran >5% sulfur, a thermo chemical correction must be entered before analyzing the Btu/lb value. Proceed with the following steps to do so:

- At the main menu, press "Thermo Chemical Corrections" and "Enter".
- Highlight "Fixed Sulfur Correction" (item #6) found under the "Determination" section and press "Skip".
- Type in the percent sulfur in the sample and press "Enter".
- Once the Btu/lb analysis has finished, the sulfur correction factor is to be changed back to zero.

Troubleshooting

1.Firing pin may be out of place

"Misfire-Fuse Intact" – Thread burned without igniting sample. Replace thread, being careful not to touch the sides of the crucible.

- Thread was wet, replace.
- Fuse wire burned into, replace.

2. "Refill Bomb Rinse Tank" – The rinse tank needs refilling.

Any printed copy of this SOP and all copies of this SOP outside of Pace are uncontrolled copies. Uncontrolled copies are not tracked or replaced when new versions are released, or the SOP is made obsolete. Users of the SOP should verify the copy in possession is the current version of the SOP before use.

COPYRIGHT © 2020 Pace Analytical Services, LLC

3. "Lid Failed to Lock" – Press lid firmly. If this doesn't work, you probably have a bad sensor.

4. "Temperature Rise Exceeds Limit" – The temperature rise was exceeded. Repeat analysis using a small amount of sample. If sample was spiked, use a smaller amount of spike.

5. "Bomb Firing Count Exceeds Limit" – The calorimeter count has reached its limit of 500 counts. Do routine maintenance. Once this has been done, refer to Section for testing bomb firing counter.

6. "02 Low Pressure" – Check pressure gauge, if below 450 psi, change cylinder. If pressure on the gauge is adequate, check the piston in the bottom of the bomb bucket to see that the o-ring is not worn. Replace if needed.

7. "Open Fuse" – Check and/or replace the bomb heating wire. Check the "water diffuser screw," tighten if needed.

Filling Rinse Tank:

1. The instrument will give you a "Refill Bomb Rinse Tank" alarm when the tank needs refilling. 750 washings is the limit.

2. Turn off nitrogen supply pressure (both valves) behind the hood marked "1".

3. Open cabinet door. Set rinse tank outside cabinet.

4. Open pressure relief valve.

5. Once pressure has bled off, open the lid to the rinse tank

6. Using only deionized water. Fill the rinse tank as close to the top without running over.

7. Replace lid. Close pressure relief valve.

8. Set rinse tank back in the cabinet.

9. Turn on nitrogen supply pressure

10. From the instrument software go to "Operating Controls" and "Enter"

11. Arrow to "Bomb rinse tank Controls" (#4). "Enter".

12. Arrow to "Reset rinse tank Counter" (#3). "Enter".

13. This will reset the counter to 750 washings.

14. Press "Escape" to get back to "Calorimeter Operation".

Reset Bomb Firing Counter:

1. Go to "Main Menu". "Enter"

2. Go to "Calibration data and Controls". "Enter".

3. Go to "Bomb Service Interval"- this is to be reading 500. NOTE: An entry will not have to be made at this point unless the number on the display is reading something other than 500. If so, change the display reading to 500 and continue with next step

COPYRIGHT © 2020 Pace Analytical Services, LLC

4. Use arrow keys to select either bomb #1 or bomb # 2 (depending on the instrument being used.) and “Enter”.

5. Arrow to “Bomb Firing Count”. Enter “0”. This resets your counter.

6. Escape back to Main menu.

Determination of Selected Perfluorinated Alkyl Substances by Solid Phase Extraction and Liquid Chromatography/Tandem Mass Spectrometry Isotope Dilution (LC/MS/MS)

References: EPA Method 537.1, Version 2, March 2020, EPA Document #: EPA/600/R-20/006

EPA Method 533, November 2019, EPA Document #: 815-B-19-020

ISO 25101, First Edition, March 2009, Reference #: ISO 25101:2009(E)

Department of Defense, Quality Systems Manual for Environmental Laboratories, Version 5.4, 2021

1. Scope and Application

Matrices: Drinking water, Non-potable Water, Tissues, Biosolids and Soil Matrices
(Drinking water is applicable for specific state regulatory requirements for this method)
Definitions: Refer to Alpha Analytical Quality Manual.

1.1. This is a liquid chromatography/tandem mass spectrometry (LC/MS/MS) method for the determination of selected perfluorinated alkyl substances (PFAS) in Non-Drinking Water and soil Matrices. Accuracy and precision data have been generated in reagent water, finished ground and surface waters, and soils for the compounds listed in Table 1.

1.2. The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one or more of the following laboratory personnel before performing the modification: Area Supervisor, Department Supervisor, Laboratory Director, or Quality Assurance Officer.

1.3. This method is restricted to use by or under the supervision of analysts experienced in the operation of the LC/MS/MS and in the interpretation of LC/MS/MS data. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

2. Summary of the Method

2.1. A 250-mL water sample is fortified with extracted internal standards (EIS) and passed through a solid phase extraction (WAX) cartridge containing a mixed mode, Weak Anion Exchange, reversed phase, water-wettable polymer to extract the method analytes and isotopically labeled compounds. The compounds are eluted from the solid phase in two fractions with methanol followed by a small amount of 2% ammonium hydroxide in methanol solution. The extract is concentrated with nitrogen in a heated water bath and then adjusted to a 1-mL volume with 80:20% (vol/vol) methanol:water.

2.2. A 0.5 to 4 gram soil, solid, tissue, or biosolid sample is fortified with extracted internal standards (EIS), diluted in methanol, and agitated rigorously. An aliquot of the methanol is passed across an SPE-based clean-up cartridge and the eluate is collected. The extract is concentrated with

nitrogen in a heated water bath and then adjusted to a 1-mL volume with 80:20% (vol/vol) methanol:water.

2.3. A sample extract is injected into an LC equipped with a C18 column that is interfaced with an MS/MS. The analytes are separated and identified by comparing the acquired mass spectra and retention times to reference spectra and retention times for calibration standards acquired under identical LC/MS/MS conditions. The concentration of each analyte is determined by using the isotope dilution technique. Extracted Internal Standards (EIS) analytes are used to monitor the extraction efficiency of the method analytes.

2.4. Method Modifications from Reference

2.4.1. None.

3. Reporting Limits

3.1. The reporting limit for PFAS's is 2 ng/L for aqueous samples (20 ng/L for HFPO-DA) and 0.25 - 1 ng/g (2.5 ng/g for HFPO-DA) for soil samples.

4. Interferences

4.1. PFAS standards, extracts and samples should not come into contact with any glass containers or pipettes as these analytes can potentially adsorb to glass surfaces. PFAS analyte and EIS standards commercially purchased in glass ampoules are acceptable; however, all subsequent transfers or dilutions performed by the analyst must be prepared and stored in polypropylene containers.

4.2. Method interferences may be caused by contaminants in solvents, reagents (including reagent water), sample bottles and caps, and other sample processing hardware that can lead to discrete artifacts and/or elevated baselines in the chromatograms. The method analytes in this method can also be found in many common laboratory supplies and equipment, such as PTFE (polytetrafluoroethylene) products, LC solvent lines, methanol, aluminum foil, SPE sample transfer lines, etc. All items such as these must be demonstrated to be free from interferences (less than 1/3 the RL for each method analyte) under the conditions of the analysis by analyzing laboratory reagent blanks whenever a new vendor or reagent is brought online as described in Section 9.1,

and by continuous evaluation of method blanks and/or instrument blanks. **Subtracting blank values from sample results is not permitted.**

4.3. Matrix interferences may be caused by contaminants that are co-extracted from the sample. The extent of matrix interferences will vary considerably from source to source, depending upon the nature of the water. Humic and/or fulvic material can be co-extracted during SPE and high levels can cause enhancement and/or suppression in the electrospray ionization source or low recoveries on the SPE sorbent. Total organic carbon (TOC) is a good indicator of humic content of the sample.

4.4. SPE cartridges can be a source of interferences. The analysis of field and laboratory reagent blanks can provide important information regarding the presence or absence of such interferences. Brands and lots of SPE devices should be tested to ensure that contamination does not preclude analyte identification and quantitation.

5. Health and Safety

5.1. The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material safety data sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

5.2. All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

5.3. PFOA has been described as “likely to be carcinogenic to humans.” Pure standard materials and stock standard solutions of these method analytes should be handled with suitable protection to skin and eyes, and care should be taken not to breathe the vapors or ingest the materials.

6. Sample Collection, Preservation, Shipping and Handling

6.1. Sample Collection for Aqueous Samples

6.1.1. Samples must be collected in two (2) 250-mL high density polyethylene (HDPE) container with an unlined plastic screw cap.

6.1.2. The sample handler must wash their hands before sampling and wear nitrile gloves while filling and sealing the sample bottles. PFAS contamination during sampling can occur from a number of common sources, such as food packaging and certain foods and beverages. Proper hand washing and wearing nitrile gloves will aid in minimizing this type of accidental contamination of the samples.

6.1.3. Open the tap and allow the system to flush until the water temperature has stabilized (approximately 3 to 5 min). Collect samples from the flowing system.

6.1.4. Fill sample bottles. Samples do not need to be collected headspace free.

6.1.5. After collecting the sample and cap the bottle. Keep the sample sealed from time of collection until extraction.

6.1.6. Field Reagent Blank (FRB)

6.1.6.1. An FRB must be handled along with each sample set. The sample set is composed of samples collected from the same sample site and at the same time. At the laboratory, fill the field blank sample bottle with reagent water and preservatives, seal, and ship to the sampling site along with the sample bottles. For each FRB shipped, an empty sample bottle (no preservatives) must also be shipped. At the sampling site, the sampler must open the shipped FRB and pour the reagent water into the empty shipped sample bottle, seal and label this bottle as the FRB. The FRB is shipped back to the laboratory along with the samples and analyzed to ensure that PFAS's were not introduced into the sample during sample collection/handling.

6.1.6.2. The reagent water used for the FRBs must be initially analyzed for method analytes as a MB and must meet the MB criteria in Section 9.1.1 prior to use. This requirement will ensure samples are not being discarded due to contaminated reagent water rather than contamination during sampling.

6.2. Sample Collection for Soil and Sediment samples

6.2.1. Grab samples are collected in polypropylene containers. Sample containers and contact surfaces containing PTFE shall be avoided.

6.3. Sample Preservation

6.3.1. Not applicable.

6.4. Sample Shipping

6.4.1. Samples must be chilled during shipment and must not exceed 10 °C during the first 48 hours after collection. Sample temperature must be confirmed to be at or below 10 °C when the samples are received at the laboratory. Samples stored in the lab must be held at or below 6 °C until extraction but should not be frozen.

6.4.2. **NOTE:** Samples that are significantly above 10° C, at the time of collection, may need to be iced or refrigerated for a period of time, in order to chill them prior to shipping. This will allow them to be shipped with sufficient ice to meet the above requirements.

6.5. Sample Handling

6.5.1. Holding Times

6.5.1.1. Aqueous samples should be extracted as soon as possible but must be extracted within 28 days and stored at 0° - 6° C in the dark. Solid and tissue matrices should be extracted within 90 days and stored at 0° - 6° C in the dark. Extracts are stored at <10° C and analyzed within 90 days after extraction.

6.5.1.2. The holding time for extraction for all matrices reporting to the State of Maine is 14 days stored at 0-6°C or -20°C; analytical holding time is 28 days for extracts stored at 0-4°C.

7. Equipment and Supplies

7.1. SAMPLE CONTAINERS – 250-mL high density polyethylene (HDPE) bottles fitted with unlined screw caps. Sample bottles must be discarded after use.

7.2. SAMPLE JARS – 8-ounce wide mouth high density polyethylene (HDPE) bottles fitted with unlined screw caps. Sample bottles must be discarded after use.

7.3. POLYPROPYLENE BOTTLES – 4-mL narrow-mouth polypropylene bottles.

7.4. CENTRIFUGE TUBES – 50-mL conical polypropylene tubes with polypropylene screw caps for storing standard solutions and for collection of the extracts.

7.5. AUTOSAMPLER VIALS – Polypropylene 0.7-mL autosampler vials with polypropylene caps.

7.6. NOTE: Polypropylene vials and caps are necessary to prevent contamination of the sample from PTFE coated septa. However, polypropylene caps do not reseal, so evaporation occurs after injection. Thus, multiple injections from the same vial are not possible.

7.7. POLYPROPYLENE GRADUATED CYLINDERS – Suggested sizes include 25, 50, 100 and 1000-mL cylinders.

7.8. Auto Pipets – Suggested sizes include 5, 10, 25, 50, 100, 250, 500, 1000, 5000 and 10,000-µls.

7.9. PLASTIC PIPETS – Polypropylene or polyethylene disposable pipets.

7.10. ANALYTICAL BALANCE – Capable of weighing to the nearest 0.0001 g.

7.11. ANALYTICAL BALANCE – Capable of weighing to the nearest 0.1 g.

7.12. SOLID PHASE EXTRACTION (SPE) APPARATUS FOR USING CARTRIDGES

7.13. SPE CARTRIDGES – 0.5 g SPE cartridges containing a reverse phase copolymer characterized by a weak anion exchanger (WAX) sorbent phase.

