Compound	CAS Registry	Aqueous in µg/L	Solid in µg/Kg	PUF in ng/PUF
Aroclor 1221	11104-28-2	0.02	2.5, 15	100
Aroclor 1232	11141-16-5	0.02	2.5, 15	30
Aroclor 1242	53469-21-9	0.02	2.5, 15	20
Aroclor 1248	12672-29-6	0.02	2.5, 15	20
Aroclor 1254	11097-69-1	0.02	2.5, 15	20
Aroclor 1260	11096-82-5	0.02	2.5, 15	20
Aroclor 1262	11100-14-4	0.02	2.5, 15	20
Aroclor 1268	37324-23-5	0.02	2.5, 15	20

Table II

LCS/LCSD, MS/MSD and Precision and Accuracy Evaluation Criteria

Spiked Component	Aqueous/Solid/Tissue/PUF (% recovery)	RPD
AR1016	40-140	50
AR1260	40-140	50

Table III

Surrogate Recovery Evaluation Criteria

Surrogate	Aqueous/Solid/Tissue (% recovery)	PUF (% recovery)
2,4,5,6-tetrachloro-m-ylene(TMX)	30-150	60-120
Decachlorobiphenyl (DCB)	30-150	60-120

NOTE: Depending on project specific requirements, MS/LCS/Surrogate recoveries may be validated against a specified project QAPP, 8082 SW-846, TO-10A, CLP OLM04.2, DoD QSM 5.3, or in-house determined limits.

Total Petroleum and Saturated Hydrocarbons by Gas Chromatography/Flame Ionization Detector

References: USEPA, Method **8015D** – "Nonhalogenated Organics Using GC/FID", in Test Methods for Evaluating Solid Waste, SW-846, Revision 4, June 2003.

1. Scope and Application

Matrices: This standard operating procedure (SOP) describes a method for quantification and qualitative fingerprinting of petroleum products in extracts of water, soil, sediment and petroleum products. Extractable petroleum hydrocarbon in petroleum products such as kerosene, aviation fuels, diesel and heating oils may be analyzed by this method, but products with primarily volatile constituents such as gasoline range organic compounds are not amenable to this method. To determine volatile organic material, see Alpha Analytical Lab SOP 2255, *PIANO Volatiles by GC/MS*.

Definitions: Refer to Alpha Analytical Quality Manual.

This method is applicable to the quantification and qualitative fingerprinting of petroleum products. If quantifying petroleum ranges using the individual n-alkanes, the reporting limit for the petroleum ranges is calculated by taking the sample concentration factor and multiplying it by the summation of the number of calibrated analyte(s) that elute in the range. The quantifying total petroleum ranges are generally C_9-C_{44}. Client specific ranges, as requested, are accommodated (*i.e.*, C_{10}-C_{28}, C_9-C_{36}, and C_9-C_{40}). The qualitative identification is dependent on the product pattern, how weathered it may be, and how much is present. This is the subjective aspect of the analysis that requires an experienced analyst. Care should be taken to ensure consistency in petroleum identification. Pattern books generated from the analysis of "typical" petroleum products (Section 8.12), analyzed under the same conditions as the samples may be used for reference.

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one or more of the following laboratory personnel before performing the modification: Area Supervisor, Department Supervisor, Laboratory Director, or Quality Assurance Officer.

This method is restricted to use by or under the supervision of analysts experienced in the operation of the GC-FID and in the interpretation of GC-FID data. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

2. Summary of Method

Please refer to the appropriate Alpha Analytical Lab SOPs for extraction methods and sample preparation information:

- *Method 3510C – Extraction of Water Samples by Separatory Funnel* (2165).
- *Shaker Table Extraction* (2261).
- *Tissue Preparation and Homogenization* (2166) and *Tissue Extraction* (2264)
- *Organic Waste Dilution* (2265)
- *Gravimetric Determination* (2263)

Analytes are introduced into the GC/FID by injecting a known volume of the calibration standards, quality control samples, and sample extracts into the GC equipped with a narrow-bore capillary column. The GC column is temperature programmed to separate the analytes, which are then detected with a flame ionization detector. Identification of target analytes is accomplished by comparing their retention time with the retention time of the calibration standards. Concentrations are determined using mean relative response factors from a multi-level calibration curve. Response factors for target analytes and surrogate compounds are determined relative to the internal standards. Typically, Petroleum Fuel/Hydrocarbon Ranges (TPH ranges listed by example in Section 1.0) are assigned the response factors (Rf) of the average of the calibrated n-alkanes and isoprenoids. The isoprenoids and the alkane n-Nonatriacontane (C39) are assigned the response factors (Rf) of the calibrated alkane eluting immediately after (for example the isoprenoid 1380 is assigned the response factor (Rf) of n-Tetradecane (C14). If defined by client or project data quality objectives (DQOs) or other specifications, sample concentrations may be measured by calibrating with a Diesel fuel or another site specific NAPL, or product. Sample quantification in these cases would be from the average Rf obtained from a multi-level calibration curve for the fuel product.

2.1 Method Modifications from Reference

The continuing calibration verification %D for each calibrated compound must be below 25%, with no more than 10% of all compounds greater than 25% but less than 35%. Each CCV must be analyzed within 24 hours of the previous CCV.

Matrix spike and duplicate samples are analyzed only if requested by the client.

3. Reporting Limits

Reporting limits for the individual n-alkane and isoprenoid are 200 mg/Kg (ppm) for petroleum products, 0.0667 mg/Kg (ppm) for soil/sediment samples, 0.267 mg/Kg (ppm) for tissue samples, and 0.001 mg/L (ppm) for water samples. The associated reporting limits for TPH (C9-C44) are as follows: 6600 mg/kg for petroleum products, 2.2 mg/kg for soil/sediment samples, 6.6 mg/kg for tissue samples, and 0.033 mg/L for water samples.

4. Interferences

4.1 Contaminants in solvents, reagents, glassware, and other sample processing hardware may cause interferences that lead to discrete artifacts and/or elevated baselines in the chromatogram. Demonstrate that all of these materials are free from interferences under the conditions of the preparation and analysis by extracting and analyzing a laboratory method blank with each batch of up to 20 samples.

4.2 Emulsions can form during the extraction especially in aqueous samples with high concentrations of petroleum contamination. This may require mechanical means to disperse such as glass stirring rods or centrifugation. Alternatively, filtration of emulsions through pre-dried sodium sulfate can be employed. Additional filtration through sodium sulfate after emulsion reduction is required to ensure adequate sample drying has been achieved.

4.3 The injector system of the GC can become contaminated with non-volatile components from prepared samples, decreasing the resolution and responsiveness of the system. High molecular weight polyaromatic hydrocarbons (PAH) in the calibration mix can act as indicators of chromatographic problems. C_{40} response decreases with increased injector contamination and is a good indicator compound. Maintenance of the analytical system should be performed when system performance degrades.

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material safety data sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

Aqueous samples: Collected in pre-cleaned 1-L amber glass bottles.

Soil/sediment samples: Typically collected in a pre-cleaned 250ml soil jar with a teflon lined screw cap.

6.2 Sample Preservation

Aqueous samples: Stored without preservative and at 4°C.

Soil/sediment samples: Preserved by storing at 4°C.

6.3 Sample Shipping

No special shipping requirements.

6.4 Sample Handling

Aqueous samples: Extraction is performed within 7 days. Sample extracts are analyzed within 40 days of extraction.

Soil/sediment samples: Extraction is performed within 14 days of collection; extract is analyzed within 40 days of extraction.

There is no extraction holding time applied to petroleum product samples. If sediment samples are frozen, this suspends holding time until removal from the freezer. All extracts must be analyzed within 40 days of the extraction date.

7. Equipment and Supplies

7.1 Gas Chromatograph - The instrumentation includes a temperature-programmable gas chromatograph and all required accessories including syringes, analytical columns, and gases. The injection port is designed for splitless injection onto a capillary column. The injection port includes a silanized glass liner containing a plug of silanized glass wool to reduce high-molecular-weight mass discrimination. The model is HP6890 or equivalent. The injector port will require maintenance on an as needed basis if degradation or contamination is apparent. Please refer to the front of the *Instrument Maintenance Logbook*, which outlines the routine maintenance procedures.

7.2 Column – Restek 60-m x 0.25 mm ID, 0.25um film thickness, fused-silica capillary column with RTX-5 bonded phase, or equivalent.

7.3 Flame Ionization Detector (FID) – The FID must operate at 20Hz data collection rate and have the attenuation optimized for signal to noise response. The GC capillary column is fed directly into the flame ionization detector. The FID will require cleaning and/or jet replacement on an as needed basis. Please refer to the instrument hardware manual for detailed procedures, located in the laboratory next to the instrument.

7.4 Auto sampler - Adapted onto the Gas Chromatograph. The model is HP 6890 series autosampler with a GC autosampler controller, or equivalent.

7.5 Computer - with Windows XP operating software utilizing HP Enviroquant G1701DA Version D.01.02 software or a more current release; Audit Trail: audit.txt function is used for audit trail purposes.

7.6 Hydrogen – Ultra high purity grade (99.9999% pure).

7.7 Air – Ultra Zero high purity grade (99.9999% pure).

7.8 Helium - Ultra Zero high purity grade (99.9999% pure).

7.9 Glassware - Assorted Class-A volumetric flasks consisting of 5mL through 200mL flasks with ground-glass stoppers for preparing reagents, standards, and measuring sample volumes for sample requiring dilution beyond 1:100.

7.10 Pipettes: Disposable Pasteur brand, or equivalent.

7.11 Cahn balance: Capable of accurate measurement to the nearest 0.001 mg.

7.12 Analytical balance: Capable of accurate measurement to the nearest 0.0001 g.

7.13 Top-loading analytical balance: Capable of accurate measurement to the nearest 0.1g.

7.14 Micro syringes - 10, 25, 50, 100, 250, 500, and 1000 μL.

7.15 VOA vials: Non-preserved, certified, pre-cleaned, 40 mL, with Teflon-lined screw caps.

7.16 Vials, 2 mL: with Teflon-lined crimp caps for standard solutions.

7.17 Spatula - Stainless steel.

8. Reagents and Standards

Use reagent grade chemicals for all reagents. Deionized (DI) water is ASTM Type II laboratory reagent grade water.

All stock standard solutions are purchased from commercial vendors as ampulated certified solutions or prepared in house from neat materials. Standards are stored according to the vendor recommendations. When an ampulated stock solution is opened, or prepared fresh from neat materials, it must be transferred into a PTFE-lined screw capped vial. Any extraction working standards are stored at -10 to -20°C, away from light, when not in use. All analytical working standard solutions are stored at room temperature. They are discarded after 1 year unless the vendor expiration date states otherwise or if breakdown is observed.

8.1 Methylene Chloride: ACS approved, Pesticide grade, see Alpha Analytical Lab SOP *Reagent, Solvent and Standard Control* (1816) for additional details regarding solvent purity.

8.2 Acetone: ACS approved, Pesticide grade, see Alpha Analytical Lab SOP *Reagent, Solvent and Standard Control* (1816) for additional details regarding solvent purity.

8.3 Hexane: ACS approved, Pesticide grade, see Alpha Analytical Lab SOP *Reagent, Solvent and Standard Control* (1816) for additional details regarding solvent purity.

8.4 Multi State Hydrocarbon Standard: Obtained from Accustandard at 500ug/mL

8.5 Internal Standard Calibration Stock: 5-alpha-androstane custom standard from Accustandard at 10,000ug/mL. Prepare a 1:20 dilution (2500ul into 50mL Methylene Chloride) for a 500ug/mL solution.

8.6 Surrogate Stock: Ortho-terphenyl custom from Accustandard and n-Tetracosane-d50 custom from Chemservice both at 20,000ug/mL. Prepare a 1:20 combined stock solution (5mL of each surrogate standard at 20,000ug/mL into 100mL Methylene Chloride) for a 1,000ug/mL solution.

8.7 Surrogate Spiking Solution (SIS): Prepare a solution by taking 2.5mL of each surrogate into 100mL of Methylene Chloride for a 500ug/mL spiking solution. The solution must be assayed for use by analysis before release to the preparation lab. All compounds must be within 10% of their true value. A manager's approval is needed for all surrogate spiking solutions before use. 100ul is spiked into each QC and field sample. This amount may be adjusted to meet project specific concentrations, as needed.

8.8 Internal Standard (RIS): Prepare a solution by taking 10mL of 5-alpha-androstane into 200mL of Methylene Chloride for a 500ug/mL spiking solution. 100ul is spiked into each QC sample and field sample.

8.9 Laboratory Control Sample, Matrix Spike, and Matrix Spike Duplicate (LCS/MS/MSD): A solution of 14 alkanes from Ultra Scientific, or equivalent, at 1000ug/mL. This is a source separate from the calibration curve. Prepare a spike mix by adding 10mL of solution to 50mL of Methylene Chloride for a 200ug/mL LCS/MS/MSD spiking solution. The solution must be assayed for use by analysis before release to the preparation lab. All compounds must be within 20% of their true value. 100ul is spiked into each QC and field QC sample. This amount or component type may be adjusted to meet project specific concentrations, as needed.

8.10 Alaska North Slope Crude Oil: Neat. Weigh approximately 1.0g into 90mL of Methylene Chloride. To the 90mL add 10mL of the internal standard (RIS) for a stock solution of 50ug/mL.

8.11 Independent Calibration Verification Standard (ICV): A solution of all calibrated alkanes that are a separate lot from the calibration mixture can be obtained from Accustandard. The solution is prepared to the exact specs of the Continuing Calibration Verification standard.

8.12 Petroleum Hydrocarbon Reference Standards: These standards are used for a chromatographic library and qualitative identification. If requested, any of these petroleum standards may be used for instrument calibration or LCS Solution. All standards are diluted to be at a concentration of 5mg/mL for analysis when used as part of the Reference Library. The library should include but not be limited to standards of PAH, gasoline, jet fuels, kerosene, fuel oils, paint thinner, asphalt, lubricating oils, creosote, coal tar, cutting oil and hydraulic oil. Because reference materials cannot always be obtained as certified materials, the source of the reference standards should be documented (*i.e*. Fuel Oil #2 obtained from a particular fuel oil company on a particular date). Several reference standards can be obtained from Accustandard's complete list of Total Petroleum Hydrocarbon Recognition Standards.

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

9.1 Blank(s)

A method blank must be extracted (spiked with surrogates and internal standards) and analyzed once per every 20 samples or per extraction batch, whichever is more frequent.

Acceptance Criteria: Method Blanks should not contain any individual compound at or above the concentration of the reporting limit. If a blank does contain target compounds greater than the reporting limit, they should be less than 10% of any sample results for the same compound(s). Individual compounds may be detected in the blank below the reporting limit. Associated sample results are flagged with a “B” qualifier if the concentration of the analyte in the sample is less than 10x the concentration in the blank.

Corrective Action: If the blank does not meet the above criteria, all efforts must be made to identify and eliminate any source of contamination, and all samples associated with the contaminated blank should be re-extracted and reanalyzed. Exceptions may be made with the approval of the Department Manager. Any exceedances are noted in the case narrative.

9.2 Laboratory Control Sample / Laboratory Control Sample Duplicate (LCS/LCSD)

The LCS spike is from a second source and can additionally be used to verify the accuracy of the standard curve. The LCS spiking solution is a mixture of 14 n-alkanes spread over the C_9 to C_{40} calibration range. The LCS and LCSD are extracted along with the samples as a measure of precision and accuracy. At a minimum, one LCS/LCSD must be analyzed at a frequency of once per 20 samples, or per analytical batch, whichever is more frequent.

Acceptance Criteria: All LCS compound recoveries must be between 50-130% of the true values. The acceptable recovery QC limits are found in Section 12 for aqueous, solid, tissue, and product LCSs.

Corrective Action: Repeat analysis once to see if an analytical error has occurred. If the LCS/ LCSD % RPD or % Recovery is still out of the control limit check the sample archive. Samples cannot be analyzed until an acceptable LCS is obtained. The samples associated to the LCS/ LCSD may need to be re-extracted. Exceptions may be made with approval of the Section Head if the samples associated with the out-of-control LCS/ LCSD are also associated with a MS/MSD pair that is in control. This is an acceptable measure of precision and accuracy of analytical procedures. An explanation of this out-of-control LCS/LCSD recovery must be included in the project narrative to the client and the sample data reported noting the acceptable MS/MSD results as the batch QC.

9.3 Initial Calibration Verification (ICV)

The analysis of an ICV standard must follow the initial calibration curve.

After final processing, calculate the percent recovery of each n-alkane and isoprenoid by using the following calculation:

% Recovery = Found Amount / True Value x 100

Acceptance Criteria: All recoveries must be +/- 20% of the true values.

Corrective Action: If the initial calibration fails, perform instrument maintenance and repeat.

9.4 Continuing Calibration Verification (CCV)

A continuing calibration verification (CCV) standard, at the concentration of a mid-level initial calibration standard, must be analyzed at the beginning and end of every analytical sequence, and every 24 hours within the sequence, to confirm instrument stability, via response factor, for each calibrated n-alkane.

Acceptance Criteria: Compare the CCV resulting response against the average response for the initial calibration for each calibrated n-alkane and isoprenoid. The %D for each calibrated compound must be below 25%, with no more than 10% of all compounds greater than 25% but less than 35%. If multiple CCVs are analyzed within an analytical sequence, each CCV must be analyzed within 24 hours of the previous CCV. Each CCV, including the ending CCV must meet the acceptance criteria. The acceptable QC limits are found in Section 12.

Corrective Action: If the CCV does not meet the acceptance criteria for each calibrated n-alkane and isoprenoid, perform instrument maintenance and repeat the continuing calibration. Re-analyze all affected samples. Reported results for the failing CCV may be "J" qualified. If the failure of the suspect response appears related to a loss in FID sensitivity, instrument maintenance and repeat analysis of the continuing calibration, and all affected samples, must be performed. Exceptions may be made with the approval of the Department Section Head. Any exceedances are noted in the case narrative.

9.5 Matrix Spike / Matrix Spike Duplicate (MS / MSD)

Matrix spike samples are analyzed only if requested by the client. Matrix duplicate analyses (as an MS/MSD pair) can be performed once per 20 samples (5% frequency) at the clients' request. It is preferable to extract samples that have been selected specifically by the client. If none have been assigned, then the laboratory analyst must choose a representative sample for each type of matrix prepared. Aqueous duplicates can only be done if the client supplies sufficient sample. These samples are also spiked with extraction surrogate.

Acceptance Criteria: All matrix spike compound recoveries must be between 50-150% of the true values. The acceptable recovery QC limits are found in Section 12 for an aqueous, solid, tissue, and product matrix spike analysis.

Acceptable relative percent difference (RPD) for matrix spike analysis is ± 30 % for both aqueous and solid matrices. Acceptance criterion is not applicable to sample concentrations less than 5 times the reporting limit. Calculate RPD as follows:

$$RPD = \frac{R1 - R2}{\frac{[R1 + R2]}{2}} \times 100$$

Corrective Action: Repeat analysis once to see if an analytical error has occurred. If the % RPD or % Recovery still exceeds the control limits and the LCS/ LCSD is compliant; include a project narrative with the results to the client noting that there may be potential matrix effects on the precision of the affected results as evidenced by the MS/MSD recoveries or %RPD outside of QC limits.

9.6 Laboratory Duplicate

Acceptance Criteria: Laboratory matrix or sample duplicates are analyzed if requested by the client. The QC limit is 30% RPD for target compounds found above 5 times the reporting limit.

Corrective Action: If the %RPD exceeds the 30% control limit and the associated MS/MSD %RPD is within 30%, include a project narrative with the results to client noting that there may be potential matrix effects on the precision of the results isolated to this sample, as evidenced by the matrix duplicate exceedence and the MS/MSD acceptance. If both the sample/duplicate and the MS/MSD exceed the control limits, include a project narrative with the results to client noting that there may be potential matrix effects on the precision of the results as evidenced by the sample/duplicate and the MS/MSD exceedences.

9.7 Method-specific Quality Control Samples

9.7.1 Surrogates

Acceptance Criteria: All surrogate recoveries must be between 50-130% of the true values. Surrogates are monitored for percent recovery for all matrices. The recovery limits are found in Section 12.

Corrective Action: If the surrogate does not fall within the QC limits, check to be sure there are no errors in peak integration, calculations, and surrogate solutions. If only one surrogate falls below the 50% recovery limit, the exceedence is noted, with approval of the Department Manager, and the results are reported to the client with a notation in the case narrative. If all surrogates are recovered below the 50% limit, re-extract the sample and report the re-extract results along with the original results, if re-extraction occurred beyond the holding time, and the re-extract surrogates are within the QC limits. If the surrogates are recovered below 50% in the re-extract, this confirms a suspected matrix interference on the surrogates, and only the original analysis needs to be reported. If the chromatogram shows obvious matrix interference, no re-analysis or re-extraction is necessary. *This decision must be made with approval of the* Department Manager. Surrogate outliers and sample re-extracts must be noted in the case narrative to the client.

9.7.2 Internal Standards

Acceptance Criteria: Internal standards are added to every field sample, QC sample, standard, and method blank. The acceptance limits are 50-200% of the internal standard response (or area) of the daily continuing calibration verification standard.

Corrective Action: Check to see if an analytical, dilution or spiking error occurred. If the chromatogram shows obvious matrix interference, no re-analysis is necessary. This decision must be made with approval of the Department Manager. Note the exceedence in the case narrative to the client. If no obvious interference is present, re-analyze the extract. If internal standards are now within the acceptance limits, report only the re-analysis, as long as the re-analysis occurred within the 40-day analytical hold time. If the re-analysis occurred outside of the 40-day analytical hold time, both the original and re-analysis must be reported. If the internal standards again are outside the acceptance limits, after re-analysis, either within or outside of the 40-day hold time, report only the original analysis, and include a narrative to the client that the suspected matrix interference on the internal standards was confirmed by sample re-analysis.

9.8 Method Sequence

Samples are prioritized for analysis by the Department Manager or Team Leader based on client due date and sample analytical hold time. Samples are retrieved from the sample storage refrigerator.

The sequence is prepared and run using the Enviroquant software. Printouts of all sequences are kept in a three-ring notebook for each instrument. The sequence printouts are used to document run sequences; notations are manually added of any reruns or dilutions that will need to be performed in the daily SHC continuing calibration verification packages.

- Instrument Primer
- Crude Oil Reference Standard
- Continuing Calibration Verification (CCV)
- Instrument Solvent Blanks
- Method Blank
- Laboratory control samples (LCS/LCSD)
- Samples (1-10)
- Continuing Calibration Verification (CCV)

10. Procedure

Prior to performing Total Petroleum and Saturated Hydrocarbon GC/FID analysis, the operator must read and become familiar with the operating procedure guidelines specified in the instrument operating manuals. The analyst must be trained and familiarized with the instrument software provided by the manufacturer. The instrument must be set up with the proper operating parameters (data acquisition and processing) and conditions described in the operating manual. The criteria for the analytical calibration ranges and method and instrument detection limits must be established and documented prior to initial calibration.

All samples and standard solutions must be allowed to warm to ambient temperature before analysis.

10.1 Equipment Set-up

10.1.1 GC Instrumental Conditions

Inject a 1uL aliquot of sample extract or standard solution into the capillary column of the gas chromatograph at the following conditions.

GC Parameter	Setting
Injector Temp:	280 °C
Initial Oven Temp:	40 °C
Initial Hold Time:	1 minute
Column Flow:	3.0 mL/ minute
Ramp Rate:	6 °C / minute
Final Temperature:	315 °C
Final Hold Time:	30 minutes
Total runtime:	76.83 minutes
Mode:	Pulsed Splitless
Pulse:	15psi for 0.5 minute
Purge:	20 mL / minute – on at 0.8 minutes
FID Temperature	325 °C

10.2 Initial Calibration

	Volume added			
Calibration Level	**Alkane Standard**	**Surrogate Stock**	**Internal Standard Stock**	**Final Volume in Methylene Chloride**
Level 1 -1ug/mL	20ul	10ul	1000ul	10mL
Level 2 -10ug/mL	200ul	100ul	1000ul	10mL
Level 3 -50ug/mL	5000ul	2500ul	5000ul	50mL
Level 4 -100ug/mL	2000ul	1000ul	1000ul	10mL
Level 5 -200ug/mL	4000ul	2000ul	1000ul	10mL
Level 6 -500ug/mL	NA	5000ul	1000ul	10mL
SHC - ICV	1000ul	500ul	1000ul	10mL

10.2.1 Before analysis of sample extracts, establish a multi-point response factor calibration curve showing the linear range of the analysis for all individual target analytes. Use standard concentrations of 1, 10, 50, 100, 200 and 500, ug/mL to construct the curve. See Section 8 and Table above for the preparation of the standard solutions for the initial calibration curve. Conversely, and if project specifications require, a minimum 5-point calibration curve may also be constructed using a specified fuel product of interest. The calibration range, and thus the reporting limit for this type of calibration, is several factors higher than for the individual component calibration. A Fuel Product calibration curve is typically 100ug/mL to 50,000ug/mL. Section 8.12 lists fuel products typically used.

10.2.2 Run a sequence with the initial calibration standards.

- Create a processing method from a previous method on that instrument. Set retention time windows using a mid level standard.
- Quantitate and QEDIT the initial calibration standards. Update the method with these standards.
- Additionally, the response for the petroleum ranges must be populated into the method using the Abacus CalTools macro. The average area of all individual components is used to calculate the Rf for the petroleum ranges. The ranges are typically specified by the client or project DQOs. **NOTE**: It should be noted that quantification of a Fuel Product Range using the Rf generated from individual n-alkanes can lead to a *20% - 30% low bias* of the reported TPH range.
- The response factors for reportable DRO, ORO and TPH ranges are defined by taking the average RSD of target peaks within the relative ranges retention time ranges. C10-C28 DRO, C28-C40 ORO and C9-C44 TPH.
- To avoid the low bias discussed above, calibration of the Fuel Product of interest is recommended. The product of interest should be prepared at five concentrations, as in 10.2.1 above, to construct a calibration curve, integrated for the range of interest, which is typically specified by the client. The resulting average Rf for the fuel of interest is used to quantify the associated field samples. Typical fuel products are listed in Section 8.12. Calculations are found in Section 11.0.

Acceptance Criteria: 25% RSD for all individual target compounds and 20% RSD for fuel products. All calibration standards must be analyzed within 24 hours.

10.2.3 Initial Calibration Verification (ICV)

- The analysis of an ICV standard must follow the initial calibration curve.

- After final processing, calculate the percent recovery of each compound by using the following calculation:

% Recovery = Found Amount / True Value x 100

- Acceptance Criteria: All recoveries must be +/- 20% of the true values.
- ICALs are documented on the *TPH SHC Initial Calibration Checklist (13151)*. The initial calibration must be secondary reviewed before analyzing samples

The following *corrective actions* are recommended for failing initial calibrations:

- Check the calibration of the standard preparation that was performed. If the problem appears to be isolated to a single standard, the standard may be reanalyzed within twelve hours. The %RSD may then be recalculated.
- If chromatographic problems are indicated by the standard chromatograms already analyzed, then the injection port should be maintenanced. About 6 to 12 inches should be cut off the column, and the liner should be replaced. If applicable the septa should also be replaced. If the system continues to fail after maintenance and has poor sensitivity it is possible the detector jet may need to be cleaned or replaced. The gold seal at the base of the injection port may also need to be replaced. After maintenance is performed repeat the initial calibration and check the re-calculated %RSDs.
- If calibration continues to fail, determine if the column has degraded and should be replaced. The choice of corrective active must be made in consultation with the Department Manager. In some cases, the decision may need consultation from the QA Manager and Project Manager.

10.3 Equipment Operation and Sample Processing

Instructions on equipment operation and data processing can be found in the Agilent Enviroquant manuals. Operation of equipment and sample processing must only be performed by experienced and trained analysts. See Sections 10 and 11 for additional details.

The internal standard (100uL of a 500ug/mL solution to 900uL extract) is manually added to each sample extract prior to analysis. A 1ul aliquot of sample extract is injected into the column. Dilutions may be necessary to provide results within the calibration of the analytical instrument. Samples will be re-analyzed after a highly concentrated sample(s) exceed calibration due to potential carryover contamination. The internal standard should be within the control limits listed in Section 12.0. If the Internal Standard is outside this criterion; reanalyze. If the reanalysis confirms the initial analysis, then the results are reported and narrated appropriately.

Surrogate recoveries should be within the control limits listed in Section 12.0. If any surrogate recoveries are outside the control limits reanalysis or reextraction may be necessary. Any anomalous conditions, such as emulsions during extraction or matrix interference, could be the cause of poor surrogate recoveries. If these conditions occur, then the results are reported and narrated appropriately.

10.4 Continuing Calibration

The systems performance and calibration for each compound of interest must be checked and verified once every 24 hours of analysis time. This is accomplished by analyzing a Continuing Calibration Verification (CCV) n-alkane standard that is at a concentration near the midpoint for the working range of the GC/FID, 50µg/mL.

- Analysis of samples must be bracketed by a valid continuing calibration check standard.

- If a CCV fails the criteria outlined in Section 12, all samples since the last acceptable CCV must be re-analyzed.
- The analyst judgment from continuous daily use of the instrument is important in determining the validity of a continuing calibration. Even if the %D criteria is met, the peak shape may have deteriorated to a point of maintenance is required and a new initial calibration is in order.
- A low response for C_{40} is an indication that the GC liner should be replaced.
- When analyzing for extended lists of hydrocarbons, the ratio of phytane to n-C_{18} must be 60% or better for the test to appropriately provide weathering information. If the ratio is acceptable, it is assumed that the n-C_{17} to pristane ratio is also acceptable.
- Some programs / projects may require the mass discrimination evaluation between n-C36 and n-C20.
- The area counts of the internal standards within the continuing calibration must be within 50 to 200% of the mid-level in previous ICAL.
-

10.5 Preventive Maintenance

All maintenance records including routine upkeep and outside service visits are maintained in the instrument maintenance logbooks for all FID systems. The maintenance logbook contains the minimum preventative maintenance and a history of all instrument maintenance. The instrument operating manuals provide more detailed information. These instruments are NOT under a maintenance service contract with the vendors. For repairs beyond the scope of routine upkeep and preventative maintenance, an independent service contractor must be called for on-site service and repairs.

Injection Port and Column Maintenance: Maintenance should be done when the daily CCV starts to demonstrate degradation. The type of samples analyzed will have an effect on how soon maintenance should be performed. The injection port can be cleaned using cotton swabs and DCM until no contamination is observed. Generally, maintenance is performed by trimming 6 cm off the front of the column. The column is then installed into the injection port liner and the inlet nut is tightened. After cleaning the instrument must be checked for any air leaks while cooling. The first injection should be a primer to remove any active sites and to check if any of the windows need updating.

Merlin Maintenance: The Merlin High Pressure Microseal (Part #410 Phenomenex) should be replaced when it cannot hold back pressure. A septum may be used as a backup or for troubleshooting.

11. Data Evaluation, Calculations and Reporting

11.1 Qualitative Identification of the n-alkane compounds is based on gas chromatographic relative retention times (RRTs) from the analysis of the mid-level initial calibration standard. For these compounds, manual quantitations are performed, if necessary, by integrating the area of the quantitation peak. For *petroleum ranges*, the starting and ending n-alkanes are used as integration markers.

Note: Manual integration is not to be used solely to meet QC criteria, nor is it to be used as a substitute for corrective action on the chromatographic system. Refer to Manual Integration and Compound Rejection SOP 1731.

11.2 An Instrument Blank run within the analytical sequence with the samples shall be used to mathematically correct the range analyte areas to account for the normal baseline rise of the instrument. The instrument blank selected for this purpose will be selected on 1) the similarity of the baseline performance between the instrument blank and the sample, and 2) the conservative preference for using an instrument blank with a low minimum response voltage. The instrument blank for baseline correction shall represent the lowest baseline response within the sequence. The blank is integrated for petroleum ranges only. This integration is then applied to the samples, so an identical amount of baseline drift is removed from the sample leaving only petroleum contributions in the range amount.

11.3 The chromatograms produced by the analysis are compared to reference chromatograms for qualitative identification. The reference chromatograms are stored as hard copy results as well as electronically in the data acquisition software. Electronic storage allows for evaluation using computer software.

11.4 The qualitative analysis can be time consuming. Retention time information for the alkanes and any Unresolved Complex Mixtures is essential. The graphical comparison of sample patterns to standard patterns is extremely useful in the interpretation of results. For example, a low range UCM may indicate the presence of a petroleum based lubricant. A mid range UCM may indicate the presence of fuel oil. High range UCM may indicate heavy lubricating oils or asphalt materials. No UCM in a chromatogram may indicate the presence of gasoline. Hard copy reports of comparisons should be retained for future reference.

11.5 To calculate the ***Relative Standard Deviation*** (RSD) of all target analytes and surrogate compounds for the initial calibration use the formula below. The RSD of each target compound and surrogate must be below 25%. Additionally, use the initial six-point calibration to determine ***Relative Response Factors*** (RRF_Is) at each concentration level. Average the RRF_Is, to generate mean RRF_Is, for quantification of all target analytes and surrogate compounds. The RRF_Is are based on the internal standard compounds and are calculated using the formula below. (The relative response factors for the continuing calibration verifications (RRF_Cs) are calculated using the same formula). See Section 16, Table I, for the listing of target compounds.

$$\mathbf{RSD = SD / mean\ RRF_I \times 100}$$

where:

SD = Standard deviation between the five points, for that target analyte.

$$\mathbf{RRF_I = (A_c \times C_{IS}) / (A_{IS} \times C_c)}$$

where:

A_c = Area of the characteristic ion for the standard compound to be measured.
A_{IS} =Area of the characteristic ion for the representative internal standard compound.
C_{IS} = Concentration of the representative internal standard compound (ng/mL).
C_c = Concentration of the standard compound to be measured (ng/mL).

11.6 Based on the mean RRF_Is, calculate the ***Sample Extract Amount*** for each target analyte and surrogate in the extracts using the following formula:

$$\mathbf{Q_e = (A_a \times Q_{IS}) / (A_{IS} \times RRF_I)}$$

where:
Q_e = Sample extract amount (ng) of target analyte, from quantitation report.
A_a = Area of the characteristic peak for the target analyte.
A_{IS} = Area of the characteristic peak for the representative internal standard compound.
Q_{IS} = Amount of internal standard compound added to each extract (ng).