7.14. VACUUM EXTRACTION MANIFOLD – A manual vacuum manifold with large volume sampler for cartridge extractions, or an automatic/robotic sample preparation system designed for use with SPE cartridges, may be used if all QC requirements discussed in Section 9 are met. Extraction and/or elution steps may not be changed or omitted to accommodate the use of an automated system. Care must be taken with automated SPE systems to ensure the PTFE commonly used in these systems does not contribute to unacceptable analyte concentrations in the MB (Sect. 9.1.1).

7.15. SAMPLE DELIVERY SYSTEM – Use of a polypropylene transfer tube system, which transfers the sample directly from the sample container to the SPE cartridge, is recommended, but not mandatory. Standard extraction manifolds come equipped with PTFE transfer tube systems. These can be replaced with 1/8" O.D. x 1/16" I.D. polypropylene or polyethylene tubing cut to an appropriate length to ensure no sample contamination from the sample transfer lines. Other types of non-PTFE tubing may be used provided it meets the MB (Sect. 9.1.1) and LCS (Sect. 9.2) QC requirements.

7.16. Extract Clean-up Cartridge – 250 mg 6mL SPE Cartridge containing graphitized polymer carbon.

7.17. EXTRACT CONCENTRATION SYSTEM – Extracts are concentrated by evaporation with nitrogen using a water bath set no higher than 65 °C.

7.18. LABORATORY OR ASPIRATOR VACUUM SYSTEM – Sufficient capacity to maintain a vacuum of approximately 10 to 15 inches of mercury for extraction cartridges.

7.19. LIQUID CHROMATOGRAPHY (LC)/TANDEM MASS SPECTROMETER (MS/MS) WITH DATA SYSTEM

7.20. LC SYSTEM – Instrument capable of reproducibly injecting up to 10-µL aliquots and performing binary linear gradients at a constant flow rate near the flow rate used for development of this method (0.4 mL/min). The LC must be capable of pumping the water/methanol mobile phase

without the use of a degasser which pulls vacuum on the mobile phase bottle (other types of degassers are acceptable). Degassers which pull vacuum on the mobile phase bottle will volatilize the ammonium acetate mobile phase causing the analyte peaks to shift to earlier retention times over the course of the analysis batch. The usage of a column heater is optional.

7.21. LC/TANDEM MASS SPECTROMETER – The LC/MS/MS must be capable of negative ion electrospray ionization (ESI) near the suggested LC flow rate of 0.4 mL/min. The system must be capable of performing MS/MS to produce unique product ions for the method analytes within specified retention time segments. A minimum of 10 scans across the chromatographic peak is required to ensure adequate precision.

7.22. DATA SYSTEM – An interfaced data system is required to acquire, store, reduce, and output mass spectral data. The computer software should have the capability of processing stored LC/MS/MS data by recognizing an LC peak within any given retention time window. The software must allow integration of the ion abundance of any specific ion within specified time or scan number limits. The software must be able to calculate relative response factors, construct linear regressions or quadratic calibration curves, and calculate analyte concentrations.

7.23. ANALYTICAL COLUMN – An LC BEH C18 column (2.1 x 50 mm) packed with 1.7 µm dp C18 solid phase particles was used. Any column that provides adequate resolution, peak shape, capacity, accuracy, and precision (Sect. 9) may be used.

8. Reagents and Standards

8.1. GASES, REAGENTS, AND SOLVENTS – Reagent grade or better chemicals must be used.

8.1.1. REAGENT WATER – Purified water which does not contain any measurable quantities of any method analytes or interfering compounds greater than 1/3 the RL for each method analyte of interest. Prior to daily use, at least 3 L of reagent water should be flushed from the purification system to rinse out any build-up of analytes in the system's tubing.

8.1.2. METHANOL (CH_3OH, CAS#: 67-56-1) – High purity, demonstrated to be free of analytes and interferences.

8.1.3. AMMONIUM ACETATE ($NH4C2H3O2$, CAS#: 631-61-8) – High purity, demonstrated to be free of analytes and interferences.

8.1.4. ACETIC ACID (H_3CCOOH, CAS#: 64-19-7) - High purity, demonstrated to be free of analytes and interferences.

8.1.5. 1M AMMONIUM ACETATE/REAGENT WATER – High purity, demonstrated to be free of analytes and interferences.

8.1.6. 2mM AMMONIUM ACETATE/METHANOL:WATER (5:95) – To prepare, mix 2 mL of 1M AMMONIUM ACETATE,1 mL ACETIC ACID and 50 mL METHANOL into I Liter of REAGENT WATER.

8.1.7. Methanol/Water (80:20) – To prepare a 1 Liter bottle, mix 200 mL of REAGENT WATER with 800 mL of METHANOL.

8.1.8. AMMONIUM HYDROXIDE (NH_3, CAS#: 1336-21-6) – High purity, demonstrated to be free of analytes and interferences.

8.1.9. Sodium Acetate ($NaOOCCH_3$, CAS#: 127-09-3) – High purity, demonstrated to be free of analytes and interferences.

8.1.10. 25 mM Sodium Acetate Buffer – To prepare 250 mLs, dissolve .625 grams of sodium acetate into 100 mLs of reagent water. Add 4 mLs Acetic Acid and adjust the final volume to 250 mLs with reagent water.

8.1.11. NITROGEN – Used for the following purposes: Nitrogen aids in aerosol generation of the ESI liquid spray and is used as collision gas in some MS/MS instruments. The nitrogen used should meet or exceed instrument manufacturer's specifications. In addition, Nitrogen is used to concentrate sample extracts (Ultra High Purity or equivalent).

8.1.12. ARGON – Used as collision gas in MS/MS instruments. Argon should meet or exceed instrument manufacturer's specifications. Nitrogen gas may be used as the collision gas provided sufficient sensitivity (product ion formation) is achieved.

8.2. STANDARD SOLUTIONS – When a compound purity is assayed to be 96% or greater, the weight can be used without correction to calculate the concentration of the stock standard. PFAS analyte and IS standards commercially purchased in glass ampoules are acceptable; however, all subsequent transfers or dilutions performed by the analyst must be prepared and stored in polypropylene containers. Standards for sample fortification generally should be prepared in the smallest volume that can be accurately measured to minimize the addition of excess organic solvent to aqueous samples.

NOTE: Stock standards and diluted stock standards are stored at ≤4 °C.

8.2.1. ISOTOPE DILUTION Extracted Internal Standard (ID EIS) STOCK SOLUTIONS - ID EIS stock standard solutions are stable for at least 6 months when stored at 4 °C. The stock solution is purchased at a concentration of 1000 ng/mL.

8.2.2. ISOTOPE DILUTION Extracted Internal Standard PRIMARY DILUTION STANDARD (ID EIS PDS) – Prepare the ID EIS PDS at a concentration of 500 ng/mL. The ID PDS is prepared in methanol. The ID PDS is stable for 1 year when stored at ≤4 °C (table 2a).

Table 2a

Isotope Labeled Standard	Conc. of EIS Stock (ng/mL)	Vol. of EIS Stock (mL)	Final Vol. of EIS PDS (mL)	Final Conc. of EIS PDS (ng/mL)

8.2.3. ANALYTE STOCK STANDARD SOLUTION – Analyte stock standards are stable for 1 year when stored at 4 °C. When using these stock standards to prepare a PDS, care must be taken to ensure that these standards are at room temperature and adequately vortexed.

8.2.4. ANALYTE PRIMARY SPIKING STANDARD – Prepare the spiking standard at a concentration of 500 ng/mL in methanol. The spiking standard is stable for at least two months when stored in polypropylene centrifuge tubes at room temperature.

8.2.5. Analyte Secondary Spiking Stock (SS): Prepare the spiking solution of additional add on components for project specific requirements only.

Table 5: Final PDS solution

Stock	Conc of Stock	Vol of Stock (mL)	Final Vol of PDS (mL)	Final conc (ng/mL)
PFAC30PAR	**Varies (see Table 3)**	**2**	**4**	**500 (varies)**
Secondary Stock	**Varies (see Table 4)**	**1**	**4**	**500 (varies)**

8.2.6. LOW, MEDIUM, AND HIGH LEVEL LCS – The LCS's will be prepared at the following concentrations and rotated per batch; 2 ng/L, 40 ng/L, 500 ng/l for drinking water. The analyte PDS contains all the method analytes of interest at various concentrations in methanol. The analyte PDS has been shown to be stable for six months when stored at ≤ 4 °C.

8.2.7. Isotope Dilution Labeled Recovery Stock Solutions (ID REC) – ID REC Stock solutions are stable for at least 1 year when stored at 4 °C. The stock solution is purchased at a concentration of 2000 ng/mL.

8.2.8. Isotope Dilution Labeled Recovery Primary Dilution Standard (ID REC PDS) - Prepare the ID REC PDS at a concentration of 500 ng/mL. The ID REC PDS is prepared in methanol. The ID REC PDS is stable for at least 1 year when stored in polypropylene centrifuge tubes at ≤4 °C.

Table 5

Analyte	Conc. of REC Stock (ng/mL)	Vol. of REC Stock (mL)	Final Vol. of REC PDS (mL)	Final Conc. of REC PDS (ng/mL)
M2PFOA	2000	1	4	500
M2PFDA	2000	1	4	500
M3PFBA	2000	1	4	500
M4PFOS	2000	1	4	500

8.2.9. CALIBRATION STANDARDS (CAL)

Current Concentrations (ng/mL): 0.25 (optional), 0.5, 1.0, 5.0, 10.0, 25, 50.0, 100, 250.

Prepare the CAL standards over the concentration range of interest from dilutions of the analyte PDS in methanol containing 20% reagent water. 20 µl of the EIS PDS and REC PDS are added to the CAL standards to give a constant concentration of 10 ng/mL. The lowest concentration CAL standard must be at or below the RL (2 ng/L), which may depend on system sensitivity. The CAL standards may also be used as CCVs (Sect. 9.8).

Table 6

Calibration Standard Concentration	Final Aqueous Cal STD Concentration	Final Soil Cal STD Concentration	30 Compound Stock Added (uL)	Individual Analyte Stocks Added (uL)	500 ng/mL Dilution Added (uL)	Final Volume in MeOH/H2O (80:20)
.5 ng/mL	2 ng/L	.25 ng/g	6.25		25	25 mLs
1 ng/mL	4 ng/L	.5 ng/g	5		20	10 mLs
5 ng/mL	20 ng/L	1 ng/g	25		100	10 mLs
10 ng/mL	40 ng/L	5 ng/g	125	5		25 mLs
50 ng/mL	200 ng/L	25 ng/g	250	10		10 mLs
125 ng/mL	500 ng/L	62.5 ng/g	625	25		10 mLs
150 ng/mL	600 ng/L	75 ng/g	750	30		10 mLs
250 ng/mL	1000 ng/L	125 ng/g	625			5 mLs
500 ng/mL	2000 ng/L	250 ng/g	1250			5 mLs

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

9.1. Blanks

9.1.1. METHOD BLANK (MB) - A Method Blank (MB) is required with each extraction batch to confirm that potential background contaminants are not interfering with the identification or quantitation of method analytes. Prep and analyze a MB for every 20 samples. If the MB produces a peak within the retention time window of any analyte that would prevent the determination of that analyte, determine the source of contamination, and eliminate the interference before processing samples. Background contamination must be reduced to an acceptable level before proceeding. Background from method analytes or other contaminants that interfere with the measurement of method analytes must be below the RL. If the method analytes are detected in the MB at concentrations equal to or greater than this level, then all data for the problem analyte(s) must be considered invalid for all samples in the extraction batch. Because background contamination is a significant problem for several method analytes, it is highly recommended that the analyst maintains a historical record of MB data.

9.1.1.1. Corrective Action: Samples should not be analyzed until an acceptable method blank analysis is obtained. The results are qualified with a “B” flag for any associated sample concentrations that are less than 10x the blank concentration for the analyte. Sample results are qualified with a “B” flag for analytes observed in the blank > RL. Exceptions may be made if the samples associated with the out-of-control method blank

are non-detect for the compound of interest, or if sample concentrations are greater than 10x the blank levels. In such cases when the sample results are accepted, the client is notified in a project narrative associated with the sample results.

9.1.2. **FIELD REAGENT BLANK (FRB)** - The purpose of the FRB is to ensure that PFAS's measured in the Field Samples were not inadvertently introduced into the sample during sample collection/handling. Analysis of the FRB is performed on a project specific basis. The FRB is processed, extracted, and analyzed in exactly the same manner as a Field Sample.

9.2. Laboratory Control Sample (LCS) and Laboratory Control Sample Duplicates (LCSD)

9.2.1. An LCS is required with each extraction batch. The fortified concentration of the LCS may be rotated between low, medium, and high concentrations from batch to batch. Default limits of 50-150% (60 – 140% for New Jersey programs) of the true value may be used for analytes until sufficient replicates have been analyzed to generate proper control limits. Calculate the percent recovery (%*R*) for each analyte using the equation:

$$\%R = \frac{A \times 100}{B}$$

Where:

A = measured concentration in the fortified sample
B =fortification concentration.