11.7 Based on the area calculate the **Corrected Range Amount** for the petroleum ranges:

$$\mathbf{Q_e = ((A_{SR}-A_{IB})/A_{SR})*C_S}$$

where:

Q_e = Corrected sample extract amount (ng) of petroleum range.
A_{SR} = Area of the sample petroleum range.
A_{IB} = Area of the Instrument Blank petroleum range.
C_S = Sample extract amount for petroleum range, from quantitation report.

The corrected range amount is then brought through the sample calculation found in Section 11.6

11.8 Calculate the ***Sample Concentration*** (C) for each compound by the following formula:

$$\mathbf{C = (Q_e / V_s) \times DF}$$

where:

C = Concentration in sample (ng/L water, ug/Kg sediment/tissue, or mg/Kg product).
V_s = Original volume or weight of sample extracted.
DF = Dilution factor or fraction of the original extract to which internal standard added.

11.9 If the response of any target compound in a sample exceeds the linear response range, as defined by the initial calibration standards in Section 10.2, dilute the extract so that the concentrations of all target compounds fall within the range of the calibration curve. If the response of any target compound in a sample exceeds the MDL but is below the reporting limit (RL), qualify the reported concentration with a “J”. If any target compound is found in the method blank and in the associated sample(s) at or below 10x the blank concentration, qualify the reported result with a “B”.

11.10 Calculate the ***Surrogate Recoveries*** relative to the internal standards by the following formula:

$$\mathbf{\%R_{sc} = (A_{sc} / A_{is}) \times (Q_{is} / Q_{sc}) \times (100 / RRF_{sc}) \times DF}$$

where:

Q_{is} = Amount of the representative internal standard (ng).
DF = Dilution factor or fraction of the original extract.

11.11 Compare response factors for each compound in the ***Continuing Calibration Verification*** (CCV), to those of the initial calibration curve by determining the percent difference.

Percent Difference (%D) = ($[RRF_I - RRF_C] / RRF_I$) x 100

where:

RRF_I = Mean response factor from initial calibration.
RRF_C = Response factor from CCV.

11.12 External Standard Calibration:

$$\textbf{Calibration Factor (CF)} = \frac{\text{Total area w/in RT Range}}{\text{Mass injected (ng)}}$$

$$\textbf{\%RSD} = \frac{\text{SD}}{\text{Ave. CF}} \times 100$$

$$\textbf{Raw Sample Concentration, C, (ng)} = \frac{\text{Total area w/in RT Range}}{\text{Ave. CF}}$$

$$\textbf{Final Sample Concentration} = (C / V_s) \times DF$$

11.13 All solids including soils, sediments, and sludges must be reported on a dry-weight basis. Tissue results may be reported in wet weight depending upon client request. Petroleum results are reported “as received” or on a wet-weight basis.

11.14 The primary analyst does data entry, or uploading of the data, into the LIMS system. The LIMS is “linked” to the instrument, so the analyst must choose the sample(s) to be reported from that instrument’s analytical sequence. All associated preparation and instrumental QC samples and dilutions are also chosen. Once the data/samples have been selected and “associated” with the proper QC samples, the batched data set is sent to be reported.

11.15 The laboratory generates two types of data packages from the LIMS: “Commercial” or “Standard” for routine projects, and “Full Deliverable” or “CLP-like” for fully data validated projects. A Commercial or Standard package consists of sample results and the associated method blank and LCS results. A Full Deliverable or CLP-like package includes all sample results, all preparation and instrumental QC results and the associated supporting raw data. Check the “Report Type” on the project folder to ensure all required deliverables are included. Checklists are used for primary and secondary review of analytical results.

11.16 Procedures for data and record management must adhere to the Quality Systems Manual, other subordinate documents covering record keeping, and the *Document Control* SOP, 1729. All records shall be stored in such a manner as to be safe and accessible for at least 10 years.

11.17 Notebooks: Laboratory notebooks are designed to accommodate specific analysis. Instrument printouts are used to document run sequences, and each daily sequence printout is filed in a three-ring notebook. If a sample requires re-analysis or re-extraction for any reason, a notation is made next to the sample entry on the sequence log in the FID continuing calibration package. After one month of sample analysis, the sequence run log is permanently bound, assigned an internal ID number, and filed accordingly. Such files shall be archived to remain available for at least 10 years. All laboratory notebooks must follow

the specifications in the Laboratory Notebook Usage Work Instructions WI/1556, and all record keeping and document control practices.

11.18 Electronic records: All data files from computers, attached to instruments, shall be backed up daily onto the proper directory on the server. The backups shall be stored to be accessible for 10 years. Movement of the data files to the server is the responsibility of the primary analyst. Server backup and storage is the responsibility of the IT department.

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

All Total Petroleum Hydrocarbon results are reportable without qualification if analytical holding times are met, preservation (including pH and cooler temperatures) are met, and all QC criteria defined in the table below are met. If any of the below QC parameters are not met, all associated samples must be evaluated for re-analysis. See Section 9 for additional QC discussion including corrective actions for any QC outliers.

QC Parameter	Acceptance Criteria
Initial Calibration Curve	≤ 25 %RSD for all compounds and within 0.06 RRT units for all compounds Fuel Product: ≤20% RSD
24 Hour Continuing Calibration Verification	≤ 25%D for all individual compounds with exception for 10% of target analytes can be >25%, but ≤ 35% Fuel Product: ≤20%D
Method Blank	No analyte at or above the reporting limit, “B” qualify analyte if detected in the samples ≤ 10x the concentration in the blank
LCS/LCSD	50-130% recovery
MS/MSD	50-150% recovery, 30%RPD
Matrix Duplicate	30%RPD for results >5X reporting limit
Surrogates	50-130% recovery
Internal Standards	IS area must be within 50-200% of the last CCV and the IS retention time must be with 30 seconds of the last CCV.

Section 9 outlines sample batch QC acceptance criteria. If non-compliant Total Petroleum Hydrocarbon results are to be reported, the Department Manager, and/or the Laboratory Director, and/or the QA Officer must approve the reporting of these results. The laboratory Project Manager shall be notified, and may choose to relay the non-compliance to the client, for approval, or other corrective action, such as re-sampling and re-analysis. The analyst or Department Manager performing the secondary review initiates the project narrative, and the narrative must clearly document the non-compliance and provide a reason for acceptance of these results.

13. Method Performance

13.1 Method Detection Limit Study (MDL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the MDL, LOD, and/or LOQ as outlined in Alpha SOP/1732. These studies performed by the laboratory are maintained on file for review.

13.2 Demonstration of Capability Studies

Refer to Alpha SOP/1739 for further information regarding IDC/DOC Generation.

13.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

14. Pollution Prevention and Waste Management

Refer to Alpha's Chemical Hygiene Plan and Waste Management and Disposal SOP for further pollution prevention and waste management information.

Once satisfactory Petroleum results have been generated, the extracts are held for 30 days, or longer if specified by a client contract, then discarded into a 55-gallon drum labeled "Vial Waste".

Biochemical Oxygen Demand (BOD), 5-Day

Soluble BOD (SBOD), 5-Day
Carbonaceous BOD (cBOD), 5-Day

Reference Methods: **SM 5210B,** Standard Methods for the Examination of Water and Wastewater. APHA-AWWA-WEF. Standard Methods Online.

1. Scope and Application

Matrices: This method is applicable to most water and wastewater samples.

Definitions: See Alpha Laboratories Quality Manual Appendix A

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one of the following laboratory personnel before performing the modification: Area Supervisor, Laboratory Services Manager, Laboratory Director, or Quality Assurance Officer

This method is restricted to use by or under the supervision of analysts experienced in the operation of the Dissolved Oxygen (DO) Meter and in the interpretation of Dissolved Oxygen data. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

The biochemical oxygen demand (BOD) test is used to determine the relative oxygen requirements of wastewaters, effluents, and polluted waters. The test has its widest application in measuring waste loadings to treatment plants and in evaluating the BOD-removal efficiency of such treatment systems. The test measures the oxygen utilized during a specified incubation period for the biochemical degradation of organic material (carbonaceous demand) and the oxygen used to oxidize inorganic materials such as sulfides and ferrous iron. It also may measure the oxygen used to oxidize reduced forms of nitrogen (nitrogenous demand). The seeding and dilution procedures provide an estimate of the BOD at pH 6.5 to 7.5.

The BOD concentration in most wastewaters exceeds the concentration of dissolved oxygen (DO) available in an air-saturated sample. Therefore, it is necessary to dilute the sample before incubation to bring the oxygen demand and supply into appropriate balance. Because bacterial growth requires nutrients such as nitrogen, phosphorus, and trace metals, these are added to the dilution water, which is buffered to ensure that the pH of the incubated sample remains in a range suitable for bacterial growth. Complete stabilization of a sample may require a period of incubation too long for practical purposes; therefore, 5 days has been accepted as the standard incubation period.

2. Summary of Method

The method consists of filling with sample, an airtight bottle of the specified size and incubating it at the specified temperature for 5 days. Dissolved oxygen is measured initially and after incubation, and the BOD is computed from the difference between initial and final DO.

2.1 Method Modifications from Reference

Soluble BOD determinations: Soluble BOD determinations may be performed by filtration of the sample through 0.45µm filter. Following filtration, the sample is placed in a 1L plastic

bottle and shaken vigorously for 1 minute, before any sample pretreatment procedures are performed.

3. Detection Limits

The minimum calculated RL for BOD is 2 mg O_2 / L, based on a 50% dilution of the sample (i.e. 150mL sample in the 300mL BOD bottle.)

The minimum dilution of the sample that meets acceptance criteria is used to determine the final calculated RL for the sample as follows:

$$\text{Reporting Limit, } BOD_5\text{, mg } O_2 / L = \frac{1}{\frac{\text{(mL sample used for minimum dilution meeting criteria)}}{300}}$$

Refer to Table 1.

4. Interferences

4.1 Instrumental

The DO Meter must be calibrated and maintained according to manufacturer's instructions in order to avoid any instrumental interferences.

BOD Analyzer must be maintained according to manufacturer's suggestions for optimum performance.

4.2 Parameters

The samples must be free of biological poisons or materials that produce oxygen.

5. Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material data handling sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

Samples are collected in 1L plastic containers.

6.2 Sample Preservation

No preservative is added to samples.

6.3 Sample Shipping

No special shipping requirements other than samples should be on ice.

6.4 Sample Handling

Samples for BOD analysis may degrade significantly during storage between collection and analysis, resulting in low BOD values. Minimize reduction of BOD by analyzing sample promptly or by cooling it to near-freezing temperature during storage.

6.4.1 Grab samples: If analysis is begun within 2 hours of collection, cold storage is unnecessary. If analysis is not started within 2 hours of sample collection, keep sample at or below 4ºC, but not freezing, from the time of collection. Analysis must begin within 48 hours of collection.

6.4.2 Composite samples: Use the same criteria as for storage of grab samples, starting the measurement of holding time from the end of the compositing period. Analysis must begin within 48 hours of collection.

7. Equipment and Supplies

7.1 Backup use only: BOD Incubation Bottles: 300mL capacity, glass bottles with glass stoppers and plastic snap-caps. Clean bottles, stoppers and snap-caps with a laboratory grade detergent; rinse thoroughly, and drain before use.

7.2 Primary use: BOD Incubation Bottles: 300mL capacity “PET resin” disposable plastic BOD bottles (Environmental Express, part # D1001), with glass stoppers and plastic snap-caps.

7.3 Air Incubator: Thermostatically controlled at 20 ± 1ºC. Exclude all light to prevent possibility of photosynthetic production of DO.

7.4 pH Paper: Range 0-14

7.5 15mL Centrifuge Tubes.

7.6 COD Reactor: 150° C, Hach, Hanna Instruments or equivalent

7.7 Spectrophotometer: Model Genesys 10S UV-VIS or equivalent

7.8 Pipets: Disposable plastic, , 1mL to 30 mL graduated.

7.9 YSI Model DO Meter with DO Electrode: YSI ProOBOD or equivalent.

7.10 BOD Analyst Software: Seal Program or equivalent

7.11 Volumetric Flasks: 100mL volume, 1 L volume; Class A

7.12 Autopipettor: With disposable tips, 0.5 - 5mL volume.

7.13 Peroxide Test Strips: Range 0 – 30 mg/L.

7.14 BOD Analyzer System: By MANTECH, with AutoMax 122, and all associated equipment. Or BOD (Minilab) Analyzer System by Seal Analytical with all associated equipment.

7.15 Stir plates: 1 with heat; 1 without heat

7.16 Wide-mouth 500ml flask

7.17 pH Meter: Laboratory benchtop pH meter with automatic temperature compensator and combination electrode.

7.18 Disposable, plastic transfer pipettes: VWR # 16001-180

7.19 Stir bars, 1" length

7.20 50mL Centrifuge Tubes

8. Reagents and Standards

8.1 Glucose-Glutamic Acid:

8.1.1 Purchased, premade Glucose-Glutamic Acid standard solution ampules: Use 1 ampule per LCS bottle for analysis. Carefully empty all contents into a clean/new bod bottle. Rinse with nutrient solution from working tank for batch, using clean/new, plastic, disposable transfer pipette.

InterLab, product # P910	pk of 48 vials	or equivalent.
InterLab product # P510	bottle 125mL	or equivalent.

8.1.2 Lab prepared, Glucose-Glutamic Acid (for LCS and Spike): Dry reagent-grade glucose and reagent-grade glutamic acid at 105ºC for a minimum of one hour, and cool before use.

8.1.2.1 For LCS Stock Solution (198ppm): In a 1L volumetric flask, add 150mg (0.15g) glucose and 150mg (0.15g) glutamic acid to distilled water and dilute to volume. Stir this solution until dissolved; stir for at least 45 minutes. Prepare fresh immediately before use.

8.1.2.1.1 198ppm LCS: While stirring, withdraw 6mL of the glucose-glutamic acid stock solution (Section 8.1.2.1) and add to non-empty BOD bottles for analysis.

8.1.2.2 For Spike Stock Solution: In a 100mL volumetric flask, add 1.5g glucose and 1.5g glutamic acid to distilled water and dilute to volume. Slightly heat this solution until dissolved; stir for at least 45 minutes. Prepare fresh immediately before use.

8.1.2.2.1 100ppm Spike: While stirring, withdraw 0.5mL of the glucose-glutamic acid stock solution (Section 8.1.2.2) and add to 100mL of sample.

8.1.2.2.2 198ppm Spike: While stirring, withdraw 1mL of the glucose-glutamic acid stock solution (Section 8.1.2.2) and add to 100mL of sample.

8.2 BOD Nutrient Solution/Dilution Water: Fill tank with DI at least a day prior to use. Aerate tank with DI for 4 hours. The Nutrient Solution/ Dilution Water can be used for 3 days from the time of aeration/pillow addition. Store in the dark at room temperature.

- Fill carboy to 38L with DI water.
- After filling, saturate with DO by aerating for 4 hours. Protect water quality by using clean tubing.
- Just before sample batch preparation, add 2 BOD Nutrient Buffer Pillows (HACH Brand, 1 pillow is for preparation of 19L). Agitate tank vigorously for 1 minute to mix after adding pillows.
- Tank is now ready for use; expiration is 3 days from aeration/pillow addition.

8.3 Sulfuric Acid Solution (1N): For neutralization of caustic samples. Slowly and while stirring, add 2.8mL concentrated H_2SO_4 to distilled water. Dilute to 100mL with DI. Store refrigerated at 1-4 °C. Expires one year from date of preparation.

8.4 Sodium Hydroxide Solution (4N): For neutralization of acidic samples. Dissolve 40g sodium hydroxide (NaOH) in distilled water. Dilute to 250mL with DI. Store refrigerated at 1-4 °C. Expires one year from date of preparation.

8.5 Sodium Sulfite Solution: Dissolve 0.1575g Na_2SO_3 in 100mL distilled water. This solution is not stable; prepare fresh immediately before use.

8.6 Polyseed Inoculum: Dissolve one Polyseed capsule (InterLab Supply, commercial BOD seed inoculum) in 500mL nutrient solution; stir for a minimum of two hours prior to use. Stir at a spin speed which permits approximately ½ inch vortex. Warning: If the seed is set to spin too quickly, this could lead to the death of organisms in the seed and therefore a low recovery value. The Polyseed solution is viable for 6 hours from time of preparation. The sample can also be aerated for a minimum of 1 hour in place of stirring.

Adjust the Polyseed volume added to each batch based on the Polyseed lot strength. The desired seed recovery range is 0.6 – 1.0 mg/L. Test each lot of Polyseed prior to use to determine a volume that will produce results within this acceptance range.

8.6.1 If the Polyseed is to be used with the BOD Analyzer procedure (note: only when using the automated seed pump), then stop spinning the Polyseed after the minimum of 2 hours, allow sediment to settle for 5 minutes, then carefully pour the top portion of the solution into a different, clean 500ml flask, trying not to disturb any of the settled material while doing so.

8.6.2 This poured off portion of the Polyseed becomes the solution used with BOD and cBOD setup with the BOD Analyzer (to avoid having sedimentary material caught in the equipment lines).

Note: A capsule from new lots of polyseed should be analyzed *in advance*, to determine the correct dilution range. Record the use of a new lot of polyseed in the Bod logbook.

8.7 DPD Free Chlorine Reagent Powder HACH brand, Swiftest: for 10mL sample. Use with HACH Swiftest free chlorine reagent dispenser. Store at room temperature. Expires upon manufacturer specified date.