9.2.2. Where applicable, in the absence of additional sample volume required to perform matrix specific QC, LCSD's are to be extracted and analyzed. The concentration and analyte recovery criteria for the LCSD must be the same as the batch LCS. The RSD's must fall within ≤30% of the true value for medium and high-level replicates, and ≤50% for low level replicates. Calculate the relative percent difference (RPD) for duplicate MSs (MS and MSD) using the equation:

$$RPD = \frac{|LCS - LCSD|}{(LCS + LCSD) / 2} \times 100$$

9.2.3. If the LCS and or LCSD results do not meet these criteria for method analytes, then all data for the problem analyte(s) must be considered invalid for all samples in the extraction batch.

9.2.4. Corrective Action: All compounds should be recovered within the specified limits. If the LCS recovery is still out of control, re-extract and/or re-analyze the LCS and all associated samples. Samples cannot be reported until an acceptable LCS is obtained. Exceptions may be made in some cases for documented difficult/poor performing compounds such as PFODA, FOSA, and NFDHA. An explanation of any out-of-control LCS recovery must be included in the project narrative to the client.

9.3. Labeled Recovery Standards (REC)

9.3.1. The analyst must monitor the peak areas of the REC(s) in all injections during each analysis day.

9.4. Extracted Internal Standards (EIS)

9.4.1. The EIS standard is fortified into all samples, CCVs, MBs, LCSs, MSs, MSDs, FD, and FRB prior to extraction. It is also added to the CAL standards. The EIS is a means of assessing method performance from extraction to final chromatographic measurement. Calculate the recovery (%R) for the EIS using the following equation:

$$\%R = (A / B) \times 100$$

Where:

A = calculated EIS concentration for the QC or Field Sample

B = fortified concentration of the EIS.

9.4.2. EIS recoveries are evaluated according to their matrix specific control limits in the LIMS. Any samples with EIS recoveries < 5% (< 10 % for New York) must be re-extracted. Any data associated with EIS recoveries <2% cannot be reported and the project manager needs to be notified. A low or high percent recovery for a sample, blank, or CCV does not require discarding the analytical data, but it may indicate a potential problem with future analytical data. When EIS recovery from a sample, blank, or CCV are outside control limits, check 1) calculations to locate possible errors, 2) standard solutions for degradation, 3) contamination, and 4) instrument performance. For CCVs and QC elements spiked with all target analytes, if the recovery of the corresponding target analytes meet the acceptance criteria but the EIS is outside criteria, the data can be used. If the associated target analytes do not meet the acceptance criteria, the data must be reanalyzed.

9.5. Matrix Spike (MS)

9.5.1. Analysis of an MS is required in each extraction batch and is used to determine that the sample matrix does not adversely affect method accuracy. Assessment of method precision is accomplished by analysis of a Field Duplicate (FD) (Sect. 9.6); however, infrequent occurrence of method analytes would hinder this assessment. If the occurrence of method analytes in the samples is infrequent, or if historical trends are unavailable, a second MS, or MSD, must be prepared, extracted, and analyzed from a duplicate of the Field Sample. Extraction batches that contain MSDs will not require the extraction of a field sample duplicate. If a variety of different sample matrices are analyzed regularly, for example, drinking water from groundwater and surface water sources, method performance should be established for each. Over time, MS data should be documented by the laboratory for all routine sample sources.

9.5.2. Within each extraction batch, a minimum of one Field Sample is fortified as an MS for every 20 Field Samples analyzed. The MS is prepared by spiking a sample with an appropriate amount of the Analyte Stock Standard (Sect. 8.2.3). Use historical data and rotate through the low, mid and high concentrations when selecting a fortifying concentration. Calculate the percent recovery (%*R*) for each analyte using the equation:

$$\%R = \frac{(A - B)}{C} \times 100$$

Where:

A = measured concentration in the fortified sample
B = measured concentration in the unfortified sample
C = fortification concentration.

9.5.3. Analyte recoveries may exhibit matrix bias. For samples fortified at or above their native concentration, recoveries should range between 50-150%. If the accuracy of any analyte falls outside the designated range, and the laboratory performance for that analyte is shown to be in control in the LCS, the recovery is judged to be matrix biased. The result for that analyte in the unfortified sample is labeled suspect/matrix to inform the data user that the results are suspect due to matrix effects.

9.6. Laboratory Duplicate

9.6.1. FIELD DUPLICATE OR LABORATORY FORTIFIED SAMPLE MATRIX DUPLICATE (FD or MSD) – Within each extraction batch (not to exceed 20 Field Samples), a minimum of one FD or MSD must be analyzed. Duplicates check the precision associated with sample collection, preservation, storage, and laboratory procedures. If method analytes are not routinely observed in Field Samples, an MSD should be analyzed rather than an FD.

9.6.1.1. Calculate the relative percent difference (*RPD*) for duplicate measurements (*FD1*

and *FD2*) using the equation:

$$RPD = \frac{|FD1 - FD2|}{(FD1 + FD2) / 2} \times 100$$

9.6.2. RPDs for FDs should be ≤30%. Greater variability may be observed when FDs have analyte concentrations that are within a factor of 2 of the RL. At these concentrations, FDs should have RPDs that are ≤50%. If the RPD of any analyte falls outside the designated range, and the laboratory performance for that analyte is shown to be in control in the CCV, the recovery is judged to be matrix biased. The result for that analyte in the unfortified sample is labeled suspect/matrix to inform the data user that the results are suspect due to matrix effects.

9.6.3. If an MSD is analyzed instead of a FD, calculate the relative percent difference (RPD) for duplicate MSs (MS and MSD) using the equation:

$$RPD = \frac{|MS - MSD|}{(MS + MSD) / 2} \times 100$$

9.6.4. RPDs for duplicate MSs should be ≤30% for samples fortified at or above their native concentration. Greater variability may be observed when MSs are fortified at analyte concentrations that are within a factor of 2 of the RL. MSs fortified at these concentrations should have RPDs that are ≤50% for samples fortified at or above their native concentration. If the RPD of any analyte falls outside the designated range, and the laboratory performance for that analyte is shown to be in control in the LCSD where applicable, the result is judged to be matrix biased.

9.7. Initial Calibration Verification (ICV)

9.7.1. After each ICAL, analyze a QCS sample from a source different from the source of the CAL standards. If a second vendor is not available, then a different lot of the standard should be used. The QCS should be prepared and analyzed just like a CCV. Acceptance criteria for the QCS are identical to the CCVs; the calculated amount for each analyte must be ± 30% of the expected value. If measured analyte concentrations are not of acceptable accuracy, check the entire analytical procedure to locate and correct the problem.

9.8. Continuing Calibration Verification (CCV)

9.9. CCV Standards are analyzed at the beginning of each analysis batch, after every 10 Field Samples, and at the end of the analysis batch. See Section 10.11 for concentration requirements and acceptance criteria.

9.10. Method-specific Quality Control Samples

9.10.1. None

9.11. Method Sequence

- CCV-LOW
- MB
- LCS
- LCSD (where applicable)
- MS
- Duplicate or MSD
- Field Samples (1-10)
- CCV-MID
- Field Samples (11-20)
- CCV-LOW

10. Procedure

10.1. Equipment Set-up

10.1.1. This procedure may be performed manually or in an automated mode using a robotic or automatic sample preparation device. If an automated system is used to prepare samples, follow the manufacturer's operating instructions, but all extraction and elution steps must be the same as in the manual procedure. Extraction and/or elution steps may not be changed or omitted to accommodate the use of an automated system. If an automated system is used, the MBs should be rotated among the ports to ensure that all the valves and tubing meet the MB requirements (Sect. 9.1).

10.1.2. Some of the PFAS's adsorb to surfaces, including polypropylene. Therefore, the aqueous sample bottles must be rinsed with the elution solvent (Sect 10.3.4) whether extractions are performed manually or by automation. The bottle rinse is passed through the cartridge to elute the method analytes and is then collected (Sect. 10.3.4).

10.1.3. NOTE: The SPE cartridges and sample bottles described in this section are designed as single use items and should be discarded after use. They may not be refurbished for reuse in subsequent analyses.

10.2. Sample Preparation and Extraction of Aqueous Samples

10.2.1. Samples are preserved, collected, and stored as presented in Section 6. The entire sample that is received must be sent through the SPE cartridge. In addition, the bottle must be solvent rinsed and this rinse must be sent through the SPE cartridge as well. The method blank (MB) and laboratory control sample (LCS) must be extracted in the same manner (i.e., must include the bottle solvent rinse). It should be noted that a water rinse alone is not sufficient. This does not apply to samples with high concentrations of PFAS that are prepared using serial dilution and not SPE.

10.2.2. Determine sample volume. Weigh all samples to the nearest 1g. If visible sediment is present, centrifuge and decant into a new 250mL HDPE bottle and record the weight of the new container.

NOTE: Some of the PFAS's adsorb to surfaces, thus the sample volume may NOT be transferred to a graduated cylinder for volume measurement.

10.2.3. The MB, LCS and FRB may be prepared by measuring 250 mL of reagent water with a polypropylene graduated cylinder or filling a 250-mL sample bottle to near the top.

10.2.4. Adjust the QC and sample pH to 3 by adding acetic acid in water dropwise.

10.2.5. Add 20 µL of the EIS PDS (Sect. 8.2.2) to each sample and QC, cap and invert to mix.

10.2.6. If the sample is an LCS, LCSD, MS, or MSD, add the necessary amount of analyte PDS (Sect. 8.2.4 and Sect 8.2.5). Cap and invert each sample to mix.

10.3. Cartridge SPE Procedure

10.3.1. CARTRIDGE CLEAN-UP AND CONDITIONING – DO NOT allow cartridge packing material to go dry during any of the conditioning steps. Rinse each cartridge with 3 X 5 mL of 2% ammonium hydroxide in methanol, followed by 5mLs of methanol. Next, rinse each cartridge with 5 mLs of the 25 mM acetate buffer, followed by 15 mL of reagent water, without allowing the water to drop below the top edge of the packing. If the cartridge goes dry during the conditioning phase, the conditioning must be started over. Add 4-5 mL of reagent water to

each cartridge, attach the sample transfer tubes (Sect. 7.11.3), turn on the vacuum, and begin adding sample to the cartridge.

10.3.2. SAMPLE EXTRACTON – Adjust the vacuum so that the approximate flow rate is approximately 4 mL/min. Do not allow the cartridge to go dry before all the sample has passed through.

10.3.3. SAMPLE BOTTLE AND CARTRIDGE RINSE – After the entire sample has passed through the cartridge, rinse the sample bottles with 4 mL reagent water followed by 4 mL 25 mM acetate buffer at pH 4 and draw the aliquot through the sample transfer tubes and the cartridges. Draw air or nitrogen through the cartridge for 5-10 min at high vacuum (10-15 in. Hg). NOTE: If empty plastic reservoirs are used in place of the sample transfer tubes to pass the samples through the cartridges, these reservoirs must be treated like the transfer tubes. After the entire sample has passed through the cartridge, the reservoirs must be rinsed to waste with reagent water.

10.3.4. SAMPLE BOTTLE AND CARTRIDGE ELUTION, Fraction 1 – Turn off and release the vacuum. Lift the extraction manifold top and insert a rack with collection tubes into the extraction tank to collect the extracts as they are eluted from the cartridges. Rinse the sample bottles with 12 mLs of methanol and draw the aliquot through the sample transfer tubes and cartridges. Use a low vacuum such that the solvent exits the cartridge in a dropwise fashion.

10.3.5. NOTE: Due to the possible volatility and suspect degradation of sulfonamides and sulfonamide ethanols when exposed to heat, a portion of the methanol fraction may be retained and analyzed independently with no evaporation for these analytes.

10.3.6. SAMPLE BOTTLE AND CARTRIDGE ELUTION, Fraction 2 In a separate collection vial, rinse the sample bottles with 12 mL of 2% ammonium hydroxide in methanol and elute the analytes from the cartridges by pulling the 4 mL of methanol through the sample transfer tubes and the cartridges. Use a low vacuum such that the solvent exits the cartridge in a dropwise fashion.

10.3.7. NOTE: If empty plastic reservoirs are used in place of the sample transfer tubes to pass the samples through the cartridges, these reservoirs must be treated like the transfer tubes. After the reservoirs have been rinsed in Section 10.3.3, the elution solvent used to rinse the sample bottles must be swirled down the sides of the reservoirs while eluting the cartridge to ensure that any method analytes on the surface of the reservoirs are transferred to the extract.

10.3.8. CLEAN-UP CARTRIDGE ELUTION, Elute the clean-up cartridge with 8 additional mLs of methanol and draw the aliquot through the cartridge. Use a low vacuum such that the solvent exits the cartridge in a dropwise fashion.

10.3.9. Fractions 1 and 2 are to be combined during the concentration stage (section10.8).

10.4. Sample Prep and Extraction Protocol for Soils, Solids and Sediments.

10.4.1. Homogenize and weigh 4 grams of sample (measured to the nearest hundredth of a gram) into a 50 mL polypropylene centrifuge tube. For laboratory control blanks and spikes, 4 grams of clean sand is used.

10.4.2. Add 40 µL of the EIS PDS (Sect. 8.2.2) to each sample and QC.

10.4.3. If the sample is an LCS, LCSD, MS, or MSD, add the necessary amount of analyte PDS (Sect. 8.2.6). Cap and invert each sample to mix.

10.4.4. To all samples, add 10 mLs of methanol, cap, vortex for 25 seconds at 2500 RPM.

10.4.5. Following mixing, sonicate each sample for 30 minutes and let samples sit overnight (at least 2 hours is required for RUSH samples).

10.4.6. Centrifuge each sample at 3500RPM for 10 minutes.

10.4.7. Remove 5mL of supernatant, and reserve for clean-up.

10.5. Sample Prep and Extraction Protocol for Tissues, Oils and Biosolids.

10.5.1. Homogenize and weigh 2-8 grams of sample (measured to the nearest hundredth of a gram) into a 50 mL polypropylene centrifuge tube. For laboratory control blanks and spikes, 4 grams of clean sand is used.

10.5.2. Add 40 µL of the EIS PDS (Sect. 8.2.2) to each sample and QC.

10.5.3. If the sample is an LCS, LCSD, MS, or MSD, add the necessary amount of analyte PDS (Sect. 8.2.6). Cap and invert each sample to mix.

10.5.4. Add 100 ul of Ammonium Hydroxide.

10.5.5. To all samples, add 10 mLs of methanol, cap, vortex for 25-30 seconds at 2500 RPM.

10.5.6. Following mixing, sonicate each sample for 30 minutes and let samples sit for 2 hours.

10.5.7. Centrifuge each sample at 3500RPM for 10 minutes.

10.5.8. Remove 5 mLs of the supernatant, and reserve for clean-up.

10.6. Extract Clean-up: Soils, Solids and Sediment Matrices

10.6.1. CARTRIDGE CLEAN-UP AND CONDITIONING –. Rinse each cartridge with 15 mL of methanol and discard. If the cartridge goes dry during the conditioning phase, the conditioning must be started over. Attach the sample transfer tubes (Sect. 7.11.3), turn on the vacuum, and begin adding sample to the cartridge. For Soils extracts, transfer 5 mLs of the MeOH eluate to the cartridge. Samples should be allowed to pass through the cartridge by gravity feed at a dropwise rate to ensure adequate contact time with the cartridge sorbent. Vacuum is only applied if the flow of solvent through the cartridge stops.

10.6.2. Adjust the vacuum so that the approximate flow rate is 1-2 mL/min. Do not allow the cartridge to go dry before all the sample has passed through.

10.6.3. SAMPLE BOTTLE AND CARTRIDGE RINSE – After the entire sample has passed through the cartridge, rinse the sample collection vial with two 4-mL aliquots of methanol and draw each aliquot through the cartridges. Draw air or nitrogen through the cartridge for 5 min at high vacuum (10-15 in. Hg).

10.6.4. If extracts are not to be immediately evaporated, cover collection tubes and store at ambient temperature till concentration.

NOTE: Due to the possible volatility and suspect degradation of sulfonamides and sulfonamide ethanols when exposed to heat, a portion of the eluate may be retained and analyzed independently with no evaporation for these analytes.

10.7. Extract Clean-up: Tissues, Oils and Biosolids

10.7.1. CARTRIDGE CLEAN-UP AND CONDITIONING –. Stack a 500 mg WAX cartridge onto a 250 mg GCB cartridge. Rinse each cartridge set with 10 mL of 2% NH_4OH and discard. Immediately rinse each cartridge stack with 15 mLs MeOH and discard, If the cartridge goes

dry during the conditioning phase, the conditioning must be started over. Attach the sample transfer tubes (Sect. 7.11.3), turn on the vacuum.

10.7.2. Adjust the vacuum so that the approximate flow rate is 1-2 mL/min. Do not allow the cartridge to go dry before all the sample has passed through.

10.7.3. SAMPLE elution AND CARTRIDGE RINSE – Load 5 mLs of the MeOH sample extract to the cartridge. After the entire sample has passed through the cartridge, rinse the cartridges with 5-mLs of methanol and draw through the cartridges. Immediately add and elute 2 5mL aliquots of 2% NH_4OH to the cartridges, collecting the eluate with the MeOH eluate.

10.7.4. If extracts are not to be immediately evaporated, cover collection tubes and store at ambient temperature till concentration.

10.7.5. NOTE: Due to the possible volatility and suspect degradation of sulfonamides and sulfonamide ethanols when exposed to heat, a portion of the eluate may be retained and analyzed independently with no evaporation for these analytes.

10.8. Extract Concentration

10.8.1. Concentrate the extract to dryness under a gentle stream of nitrogen in a heated water bath (60-65 °C) to remove all the water/methanol mix. Add the appropriate amount of 80:20% (vol/vol) methanol:water solution and 20 µl of the ID REC PDS (Sect. 8.2.8) to the collection vial to bring the volume to 1 mL and vortex. Transfer two aliquots with a plastic pipet (Sect. 7.8) into 2 polypropylene autosampler vials.

10.8.2. NOTE: It is recommended that the entire 1-mL aliquot not be transferred to the autosampler vial because the polypropylene autosampler caps do not reseal after injection. Therefore, do not store the extracts in the autosampler vials as evaporation losses can occur occasionally in these autosampler vials. Extracts can be split between 2 X 700 µl vials (Sect. 7.5).

10.9. Sample Volume Determination

10.9.1. If the level of the sample was marked on the sample bottle, use a graduated cylinder to measure the volume of water required to fill the original sample bottle to the mark made prior to extraction. Determine to the nearest 10 mL.

10.9.2. If using weight to determine volume, weigh the empty bottle to the nearest 10 g and determine the sample weight by subtraction of the empty bottle weight from the original sample weight (Sect. 10.2.2). Assume a sample density of 1.0 g/mL. In either case, the sample volume will be used in the final calculations of the analyte concentration (Sect. 11.2).

10.10. Initial Calibration - Demonstration and documentation of acceptable initial calibration is required before any samples are analyzed. After the initial calibration is successful, a CCV is required at the beginning and end of each period in which analyses are performed, and after every tenth Field Sample.

10.10.1. ESI-MS/MS TUNE

10.10.1.1. Calibrate the mass scale of the MS with the calibration compounds and procedures prescribed by the manufacturer.

10.10.1.2. Optimize the [M-H]- for each method analyte by infusing approximately 0.5-1.0 µg/mL of each analyte (prepared in the initial mobile phase conditions) directly into the MS at the chosen LC mobile phase flow rate (approximately 0.4 mL/min). This tune can be done on a mix of method analytes. The MS parameters (voltages, temperatures, gas flows, etc.) are

varied until optimal analyte responses are determined. The method analytes may have different optima requiring some compromise between the optima.

10.10.1.3. Optimize the product ion for each analyte by infusing approximately 0.5-1.0 µg/mL of each analyte (prepared in the initial mobile phase conditions) directly into the MS at the chosen LC mobile phase flow rate (approximately 0.4 mL/min). This tune can be done on a mix of method analytes. The MS/MS parameters (collision gas pressure, collision energy, etc.) are varied until optimal analyte responses are determined. Typically, carboxylic acids have very similar MS/MS conditions and sulfonic acids have similar MS/MS conditions.

10.10.2. Establish LC operating parameters that optimize resolution and peak shape. Modifying the standard or extract composition to more aqueous content to prevent poor shape is not permitted.

10.10.2.1. Cautions: LC system components, as well as the mobile phase constituents, contain many of the method analytes in this method. Thus, these PFAS's will build up on the head of the LC column during mobile phase equilibration. To minimize the background PFAS peaks and to keep background levels constant, the time the LC column sits at initial conditions must be kept constant and as short as possible (while ensuring reproducible retention times). In addition, prior to daily use, flush the column with 100% methanol for at least 20 min before initiating a sequence. It may be necessary on some systems to flush other LC components such as wash syringes, sample needles or any other system components before daily use.

10.10.3. Inject (2µl for Sciex systems, 3µl for Waters systems, 20µl for MeOH fractions) a mid-level CAL standard under LC/MS conditions to obtain the retention times of each method analyte. If analyzing for PFTA, ensure that the LC conditions are adequate to prevent co-elution of PFTA and the mobile phase interferants. These interferants have the same precursor and products ions as PFTA, and under faster LC conditions may co-elute with PFTA. Divide the chromatogram into retention time windows each of which contains one or more chromatographic peaks. During MS/MS analysis, fragment a small number of selected precursor ions ([M-H]-) for the analytes in each window and choose the most abundant product ion. For maximum sensitivity, small mass windows of ±0.5 daltons around the product ion mass were used for quantitation.

10.10.4. Inject a mid-level CAL standard under optimized LC/MS/MS conditions to ensure that each method analyte is observed in its MS/MS window and that there are at least 10 scans across the peak for optimum precision.

10.10.4.1. NOTE: PFHxS, PFOS, NMeFOSAA, and NEtFOSAA have multiple chromatographic peaks using the LC conditions in Table 7 due to chromatographic resolution of the linear and branched isomers of these compounds. Most PFAS's are produced by two different processes. One process gives rise to linear PFAS's only while the other process produces both linear and branched isomers. Thus, both branched and linear PFAS's can potentially be found in the environment. For the aforementioned compounds that give rise to more than one peak, all the chromatographic peaks observed in the standard must be integrated and the areas totaled. Chromatographic peaks in a sample must be integrated in the same way as the CAL standard.

10.10.5. Prepare a set of CAL standards as described in Section 8.2.9. The lowest concentration CAL standard must be at or below the RL (2 ng/L), which may depend on system sensitivity.

10.10.6. The LC/MS/MS system is calibrated using the isotope dilution technique. Target analytes are quantitated against their isotopically labeled analog (Extracted Internal Standard) where commercially available. If a labeled analog is not commercially available, the extracted internal standard with the closest retention time and /or closest chemical similarity is to be used. Use the LC/MS/MS data system software to generate a linear regression or quadratic calibration curve for each of the analytes. This curve must always be forced through zero and may be concentration weighted, if necessary. Forcing zero allows for a better estimate of the background levels of method analytes. A minimum of 5 levels are required for a linear calibration model and a minimum of 6 levels are required for a quadratic calibration model.

10.10.7. CALIBRATION ACCEPTANCE CRITERIA – A linear or quadratic fit is acceptable if the coefficient of determination (r^2) is greater than 0.990. All curves must force through zero (some of the SCIEX software versions do not allow forcing through zero for quadratic curves, therefore an additional standard at approximately half the RL must be analyzed). Any target analyte calibrated using average response must have a relative standard deviation (RSD) of ≤20%. When quantitated using the initial calibration curve, each calibration point, except the lowest point, for each analyte must calculate to be within 70-130% of its true value. Any CAL point within 2x the RL must calculate to be within 50-150% of its true value. If these criteria cannot be met, the analyst will have difficulty meeting ongoing QC criteria. It is recommended that corrective action is taken to reanalyze the CAL standards, restrict the range of calibration, or select an alternate method of calibration (forcing the curve through zero is still required). EIS compounds must have an RSD of ≤20%; the fluorotelomer EIS compounds must have an RSD ≤30%.

10.10.7.1. **CAUTION:** When acquiring MS/MS data, LC operating conditions must be carefully reproduced for each analysis to provide reproducible retention times. If this is not done, the correct ions will not be monitored at the appropriate times. As a precautionary measure, the chromatographic peaks in each window must not elute too close to the edge of the segment time window.

10.10.8. CONTINUING CALIBRATION CHECK (CCV) – Minimum daily calibration verification is as follows. Verify the initial calibration at the beginning and end of each group of analyses, and after every tenth sample during analyses. In this context, a “sample” is considered to be a Field Sample. MBs, CCVs, LCSs, MSs, FDs FRBs and MSDs are not counted as samples. The beginning CCV of each analysis batch must be at or below the RL in order to verify instrument sensitivity prior to any analyses. If standards have been prepared such that all low CAL points are not in the same CAL solution, it may be necessary to analyze two CAL standards to meet this requirement. Alternatively, the analyte concentrations in the analyte PDS may be customized to meet these criteria.

10.10.8.1. Inject an aliquot of the appropriate concentration CAL standard and analyze with the same conditions used during the initial calibration.

10.10.8.2. Calculate the concentration of each analyte and EIS in the CCV. The calculated amount for each analyte for medium level CCVs must be within 70 – 130% of the true value with an allowance of 10% of the reported analytes to be less than 70% (minimum recovery is 10%) for compounds without their own labelled EIS. For CCVs, if the recovery of the corresponding target analytes meets the acceptance criteria but the EIS is outside criteria, the data can be used. The calculated amount for the lowest calibration point for each analyte must be within 50-150%. If these conditions do not exist, then all data for the problem analyte must be considered invalid, and remedial action should be taken which may require recalibration. Any Field or QC Samples that have been analyzed since the last acceptable calibration verification should be reanalyzed after adequate calibration has been restored, with the following exception. If the CCV fails

because the calculated concentration is greater than 130% (150% for the low-level CCV) for a particular method analyte, and Field Sample extracts show no detection for that method analyte, non-detects may be reported without re-analysis.

10.10.8.3. REMEDIAL ACTION – Failure to meet CCV QC performance criteria may require remedial action. Major maintenance, such as cleaning the electrospray probe, atmospheric pressure ionization source, cleaning the mass analyzer, replacing the LC column, etc., requires recalibration (Sect 10.10) and verification of sensitivity by analyzing a CCV at or below the RL (Sect 10.11).