8.7.1 Hach Swiftest DPD free chlorine reagent dispenser: cat # 28023-00

8.7.2 Hach Swiftest DPD free chlorine reagent powder vial refill for 10ml sample cat # 2105560

8.8 COD Tubes:

8.8.1 CPI (catalog # COD1500), range 0 – 1500 mg/L.

8.8.2 Environmental Express (catalog # B1015), range 0 – 1500 mg/L. Store at room temperature. Expires upon manufacturer specified date.

8.9 1:1 Acetic Acid Solution: 50mL of DI + 50mL Acetic Acid. Dilute to 100mL with DI. Store refrigerated at 1-4 °C. Expires one year from date of preparation

8.10 KI Solution: 10 grams KI per 100mL DI. Dilute to 100mL with DI. Store refrigerated at 1-4 °C. Expires one year from date of preparation

8.11 Starch Indicator Solution: HACH brand. Store at room temperature. Expires upon manufacturer specified date.

8.12 Nitrification Inhibitor: HACH brand, with 0.2g dispensing scoop. Store at room temperature. Expires upon manufacturer specified date.

8.13 Respirometric BOD Nutrient Buffer Solution Pillows: HACH brand, Product #2962266. Store at room temperature. Expires upon manufacturer specified date.

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

9.1 Blank(s)

9.1.1 Dilution Water Check: Determine initial DO for 3 BOD bottles of dilution water for each analytical batch (Section 8.2). Incubate these bottles along with the samples for 5 days at 20 ± 1ºC. Determine the final DO.

The DO depletion after 5 days at 20 ± 1ºC should not be more than 0.2mg/L and preferably not more than 0.1mg/L. If the blank depletion falls outside of these limits, the analytical batch may be considered invalid. All other QC parameters must be evaluated. Notation should be done in the raw data. Notify the Department Supervisor and/or the Laboratory Manager for instructions on how to proceed.

9.1.2 Method Blank: Determine initial DO for 3 BOD bottles of DI water with volumes of 30mL, 60mL and 150mL for each analytical batch (Section 8.2). Incubate these bottles along with the samples for 5 days at 20 ± 1ºC. Determine the final DO after incubation for 5 days at 20 ± 1ºC. Results must be less than the RL. If failure occurs, the Inorganics Supervisor is notified.

9.2 Laboratory Control Sample (LCS)

Determine initial DO for the LCS as stated in Section 8.1.1 purchased, or 8.1.2.1.1 for in-house prepared standard. Incubate these bottles along with the samples for 5 days at 20 ± 1ºC. Determine the final DO.

The true value of the LCS equals 198mg O_2/L. The % Recovery must be between 85 – 115%. If the % Recovery for the LCS falls outside these limits, the analytical batch is not valid. Notify the Department Supervisor and/or the Laboratory Manager for instructions on how to proceed.

9.3 Initial Calibration Verification (ICV)

Not applicable.

9.4 Continuing Calibration Verification (CCV)

Not applicable.

9.5 Matrix Spike

Prepare and analyze a matrix spike for one sample (as determined in Section 8.1.2.2.1 or 8.1.2.2.2) per batch of 20 samples or less. % Recovery must be 85-115%, or according to in house control limits.

9.6 Laboratory Duplicate

Prepare and analyze a duplicate set of dilutions for one sample per batch of 20 samples or less. % RPD must be ≤ 20%, or according to in house control limits.

9.7 Method-specific Quality Control Samples

9.7.1 Seed

Determine initial DO for the volumes of Polyseed as stated in Section 8.6. Incubate these bottles along with the samples for 5 days at 20 ± 1ºC. Determine the final DO.

The final seed depletion after 5-day incubation at 20 ± 1ºC ideally should be between 0.6 and 1.0 mg/L.

9.8 Method Sequence

The analytical sequence is:

- Dilution Water Blank
- Seed
- Glucose-Glutamic Acid LCS
- Method Blank
- Samples 1-20 or less
- Duplicate
- Matrix Spike

10. Procedure

10.1 Equipment Set-up

10.1.1 Preparation of Dilution Water Blank: Fill three 300mL BOD bottles with Nutrient Solution/Dilution Water (Section 8.2). Determine the BOD of the Dilution Water as for any other sample. (If setup is done with BOD Analyzer, skip to step 10.1.3).

Note: If more than 150 ml of the sample has to be used for analysis (per customer instructions only) , then additional Nutrient solution has to be added. It has to be done by adding one pillow of Respirometric BOD Nutrient Buffer Solution (8.13) to each bottle.

10.1.2 Preparation of Polyseed Value: Make dilutions of the Polyseed solution (Section 8.6) using volumes of 8mL, 10mL, 12mL, and 14mL (or 15mL, 18mLs and 21mLs). Determine the BOD of the seeding material as for any other sample. (If setup is done with BOD Analyzer, skip to step 10.1.3). This varies as the seed value is adjusted per lot of Polyseed.

10.1.3 Preparation of LCS

10.1.3.1 Purchased LCS ampules: Use as instructed in section 8.1.1.

10.1.3.2 In House Preparation of LCS: Use 6mL, 6mL, and 6mL volumes of the 198ppm LCS solution (Section 8.1.2.1.1). Determine the BOD of the LCS as for any other sample.

10.1.4 Preparation of Method Blank: Fill 3 bottles with DI volumes of 30mL, 60mL and 150mL. (If setup is done with BOD Analyzer, skip to step 10.1.5).

10.1.5 cBOD Dilution Bottle Preparation: If samples are to be analyzed for cBOD, add 0.2g (1 scoop) of Nitrification Inhibitor (Section 8.12) to each dilution bottle and QC bottle, prior to filling with sample, and prior to filling/reading on BOD Analyzer.

10.1.6 Sample Pretreatment:

10.1.6.1 Samples containing caustic alkalinity or acidity: Check the pH of all samples using pH paper. If the sample pH is between 6.0 and 8.0, then do not adjust the pH, but record the pH value in the BOD preparation logbook. However, any samples that are outside the range of 6.0 to 8.0 require pH adjustment. Neutralize these samples to pH 7.0 to 7.2 with sulfuric acid solution (Section 8.3) **or** sodium hydroxide solution (Section 8.4) using pH meter. *NOTE: Do not use both solutions on the same sample.*

The quantity of reagent added must not dilute the sample by more than 0.5%. If 0.5% is exceeded, notify the Department Supervisor and/or the Laboratory Manager for instructions on how to proceed.

10.1.6.2 Samples containing residual chlorine compounds: Test samples for chlorine by adding 1 DPD free chlorine reagent powder pillow (Section 8.7) to a 15mL centrifuge tube. Add 5mL sample. Mix. Chlorine is present if sample turns a pinkish color. If there is no color change, no chlorine is present. Proceed to Section 10.1.6.3.

(**NOTE:** If there is a change to a very rosy pink color, sample is checked for peroxide using a peroxide strip. If the sample is positive for peroxide, sample analysis is ended and results are narrated as invalid due to peroxide interference.)

If chlorine is present, it must be removed from the sample. To do this, it is necessary to determine the required volume of Sodium Sulfite (Na_2SO_3) solution (Section 8.5) to add to a 100mL portion of neutralized sample. Do this by adding 1mL of 1:1 acetic acid solution (Section 8.9), 1mL potassium iodide (KI) solution (Section 8.10) and 1mL starch indicator solution (Section 8.11) to 100mL of sample, and titrating with Na_2SO_3 solution to the starch-iodine end point. The end point is reached when blue color disappears.

Determine the volume titrated. This is the volume of Na_2SO_3 solution necessary to dechlorinate 100mL of sample. (**NOTE:** If the volume of Na_2SO_3 solution is greater than 10mL for 100mL sample, consult the Department Supervisor and/or the Laboratory Manager before proceeding.) (**NOTE**: Discard titrated sample.) Add this determined volume of Na_2SO_3 solution per 100mL of sample. Mix. After 10 to 20 minutes, check sample again for residual chlorine. (**NOTE**: Excess Na_2SO_3 exerts an oxygen demand and reacts slowly with certain organic chloramine compounds that may be present in chlorinated samples.)

10.1.6.3 COD Check for Determination of BOD Dilutions: A COD allowed to reflux for 30 minutes is enough time to be able to calculate an estimated BOD value. (Refer to the Standard Operating Procedure for COD ID#2208.) Once a COD value is calculated, use TABLE 1 to select dilutions for the BOD. TABLE 1 is based on the RDL at each dilution. Compare the COD result to the BOD RDL in TABLE 1. Since the BOD is always less than the COD, choose the 5 BOD sample volumes less than the COD value. In the case of a COD less than 20mg O_2/L, choose the 30mL, 60mL, and 150mL volumes (10, 20, 50% of a 300mL BOD bottle).

10.1.6.4 Sample temperature adjustment: Bring samples to 20 ± 1ºC before making dilutions.

10.2 Initial Calibration

10.2.1 If following the Manual procedure in Section 10.3.1, calibrate the YSI Dissolved Oxygen Meter per manufacturer's instructions.

10.2.2 Winkler Titration Calibration – Weekly Check

Note: This check is not needed for the YSI ProOBOD Optical Probes.

10.2.2.1 Fill 1 extra BOD bottle with only Nutrient Solution. Prepare this bottle for dissolved oxygen analysis as per the Dissolved Oxygen SOP 2249.

10.2.2.2 Immediately following the probe reading of the first blank BOD bottle in the batch (Section 10.3.2), titrate the extra Nutrient Solution bottle prepared in Section 10.2.2.1. according to the Dissolved Oxygen SOP 2249. Record the D.O. result from the Winkler titration in the BOD logbook

The D.O. results obtained from the probe and the Winkler titration should be very similar. If results are not within these criteria, refer to Section 10.5 for preventive maintenance procedures for the D.O. probe, and repeat Sections 10.2.2.1 – 10.2.2.2.

10.3 Equipment Operation and Sample Processing

10.3.1 MANUAL PROCEDURE: USE OF BOD ANALYST SOFTWARE

10.3.1.1 Using a wide-tip pipet, add the desired volumes of Polyseed, LCS and samples to the individual BOD bottles and dilute with BOD Nutrient Solution/Dilution Water (Section 8.2).

Note: Add approximately 25ml of Nutrient Solution to Polyseed bottles **before** adding the seed volumes.

For sample dilutions greater than 1:100, make a primary dilution using BOD Nutrient Solution/Dilution Water in a volumetric flask before making the final dilution in the BOD bottle

10.3.1.2 Preparing the Matrix Spike:

The spike concentration chosen (either Section 8.1.2.2 or Section 8.1.2.3), should be greater than or equal to the expected sample value as determined in Section 9.1.5.3. Therefore, choose a sample to spike that has both of the following:

(1) a COD result less than or equal to the spike amount chosen and

(2) enough volume in the sample container to allow setting both the sample and the spike.

Determine the BOD dilutions for the spike as in Section 8.1.2.1 or 8.1.2.3. Be sure to calculate the sample COD value and add in the spike amount chosen. Use this value to compare with TABLE 1. Four volumes are needed when setting the spike.

10.3.1.3 Using the autopipettor set at 2.0mL, add 2mL of seed material to the individual BOD bottles for the LCS and samples. ((Note: The seed volume added to the batch may vary, depending on the current seed value of the polyseed lot currently in use (Section 8.6)).

10.3.1.4 Fill BOD bottles with enough nutrient solution so as to come halfway up the neck of the bottle.

10.3.1.5 **Determination of Initial DO:** Following the manufacturer's instructions, use the DO electrode, DO meter, and BOD Analyst Software to determine initial DO for all sample dilutions, dilution water blanks, seed controls, and the glucose-glutamic acid LCS. Rinse electrode between determinations to prevent cross-contamination of samples.

10.3.1.6 Tightly insert a glass stopper to displace all air, leaving no bubbles and creating a water-seal. Place a plastic snap-cap over the flared mouth of the bottle to prevent evaporation.

10.3.1.7 Incubation:

10.3.1.7.1 Incubate BOD bottles for 5 days at 20 ºC ± 1 ºC.

10.3.1.7.2 Note the time IN and Incubator ID in the BOD prep logbook. (The initial incubation date/time is used as the "prep time" for the data).

10.3.1.8 Determination of Final DO:

10.3.1.8.1 After a 5-day incubation period, determine final DO for all sample dilutions, dilution water blanks, seed controls and the glucose-glutamic acid LCS, using the membrane electrode, DO meter and BOD Analyst Software.

10.3.1.8.2 Note the time OUT in the Bod prep logbook. (The final DO reading (end of incubation) date/time is used as the "analysis time" for the data).

10.3.1.8.3 The OUT time is derived from absolutely no more than +/- 6 hours of the IN date/time of the BOD batch of samples to the incubator. (example: If the IN time is 12:00pm, then the batch must be taken out of the incubator and the final DO readings conducted no earlier than 6:00am and no later than 6:00pm).

10.3.2 AUTOMATED PROCEDURE: USE OF BOD ANALYZER

10.3.2.1 Setup of Solutions Prior to Analysis of Samples

1. Make Nutrient Solution/Dilution Water (refer to Section 8.2). This should be made several hours in advance in order for the dissolved oxygen level of the tank to be relatively stable prior to use.
2. Make LCS/SPK stock standard (refer to Section 8.1) a minimum of two hours prior to use of analyzer.
3. Make Polyseed (refer to Section 8.6) a minimum of two hours prior to use of analyzer.

10.3.2.2 Setup of Equipment Prior to Sample Analysis

1. Turn on analyzer and associated computer. The analyzer should have 5 lights lit on the equipment, indicating that all pieces are powered on.
2. Make sure that the manifold shelf is pushed back behind the autosampler main section. (VERY IMPORTANT: if this is not in the correct location, the autosampler arm will crash during operation and disrupt analysis).
3. Fill the DI tank so there is ample water to supply the probe washing station.
4. Make sure that the autosampler tray base is completely on the laboratory countertop (refer to arrow markings on either side), to ensure the base does not become unstable during use.

10.3.2.3 Setup of Samples Prior to Analysis (Preparing Dilutions Directly in BOD Bottles)

10.3.2.3.1 Preparing the Polyseed Value and LCS bottles

Using a calibrated pipet or calibrated autopipettor, add the desired volumes of Polyseed and LCS to the individual BOD bottles. Use wide-mouth pipets for samples. (Do not **fill** the bottles with NS/Dilution water. It will be added automatically by the Analyzer).

Note: Only add polyseed to bottles as each rack for the autosampler becomes ready for Initial D.O. reading, to ensure samples are not seeded prematurely while waiting to be read.

Note: Add approximately 25ml of Nutrient Solution to Polyseed bottles **before** adding the seed volumes.

For sample dilutions greater than 1:100, make a primary dilution using BOD Nutrient Solution/Dilution Water in a volumetric flask before making the final dilution in the BOD bottle.

10.3.2.3.2 Preparing the Matrix Spike and Sample Bottles

The spike concentration chosen (either Section 8.1.2 or Section 8.1.3), should be greater than or equal to the expected sample value as determined in Section 10.1.6.3. Therefore, choose a sample to spike that has both of the following:

1. A COD result less than or equal to the spike amount chosen

   and

2. Enough volume in the sample container to allow setting both the sample and the spike.

Determine the BOD dilutions for the spike as in Section 10.1.6.3. Be sure to calculate the sample COD value and add in the spike amount chosen. Use this value to compare with TABLE 1. Four volumes are needed when setting the spike. Use a calibrated pipet or calibrated autopipettor to dispense spiked sample solution.

10.3.2.3.3 Preparing the Polyseed bottles

(Skip this section if the Polyseed is to be added automatically by the Analyzer).

Note: Add approximately 25ml of Nutrient Solution to Polyseed bottles **before** adding the seed volumes.

Using the autopipettor set at 2.0 mL, add 2mL of seed material to the individual BOD bottles for the LCS and samples. [Note: The seed volume added to a batch is determined in advance per lot of Polyseed to ensure the value should fall within the ideal range. (Refer to Section 8.6).]

10.3.2.4 Preparation of Analyzer Equipment for Use

10.3.2.4.1 On the computer desktop screen, double-click on the yellow “Z lightning bolt” icon to open the BOD Analyzer software.

10.3.2.4.2 The page which opens will be entitled “PC-BOD Main Menu”. (This will be referred to as the Main Menu screen going forward.)

NOTE: If a batch is being set up for initial readings, then proceed here. If a batch is to be read for final Bod/CBod, then skip to Section 10.3.A.9.

10.3.2.4.3 On the bottom of the Main Menu screen, there are several icons. They are defined as follows:

- #1 = BOD daily
- #2 = CBOD daily
- Blue/purple spots = change membrane
- Green cup = prime pumps
- Water drip = probe calibration
- Ringing bell = park the probe
- Raindrops = clean the system

10.3.2.5 Priming the System

10.3.2.5.1 Double-click on the prime pumps icon; this will initialize the software communication. A new page will open, called the Timetable/Sample Entry Screen. (This will be referred to as the Timetable screen going forward.)

10.3.2.5.2 Unhook the bod bottle from the autosample arm/probe (Note: HOLD autosampler arm/probe with one hand and gently twist bod bottle off to lower to tray. DO NOT twist and remove bottle without holding the arm/probe while doing this!)