10.10.9. EXTRACT ANALYSIS

10.10.9.1. Establish operating conditions equivalent to those summarized in Tables 7-9 of Section 16.

10.10.9.2. Establish an appropriate retention time window for each analyte. This should be based on measurements of actual retention time variation for each method analyte in CAL standard solutions analyzed on the LC over the course of time. A value of plus or minus three times the standard deviation of the retention time obtained for each method analyte while establishing the initial calibration can be used to calculate a suggested window size. However, the experience of the analyst should weigh heavily on the determination of the appropriate retention window size.

10.10.9.3. Calibrate the system by either the analysis of a calibration curve (Sect. 10.10) or by confirming the initial calibration is still valid by analyzing a CCV as described in Section 10.11.

10.10.9.4. Begin analyzing Field Samples, including QC samples, at their appropriate frequency by injecting the same size aliquots under the same conditions used to analyze the CAL standards.

10.10.9.5. At the conclusion of data acquisition, use the same software that was used in the calibration procedure to identify peaks of interest in predetermined retention time windows. Use the data system software to examine the ion abundances of the peaks in the chromatogram. Identify an analyte by comparison of its retention time with that of the corresponding method analyte peak in a reference standard.

10.10.9.6. The analyst must not extrapolate beyond the established calibration range. If an analyte peak area exceeds the range of the initial calibration curve, the sample should be re-extracted with a reduced sample volume in order to bring the out of range target analytes into the calibration range. If a smaller sample size would not be representative of the entire sample, the following options are recommended. Re-extract an additional aliquot of sufficient size to insure that it is representative of the entire sample. Spike it with a higher concentration of internal standard. Prior to LC/MS analysis, dilute the sample so that it has a concentration of internal standard equivalent to that present in the calibration standard. Then, analyze the diluted extract.

11. Data Evaluation, Calculations and Reporting.

11.1. Complete chromatographic resolution is not necessary for accurate and precise measurements of analyte concentrations using MS/MS. In validating this method, concentrations were calculated by measuring the product ions listed in Table 9.

11.2. Calculate analyte concentrations using the multipoint calibration established in Section 10.9. Do not use daily calibration verification data to quantitate analytes in samples. Adjust final analyte concentrations to reflect the actual sample volume determined in Section 10.8

Cex = (Area of target analyte * Concentration of Labeled analog) / (area of labeled analog * CF)

C_s = (Cex / sample volume in mL) * 1000

Cex = The concentration of the analyte in the extract
CF = calibration factor from calibration.

11.3. Prior to reporting the data, the chromatogram should be reviewed for any incorrect peak identification or poor integration.

11.4. PFHxS, PFOS, PFOA, NMeFOSAA, and NEtFOSAA have multiple chromatographic peaks using the LC conditions in Table 7 due to the linear and branch isomers of these compounds (Sect. 10.10.4.). The areas of all the linear and branched isomer peaks observed in the CAL standards for each of these analytes must be summed and the concentrations reported as a total for each of these analytes.

11.5. Calculations must utilize all available digits of precision, but final reported concentrations should be rounded to an appropriate number of significant figures (one digit of uncertainty), typically two, and not more than three significant figures.

11.6. Peak responses must be at least 3 times the background noise level (S/N 3:1). If the S/N ratio is not due to high background noise, the sample may be diluted (either by extraction or analytically) to reduce the noise.

11.7. Target analytes, Extracted Internal Standards, and Response Internal Standard RTs must fall within +/-0.4minutes of the predicted retention times of the midpoint of the initial calibration curve or daily calibration verification standard. Additionally, a target analyte with a corresponding isotopically labelled analog must elute within +/- 0.1minutes of the associated EIS.

11.8. The ion ratio between the quantification ion and confirmation ion response must fall within +/-50% of the ratio observed in the mid-point initial calibration standard. When this ratio is not met, the data must be flagged.

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

12.1. Section 9.0 outlines sample batch QC acceptance criteria. If non-compliant organic compound results are to be reported, the Organic Section Head and/or the Laboratory Director, and the Operations Manager must approve the reporting of these results. The laboratory Project Manager shall be notified and may choose to relay the non-compliance to the client, for approval, or other corrective action, such as re-sampling and re-analysis. The analyst, Data Reviewer, or Department Supervisor performing the secondary review initiates the project narrative, and the narrative must clearly document the non-compliance and provide a reason for acceptance of these results.

12.2. All results for the organic compounds of interest are reportable without qualification if extraction and analytical holding times are met, preservation requirements (including cooler temperatures) are met, all QC criteria are met, and matrix interference is not suspected during extraction or analysis of the samples. If any of the below QC parameters are not met, all associated samples must be evaluated for re-extraction and/or re-analysis.

13. Method Performance

13.1. Detection Limit Study (DL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

13.1.1. The laboratory follows the procedure to determine the DL, LOD, and/or LOQ as outlined in Alpha SOP ID 1732. These studies performed by the laboratory are maintained on file for review.

13.2. Demonstration of Capability Studies

13.2.1. Refer to Alpha SOP ID 1739 for further information regarding IDC/DOC Generation.

13.2.2. The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

14. Pollution Prevention and Waste Management

14.1. Refer to Alpha's Chemical Hygiene Plan and Hazardous Waste Management and Disposal SOP for further pollution prevention and waste management information.

14.2. This method utilizes SPE to extract analytes from water. It requires the use of very small volumes of organic solvent and very small quantities of pure analytes, thereby minimizing the potential hazards to both the analyst and the environment as compared to the use of large volumes of organic solvents in conventional liquid-liquid extractions.

14.3. The analytical procedures described in this method generate relatively small amounts of waste since only small amounts of reagents and solvents are used. The matrices of concern are finished drinking water or source water. However, laboratory waste management practices must be conducted consistent with all applicable rules and regulations, and that laboratories protect the air, water, and land by minimizing and controlling all releases from fume hoods and bench operations. Also, compliance is required with any sewage discharge permits and regulations, particularly the hazardous waste identification rules and land disposal restrictions.

16. REVISION HISTORY

Revisions Made from Prior Version

Section	Description of Change
6.5.1.1	Updated Hold Time for Aqueous, Soils and Tissues.
6.5.1.2	Added specific hold time criteria for Maine
8.2.9	Revised the calibration standard levels
9.1.1.1	Added Corrective Action for Method Blanks
9.1.2	Changed FRB to project-specific basis
9.2.1	Added LCS criteria specific to NJ
9.2.4	Added Corrective Action for LCS
9.4.2	Revisions to EIS criteria
10.10.7	Revisions to Calibration Acceptance Criteria

Determination of Polychlorinated Biphenyls (PCBs) as Aroclors by Gas Chromatography/Electron Capture Detection (GC/ECD)

References: Method 8082A, Rev. 1, February 2007 and Method 8000C Test Methods for Evaluating Solid Waste, SW-846, Third Edition, Final update III, December 1996 (USEPA, Office of Solid Waste and Emergency Response, Washington, DC).

Quality Assurance and Quality Control for SW-846 Method 8082, Polychlorinated Biphenyls (PCBs) by Gas Chromatography (GC) for the Massachusetts Contingency Plan (MCP)

State of Connecticut, Department of Environmental Protection, RRCP, Version 2.0, July 2006.

Compendium Method TO10A – Determination of Pesticides and PCBs in Ambient Air Using Low Volume Polyurethane Foam (PUF) Sampling Followed by GC/ECD Detection

Compendium Method TO-4A – Determination of Pesticides and PCB's in Ambient Air Using High Volume Polyurethane Foam (PUF) Sampling Followed by Gar Chromatographic/Multi-Detector Detection (GC/MD)

1. Scope and Application

Matrices: Water, soil, sediment, sludge, product, PUF, and tissue (either animal or vegetable)

Definitions: Refer to Alpha Analytical Quality Manual.

This method is applicable to the analysis and quantification of sample extracts for Polychlorinated Biphenyls (PCB) Aroclors as Total PCB by gas chromatography/electron capture detector. See Table I for the target compound list of PCB as Aroclors with associated CAS Registry Numbers.

The sensitivity of the method usually depends on the concentration of interferences rather than on instrumental limitations. If interferences prevent detection of the analytes, the method may also be performed on samples that have undergone cleanup.

The following extraction and cleanup methods may apply, prior to sample analysis:

- *Extraction of Water Samples by Separatory Funnel* (2156),
- *Microscale Solvent Extraction - 3570* (2172)
- *Soxhlet Extraction (2173)*
- *Soxhlet Extraction of PUFs (*2167*)*
- *Tissue Preparation and Homogenization* (2166),
- *Shaker Table Extraction* (2261),
- *Sulfur Cleanup* (2168),
- *Sulfuric Acid Cleanup* (2169),
- *Silica Gel cleanup* (2170)
- *GPC Cleanup by HPLC* (2167)

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one or more of the following laboratory personnel before performing the modification: Area Supervisor, Department Supervisor, Laboratory Director, or Quality Assurance Officer.

This method is restricted to use by or under the supervision of analysts experienced in the operation of the GC-ECD and in the interpretation of GC-ECD data. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

2. Summary of Method

Sample extracts are analyzed on a gas chromatograph which is fitted with two capillary columns of differing polarities each employing separate detectors. The extracts are spiked with internal standard prior to analysis. The target analytes are resolved on each column and detected using an electron capture detector (ECD). Analytes are introduced into the GC/ECD by injecting a known volume of the calibration standards, quality control samples, and sample extracts into the GC which is temperature and flow programmed to separate the analytes. Identification of target analytes is accomplished by confirming a target hit on two dissimilar columns using Retention Time (RT) and Pattern Recognition (PR). Concentrations are calculated from the ECD response using internal standard techniques. Concentrations are determined using mean Relative Response Factor derived from multi-level calibration curve.

2.1 Method Modifications from Reference

Internal standard calibration is used. The internal standard used is 1-bromo-2- nitrobenzene.

3. Reporting Limits

The Reporting Limit for aqueous samples is 0.02 ug/L for individual Aroclors. This value is based on a 1mL final volume and 500 or 1000 mL of environmental sample extracted. The Reporting Limit for solid/tissue samples is 2.5ug/kg and 15 ug/Kg for individual Aroclors. This value is based on 2 mL final volume and 10-30 grams of environmental sample extracted (wet weight) using extraction method 3570 (MSE). The reporting limit for Aroclors in PUF air samples is 20-100ng/PUF cartridge, based on the Soxhlet extraction of one low or high volume PUF and a final volume of 1mL. Detection limits will vary with the individual sample matrix, sample preparation procedures, instrument calibration range, and volume of sample analyzed.

4. Interferences

4.1 Instrumental

4.1.1 Only high purity gases are used in the GC system to eliminate this source of possible contamination. Both Hydrogen (carrier gas) and Nitrogen (detector make-up gas) are certified by the gas supplier.

4.1.2 Preventive instrument maintenance is performed routinely, and whenever highly contaminated extracts are analyzed that could result in chromatographic interferences or result in degradation of system performance.

4.1.3 Glassware must be scrupulously cleaned. This procedure is detailed in the Laboratory Glassware cleaning SOP/1753. Store dry glassware in a clean environment.

4.2 Parameters

4.2.1 Contaminants co-extracted from the sample may cause matrix interferences. The extent of matrix interferences will vary considerably from sample to sample, depending upon the nature of the environment and matrix being investigated. In some cases depending on the severity of the observed interferences, a target hit on one column may be biased high when interfered with. Skilled analyst judgment is imperative in determining if a chromatographic peak appears interfered. In these cases the non-interfered, non-biased hit can be forced for reporting purposes providing a more suitable value. In extreme cases of interference

additional cleanups can be employed, or it may be necessary to analytically re-run the sample at a dilution.

4.2.2 The ECD is theoretically a halogen specific detector. However, phthalate esters can be a major source of contamination in that they do respond to the ECD and can interfere with accurate determination of the analytes of interest. No forms of plastic or any material containing plasticizers (phthalates) should be used in conjunction with any part of this analysis.

4.2.3 Elemental sulfur is readily extracted from soil samples and may cause chromatographic interferences in the determination of pesticides. Sulfur can be removed through the use of Method 3660B. In addition, all samples for PCB analysis are acid cleaned following Method 3665A. Associated SOPs are noted in Section 1.0, above.

4.2.4 Care must be taken to ensure a complete hexane exchange is performed on the extract, because residual methylene chloride would be an interferent in the analysis. Residual methylene chloride can also damage the electron capture detectors.

4.2.5 The injector system of the gas chromatograph can become contaminated with non-volatile components from samples. This can act to decrease the resolution and responsiveness of the system. Maintenance of the analytical system should be performed when system performance degrades (liner changes, injection port cleaning, etc.) to avoid prolonged down time.

4.2.6 Aldol condensation products (4-methyl-4-hydroxy-2-pentanone and 4-methyl-3-pentene-2-one) can arise during soil extraction when using methylene chloride:acetone. These products may interfere with detection of analytes and should be monitored.

4.2.7 Raw GC data from all blanks, samples, and spikes must be evaluated for interferences or carryover. Contamination by carryover can occur whenever high-concentration and low-concentration samples are sequentially analyzed.