10.3.2.5.3 Hit the start button (green rectangle on bottom right of Timetable page). A box will appear, asking “enter a valid rack #”. Type “0”. Hit ok. A box will appear, asking “is seed reservoir filled?”. (Refer to Section 8.6 for Polyseed preparation.) If yes, then hit ok. A box will appear, asking “is dilution water reservoir filled?”. (Refer to Section 8.2 for NS/dilution water preparation.) If yes, then hit ok.

10.3.2.5.4 At this time, the autosampler will move to wash the probe at the washing station. It is normal equipment behavior that some water will overflow during this process. When the priming of the system is completed, a box will appear, stating “pumps are now primed and ready for use”. Hit ok. Then hit the done button at the bottom right of the Timetable page. This will close the page back out to the Main Menu screen.

NOTE: Make sure the drain/waste line is secured to the equipment, and able to flow in a gravimetrically and unobstructed fashion, to prevent backwash into the equipment.

10.3.2.6 Calibrating the Probe

10.3.2.6.1 On the Main menu screen, press the water drip icon, for calibrating the probe. This will open the Timetable page.

10.3.2.6.2 On the Timetable page, press the start button (green rectangular box). A box will appear, asking “enter a valid rack #”. Enter “0”, and hit ok.

10.3.2.6.3 After the probe is finished at the washing station, a box will appear, asking to “wipe off excess water from probe”. Do this VERY GENTLY, just blotting the tip with a soft towel, so as not to tear or otherwise damage the membrane. Hit ok.

10.3.2.6.4 A box will appear, asking “is a bottle with 1 inch of water in position #1?”. If yes, then hit ok. Another box will appear, stating to “attach the probe to the bottle for a good seal”.

10.3.2.6.5 At this time, the system will automatically become immobile for 10 minutes, during the countdown to ensure probe stability prior to calibration.

10.3.2.6.6 Once the 10 minutes has passed, a box will appear, asking "is the reading stable?". At this time, the probe needs to be calibrated manually, as follows: [Refer to Section 10.2.A.1 for further information on calibrating the probe per the manufacturer's instructions.]

- Press the mode button on the probe meter twice to return the meter to the main menu, hit ok.
- Press the calibrate button, then adjust the meter reading to 100%, hit ok.
- Press the mode button twice, then the remote button twice to return the meter to the remote mode, hit ok.
- Make sure the meter is in remote mode, hit ok.
- **Very important!!** Unhook the BOD bottle from the probe.

10.3.2.6.6.1 The reading should be within 85 – 115 % on the probe meter. If yes, then hit ok.
The Shazam Report Wizard page will open; hit "X" to close (this page is not needed at this time). After closing this Shazam page, the green start button will be visible again.

10.3.2.6.6.2 A box will appear, stating that "now the system is primed and calibrated, and ready for use". Hit ok, and then done, to close out of the calibration page.

10.3.2.6.6.3 Park the probe!!! (Section 10.3.2.10)

10.3.2.7 Running a Batch of BOD/CBOD Samples

10.3.2.7.1 On the bottom left part of the Main Menu screen, there are 2 icons. The '1" is for BOD daily, and the "2" is for CBOD daily. Select the appropriate icon button for the samples to be analyzed. This will open the Timetable page.

10.3.2.7.2 Hit the edit button, located near the middle of the page, to enter sample/batch information. Enter name/date/time at the top of the page. Add rows as needed (using the add rows button). Hit the done edit button when the sample/batch process is completed.

10.3.2.7.3 Hit the green rectangular start button on the bottom right of the page, once the rack of sample bottles is placed on the autosampler base tray. A box will appear, asking "enter a rack #". Enter the rack #, and hit ok. The run will be initiated at this time, and the autosampler will begin to read and fill bottles.

Note: If multiple racks are used in the same batch, only the LAST rack can be less than completely full of bottles.

10.3.2.7.4 After the first rack (and each additional rack when applicable), a box will appear, instructing "remove rack and replace with next rack", at which time, the current rack is removed, the next rack is placed on the autosampler base tray, hit the start button, and a box will appear again, asking for the rack #..

Note: If there is no additional rack, then just hit ok. If all the racks have been read for the batch, then the Shazam Report Wizard page opens. Print a copy of the initial readings of the batch for future reference. Hang the copy on the appropriate BOD incubator where the batch will be housed. Close the Shazam page after printing. When the start button becomes green again, hit the done button to return to the Main Menu page.

(REMINDER: On the printout front page, write the date/time of when the BOD or cBOD batch is to come out of the incubator to be read.)

Tightly insert a glass stopper to displace all air, leaving no bubbles and creating a water-seal. Place a plastic snap-cap over the flared mouth of the bottle to prevent evaporation.

10.3.2.8 Incubation:

10.3.2.8.1 Incubate BOD bottles for 5 days at 20 ºC ± 1 ºC.

10.3.2.8.2 Note the time IN and Incubator ID in the BOD prep logbook. (The initial incubation date/time is used as the "prep time" for the data).

10.3.2.9 Cleaning the System After Use

10.3.2.9.1 On the Main Menu page, the icon with the multiple raindrops refers to the cleaning of the system. This procedure drain and rinses the dilution water and seed lines associated with the equipment.

Note: This procedure is done after all the initial and final readings are completed for the period of time that the equipment was continually in use.

10.3.2.9.2 Press the Clean System icon button. The page will appear stating that it is for the cleaning of the system. Hit the start button.

- A box will appear, asking "enter a valid rack #". Enter 0. Hit ok.
- A box will appear, instructing to "remove seed and dilution water lines from reservoirs". Hit ok. This process removes all liquid from the lines.
- Once completed, another box will appear, instructing to "put the lines in separate containers of DI". Hit ok. This process rinses DI thru the lines to clean them.
- Next, another box will appear, stating to "remove seed and dilution lines from the DI containers". Hit ok. This process will empty all remaining liquid from the lines.

- Finally, when this has been completed, a box will appear, stating that "the pumps are now clean". Hit ok.

10.3.2.10 Parking the Probe

It is important now to park the probe (the ringing bell icon).

- Push the park probe icon.
- A box will appear, stating to "place a bottle in position 1 of rack". Hit ok.
- A box will appear, stating to "snug the bottle on the probe for a good seal".

  Note: This keeps the probe membrane from drying out.
- Hit done to close the page back to the Main Menu page.
- If no further use of the equipment is necessary at this time, close out of the software by hitting the "X" at the top right of the Main Menu page. The software will automatically conduct a saving procedure, and then close entirely.

10.3.2.11 Determination of Final DO

10.3.2.11.1 After a 5-day incubation period, determine final DO for all sample dilutions, dilution water blanks, seed controls and the glucose-glutamic acid LCS, using the membrane electrode, DO meter and BOD Analyzer.

10.3.2.11.2 Note the time OUT in the Bod prep logbook. (The final DO reading (end of incubation) date/time is used as the "analysis time" for the data).

10.3.2.11.3 The OUT time is derived from absolutely no more than +/- 6 hours of the IN date/time of the BOD batch of samples to the incubator. (example: If the IN time is 12:00pm, then the batch must be taken out of the incubator and the final DO readings conducted no earlier than 6:00am and no later than 6:00pm).

- Open software (see Section 10.3.A.3) to Main Menu page.
- This page has a list of batches which need to be read, which are still in progress.
- Click on the icon "1" for Bod, or icon "2" for CBod.
- At the bottom left of the page, click on "load existing runs"
- Select the batch to read finals on (by date of setup). Hit "load selected".
- Then hit "start" (once probe calibration has been completed first! If it has not, refer to section 10.3.A.5). Probe should be unhooked from bottle at this time, and the rack of samples to be read first should be on the autosampler tray (with all plastic caps and glass corks removed).
- Read the racks, as in section 10.3.A.6, and when all readings have been finished, print data from the Shazam Wizard. Then hit "done".
- Park the probe and snug the bottle onto the probe.

- Close out of the software.
- Turn off computer, if done using for the day/night.

10.3.2.12 Printing a Previous BOD/cBOD batch

- If a copy of a previous batch is needed, simply open the software, as explained in Section 10.3.A.3, and go to the top of the Main Menu page.
- Click on the BOD heading, and then select “Post Run Bod Analysis”.
- On this new page which opens, at the bottom is a box which says “completed runs”.
- Select the start date of the batch to be opened. Click on the batch. Then hit “load selected”.
- Once the selected batch is visible, hit “run method” to provide results for the batch on the screen.
- Hit “print results”. Then select “printer”. Hit “print”. Then hit “done”.

IMPORTANT NOTE: If software is opened only to print a previous batch, then initiation of software with equipment is not necessary; therefore, the bottle does not need to be unhooked from the probe. But whenever the software AND equipment are to be used, for initial and final readings, the bottle MUST be unhooked prior to hitting ‘start”, or the probe could crash.

10.3.3 AUTOMATED PROCEDURE: USE OF SEAL BOD ANALYZER

10.3.3.1 Setup of solutions prior to analysis

Make Nutrient/Dilution water (Section 8.2)

Make Spike stock standard (Section 8.1.2.2) a minimum of two hours prior to use

Make Polyseed (Section 8.6) a minimum of two hours prior to use

10.3.3.2 Setup of equipment prior to use

- Turn on Seal Autosampler, computer, seed pump, nutrient solution pump and two DO meters. Lights will turn on and screens on DO meters will power on.
- Initilaize the system (Tools-> initialize system)
- Flush probes (Tool -> flush probes)
- Calibrate DO probes (Tools -> Cal DO probes -> Follow popup instructions to wipe down probe heads)
- On the DO meter display (Cal -> select ProODO -> then DO%)
- Place the larger plastic tubes into the Nutrient solution tank and the smaller tubes in the decanted seed.
- Prime the lines (Tool -> Flush dilution liquid and flush addition liquid)

10.3.3.3 Setup of Samples prior to analysis (preparing dilutions directly in BOD bottles)

10.3.3.3.1 Preparing the LCS Bottles

Add premeasured vial of GGA (Section 8.1.1) and rinse vial with DI

10.3.3.3.2 Preparing the Method Blank Bottles

Add 30mL, 60mLs and 150mLs of DI to bottles

10.3.3.3.3 Preparing the Matrix Spike

The spike concentration chosen (either Section 8.1.2.2.1 or Section 8.1.2.2.2), should be greater than or equal to the expected sample value as determined in Section 10.1.6.3. Therefore, choose a sample to spike that has both of the following:

- A COD result less than or equal to the spike amount

  chosen **and**

- Enough volume in the sample container to allow setting both the sample and the spike

Determine the BOD dilutions for the spike as in Section 10.1.6.3. Be sure to calculate the sample COD value and add in the spike amount chosen. Use this value to compare with TABLE 1. Four volumes are needed when setting the spike. Use a calibrated pipet or calibrated autopipettor to dispense spiked sample solution. For spike 100 use volumes 3, 6, 15 and 30mLs. For spike 200 use volumes 1.5, 5, 10, 30mLs. (i.e For spike 100 take 100mLs of sample and add 0.5 mLs of the spike stock standard. For spike 200 take 50mLs of samples and add 0.5 mLs of spike stock standard.)

10.3.3.3.4 Preparing the Sample bottles

Using the COD screening results in Table 2 add the specified volumes to each bottle

10.3.3.4 Sample Analysis

- In SEAL program go to “New table by template”
  - Name new sequence by the WG#
  - Add lines to sequence by hitting the down arrow
  - Scan samples 3 to 6 times, depending on the different dilutions / volumes needed
  - Fill in different volumes and dilution factors
- Under table -> Measure Start DO, Right click tray holders and select Load BOD tray. Once all bottles are loaded select start routine
- Number all the bottles (1, 2, 3, 4 etc)
- Remove from trays and stopper and cap each bottle
- Add samples to incubator for 5 days +/- 6 hours

10.3.3.5 Cleaning System and Determining of Final DO

- Flush the nutrient solution and seed lines with DI and then air
- Under start select “open active table”
- Remove caps and stoppers from bottles and load onto trays in numerical order
- Under table select “measure end DO”
- Start routine
- At end of run hit calculate

10.3.3.6 Data

- Export the file to BOD FINAL and name as WG#
- Select print data from table (Print to PDF)
- Always save as BOD final report (regardless of product)
- When printing select ALL and save as WG#_rawdata in the BOD rawdata folder
- Open the CSV file associated with WG and expand volumes to include all data
- Add WG# to each sample (WG column) and BOD11 to instrument ID for all samples
- Change start time DO and end time DO to the times in the preplog corresponding to Date/Time In and Date/Time Out
- Change LCS samples to WG#-2 and Method Blank to WG#-1,
- the operator is “sealbod” change that to the initials of the person who ran the batch
- For Soluble BOD add the letter S, cBOD the letter C and soluble cBOD SC
- Save, Drag and drop the CSV file in PC_BOD drive, Drag and drop the WG#_rawdata in to the WG_files drive. Scan and drop the preplog
- Approve data in LIMS

10.4 Continuing Calibration

Not applicable.

10.5 Preventative Maintenance

The membrane on the DO electrode should be changed and the electrode tip serviced at regular intervals per the manufacturer’s instructions (for membrane probes).

Temperatures of the BOD incubators are recorded continuously by an automated datalogger. The temperatures are checked by the analysts twice daily (with a minimum of 4 hours between readings) and adjusted as necessary.

The BOD incubators are calibrated on an annual basis by an instrument service company. These records are kept on file.

BOD Analyzer and optical probes must be maintained according to manufacturer’s suggestions for optimum performance.

11. Data Evaluation, Calculations and Reporting

11.1 Both the BOD Analyst Software and the BOD Analyzer Software will calculate the BOD results automatically upon completion of final dissolved oxygen readings. However, the following is an explanation of the manual calculation should it be necessary:

$$BOD_5, \text{ mg } O_2 / L = \frac{[\,(D_1 - D_2) - f\,]}{P}$$

where:

D_1 = DO of diluted sample immediately after preparation, mg/L,
D_2 = DO of diluted sample after 5-day incubation at 20ºC, mg/L,
P = Decimal volumetric fraction of sample used,
f = Average DO depletion for 2mL of seed.

11.2 If more than one sample dilution meets the criteria of a final DO of at least 1mg/L and a DO depletion of at least 2mg/L, and there is no evidence of toxicity at higher sample concentrations or the existence of an obvious anomaly, then calculate the average of the BOD results in the acceptable range.

11.3 In these calculations, do not make corrections for DO depletion by the dilution water blank during incubation. This correction is unnecessary if dilution water meets the blank criteria specified in Section 9.1.2.

11.3.1 If the dilution water does not meet these criteria, proper corrections are difficult and results become questionable. Notify the Department Supervisor and/or the Laboratory Manager for instructions on how to proceed.

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

12.1 Dilution Blank (Section 9.1.1) If this falls outside the acceptance limit, a lab note is included with the batch if the seed is within the acceptable range. If the dilution blank and seed are both out of range, then the batch is invalid and the client is notified.

12.2 Seed (Section 9.7.1) If the seed is outside the ideal acceptance range, the reason for the failure is evaluated and eliminated by adjusting the seed volume used in future sample batches. If any batch falls outside of the ideal acceptance range, but the LCS is still within acceptable range, the data is released without further action to the client. However, if the LCS falls outside acceptable range for the method, the client is notified and the data is only released (with an appropriate narrative) upon the client's request.

12.3 LCS (Section 9.2) If the LCS is outside of the acceptance range, and the seed is within its acceptance range, then a narrative is included on the Client report and the data is reported (per the department manager evaluation of the data).

12.4 Method Blank (Section 9.1.2) If the method blank is too high, either a narrative is included on the Client report (per department manager) or the batch is considered invalid and the client is notified.

12.5 Matrix Spike (Section 9.5) If the spike is outside of the acceptance limits, the data is reported with a narrative that is included on the Client report.

12.6 Laboratory Duplicate (Section 9.6) If the duplicate is outside of the acceptance limits, the data is reported with a narrative that is included on the Client report.

12.7 Evaluation of data: Samples showing large differences between calculated BOD results for different dilutions, for example, greater than 30%, may indicate the presence of a toxic substance or analytical problems. If test replicates show more than 30% difference between high and low values, a narrative is added to the Alpha report. Canned narrative #1312 should be used.

13. Method Performance

13.1 Method Detection Limit Study (MDL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the MDL, LOD, and/or LOQ as outlined in Alpha SOP/1732. These studies performed by the laboratory are maintained on file for review.

However, for BOD and CBOD analyses, the MDL is a calculated value. Therefore, MDL studies are not performed.

13.2 Demonstration of Capability Studies

Refer to Alpha SOP/1734 and 1739 for further information regarding IDC/DOC Generation.

13.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method

14. Pollution Prevention and Waste Management

Refer to Alpha's Chemical Hygiene Plan and Waste Management and Disposal SOP for further pollution prevention and waste management information.

Process Standard Operating Procedure (SOP): Pace® Analytical Services

Pace ANALYTICAL SERVICES	**Balance Verification and Maintenance**
	Effective Date: 04/18/2024

Management Approval:
Amy Rice Approved on 4/18/2024 7:14:09 AM

© 2024, Pace® Analytical Services, LLC (PAS)

1.0 PURPOSE

This Standard Operating Procedure (SOP) specifies the policies and procedures for verifying the calibration of laboratory balances using NIST traceable weights.

2.0 SCOPE & APPLICATION

The policies and procedures specified in this SOP apply to the following locations: PAS-Mansfield, PAS-Westborough

This Standard Operating Procedure describes how to check the calibration of balances and reflects the Quality Control (QC) limits and the procedures to follow if a balance falls outside of the QC limits.

The degree of accuracy of the balance is reflected in the accuracy of all data related to weight-prepared standards, spikes and sample dilutions and sample weight determinations. Because this accuracy is critical to our operation, each balance's calibration must be verified before it is put into service each day. The results are recorded in the logbook associated with the balance.

3.0 SUMMARY OF PROCESS

Balances are verified daily or on each day of use against Class S-1 weights that are certified to be traceable to the National Institute of Standards and Technology (NIST). These working weights are verified as accurate against reference weights which are calibrated and certified by an outside vendor. Certificates are kept on file, and records are kept for the daily balance calibration checks.

4.0 DEFINITIONS

Refer to the Laboratory Quality Manual for a glossary of common lab terms and definitions.

- **PAS:** Acronym for Pace® Analytical Services, LLC

5.0 HEALTH & SAFETY

Contact your supervisor or local safety coordinator with questions or concerns regarding safety protocol or safe handling procedures for this procedure.

The following sections provide general health and safety information about chemicals and materials that may be present in the laboratory.

- The toxicity or carcinogenicity of each chemical material used in the laboratory has not been fully established. Each chemical should be regarded as a potential health hazard and exposure to these compounds should be as low as reasonably achievable.

The distribution of printed or electronic copies of this document outside of the PAS electronic document management system (eDMS) is not controlled or tracked. PAS employees must ensure any copy used for daily work, if not accessed directly from PAS eDMS, is the current version of the document.

- The laboratory maintains documentation of hazard assessments and OSHA regulations regarding the safe handling of the chemicals specified in each method. Safety data sheets for all hazardous chemicals are available to all personnel. Employees must abide by the health, safety and environmental (EHS) policies and procedures specified in this SOP and in the Pace® Chemical Hygiene / Safety Manual (COR-MAN-0001).

- Personal protective equipment (PPE) such as safety glasses, gloves, and a laboratory coat must be worn in designated areas and while handling samples and chemical materials to protect against physical contact with samples that contain potentially hazardous chemicals and exposure to chemical materials used in the procedure.

- Concentrated corrosives present additional hazards and are damaging to skin and mucus membranes. For procedures that require use of acids, use acids in a fume hood whenever possible with PPE designed for handing these materials. If eye or skin contact occurs, flush with large volumes of water. When working with acids, always add acid to water to prevent violent reactions. For procedures that that emit large volumes of solvents (evaporation/concentration processes), these activities must be performed in a fume hood or apparatus that reduces exposure.

6.0 PROCEDURE

6.1 Policy

Balances provide critical sample and reagent volume weights used to calculate sample results. Balances must be verified for accuracy using a set of certified weights traceable to NIST. Balances and their workstations must be kept clean and should be dusted before and after use. Balances must be set up on a level surface free from vibrations, and moving a balance should be kept to a bare minimum as they are sensitive pieces of equipment. Due to the sensitivity of balances, they must be allowed to acclimate to a new location for a minimum of 2 hours after being moved. Because of this, please discuss with your Manager and/or QA staff prior to moving a balance. Verification must be conducted after a balance has moved, even if verification has already been conducted for that day.

6.2 Procedure

6.2.1 Daily Verification of Laboratory balances

- Sign out weights using the Weight Sign-out Logbook. Confirm that no weights are missing, or record what weights are missing. If any weights are missing, contact your local Quality Assurance (QA) department.
- Make sure that the pan is clean (brush), and the balance is level. Please see a member of the QA Department if a brush is not available in the lab. Each balance used in the lab makes use of a bubble level and four adjustable legs. Make sure the bubble is within the circle by adjusting the balance legs.
- Tare the Balance

The distribution of printed or electronic copies of this document outside of the PAS electronic document management system (eDMS) is not controlled or tracked. PAS employees must ensure any copy used for daily work, if not accessed directly from PAS eDMS, is the current version of the document.

- Select the appropriate weight based on the weight listed in the true Value column of the balance Verification logbook. Place the weight on the pan with the forceps provided with the set of weights. Weights should never be handled directly by hand, as the oils in your skin can change the weight. Please see a member of the Quality Team for any questions regarding Balance verification ranges.
- Record the measured weight to the N^{th} number of decimal places specific for the balance. The true values of the calibration weights are indicated on each weight. Also record the date and the Analyst's initials.
- If applicable, mark the day of verification on the laminated verification tracker affixed near the balance using a dry-erase marker. This notifies potential users that the balance has been verified for that day. Check weights back in using the Weight Sign-out Logbook.

7.0 RESPONSIBILITIES

- PAS employees that perform any part this procedure in their work activities must have a signed Read and Acknowledgement Statement (R&A) in their training file for the version(s) of the SOP that were in effect during the time the employee performed the activity.
- PAS supervisors and Managers however named, are responsible for training employees on the procedures in this SOP, implementing the SOP in the work area, and monitoring on-going adherence to the SOP in the work area(s) they oversee.
- PAS employees are responsible for following the procedures in this SOP. Unauthorized deviations or departures from this SOP are not allowed except with documented approval from the local QM and only when those deviations do not violate the Pace® Code of Ethics or Professional Conduct (COR-POL-0004) or associated policy and procedure(s). Hand-edits or manual changes to the SOP are not permitted. If a change is desired or necessary, Pace® employees must follow the procedures for document revision specified in corporate SOPs ENV-SOP-CORQ-0015, *Document Management* and ENV-SOP-CORQ-0016, *SOP for Creation of SOP and SWI*.

Free Cyanide

Method Reference: Method 9016, Revision 0, June 2010, SW-846, Test Methods for Evaluating Solid Waste: Physical/Chemical Methods.

1. Scope and Application

Matrices: This test method covers the determination of free cyanide in waste waters, ground waters, surface waters, drinking waters, soils and solid wastes.

Definitions: Refer to Alpha Analytical Quality Manual.

This test method reports the cyanide that dissociates from simple cyanides or weakly-bound metal cyanide complexes at room temperature, from a solution of pH 6-6.5.

This test method does not determine strongly-bound metal cyanide complexes that resist dissociation, such as the hexacyanoferrates and gold cyanide, nor does it determine thiocyanate and cyanohydrin.

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one or more of the following laboratory personnel before performing the modification: Area Supervisor, Department Supervisor, Laboratory Director, or Quality Assurance Officer.

This method is restricted to use by or under the supervision of experienced analysts. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

Parameter	CAS
CN	57-12-5

2. Summary of Method

2.1 The sample preparation (Sec. 10.3.1) is carried out using a microdiffusion cell (Figure 1 and Figure 2) The water, wastewater or extract sample is introduced in the outer chamber of the microdiffusion cell and is buffered at pH 6 and placed in the dark for 6 hrs of diffusion. The free cyanide diffuses as HCN gas and is absorbed as CN- into the sodium hydroxide solution located in the center chamber of the microdiffusion cell.

2.2 An aliquot of the sodium hydroxide absorber solution is removed and treated with acidified phosphate buffer and chloramine-T to convert the CN- to cyanogen chloride. The cyanogen chloride is reacted with pyridine-barbituric acid to form a color complex that absorbs at 578 to 587 nm. The free cyanide is determined spectrophotometrically by measuring the absorbance of the sample and determining the concentration through comparison with a standard calibration curve (Sec. 10.2).

2.3 Solids are first extracted prior to analysis using pH 12.3-12.5 NaOH solution (Sec. 10.1.). The filtered extracts are then diffused (Sec. 10.3.1) and analyzed spectrophotometrically as

described in Sec. 10.3.2. The extraction conditions described in this method have been found to be effective at extracting free cyanide from a variety of solid wastes. Figure 3 illustrates the effects of various extraction conditions on the recovery of free cyanide in a complex, mixed-waste sample.

2.4 The extraction conditions in this method may be modified as needed to improve free cyanide extraction efficiency from other matrices. For example, certain relatively complicated wastes or waste mixtures may not yield acceptable matrix spike recoveries. In such cases, additional refinement of the extraction step and/or the use of chemical pretreatments may be necessary to improve free cyanide recovery. Such flexibility is allowed as long as the data meets the quality objectives of the specific project.

2.1 Method Modifications from Reference

None.

3. Reporting Limits

Reporting limit for water samples is 0.002 mg/l (2.0 ppb). Reporting limit for soil samples is 1.0 mg/kg

4. Interferences

4.1 Interferences, such as chlorine and sulfides, can degrade samples by reacting with the free cyanide present. All aqueous samples should be checked at the time of their collection to determine the presence of oxidizing agents and/or sulfides. If found to be present, the samples should be immediately treated, as noted in the following sections, prior to their storage for future analysis.

4.1.1 Oxidizing agents, such as chlorine, decompose free cyanide. Chlorine reacts with free cyanide to form cyanogen chloride (CNCl), which under alkaline conditions hydrolyzes to cyanate (CNO-). Chlorine interferences can be removed by adding excess amounts of sodium arsenite or sodium thiosulfate to the sample prior to storage. Both sodium arsenite and sodium thiosulfate reduce the chlorine to chloride, which does not react with free cyanide or otherwise interfere in its analysis

4.1.2 Sulfide oxidation products can rapidly convert free cyanide to thiocyanate (SCN-), especially at high pH .Sulfide interferences (namely hydrogen sulfide, metal sulfides, or other compounds that may produce sulfide) can be removed by adding an excess of either lead carbonate or lead acetate to the sample. The addition of either reagent forms insoluble lead sulfide (PbS), so that it may be removed via filtration, prior to storage or analysis

4.2 Volatility losses of free cyanide (as HCN) can occur in samples having pH values less than 12. If samples cannot be analyzed immediately after field collection and treatment for oxidizing agents and sulfides, they must be preserved by adjusting the pH to 12 or greater prior to storage.

4.3 In addition to oxidizing agents and sulfides, free cyanide can react with other chemicals such as aldehydes. Because of the reactivity of free cyanide, it is important that analysis is completed as soon as possible after sample collection. It is beyond the scope of this method to list all the possible cyanide reactions that may be encountered.

4.4 Hexacyanoferrate complexes in water samples can decompose when exposed to UV light and produce free cyanide. This decomposition is virtually eliminated during the test procedure by allowing samples to diffuse in the dark.

4.5 Solvents, reagents, glassware, and other sample processing hardware may yield artifacts and/or interferences to sample analysis. All of these materials must be demonstrated to be free from interferences under the conditions of the analysis by analyzing method blanks. Specific selection of reagents and purification of solvents by distillation in all-glass systems may be necessary. Refer to each method to be used for specific guidance on QC procedures and to Chapter Three for general guidance on the cleaning of glassware. Also, refer to the Method 9014 for additional discussion of interferences.

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material safety data sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

WARNING: KCN and NaCN are highly toxic. Avoid skin and eye contact and inhalation.

Because of the toxicity of cyanide, exercise great care in its handling. Acidification of cyanide solutions produces toxic gaseous hydrogen cyanide (HCN). Perform all manipulations in the hood so that any HCN gas that is formed is safely vented.

Some of the reagents used in these methods, such as those containing cyanide and pyridine-barbituric acid solutions, are highly toxic in the environment. Dispose of such reagents and their solutions properly, according to applicable state or local regulations.

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

All samples must be collected using a sampling plan that addresses the considerations discussed in Chapter Nine of the SW-846 manual.

Samples should be collected in plastic or glass (preferably plastic) containers that are either amber or covered with aluminum foil so as to filter light at 400 nm and below and prevent photodecomposition of metal cyanide complexes. All containers must be thoroughly cleaned and rinsed prior to use. All sample containers must be prewashed with acids, water, and metal-free detergents, if necessary, depending on the use history of the container.

All samples whose origin or composition is not well-known should be tested for the presence or absence of oxidizing agents, such as chlorine; sulfide ideally at the time of sample collection

6.2 Sample Preservation

Analyze samples immediately; otherwise preserve them at the time of collection, following any treatment for oxidizing agents or sulfides by adding 50% sodium hydroxide, until the pH is equal to or slightly greater than 12. This minimizes cyanide losses due to volatilization of HCN.

6.3 Sample Shipping

Ship and Store properly-preserved samples in the dark at 4 ± 2 °C.

6.4 Sample Handling

When properly preserved, cyanide samples can be stored for up to 14 days prior to analysis.

Extract solids within 14 days of sample collection.

Analyze extracts of solid samples within 24 hrs following extraction.

7. Equipment and Supplies

7.1 Supplies/equipment for sample collection, preservation, and handling

7.1.1 Potassium iodide-starch test paper.

7.1.2 Lead-acetate paper test paper

7.1.3 pH test paper

7.1.4 Plastic conway-type microdiffusion cell*, 83-mm OD — Equipped with a fitted lid or other type cover, for use in maintaining an airtight seal when in place manufactured by Bel-Art or other commercial vendor

7.2 Supplies/equipment for extraction of solid samples

7.2.1 Extraction bottles, HDPE, 1000-mL capacity or larger

7.2.2 Agitation apparatus — Rotary agitator (provides end-over-end motion), orbital shaker or rotary shaker or other equivalent apparatus, capable of providing thorough mixing of samples during extraction.

7.3 Supplies/equipment for microdiffusion processing and spectrophotometric analysis

7.3.1 Micropipets, 0.20-mL, 0.50-mL, 1.00-mL, 1.50-mL, 2.50-mL, 5.00-mL, 10.0-mL, 15.0-mL, and 30.0-mL

7.3.2 Adjustable pipette or calibrated syringe — Able to be adjusted to deliver exactly 3.00 mL of solution

7.3.3 Adjustable pipette or calibrated syringe — Able to be adjusted to deliver exactly 1.30 mL of solution

7.3.4 Spectrophotometer — Suitable for making absorbance measurements between 575 and 590 nm using a 1.0-cm cell

7.3.5 Spectrophotometer cell, 1-cm

8. Reagents and Standards

8.1 Reagent-grade chemicals must be used in all tests. Unless otherwise indicated, it is intended that all reagents conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society

8.2 Reagent water: Reagent water must be interference-free. All references to water in this method refer to reagent water, as defined in Chapter One of SW-846 manual.

8.3 Reagents for sample collection, preservation, and handling

8.3.1 Sodium arsenite, NaAsO2

8.3.2 Sodium thiosulfate, Na2S2O3

8.3.3 Lead acetate trihydrate, Pb(CH3COO)2 • 3H2O

8.3.4 Lead carbonate, PbCO3.

8.3.5 Sodium hydroxide solution (50% w/w; ρ = 1.53 g/mL), NaOH: Commercially prepared.

8.4 Additional reagents needed for extraction of solid samples

8.4.1 Sodium hydroxide solution (50% w/w) (see Sec. 8.3.5)

8.4.2 Sodium hydroxide extraction solution (pH 12.3-12.5): Weigh either 2.53 g or measure 1.65 mL of 50% sodium hydroxide solution and transfer to a 1-L volumetric flask containing approximately 800 mL of reagent water. Stir until dissolved. Adjust the final volume to 1-L using reagent water. Using pH test paper, check to ensure that the extraction solution is in the proper pH range. Add additional 50% NaOH, if necessary, to adjust the pH to the proper range

8.5 Additional reagents needed for microdiffusion processing (Sec. 10.2) and spectrophotometric analysis (Sec. 10.3).

8.5.1 Sodium hydroxide solution (2.05 g/L), NaOH: Weigh either 4.10 g or measure 2.68 mL of 50% sodium hydroxide solution and transfer to a 1-L volumetric flask containing approximately 800 mL reagent water. Stir until dissolved. Cool the solution to room temperature and adjust the final volume to 1 L using reagent water. This solution is used only for the preparation of initial demonstration of proficiency samples, method blanks, matrix spikes and laboratory control standards.

8.5.2 Sodium hydroxide solution (4.1 g/L): Weigh either 8.20 g or measure 5.36 mL of 50% sodium hydroxide solution and transfer to a 1-L volumetric flask containing approximately 800 mL of reagent water. Stir until dissolved. Adjust the final volume to 1-L using reagent water.

CAUTION: Calibration standards are commercially available from several sources.

8.5.3 Potassium cyanide, KCN; or sodium cyanide, NaCN: Commercially available 1000 ppm; expiration date according to manufacturer specification.

8.5.4 Standard cyanide solution (1 mg/L): Pipet 1.00 mL of 1000-mg/L stock cyanide solution into a 1-L volumetric flask and dilute to volume using 4.1-g/L sodium hydroxide solution. This solution is used in the preparation of calibration standards (see Sec. 10.1).

WARNING: KCN or NaCN are highly toxic. Avoid skin and eye contact and inhalation

8.5.5 Stopcock grease, petroleum jelly or mineral oil: to help in providing an air-tight seal between the microdiffusion cell and lid

8.5.6 Potassium phosphate monobasic, KH2PO4

8.5.7 Sodium hydroxide solution (100 g/L), NaOH: Weigh either 200 g or measure 131 mL of 50% sodium hydroxide solution and transfer to a 1-L volumetric flask containing approximately 800 mL reagent water. Stir until dissolved. Cool the solution to room temperature and adjust the final volume to 1 L using reagent water.