4.2.8 Per method 8082A each analytical column analyzing PCB's must be evaluated for the presence of coelutions amongst PCB congeners with pesticides. An aliquot of PCB pesticide LCS solution is prepared and analyzed routinely on each analytical column in the laboratory. The subsequent coelutions of these compounds are documented and stored internally in the "ECD Standard Verification Logbook" within the facility.

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound must be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material data handling sheets is available to all personnel involved in the chemical analysis. PCBs have been tentatively classified as known or suspected human or mammalian carcinogens. Additional references to laboratory safety are available in the Chemical Hygiene Plan. All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

5.1 Lab coats, safety glasses, and gloves must be worn when handling samples, extracts, standards or solvents.

5.2 All solvent and extract transfers must be handled in the vented bench area in the GC laboratory.

5.3 All stock standards, working standards, and vialed sample extracts must be placed into the waste bucket in the lab, for future disposal by the Hazardous Waste Manager. The container must be labeled properly with hazard warning labels indicating the container contents.

5.4 Bottles containing flammable solvents must be stored in the flammables cabinet.

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

Aqueous samples are collected in 500mL, 1L amber glass bottles and stored without preservative at 4°C

Soil/sediment/tissue samples are collected in 4-8oz. glass soil jars.

Air PUF samples are collected following the guidance in reference method TO-10A and TO-4A Compendium.

6.2 Sample Preservation

Aqueous and Air PUF samples are stored without preservative at 4°C

Tissue Samples are stored at 4°C, or if desired, frozen.

Soil/sediment samples are stored at 4°C, or if desired, frozen.

6.3 Sample Handling

The hold time for this method is 7 days for the extraction of Air PUF samples, and 14 days for the extraction of tissue samples. Aqueous and solid samples are a 1 year holding time. If a sediment or tissue samples are frozen, this suspends the holding time until removal from the freezer. All extracts must be analyzed within 40 days of the extraction date.

7. Equipment and Supplies

7.1 Gas Chromatograph, Agilent 6890, 7890: An analytical system complete with gas chromatograph configured for split-splitless injection and all required accessories including syringes, analytical columns, gases, electron capture detectors (ECD), and data system.

7.2 GC Columns: Alpha utilizes dual-column analyses. The dual-column approach involves either a single injection that is split between two columns that are mounted in a single gas chromatograph. Typical column pair used is listed below. Other columns may be used as long as method performance criteria can be met.

7.2.1 Column pair:

RTX-CLP: Cat. #11141 from Restek or equivalent; 30m, 0.32mm, 0.32µm

RTX-CLPII Cat. #11324 from Restek or equivalent; 30m, 0.32mm, 0.25µm

7.3 Guard Column:

Cat. #10027 from Restek or equivalent; 5m, 0.32mm

7.4 Class "A" Volumetric Flasks: 10mL and 25mL, for standards preparation

7.5 Syringes: 10 µL – 1000 µL

7.6 Gooseneck splitless injecton liner, Cat #20799-214.5 from Restek or equivalent
7.7 Universal "Y" Press-tight tee split: Cat. #20406 from Restek or equivalent

7.7 Autosampler: Adapted onto the Gas Chromatograph. Model is HP 7890 or 6890 series autosampler with a GC autosampler controller.

7.8 Computer: With Windows NT operating software utilizing HP Enviroquant G1701BA Version B.01.00 software.

7.9 Gases: Hydrogen, ultra high purity grade and Nitrogen of equivalent purity. Hydrogen is generally supplied by a Proton Hogen GC 600 Hydrogen generator.

7.10 Glassware: Assorted Class-A volumetric flasks consisting of 5mL through 200mL flasks with ground-glass stoppers for preparing reagents, standards, and measuring sample volumes for sample requiring dilution beyond 1:100.

7.11 Pipettes: Disposable Pasteur brand, or equivalent.

7.12 Cahn balance: Capable of accurate measurement to the nearest 0.001 mg.

7.13 Analytical balance: Capable of accurate measurement to the nearest 0.0001 g.

7.14 Non-preserved, certified, pre-cleaned 40mL VOA vials, with Teflon-lined screw caps.

7.15 2 mL amber and clear GC vials, with Teflon-lined crew caps.

7.16 Stainless steel Spatula.

8. Reagents and Standards

8.1 Solvents: All solvent expirations determined as indicated by manufacturer guidelines.

8.1.1 Methylene Chloride, ACS approved, Pesticide grade, see SOP *Reagent, Solvent, and Standard Control* (1816) for additional details regarding solvent purity.

8.1.2 Acetone, ACS approved, Pesticide grade, see SOP *Reagent, Solvent, and Standard Control* (1816) for additional details regarding solvent purity.

8.1.3 Hexane, ACS approved, Pesticide grade, see SOP *Reagent, Solvent, and Standard Control* (1816) for additional details regarding solvent purity.

8.1.4 Methanol, Purge and Trap grade, see SOP *Reagent, Solvent, and Standard Control* (1816) for additional details regarding solvent purity.

8.1.5 Diethyl ether, High purity, glass distilled

8.2 Primary Standard Solutions: All Primary standard solutions are purchased from commercial vendors as flame sealed ampule certified solutions. When a flame sealed ampule primary solution is opened, it is transferred to a labeled amber 2mL vial.

Primary Standards are stored as indicated by the vendor, away from light when not in use. Primary standards are discarded as indicated by the vendor expiration. If breakdown of a solution is observed, the solution will be discarded.

8.2.1 Aroclor 1016 Solution: Obtained from Accustandard at a concentration of 100ug/mL (catalog # C-216S-H-10X-PAK) – for the calibration curve and LCS and obtained from Restek at a concentration of 1000 ug/mL (catalog # 32006) – for ICV.

8.2.1 Aroclor 1260 Solution: Obtained from Accustandard at a concentration of 100ug/mL (catalog # C-260S-H-10X-PAK) – for the calibration curve and LCS and

obtained from Restek at a concentration of 1000ug/mL (catalog # C32012) – for LCS and ICV.

8.2.2 Primary source calibration solutions

Compound	Part Number
Aroclor 1016	C-261S-H-10X-PAK
Aroclor 1221	APP-9-159
Aroclor 1232	APP-9-160
Aroclor 1242	C-242S-H-10X
Aroclor 1248	C-248S-H-10X
Aroclor 1254	C-254S-H-10X
Arocor 1260	C-260S-H-10X-PAK
Aroclor 1262	APP-9-165
Aroclor 1268	APP-9-166

8.2.3 ICV Aroclor Solutions: Obtained from Ultra at a concentration of 100ug/mL

Compound	Part Number
Aroclor 1016	32006
Aroclor 1221	PP-291
Aroclor 1232	PP-301
Aroclor 1242	PP-311
Aroclor 1248	PP-341
Aroclor 1254	PP-351
Aroclor 1260	C32012
Aroclor 1262	PP-371
Aroclor 1268	PP-381

8.2.4 Pesticides Surrogate Standard Spiking Solution: Obtained from Ultra at a concentration of 200ug/mL (catalog # ISM-320) – for PCB Aroclors analysis.

8.2.5 Internal Standard Solution: 1-Bromo-2-nitrobenzene (Ultra, Cat. #PPS-351) is used as the internal standard and is added to all single-component calibration standards and sample extracts to achieve a concentration of 0.25µg/mL.

8.3 Stock Standard Solutions: All Stock Standard Solutions are prepared volumetrically by diluting and mixing the appropriate primary standard solutions in hexane. Stock standards expire 1 year from the date of preparation or sooner if routine QC tests indicate a problem. All stock solutions are stored in the freezer (-20°C -10C) in 10-40mL vials depending on the amount prepared. If breakdown of a solution is observed, the solution will be discarded.

8.3.1 Aroclor 1660 Calibration Stock Solution: Consists of the Aroclor 1016 and 1260 from Accustandard or equivalent, mixed with the extraction surrogates (TMX and DCB), at a stock concentration of 20,000ug/L for AR1660 and 1000ug/L for surrogates, in hexane. To prepare calibration stock solution, add 1mL of *Aroclor 1016/1260 Primary Solution* at 1000ug/mL and 0.5mL of *Pesticides Surrogate Standard Spiking Solution* at 200ug/mL to a 50mL volumetric flask. Dilute to the volume with hexane.

8.3.2 Aroclor 1660 ICV Stock Solution: Consists of the Aroclor 1016 and 1260 from Restek or equivalent, at a stock concentration of 20,000ug/L in hexane. To prepare calibration stock solution, add 1mL of an individual *Aroclor Primary Solution* at 1000ug/mL to a 50mL volumetric flask. Dilute to the volume with hexane.

8.3.3 Other Aroclors Calibration Stock Solution: Consists of the individual Aroclor from Accustandard or equivalent at a stock concentration of 20,000ug/L, in hexane. To prepare calibration stock solution, add 1mL of an *Aroclor Primary Solution* at 1000ug/mL to a 50mL volumetric flask. Dilute to the volume with hexane.

8.3.4 Other Aroclors ICV Stock Solution: Consists of the individual Aroclor from Ultra or equivalent at a stock concentration of 10,000ug/L, in hexane. To prepare calibration stock solution, add 1mL of an *Aroclor Primary Solution* at 100ug/mL to a 10mL volumetric flask. Dilute to the volume with hexane.

8.3.5 Pesticides Surrogate Stock Solution: Consists of Pesticides Surrogates (TMX and DCB) from Ultra or equivalent, at a stock concentration of 5000ug/L. To prepare pest surrogate stock solution add 0.625 mL of *Pesticides Surrogate Standard Spiking Solution* at 200ug/L to a 25mL volumetric flask. Dilute to the volume with hexane.

8.4 Working/Spiking Standard Solutions: All working/spiking standard solutions are prepared volumetrically by diluting and mixing appropriate primary or stock standard solutions in acetone, hexane or methylene chloride. Working/Spiking standards expire 6 months from the date of preparation or sooner if routine QC tests indicate the problem. All working/spiking solutions are stored in the freezer (-20℃ -10 ℃) in 10-40mL vials depending on the amount prepared. All spiking solutions must be assayed for use by analysis before release to the preparation lab***. All compounds must be within 20% of their true value.*** If breakdown of a solution is observed, the solution will be discarded.

8.4.1 Aroclor 1660 calibration standard solution: Consists of Aroclor 1016 and 1260 from our "Aroclor 1660 **calibration stock solution"** combined into one standard called Aroclor 1660 and the extraction surrogates (TMX and DCB) through dilution of Aroclor 1660 Calibration Stock solution. The extraction surrogates will only be combined with the 1660 calibration. An ICAL is run for each of the nine Aroclors before analysis. A 7 point calibration is analyzed for Aroclor 1660 while 1pt calibration is allowed per method for the other 7 aroclors. Aroclor 1660 must use average response for calibration type to have the ability to 1pt the other aroclors.

7-Level Curve Preparation for Aroclors

Calibration Level	Aroclor Conc.	Surrogate Conc.	Volume of Std Added	Final Volume in Hexane
Stock	20 00μg/L	2000μg/L		
Level1	20μg/L	2.0μg/mL	0.1mL of Level7.	10mL
Level 2	50μg/L	5.0μg/L	0.25mL of Level7	10mL
Level 3	100μg/L	10μg/mL	0.5mL of Level7	10mL
Level 4	250μg/L	25μg/mL	1.25mL of Level7	10mL
Level 5**	500μg/L	50μg/mL	1.25mL of Stock	50mL
Level 6	1000μg/L	100μg/mL	0.5mL of Stock	10mL
Level 7	2000μg/L	200μg/mL	1mL of stock	10mL

** CCV Level

8.4.2 PEST/PCB Surrogate Spike Solution: TMX and DCB obtained from All samples, blank and matrix spike are spiked with 1mL of the surrogate solution prior to extraction to monitor efficiency of sample extraction, chromatographic and calibration system. This amount may be adjusted to meet project specific concentrations, as needed.

8.4.3 **PCB Aroclors LCS/LCSD/MS/MSD:** Aroclor 1660 commercially obtained from Accustandard at the concentration of 10,000ug/L in Acetone. To prepare:

Spiking solution add 1mL of each primary solution at 1000μg/mL to a 100mL volumetric flask and bring it to volume with Acetone.

1mL is spiked into each QC and field QC sample. This amount may be adjusted to meet project specific concentrations, as needed.

8.4.4 **Independent Verification Standard (ICV) for Aroclors:** This is a source separate from the calibration curve containing one of the nine Aroclors, obtained from Ultra or Restek. Prepare from Stock Solution by diluting in hexane to the concentration of 500ug/L

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

Quality Control (QC) samples are necessary to monitor both the sample extraction and instrument analysis procedures. The Quality Control samples described below are considered the method defaults, and are the minimum requirements, except where noted. Client and Project specific Data Quality Objectives (DQOs) supersede the requirements in this section where applicable. Client or Project specified DQOs shall be included, or referenced, in the final report to the client.

9.1 Blank(s)

9.1.1 A method blank must be extracted (spiked with surrogates and/or internal standards) and analyzed once per every 20 samples or per extraction batch, whichever is more frequent. The analysis of the method blank extract will demonstrate the background contamination.