8.5.8 Concentrated phosphoric acid (sp gr 1.69), H3PO4

8.5.9 Potassium phosphate solution (190 g/L): Add 400 mL of reagent water to a 2-L beaker. Next, either weigh 29 g or measure 19 mL of 50%-sodium hydroxide solution, transfer to beaker, and dissolve. Add 190 g of potassium phosphate monobasic and stir to dissolve. Bring the volume to approximately 950-mL to aid in dissolution. Adjust the pH of the solution so that it is within the range of 5.9-6.1, using 100-g/L sodium hydroxide or concentrated phosphoric acid. Transfer the solution to a 1-L volumetric flask, and dilute to volume with reagent water.

8.5.10 Potassium phosphate buffer solution (acidified): Add 8.0 mL of concentrated phosphoric acid to 100 mL of 190-g/L potassium phosphate solution.

8.5.11 Chloramine-T reagent (10 g/L): Dissolve 1.0 g of chloramine-T in 50 mL of reagent water contained in a 100-mL volumetric flask. Dilute to volume with additional reagent water. Prepare fresh daily.

8.5.12 Barbituric acid, NHCONHCOCH2CO

8.5.13 Pyridine, C5H5N

8.5.14 Concentrated hydrochloric acid HCl

8.5.15 Pyridine-barbituric acid reagent: Add 15.0 g of barbituric acid to a 250-mL volumetric flask. Wash down the sides of the flask with just enough reagent water to moisten the barbituric acid. Add 75 mL of pyridine and swirl to mix. Slowly, add 15 mL of concentrated hydrochloric acid and swirl to mix. Using additional reagent water, bring volume to approximately 230 mL. Stir to dissolve and cool the solution to room temperature. Dilute to final volume with additional reagent water and mix. It is recommended that the reagent be prepared fresh weekly and stored in a dark place. Discard and prepare a new batch if a precipitate develops.

WARNING: Pyridine is toxic; avoid contact or inhalation. Prepare this reagent in an exhaust hood.

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

9.1 Blank(s)

A method blank (MB) is prepared from a 2.05 g/L sodium hydroxide solution and treated exactly as a field sample, including exposure to all glassware, equipment, solvents, filtration, and reagents that are used with field samples.

Any free cyanide measured in the indicates that contamination is present. The source of the contamination should be determined and corrected prior to performing any sample analysis. Any sample included in an analysis batch that has an unacceptable MB concentration should be reanalyzed in a subsequent batch after the contamination problem is resolved.

9.2 Laboratory Control Sample (LCS)

A laboratory control sample (LCS) should be included with each analytical batch. The LCS consists of an aliquot of a clean (control) matrix similar to the sample matrix and of the same weight or volume. The LCS is spiked with the same analytes at the same concentrations as the matrix spike, when appropriate

Prepare 50 ug/l LCS solution: pipet 2.5 ml of 1 ppm cyanide standard to 50ml volumetric flask Adjust volume up to 50 ml with 0.1N NaOH solution.

Prepare 100 ug/l LCS solution: pipet 5 ml of 1 ppm cyanide standard to 50ml volumetric flask Adjust volume up to 50 ml with 0.1N NaOH solution

LCS acceptance criteria 75-125%. New criteria may be established based on in house control charts.

When the LCS recovery exceeds the control limits, the analysis should be terminated, the problem corrected

9.3 Initial Calibration Verification (ICV)

Immediately after the calibration standards have been analyzed, the accuracy of the calibration must be verified by the analysis of an ICV standard. The ICV is prepared in the same manner as a calibration standard (i.e., the sample is NOT processed through the microdiffusion procedure) at a concentration level within the calibration range of the method and using a second source standard (prepared using standards different from the calibration standards) spiked into 4.1 g/L sodium hydroxide .

The control limit for the ICV is ±15% of the true value. When the ICV exceeds the control limits, the analysis should be terminated, the problem corrected, the instrument recalibrated, and the calibration re-verified.

9.4 Continuing Calibration Verification (CCV)

Once the calibration curve has been established, the continuing accuracy must be verified by analysis of a CCV after every tenth field sample, and at the end of the analysis sequence. The CCV is equivalent to or prepared in the same manner as a calibration standard (i.e., the sample is NOT processed through the microdiffusion procedure) at a concentration level within the calibration range of the method and using the same source standard (prepared using the same source standards as those used to prepare the calibration standards) spiked into 4.1 g/L sodium hydroxide (see Sec. 10.2).

CCV concentrations alternating between the low- and mid-range calibration standard concentrations are recommended.

The control limit for the low-range CCV (5 ug/L) is ± 50% and for the mid-range CCV(100 ug/L) is ± 15% of the true value.

When the CCV exceeds the control limits, the analysis should be terminated, the problem corrected, the instrument recalibrated, and the calibration re-verified using an ICV analysis. Samples that are not bracketed by acceptable CCV runs must be reanalyzed.

9.5 Matrix Spike

Both aqueous samples and solid sample extracts should be represented by a minimum of one MS sample for each respective matrix.

Pipet 2.5 ml of 1 ppm cyanide standard to 50ml volumetric flask with sample. Adjust volume up to 50 ml with sample. Final spike concentration: 50 ug/l

Pipet 5 ml of 1 ppm cyanide standard to 50ml volumetric flask Adjust volume up to 50 ml with sample. Final spike concentration 100 ug/l

MS acceptance criteria 70-130% for waters and 65-135% for soils. New criteria may be established based on in house control charts.

If the Matrix Spike recovery does not meet acceptance criteria, and the LCS recovery is acceptable, matrix interference may be assumed. The associated data may be reported with a narrative included.

9.6 Laboratory Duplicate

One duplicate per batch has to be analyzed. . If samples are expected to contain the target analyte, laboratories may use a matrix spike (MS) and a duplicate analysis of an unspiked field sample. If samples are not expected to contain the target analyte, the laboratories should use a MS/MSD pair.

% RPD for the Duplicate must be within in-house control limits. If acceptance criteria are not met, the Duplicate is reanalyzed. If failure continues, a narrative is included with the data for inclusion on the Client report.

9.7 Method-specific Quality Control Samples

None.

9.8 Method Sequence

1. Set equipment
2. Prep samples, using Microdiffusion procedure
3. Leave samples in dark place for 6 h
4. Make calibration standards and run calibration curve
5. Prep. and analyze ICV and ICB for curve verification
6. Use calorimetric procedure to analyze samples after Microdiffusion process is finished (after 6h)
7. Curve verification (ICB and ICV) after every twenty sample and at the end of the analytical run

10. Procedure

CAUTION: This method requires manual dexterity, practice, and meticulous attention to operational consistency. Best practices are noted throughout this section to assist analysts in achieving optimum results. Adherence to these practices is highly recommended for attaining precise and accurate data.

10.1 Equipment Set-up

10.1.1 Extraction of solid samples

Extract solid samples prior to microdiffusion and analysis, otherwise proceed to Section 10.3.

10.1.1.1 Weigh 250 mg $PbCO_3$ and transfer to an extraction bottle.

NOTE: Since, sulfides are often present in soils and solid wastes, lead carbonate is added to all extract samples in order to fix sulfides as PbS.

10.1.1.2 Weigh a 1 g sample of the solid to be analyzed, recording the sample mass to 0.001 g. Transfer the weighed sample to the extraction bottle containing the lead carbonate.

10.1.1.3 Add 500 mL of pH 12.3-12.5–NaOH solution to the extraction bottle and gently rotate the bottle so as to mix the contents.

10.1.1.4 10.1.4 Cap the extraction bottle, place on agitation apparatus and agitate for 5 min. After 5 min, use a strip of pH test paper check the sample mixture pH to verify that it is within the range of 12.3-12.5. If it is not, add 50% NaOH drop-wise, to bring the pH to within the proper range. Recap the bottle and restart agitation. Extract the free cyanide in this manner for a period of 60 min.

10.1.1.5 At the end of the extraction period, use a strip of pH test paper to verify that the sample mixture pH is 11 or greater. If the pH is in the correct range, the extraction may be deemed to be acceptable – proceed to Sec. 11.1.6. If it is not, extract a new sample by repeating Secs. 10.1.1-10.1.5, except using an initially higher-pH extraction solution (e.g., pH 13)

10.1.1.6 Following a successful extraction, decant the sample supernatant into a clean container. Filter the supernatant through a 0.45 µm membrane filter to remove particulate material and any PbS that may have formed.

10.1.1.7 If necessary, centrifuge the extraction mixture in order to remove fine particles and afford an adequate separation, as evidenced by a relatively clear final extract solution.

10.2 Initial Calibration

10.2.1 Preparation of calibration standards - Pipet 0, 0.20, 0.50, 1.00, 2.50, 5.00, 10.0, 15.0, and 30 mL of the 1.0-mg/L cyanide standard solution into nine separate 100-mL volumetric flasks. Dilute each of the flasks to volume with 4.1-g/L sodium hydroxide solution. These dilutions yield calibration standards that contain approximately 0, 2.0, 5.0, 10, 25, 50, 100, 150, and 300 µg/L cyanide, respectively.

NOTE: The 0 µg/L cyanide standard sample is used as the calibration blank.

10.2.2 To establish the calibration curve, analyze the calibration standards in accordance with

the procedure in Section 10.2. Prepare a duplicate set of spectrophotometric samples for each respective calibration standard (Sec. 10.3.2) to provide for duplicate spectrophotometric analyses of each standard. In order to avoid a method bias, the calibration standards must be analyzed directly and not processed through the microdiffusion procedure

10.2.3 Calculate the average absorbance reading for each duplicate set of calibration standards analyzed.

10.2.4 Establish the calibration curve by plotting average absorbance versus cyanide concentration. . A new calibration curve should be established daily with each analysis. Perform a first-order linear regression of the calibration curve (i.e., y = ax + b function). The acceptance criterion for the calibration curve should be a correlation coefficient of 0.995 or higher.

10.3 Equipment Operation and Sample Processing

10.3.1 Microdiffusion of free cyanide in aqueous samples and extracts

NOTE: At a minimum, perform microdiffusion of all samples in duplicate. More diffusion replicates can be performed, if desired, for greater statistical confidence in the final result.

10.3.1.1 Using a pipet or calibrated syringe, dispense 3.00 mL of sample into the outer chamber of a clean, dry microdiffusion cell (see Figure 2).

10.3.1.2 Using an adjustable pipet or calibrated syringe, dispense exactly 1.30 mL of 4.1-g/L sodium hydroxide solution into the center chamber of the microdiffusion cell (see Figure 2).

10.3.1.3 Smear the microdiffusion cell lid or other such cover with a sufficiently heavy layer of stopcock grease or petroleum jelly to prepare for airtight sealing of the microdiffusion cell, which occurs later in the test procedure. The most appropriate manner in which to apply the grease depends on the construction and geometry of the microdiffusion cell. In some cases a better air-tight seal may be achieved by applying the grease directly to the cell, instead of the lid. Either practice is considered to be acceptable.

NOTE: Use a liberal amount of stopcock grease or petroleum jelly in order to create an airtight seal between the microdiffusion cell and the lid.

10.3.1.4 Using a calibrated syringe (or pipet), immediately inject 1.0 mL of 190-g/L potassium phosphate solution into the sample located in the outer chamber of the microdiffusion cell. Inject at an angle in order to force the solution around the chamber.

NOTE: The force of ejection of aids in the proper mixing of the solutions.

10.3.1.5 Perform this step as quickly and carefully as possible in order to avoid loss of free cyanide: Carefully tilt and rotate the cell once to mix the constituents and immediately, use pH test paper to check the sample and ensure that it has attained a pH of 6. If the sample pH is greater than 6, add additional 190-g/L potassium phosphate solution, using 1.0-1.5 mL, increments, as necessary, to adjust the sample pH to 6.

NOTE: When analyzing an unknown sample, it is strongly recommended that the

sample be pre-tested prior to microdiffusion analysis in order to determine the exact amount of potassium phosphate solution needed to adjust the sample pH to 6. This may be accomplished by pipetting 3.0 mL of sample into a small container (e.g., volume capacity of 10 mL) followed by addition of 1.0 mL of 190-g/L potassium phosphate solution. After mixing the solutions well, determine the amount of potassium phosphate solution required to attain a pH of 6.

NOTE: The pH measurement step may be eliminated based upon historical knowledge of the sample.

10.3.1.6 Quickly, seal the cell by fitting it with a greased lid .Twist the lid and microdiffusion cell back and forth to ensure that the grease is evenly spread between the cell and the lid for an airtight seal.

10.3.1.7 Carefully tilt and rotate the cell for 5 seconds to ensure proper mixing.

NOTE: Exercise great care during mixing of solutions by tilting and rotating the microdiffusion cell carefully so as to avoid spilling or splashing the contents from one chamber of the cell to the other.

10.3.1.8 Place the covered cell in the dark at room temperature for a period of 6 hr.

NOTE: It is essential that the microdiffusion cell be protected from light at all times during the 6-hr diffusion period in order to avoid photolysis of hexacyanoferrate complexes.

10.3.1.9 Proceed to analyze the diffused samples and standards as described in Sec. 10.3.2.

10.3.2 Color development and spectrophotometric analysis of diffused samples and standards

NOTE: Ensure that the spectrophotometer cells used for analysis are optically-matched prior to use.

10.3.2.1 Prepare the spectrophotometer for analysis according to the manufacturer's instructions.

10.3.2.2 Set the spectrophotometer wavelength to 578 nm or other optimum wavelength, as determined by this method.

10.3.2.3 When the instrument has stabilized, zero the detector against the 4.1-g/L sodium hydroxide solution.

10.3.2.4 At the end of the diffusion period, pipet a 1.00-mL aliquot of the sodium hydroxide solution from the center chamber of the microdiffusion cell and dispense into a clean, dry, spectrophotometer cell.

CAUTION: Complete mixing as indicated in each of the following steps (Secs. 10.3.2.5- 10.3.2.7) is critical for accurate analysis.

10.3.2.5 Using a micropipet, dispense 0.1 mL of acidified potassium phosphate buffer into the spectrophotometer cell. Seal the cell with the stopper. The stopper should

form a watertight seal. While holding the stopper tightly against the cell, invert the cell 4-5 times to mix.

NOTE: Some spectrophotometer cell lids do not fit tightly and as such, mixing the cell contents through inversion can result in leaking and sample loss. A small piece of Parafilm M® may be used in place of the spectrophotometer stopper to provide a better seal and prevent leakage.

NOTE: In order to provide for more thorough mixing and at the same time prevent sample loss, Steps 10.3.4-10.3.7 may be carried out in a test tube instead of a spectrophotometer cell. After each addition of reagent, the sample test tube is vortexed (using a Vortex mixer) to stir the contents. Prior to spectrophotometric analysis (Sec. 10.3.8) the contents from the test tube are transferred to a clean, dry spectrophotometric cell.

10.3.2.6 Dispense 0.50 mL of chloramine-T reagent into the spectrophotometer cell using a micropipet. Seal the cell tightly again with the stopper and invert 4-5 times to mix.

10.3.2.7 Pipet 1.00 mL of pyridine-barbituric acid reagent into the spectrophotometer cell and replace the stopper. Note the time and invert the cell 8-10 times to mix.

10.3.2.8 Within 3-6 min from the start of mixing), the development of the color complex, as well as its stability, will be optimum for performing spectrophotometric readings. Read the absorbance of the spectrophotometric sample at 578 nm during this time interval. The time interval at which readings are taken must be consistent to the extent possible for all samples and standards.

NOTE: The wavelength maximum of the color-complex can vary slightly with each bottle or lot of barbituric acid reagent due solvatochromic effects. For optimum results, the absorbance maximum for the color complex can be determined by performing a spectral scan of a prepared 150-µg/L calibration standard prior to analysis each day. The sample and calibration standard absorbance readings may then be measured at the determined wavelength maximum, instead of at 578 nm.

10.3.2.9 Measure the absorbance for each sample replicate. Average the replicate results to yield a single absorbance value for each sample.

NOTE: The cells can be cleaned between usages by rinsing well with reagent water, followed by methanol. For a large number of determinations (10 or more), it may be necessary to periodically clean the cells with chromic-sulfuric acid cleaning solution or methanol-hydrochloric acid solution (prepare by mixing 3 volumes of water, 1 volume of concentrated HCI and 4 volumes of methanol). Avoid contact of these reagents with skin or eyes. Methanol may be used to dry the cell afterwards, if necessary.

WARNING: Keep any methanol used for cleaning purposes away from ignition sources.

NOTE: The total volume of liquid in the spectrophotometer cell is 2.6 mL. This is normally sufficient for measuring the absorbance in most spectrophotometers.

10.4 Continuing Calibration

Refer to Section 9.4.

10.5 Preventive Maintenance

An instrument service company calibrates the Spectrophotometers on a semi-annual basis. Certificates are kept on file.

11. Data Evaluation, Calculations and Reporting

11.1 For each spectrophotometric sample, obtain the µg/L free cyanide concentration from the calibration curve established in Sec. 10.2.

11.2 Determine the actual free cyanide concentration in an aqueous (or solid extract) sample by mathematically adjusting the free cyanide concentration determined in Sec. 11.1 to account for the concentration effect of the microdiffusion process as follows:

$$\frac{\mu g}{L}\ \text{free } CN^-\ \text{in aqueous sample} =$$

$$\frac{1.3\ \text{mL (center chamber solution volume)}}{3.0\ \text{mL (outer chamber solution volume)}} \times \frac{\mu g}{L}\ \text{free } CN^-\ \text{in spectrophotometric sample}$$

NOTE: Samples having a free cyanide concentration that exceeds that of the highest calibration standard, as determined in Sec. 11.1, must be diluted appropriately and reanalyzed spectrophotometrically Dilute the sample as needed using 4.1 g/L sodium hydroxide so that the concentration is within the calibration range. Analyze the diluted sample using a 3.00 mL aliquot as described in Section 10.3. Correct the final concentration result by multiplying by the appropriate dilution factor.