9.1.2 An *acceptable* method blank should not contain any individual compound at the concentration of reporting limit, or above. All efforts must be made to identify and eliminate the source of contamination. The presence of analytes at concentrations at or above the reporting limit will warrant application of a “B” qualifier to that target compound(s) on all associated report forms, and perhaps re-extraction of all associated samples. The results are qualified with a “B” for any associated sample concentrations that are less then 10x the blank concentration for the analyte. Surrogate and internal standard recoveries must meet the QC limits for the method blank, see Section 12. Re-extraction must be initiated immediately so that the minimum of time is wasted before re-extraction can occur - if at all possible, this re-extraction should take place within holding time. Re-extraction *corrective action* that would exceed the sample holding time criteria should be discussed with the client, Laboratory Director, QA Manager, and/or Department Manager prior to implementation. Exceptions may be made with approval of the Department Manager if the samples associated with an out of control method blank are non-detect for the affected compound(s) or if the concentrations of the affected compound(s) are greater than 5x the blank level in the samples. In such cases, the sample results are accepted without corrective action for the high method blank result. The client must be notified, via the project narrative, of any method blank non-compliance associated with the sample results. Since air PUF samples cannot be re-extracted, re-analysis for confirmation of any issues must be performed. If similar results are observed, the data is reported with a narrative note discussing the non-compliance.

9.2 Laboratory Control Sample / Laboratory Control Sample (LCS / LCSD)

9.2.1 The LCS/ LCSD are extracted along with the samples as a measure of precision and accuracy. At a minimum, one LCS/LCSD sample set must be analyzed at a frequency of once per 20 samples, or per analytical batch, whichever is more frequent. The LCS contains Aroclor 1660.

9.2.2 The acceptable recovery QC limits are found in Section 12 for an aqueous, solid, and tissue LCS.

9.2.3 Acceptable relative percent difference (RPD) for LCS/LCSD analysis is ± 50 % for both aqueous and solid matrices. See section 12 for QA acceptance criteria. Calculate RPD as follows:

$$RPD = \frac{R1 - R2}{\frac{[R1 + R2]}{2}} \times 100$$

9.2.4 Corrective Action: Repeat analysis or check to see if an analytical error has occurred. If the LCS recovery is still out of control, re-extract and re-analyze the LCS and all samples associated with that LCS/LCSD. If the LCS/LCSD do not meet quality control criteria for recovery of some of the spike and surrogate compounds, the results for the other samples and quality control samples within the batch must be evaluated to determine if this is an isolated problem for the LCS/LCSD and whether the data should be reported with the affected LCS/LCSD. If the recoveries for all components in the LCS/LCSD are outside of criteria, the entire analytical batch should be re-extracted and re-analyzed. Exceptions may be made with approval of the Department Manager if the samples associated with the out of control LCS/LCSD are also associated with a matrix spike and matrix spike duplicate that is in control which demonstrates an isolated problem pertaining to the LCS/LCSD only. An explanation of this out of control LCS/LCSD recovery must be included in the project narrative to the client and the sample data reported with the acceptable MS/MSD results as batch QC. Since air PUF samples cannot be re-extracted, re-analysis for confirmation of any issues must be performed. If similar results are observed, the data is reported with a narrative note discussing the non-compliance.

9.3 Initial Calibration Verification (ICV)

Refer to section 10.2

9.4 Continuing Calibration Verification (CCV)

Refer to section 10.4

9.5 Matrix Spike / Matrix Spike Duplicate (MS / MSD)

9.5.1 MS/MSD analyses are performed once per 20 samples (5% frequency) only per client request. It is preferable to extract samples that have been selected specifically by the client. If none have been assigned then the laboratory analyst must choose a representative sample for each type of matrix prepared. The MS/MSD must be matrix specific. Aqueous and air PUF MS/MSD cannot be done unless client supplies sufficient sample. These samples are also spiked with extraction surrogate. MS/MSD are spiked with the LCS spiking solution at the same level as LCS/LCSD.

9.5.2 The acceptable recovery and RPD QC limits are found in Section 12 for an aqueous, solid, tissue and product MS/MSDs.

9.5.3 Acceptable relative percent difference (RPD) for matrix spike analysis is ± 50 % for both aqueous and solid matrices. Calculate RPD as follows:

$$RPD = \frac{R1 - R2}{\frac{[R1 + R2]}{2}} \times 100$$

9.5.4 Corrective Action: The recovery of the matrix spikes are evaluated relative to the what was in the unspiked sample to indicate how well the methods worked on extraction of the analytes of interest from the sample matrix. The results for the unspiked and MS/MSD samples need to be compared carefully to determine how well the spiking study worked and if there was any indication of matrix-related problems that might affect the analytical batch. Re-extraction of the sample based on the MS results is rare. Repeat analysis or check to see if an analytical error has occurred. If the % recovery or %RPD still exceeds the control limits and the associated LCS is within control, include a project narrative with the results to client noting that there may be potential matrix effects on the accuracy or precision of the affected results as evidenced by the matrix spike and matrix spike duplicate exceedance. Since air PUF samples cannot be re-extracted, re-analysis for confirmation of any issues must be performed. If similar results are observed, the data is reported with a narrative note discussing the non-compliance.

9.6 Laboratory Duplicate

9.6.1 Laboratory matrix or sample duplicates are analyzed if requested by the client. The client must supply sufficient additional sample volume for this duplicate. Duplicates are used to evaluate the precision of the method. The QC limit is 50% RPD for target compounds found above 5 times the reporting limit.

9.6.2 Corrective Action: If the %RPD exceeds the 50% control limit and the associated MS/MSD %RPD is within 50%, include a project narrative with the results to client noting that there may be potential matrix effects on the precision of the results isolated to this sample, as evidenced by the matrix duplicate exceedance and the MS/MSD acceptance. If both the sample/duplicate and the MS/MSD exceed the control limits, include a project narrative with the results to client noting that there may be potential matrix effects on the precision of the results as evidenced by the sample/duplicate and the MS/MSD exceedences. Since air PUF samples cannot be re-extracted, re-analysis for confirmation of any issues must be performed. If similar results are observed, the data is reported with a narrative note discussing the non-compliance.

9.7 Method-specific Quality Control Samples

9.7.1 Surrogates

9.7.1.1 Surrogates are monitored for recovery for all matrices. Two surrogates are used, one that elutes at the beginning and one at the end of GC run: TMX/DCB. Every sample, blank, and quality control sample (LCS, MS, MSD, Dup) must be spiked with the surrogates prior to extraction. The recovery limits are found in Section 12.

9.7.1.2 Corrective Action: Check to see if an analytical, spiking, or dilution error occurred and re-calculate. If only one surrogate falls below the recovery limit and all QC samples have acceptable recovery indicating a matrix effect isolated to the sample, the exceedance is noted, with approval of the Section Supervisor, and the results are reported to the client with a notation in the case narrative. If all surrogates are recovered below the limit or there are outliers in any QC, re-extract the sample. If re-extraction occurred beyond the holding time and the re-extract surrogates are within the QC limits, report the re-extract results along with the original results. If the surrogates are recovered below the limit in the re-extract, this confirms suspected matrix interference on the surrogates, and only the original analysis needs to be reported unless a specific QAPP requires otherwise. If the chromatogram shows obvious matrix interference, no re-analysis or re-extraction is necessary. *This decision must be made with approval of the Section Supervisor and/or Project Manager.* Surrogate outliers and sample re-extracts must be noted in the case narrative to the client.

9.7.2 Internal Standards

9.7.2.1 Internal Standards will be evaluated for relative retention time drift and relative area counts compared to the associated opening CCV. Internal standards are added to every field sample, QC sample, standard, and method blank. The internal standard retention times for associated samples should be ± 0.05 minutes relative to the retention times from the associated opening CCV. The area counts for the internal standards in the associated samples should be +/-50% of the area of the internal standard calculated during initial calibration. The daily opening CCV IS areas are also compared to the ICAL.

9.7.2.2 Corrective Action: Check to see if an analytical, dilution or spiking error occurred. If the chromatogram shows obvious matrix interference, no re-analysis is necessary. *This decision must be made with approval of the Department Manager.* Note the exceedance in the case narrative to the client. If no obvious interference is present, re-analyze the extract. If internal standards are now within the acceptance limits, report only the re-analysis, as long as the re-analysis occurred within the 40-day analytical hold time. If the re-analysis occurred outside of the 40-day analytical hold time, both the original and re-analysis must be reported. If the internal standards again are outside the acceptance limits, after re-analysis, either within or outside of the 40-day hold time, report only the original analysis, and include a narrative to the client that the suspected matrix interference on the internal standards was confirmed by sample re-analysis. If specified by the client or project data quality objectives (DQOs) or other specifications, both results of both analysis might have to be reported.

9.7.3 Standard Reference Materials (SRMs)

9.7.3.1 Standard reference materials (SRMs) are available from the National Institute of Standards and Technology (NIST) and are extracted and analyzed with samples only on a project specific basis. For sediment and tissue sample batches, a certified SRM will be analyzed at the rate of one per batch of up to 20 samples per matrix. These are not used as controls, but to evaluate potential matrix effects in associated samples for the target compounds being evaluated.

9.7.3.2 Measured results will be compared against certified values for those target analytes that are certified in these SRMs as follows. Acceptance criteria for SRM analysis will vary from project to project depending upon client data quality objectives (DQOs). Generally, ± 50% difference (%D) based on the true certified values of the target compounds of interest, or 40% - 140% recovery, serve as advisory acceptance criteria.

9.7.3.3 Corrective Action: Repeat analysis and/or check to see if an analytical error has occurred. If the % recovery or %D still exceeds the control limits and the associated LCS/LCSD and/or MS/MSD are within control, include a project narrative with the results to client noting that the observed recovered of the SRM are isolated to this sample as evidenced by the LCS/LCSD and/or MS/MSD acceptance. Individual analyte exceedances will be narrated and may be used to assess potential interferences or system bias for individual analytes.

9.8 Method Sequence

9.8.1 An example calibration and sample sequence for 8082 Aroclor analysis listed below. Calibration points, ICV, CCV identifiers and/or nomenclature can be associated according to date/instrument or a specifically generated WG (workgroup) reference number assigned by the company LIMS system. Laboratory standard identification should be entered under the misc information section of each datafile for traceability of all standards utilized.

9.8.2 Listed below is an example of a calibration whereas seven calibration points were analyzed on 3/6/18. “I6” = Instrument ECD6. “CQ6” = ICV ECD6

9.8.3 Example Calibration Sequence

1. Prime and/or Hexane
2. I603161801 (calibration standard level 1 1660 + surrogates)
3. I603161802 (calibration standard level 2 1660 + surrogates)
4. I603161803 (calibration standard level 3 1660 + surrogates)
5. I603161804 (calibration standard level 4 1660 + surrogates)
6. I603161805 (calibration standard level 5 1660 + surrogates)
7. I603161806 (calibration standard level 6 1660 + surrogates)
8. I603161807 (calibration standard level 7 1660 + surrogates)
9. Hexane
10. CQ603161801 (Initial Calibration Verification Standard 1660)
11. Hexane
12. I603161808 – 2162
13. CQ603161802 – 2162
14. I603161809 – 3268
15. CQ603161803 – 3268
16. I6031618010 – 1242
17. CQ603161804 – 1242
18. I603161811 – 1248
19. CQ603161805 – 1248
20. I603161812 – 1254
21. CQ603161806 – 1254

NOTE: If multiple calibration mixtures are analyzed, it is acceptable to analyze appropriate ICVs after all calibration standards have been injected.

9.8.4 Example environmental sample sequence

An example sequence for 8082 Aroclor analysis listed below. CCV identifiers and/or nomenclature can be associated according to date/instrument or a specifically generated WG (workgroup) reference number assigned by the company LIMS system.

1.	Prime and/or Hexane	
2.	C4120401STD2162	AR1221/1262 Level 5 @ 500ug/L *
3.	C4120401STD3268	AR12321268 Level 5 @ 500ug/L *
4.	C4120401STD1242	AR1242 Level 5 @ 500ug/L *
5.	C4120401STD1248	AR1248 Level 5 @ 500ug/L *
6.	C4120401STD1254	AR1254 Level 5 @ 500ug/L *
7.	C4120401STD1660	AR1660 Level 5 @ 500ug/L
8.	Method Blank	
9.	Method LCS	
10.	Method LCSD	
11.	Up to 7 client sample injections	
12.	Repeat injections 1-11 as needed	

10. Procedure

10.1 Equipment Set-up

10.1.1 Prior to performing GC/ECD analysis, the operator must read and become familiar with the operating procedure guidelines specified in the instrument operating manuals. The analyst must be trained and familiarized with the instrument software provided by the manufacturer. The instrument must be set up with the proper operating parameters (data acquisition and processing) and conditions described in the operating manual. The criteria for the analytical calibration ranges and method and instrument detection limits must be established and documented prior to initial calibration. All analytical equipment is traceable to NIST via internal and external calibration checks and *Certificates of Analysis* that are received with the calibration standards.

10.1.2 Establish daily retention time windows as the retention time of the component in the opening verification standard ± 0.05. Retention time windows are calculated each time a new GC column is installed. It has been found that this window works well, being wide enough to eliminate false-negatives while being tight enough to eliminate false-positives. Windows that are calculated using the procedure recommended in Method 8000 tend to be very narrow, creating the risk of false negative results. The window listed above is used as guidance; however the experience of the analyst weighs heavily in the interpretation of the chromatograms.

10.1.3 GC Instrument Conditions:

The dual-column / dual-detector approach involves the use of the columns listed in section 7.2.1 the columns are connected to an injection tee or dual injection GC, and separate electron capture detectors. Alpha typical GC conditions are listed below, but may be altered as long as method performance criteria are met. Inject an aliquot of 1ul into the capillary column of the gas chromatograph at the following conditions.

Temperature1: 120 ^{0}C	Injector temperature: 250^{0}C
Time1: 0 minutes	Injector mode: Pulsed Split

Ramp1: 45^{0}C/minute	1.4:1 split, 0.20 min pulse
Temperature2: 200^{0}C	Injector Flow: 5.7 ml/min split flow
Time2: 0 minutes	Detector temperature: 350^{0}C
Ramp2: 15^{0}C/minute	Carrier gas: Helium
Temperature3: 230^{0}C	Carrier flow: 20ml/min
Time3: 0 minutes	Carrier mode: Constant flow
Ramp3: 30^{0}C/minute	Makeup gas: Nitrogen
Final temperature 330^{0}C	Total detector flow: 55ml/min
Final time: 2 minutes	Injection Volume: 1 µL

10.2 Initial Calibration

10.2.1 Prepare calibration standards using the standards listed in Section 8.

10.2.2 Establish the GC operating conditions by loading the appropriate GC method. Typical instrument conditions are listed in section 10.1.3.

10.2.3 A 1µL injection volume of each calibration standard is typically used. Other injection volumes may be employed, provided that the analyst can demonstrate adequate sensitivity for the compounds of interest. The same injection volume must be used for all standards and samples.

10.2.4 Column adsorption may be a problem when the GC has not been used for a day or more or after system maintenance. The GC column may be primed (or deactivated) by injecting a PCB standard mixture approximately 20 times more concentrated than the mid-concentration standard. Inject this standard mixture prior to beginning the initial calibration or calibration verification. Alternately, the system may be primed by baking at the final analytical temperature for approximately 30 minutes. Several analytes may be observed in the injection just following system priming. Always run an instrument blank after system priming.

10.2.5 Calibration Factor: Internal standard calibration techniques are employed in this method. In each standard, calculate the response factor (RF) for each analyte, the average RF, and the relative standard deviation (RSD) of the RFs, using the Enviroquant data processing software. The calculations are performed automatically, using the formula listed in Alpha's Quality Manual.

10.2.6 Initial Calibration Criteria If the RSD for an analyte is < 20%, then the response of the instrument for this compound is considered linear over the range and the mean calibration factor can be used to quantitate sample results. If the RSD for any analyte is > 20%, then linearity through the origin cannot be assumed. The mean response factor cannot be used for quantitation. An alternative calculation may be done by the use of linearity as long as the correlation coefficient is >0.995. If both of these quantitation methods fail criteria for any compound in the initial calibration, then the system must be reevaluated and a new calibration curve must be analyzed.

10.2.7 Initial Calibration Verification An initial calibration verification standard must be run immediately after each initial calibration, near the midpoint of the curve. The standard must be prepared using a second source that is different than the source used for the initial calibration. (Standards listed in Section 8). The %D has to be within 20%. The retention time window used for the identification of target analytes is ± 0.07 minutes.

These criteria have been adopted from the EPA CLP Statement of Work (OLM04.2). It has been found that these limits work well, being wide enough to eliminate false-negatives while being tight enough to eliminate false-positives. Windows that are calculated using the procedure recommended in Method 8000 tend to be very narrow, creating the risk of false negative results.

10.2.8 The windows listed above are used as guidance; however the experience of the analyst weighs heavily in the interpretation of the chromatograms. For example, it has been observed that certain oil matrices can cause the retention times to shift more dramatically.

10.2.9 The Relative Error (%RE) is evaluated for the midpoint of the calibration and should be 50-150%.

10.3 Equipment Operation and Sample Processing

10.3.1 The determination of PCB Aroclors is accomplished by comparing the sample chromatogram to that of the most similar Aroclor standard. The aroclor pattern must be present on both columns to confirm the Aroclor identification. The use of PCB overlays is extremely helpful, either by using hardcopies of chromatograms or by utilizing the Enviroquant software. A choice must be made as to which Aroclor is most similar and whether that standard is truly representative of the PCB in the sample. Both retention time and pattern are important when determining PCBs in a sample. Samples that contained weathered PCB present special analytical challenges. Weathering could alter the Aroclor pattern to the extent that different peaks have to be selected for quantitation. Samples that contained more than one Aroclor present similar problems. For these samples, the Analyst may have to consider selecting the earlier eluting peaks for the lower boiling Aroclor and selecting the later eluting peaks for the higher boiling Aroclors to minimize overlapping peaks. Minimum of 3 peaks must be chosen for each Aroclor. If compound identification or quantitation is precluded due to interference (e.g., broad, rounded peaks or ill-defined baselines are present) cleanup of the extract may be needed. If instrument problems are suspected, rerun the extract on another instrument to determine if the problem results from analytical hardware or the sample matrix. The laboratory must report the higher of the two columns' results unless obvious interference is present on one of the columns.

10.3.2 Verify calibration each 12-hours shift by injecting calibration verification standards prior to conducting any sample analyses. A calibration standard must also be injected at intervals of not less than once every twenty injections. A bracketing CCV is not required with the use of internal standard calibration (Method 8082A 11.6.8) with the exception of samples ran under CT RCP method. For Aroclor analysis, the calibration verification standard should be a mixture of Aroclor 1016 and 1260.

10.3.3 The response factor (for internal standard compounds) for each analyte to be quantitated must not exceed a ± 20% difference when compared to the initial calibration curve (+ 15% for CT RCP). The Target data processing software automatically calculates the %D for all analytes according to the formulae in Alpha's Quality Manual. A retention time shift >30 seconds for the internal standard necessitates reanalysis of all affected samples.

10.3.4 Routine preventive maintenance is performed to maintain GC system performance. This includes periodic replacement of injector septa, replacement of injector liner(s), and replacement of injector seals. Other Maintenance: ECD detectors may become contaminated, requiring bake out at elevated temperatures, (no greater than 375°C) or repair by the manufacturer.

10.3.5 If the on-column concentration of any compound exceeds the calibration range of 2000ug/L, the sample must be diluted, re-spiked with the appropriate amount of internal standard and re-analyzed.

10.4 Continuing Calibration

10.4.1 Verify calibration each 12-hours shift by injecting calibration verification standards prior to conducting any sample analyses. A calibration standard must also be injected at intervals of not less than once every twenty injections. A bracketing CCV is not required with the use of internal standard calibration (Method 8082A 11.6.8) with the exception of samples ran under CT RCP method. For Aroclor analysis, the calibration verification standard should be a mixture of Aroclor 1016 and 1260. The calibration verification process does not require analysis of the other Aroclor standards used for pattern recognition (Method 8082A 11.6.2)

10.4.2 The response factor (for internal standard compounds) for each analyte to be quantitated must not exceed a ± 20% difference when compared to the initial calibration curve (+ 15% for CT RCP). A retention time shift >30 seconds for the internal standard necessitates reanalysis of all affected samples.

10.5 Preventive Maintenance

10.5.1 Preventive maintenance may or may not include the following; replacing system uniliner, o-ring, merlin septum, MXTY connector or clipping a length of guard column.

10.5.2 Additionally, preventive or routine maintenance for GC/ECD systems may involve baking out the ECD detectors, replacing guard, RTX-5 or CLPII columns.

11. Data Evaluation, Calculations and Reporting

11.1 Quantitation of Aroclors

Quantitation is based on the use of a minimum of 3 of the major peaks present in the analyte, although the use of 5 of the major peaks is recommended. Each of these peaks is individually calibrated with a minimum of five calibration points based on average response factors. The %RSD must meet the criteria of <20% for the ICAL. The five major peaks are calculated as described below. After individual calculation meets criteria, the average of the peaks selected for quantitation is used to determine the final concentration.

11.2 Aqueous samples

$$\text{Concentration } (\mu g/L) = \frac{C \times DF \times Vf \times 1000}{Vo}$$

C = Extract concentration (µg/mL), NOTE: ng on column = ng/injection volume = ng/uL = ug/mL
DF = Dilution factor
Vf = Final extract volume (mL)
Vo = Sample volume (mL)

11.3 Soil/sediment samples

$$\text{Concentration } (\mu g/Kg, \text{ dry weight}) = \frac{C \times DF \times Vf \times 1000 \div \%S}{W\ (g)}$$

C = Extract concentration (µg/mL), NOTE: ng on column = ng/injection volume =

ng/uL = ug/mL
DF = Dilution factor
Vf = Final extract volume (mL)
W = Weight of the sample extracted (10g for high, 30g for low)
%S = Percent solids, as a decimal value

11.4 PUF samples

$$\text{Concentration (ng/cart)} = \frac{C \times DF \times Vf}{W}$$

C = Extract concentration (µg/L)
DF = Dilution factor
Vf = Final extract volume (mL)
W = Weight of the sample. for Air PUF, sample amount is 1

11.5 Reporting Results

After performing technical data review, validating that all QC criteria have been met and confirming all positive hits, the data report is sent electronically to the LIMS computer for generation of the client report. There are two levels of review of the data in the LIMS system prior to release of data. These reviews must be done by two separate individuals.

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

Holding time exceedance and/or improper preservation are noted on the nonconformance report form.

Perform instrument maintenance as described throughout this SOP as needed when instrument calibration criteria are not met. Record all maintenance in the instrument logbook.

All batch and sample specific QC criteria outlined in Section 10 are evaluated by the analyst prior to approval of the data. When any QC criteria fail, the cause for the failure must be identified and corrected. This may include instrument recalibration followed by sample reanalysis, sample cleanup, or sample re-extraction. If it is determined that the failure is due to sample matrix effects, a project narrative report is written into the LIMS by the analyst for inclusion in the data report. If there is insufficient sample volume to perform the re-analysis for confirmation, this is also noted in the narrative and included in the client report.

All PCB Aroclor results are reportable without qualification if analytical holding times are met, preservation requirements (including cooler temperatures) are met, and all QC criteria defined in the table below are met. If any of the below QC parameters are not met, all associated samples must be evaluated for re-analysis.

QC Parameter	Acceptance Criteria
Initial Calibration Curve	20% RSD for all target analytes Correlation coefficient must be $\geq$ 0.99 – for linear model The COD or r^2 must be $\geq$ 0.99 – for non-linear model
Independent Check Verification	+/- 20% recovery of the true values, For Aroclors the Average of the 5 representative peaks are calculated to get the %D.

Continuing Calibration Verification	Analyzed every 12hr or at the minimum of every 20 samples, 20% D for all target analytes. For Aroclors the Average of the 5 representative peaks are calculated to get the %D.
Method Blank	No analyte at or above the reporting limit, "B" qualify analyte if detected < 10x the blank contamination
Laboratory Control Sample	Soil/Tissue/Aqueous/PUF: 40-140%; 50% RPD
Matrix Spike / Matrix Spike Duplicate	Same as for LCS; 50% RPD between the duplicates.
Sample / Sample Duplicate	50% RPD between the duplicates.
Surrogates	Soil: 30-150%; Aqueous: 30-150%; PUF: 60-120%
Internal Standards	50% - 200% of the daily CCV area for the Internal Standards
SRM	Same as for LCS, 40% - 140% recovery

Any deviations and observations made about the analyses must be documented in the instrument logbook and or project narrative. If a problem arises during analysis, document the problem and initiate corrective action. If there is a problem with a sample analysis which indicates that re-extraction should be performed, and if there is no additional sample available for re-extraction, the Project Manager needs to be informed immediately so that the client can be involved in the corrective action process. Re-extraction of a sample should be done within holding time if at all possible.

Evaluation of a sample result often requires knowledge about the results of all samples within a job. Therefore, use all of the data, if possible, from a job to judge whether or not corrective actions are needed. For example, if a sample is run and the surrogates are low, one might request a re-extraction immediately only to find that a MS/MSD were also done on this sample, with low surrogate and MS recoveries, confirming a matrix effect. In this case, a re-extraction is not required and the results would be reported with a narration explaining the evidence of a matrix effect on the low surrogate recoveries. The characteristics of the overall job may be invaluable in deciding how to report the data to the client.

If non-compliant PCB Aroclor results are to be reported, the Department Manager and/or the Laboratory Director, and the QA Manager must approve the reporting of these results. The laboratory Project Manager shall be notified, and may choose to relay the non-compliance to the client, for approval, or other corrective action, such as re-sampling and re-analysis. The analyst or Department Manager performing the secondary review initiates the project narrative, and the narrative must clearly document the non-compliance and provide a reason for acceptance of these results.

13. Method Performance

13.1 Detection Limit Study (DL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the DL, LOD, and/or LOQ as outlined in Alpha SOP/1732. These studies performed by the laboratory are maintained on file for review.

13.2 Demonstration of Capability Studies

Refer to Alpha SOP/1739 for further information regarding IDC/DOC Generation.

13.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method

14. Pollution Prevention and Waste Management

Refer to Alpha's Chemical Hygiene Plan and Waste Management and Disposal SOP for further pollution prevention and waste management information.