11.3 In the case of an extract, calculate the actual free cyanide concentration in the original solid that was extracted as follows:

$$\frac{\mu g}{g}\ \text{free } CN^-\ \text{in solid sample} = \frac{\mu g}{L}\ \text{free } CN^-\ \text{in extract sample} \times \frac{\text{Final extract solution volume (L)}}{\text{Sample mass (g)}}$$

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

Refer to Section 9.

13. Method Performance

13.1 Detection Limit Study (DL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the DL, LOD, and/or LOQ as outlined in Alpha SOP/1732. These studies performed by the laboratory are maintained on file for review.

13.2 Demonstration of Capability Studies

Refer to Alpha SOP/1734, 1739 for further information regarding IDC/DOC Generation.

13.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

14. Pollution Prevention and Waste Management

Refer to Alpha's Chemical Hygiene Plan and Waste Management and Disposal SOP for further pollution prevention and waste management information.

Standard Verification Procedure GTX- SVP- 13

Technical Information

Equipment Verified:	Atterberg limit device, grooving tool, gauge, glass plate
Applicable Test Methods:	ASTM D4318
Property:	Instructions for checking the critical dimensions and calibrating the equipment used to determine liquid and plastic limits of soils
Inspection Equipment Required:	Calipers, metal ruler, steel ball and resiliency tube, balance
Tolerances:	Calipers readable to 0.001 inches, metal ruler readable to 0.001 inches, 5/16 inch diameter steel ball and resiliency tube, balance with readability of 0.1 grams, wear on the base should not exceed 10 mm (3/8 in.), cup hanger should not be able to have side to side movement greater than 3 mm (1/8 in.)
Recalibrations:	Cup should be replaced when the grooving tool has worn a depression in the cup 0.1 mm (0.004 in.) deep, or when the rim has reached half of its original thickness. Recalibration was not specified.

Standard Operating Procedure:

Liquid Limit Device:

1. Check and record critical dimensions using calipers and ruler as shown in Figure 1 of ASTM D4318.

Base:

1. Check resilience of base with 5/16 inch steel ball by dropping ball from clear plastic tube conforming to requirements set forth in Appendix A of ASTM D4318.
2. Drop the ball to check at least three locations on the base, record the rebound height shown on the outside plastic case.
3. Check wear circle on base, the wear spot should not be worn greater than 10 mm (3/8 in.).

Cup:

1. Check and record weight of cup and hanger.
2. Verify that the cup is firmly attached to the cup hanger.

Cup Hanger:

1. Make sure that the cup hanger does not bind, or allow more than 3 mm (1/8 in.) side to side movement of the lowest point on the rim.

Grooving tool:

1. Inspect the grooving tools for wear on a regular basis.

2. Check and record critical dimensions using calipers as shown in Figure 2 of ASTM D4318.

Gauge:

1. Check and record critical dimensions using calipers as shown in Figure 3 of ASTM D4318.

Glass plate:

1. Check and record for ground glass plate dimensions (length, width, and thickness).

Remove old verification sticker and place a new updated sticker on the equipment with the current information.

Analysis of

Chlorinated Herbicides by GC Using Methylation Derivatization

SW-846 Chlorinated Herbicides by 8151, State of Connecticut Department of Environmental Protection Reasonable Confidence Protocol **(RCP)**, Version 2.0, July 2006

1. Scope and Application

Matrices: Aqueous, soil and waste.

Definitions: See Alpha Laboratories Quality Manual Appendix A

Specifically, Method 8151A may be used to determine the following compounds:

Parameter		CAS No.[a]
2,4-D	[1, 2, 3]	94-75-7
2,4-DB		94-82-6
2,4,5-TP (silvex)	[1, 2, 3]	93-72-1
2,4,5-T	[1, 2]	93-76-5
Dalapon		75-99-0
Dicamba		1918-00-9
Dichloroprop		120-36-5
Dinoseb		88-85-7
MCPA		94-74-6
MCPP		93-65-2

[a] Chemical Abstract Service Registry Number

[1] RCRA List

[2] APA List

[3] TCLP List

Method 8151A is a capillary gas chromatographic (GC) method for determining certain chlorinated acid herbicides and related compounds in aqueous, soil and waste matrices.

Because these compounds are produced and used in various forms (i.e., acid, salt, ester, etc.), Method 8151A describes a hydrolysis step than can be used to convert herbicide esters into the acid form prior to analysis. Herbicide esters generally have a half-life of less than one week in soil.

When Method 8151A is used to analyze unfamiliar samples, compound identifications should be supported by at least one additional qualitative technique. Section 10.1 provides gas

chromatograph/mass spectrometer (GC/MS) criteria appropriate for the qualitative confirmation of compound identifications.

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one of the following laboratory personnel before performing the modification: Area Supervisor, Laboratory Services Manager, Laboratory Director, or Quality Assurance Officer.

This method is restricted to use by or under the supervision of analysts experienced in the use of gas chromatography and skilled in the interpretation of gas chromatograms. Only experienced analysts should be allowed to work with diazomethane due to the potential hazards associated with its use (explosive, carcinogenic). Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

2. Summary of Method

This SOP for Method 8151A details gas chromatographic conditions for the analysis of chlorinated acid herbicides in water, soil, and waste samples. The hydrolysis of esters is also described in SOP number 1964.

Water, soil, and waste samples are extracted with diethyl ether and then derivatized with diazomethane. The derivatives are determined by gas chromatography with an electron capture detector (GC/ECD). The results are reported as acid equivalents.

3. Reporting Limits

The sensitivity of Method 8151A depends on the level of interferences, in addition to instrumental limitations. Table 1 lists the estimated GC/ECD detection limits that can be obtained in aqueous and soil matrices in the absence of interferences. Detection limits for a typical waste sample should be greater.

4. Interferences

4.1 Refer to Method 8000 for instrumental interferences.

4.2 Method interferences may be caused by contaminants in solvents, reagents, glassware, and other sample processing hardware that lead to discrete artifacts or elevated baselines in gas chromatograms. All these materials must be routinely demonstrated to be free from interferences under the conditions of the analysis, by analyzing reagent blanks.

4.2.1 Glassware must be scrupulously cleaned. Clean each piece of glassware as soon as possible after use by rinsing it with the last solvent used in it. This should be followed by detergent washing with hot water and rinses with tap water, then with organic-free reagent water. Glassware should be solvent-rinsed with acetone and pesticide-quality hexane. After rinsing and drying, glassware should be sealed and stored in a clean environment to prevent any accumulation of dust or other contaminants. Store glassware inverted or capped with aluminum foil. Immediately prior to use, glassware should be rinsed with the next solvent to be used.

4.2.2 The use of high purity reagents and solvents helps to minimize interference problems.

4.3 Matrix interferences may be caused by contaminants that are coextracted from the sample. The extent of matrix interferences will vary considerably from waste to waste, depending upon the nature and diversity of the waste being sampled.

4.4 Organic acids, especially chlorinated acids, cause the most direct interference with the determination by methylation. Phenols, including chlorophenols, may also interfere with this procedure.

4.5 Alkaline hydrolysis and subsequent extraction of the basic solution removes many chlorinated hydrocarbons and phthalate esters that might otherwise interfere with the electron capture analysis. However, hydrolysis may result in the loss of Dinoseb and the formation of aldol condensation products if any residual Acetone remains from the extraction of solids.

4.6 The herbicides, being strong organic acids, react readily with alkaline substances and may be lost during analysis. Therefore, glassware must be acid-rinsed and then rinsed to constant pH with organic-free reagent water. Sodium Sulfate must be acidified.

4.7 Sample extracts must be dry prior to methylation otherwise poor recoveries will be obtained.

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material data handling sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

5.1 Lab coats, safety glasses, and gloves must be worn when handling supplies, samples, extracts, standards or solvents, and when washing glassware.

5.2 All extract concentration steps must be performed in extraction hoods. All solvent and extract transfers must also be handled in a hood.

5.3 All expired stock standards, working standards, and spent sample extracts must be placed into the waste bucket in the laboratory for future disposal by the Hazardous Waste Manager. The container must be properly labeled with hazard warning labels indicating the container contents.

5.4 Bottles containing flammable solvents must be stored in the flammables cabinet or in the vented cabinets found under the hoods. All ether bottles are to be checked for peroxide immediately upon opening.

5.5 All waste solvents must be transferred to the satellite waste storage containers located in the extraction laboratory. Separate containers are provided for chlorinated and non-chlorinated solvents and must be used accordingly. Under no circumstances are solvents to be poured down the sink drains.

5.6 Inspect all glassware prior to use. Do not use any glassware that is chipped or cracked if it could present a safety hazard. Damaged glassware is put aside for repair; otherwise the piece is discarded. A number is etched onto each KD concentrator tube to keep track of calibration (Refer to SOP/08-04, KD Tube Calibration).

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

Aqueous samples are collected in two one-liter amber glass containers. Soil samples are collected in 8oz. glass jars.

6.2 Sample Preservation

Both aqueous and soil/solid samples are stored in refrigerators to maintain a temperature of 2 – 6 °C.

6.3 Sample Shipping

No special shipping requirements.

6.4 Sample Handling

Both aqueous and soil/solid samples and extracts are stored under refrigeration (2 – 6 ºC) and protected from light. Aqueous samples must be extracted within 7 days from the time of collection; soil samples, within 14 days from collection. Sample extracts must be analyzed within 40 days following extraction.

After the extraction is completed, the sample extract is stored in a stoppered KD tube before being transferred to a crimp-top or screw cap vial for analysis and long-term storage.

7. Equipment and Supplies

7.1 Gas Chromatograph, Agilent 7890 (or equivalent): An analytical system complete with gas chromatograph configured for split-splitless injection and all required accessories including syringes, analytical columns, gases, electron capture detectors (ECD), and data system.

7.2 GC Columns: Alpha utilizes dual-column analyses. The dual-column approach involves either a single injection that is split between two columns that are mounted in a single gas chromatograph, or dual injections of the split extract on a single GC equipped with two columns. Typical column pairs used are listed below. Other columns may be used as long as method performance criteria can be met.

Column Pair:

STX-CLP: Cat.: #11546 from Restek or equivalent, 30m, 0.32mm, 0.32 µm
STX-CLPII: Cat.: #11444 from Restek or equivalent, 30m, 0.32mm, 0.25µm

7.3 Guard Column: Cat. #10027 from Restek or equivalent; 5m, 0.32mm

7.4 Class “A” Volumetric Flasks: 10mL and 25mL (and other volumes), for standards preparation

7.5 Microsyringes: 10 µL – 1000 µL

7.6 Gooseneck splitless injecton liner, Cat #23303 from Restek or equivalent

7.7 Universal “Y” Press-tight tee split: Cat. #20406 from Restek or equivalent **/ Siltek MXT Connector:** Cat. #21388 from Restek or equivalent

8. Reagents and Standards

Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

NOTE: Store the standard solutions (stock, composite, calibration, internal, and surrogate) at 4±2 °C in Teflon(R)-sealed containers in the dark. When a large volume of standard is prepared, aliquots of that lot are stored in individual small vials.

All stock standard solutions must be replaced ***after one year or sooner*** if routine QC tests indicate a problem.

All other standard solutions must be replaced ***after six months or sooner*** if routine QC indicates a problem.

8.1 Reagent water: All references to water in this method refer to reagent water from Alpha's DI water treatment system.

8.2 n-Hexane: Pesticide grade or equivalent

8.3 Acetone: Pesticide grade or equivalent

8.4 Internal Standard Stock Solution: 4,4'-dibromooctafluorobiphenyl (DBOB) (AccuStandard, Cat # M-8151-IS) is used as the internal standard.

- **Working Internal Standard Solution**: To a 10mL volumetric flask, add 1mL of the 4,4'-dibromooctafluorobiphenyl (DBOB) (AccuStandard, Cat # M-8151-IS) and bring to volume with Acetone. Final concentration is 25µg/mL. 10µL of this solution is added to the 1mL sample and QC sample extracts as well as to all Calibration Standards to achieve a concentration of 0.25µg/mL for analysis.

8.5 Calibration Standards: Appropriate vendor derivatized standard(s) are volumetrically diluted with Hexane to obtain Initial Calibration Stock Standard which is used to prepare Initial Calibration Working Standards.

8.5.1 Initial Calibration Stock Standard: to a 10mL volumetric flask, add few mLs of Hexane:

- **1mL 2,4-Dichlorophenyl acetic acid (DCAA) methyl ester solution: (**100µg/mL in MTBE, Accustandard, Cat # M515-SS) and
- **1mL of Chlorinated Herbicides Methyl Derivatives** (100/10000µg/mL in MTBE, Accustandard, Cat # M-8151) Bring to volume using Hexane. Final concentration is 10µg/mL for all analytes except MCPP and MCPA at 1000µg/mL.

8.5.1.1 Initial Calibration Working Standards

8.5.1.1.1 Cal Level 1: To a 10mL volumetric flask, add 50µL of Initial Calibration Stock Standard. Bring to volume with Hexane. Final concentration is 0.05µg/mL for all analytes except MCPP and MCPA at 5.0µg/mL.

8.5.1.1.2 Cal Level 2: To a 10mL volumetric flask, add 100µL of Initial Calibration Stock Standard. Bring to volume with Hexane. Final concentration is 0.10µg/mL for all analytes except MCPP and MCPA at 10.0µg/mL.

8.5.1.1.3 Cal Level 3: To a 10mL volumetric flask, add 200µL of Initial Calibration Stock Standard. Bring to volume with Hexane. Final concentration is 0.20µg/mL for all analytes except MCPP and MCPA at 20.0µg/mL.

8.5.1.1.4 Cal Level 4: To a 10mL volumetric flask, add 500µL of Initial Calibration Stock Standard. Bring to volume with Hexane. Final concentration is 0.50µg/mL for all analytes except MCPP and MCPA at 50.0µg/mL.

8.5.1.1.5 Cal Level 5: To a 10mL volumetric flask, add 1.0mL of Initial Calibration Stock Standard. Bring to volume with Hexane. Final concentration is 1.0µg/mL for all analytes except MCPP and MCPA at 100µg/mL.

8.5.1.1.6 Cal Level 6: To a 10mL volumetric flask, add 2.0mL of Initial Calibration Stock Standard. Bring to volume with Hexane. Final concentration is 2.0µg/mL for all analytes except MCPP and MCPA at 200µg/mL.

8.6 Second Source Standard: (ICV) Appropriate vendor derivatized standard(s) are volumetrically diluted with Hexane to obtain Initial Calibration Verification Stock Standard which is used to prepare ICV Working Standard.

8.6.1 ICV Stock Standard: to a 10mL volumetric flask, add a few mLs of Acetone (to ensure mix of Methanol from the Herbicides Mixture):

- **1mL of Methylated Herbicides Mixture** (100/10000µg/mL in Methanol, Agilent, Cat # HBM-8151M) and
- **1mL of DCAA Methyl Ester Solution: 2,4-Dichlorophenyl acetic acid (DCAA) methyl ester solution –SURROGATE (**100µg/mL in Acetone, Agilent, Cat # PPS-166). Bring to volume using Hexane. Final concentration is 10µg/mL for all analytes except MCPP and MCPA at 1000µg/mL.

8.6.1.1 ICV Working Standard: To a 50mL volumetric flask, add 1mL ICV Stock Solution. Bring to volume with Hexane. Final concentration is 0.2µg/mL for all analytes except MCPP and MCPA at 20µg/mL.

8.6.2 ICV Standard (2,4-DB only): to a 50mL volumetric flask, add few mLs of Hexane and **2,4-DB methyl ester** (1000µg/mL in Hexane, Restek, Cat # 70931). Bring to final volume using Hexane. Final concentration is 0.2µg/mL.

8.7 Extraction Surrogate Standard: 2,4-Diclorophenylacetic Acid (DCAA) (1000µg/mL in Acetone, AccuStandard, M-8150B-SS-10X) The Surrogate standard is spiked into all samples and QC samples prior to extraction.

- To a 1000mL volumetric flask, add 10mL of ampulated surrogate solution. Bring to volume with Acetone. Final concentration is 10µg/mL.

8.8 LCS/MS Spiking Solutions: The LCS/MS spiking solutions are prepared volumetrically by diluting Underivatized Chlorinated Herbicides (100/10000µg/mL in Acetone, AccuStandard, Cat # M8151A.) in Acetone

- To a 200mL volumetric flask, add 20mL of ampulated LCS/MS solution. Bring to volume with Acetone. Final concentration is 10µg/mL for all analytes except MCPP and MCPA at 1000µg/mL.

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

9.1 Blank(s)

A matrix-specific extraction blank is performed with each extraction batch of 20 or fewer samples, according to the extraction SOPs. The extraction blank must not contain any of the reportable analytes at or above the reporting limit. If any reportable analytes are detected in the blank, the entire extraction batch is suspect and re-extraction of all associated samples is required, unless the associated samples are non-detect or concentration of the analyte in the samples is 10 times greater than the concentration of this analyte in the blank. The surrogate recoveries must also be within the acceptance criteria listed in Table 3. If surrogate acceptance criteria are exceeded, the extraction batch must be evaluated to determine if re-extraction or re-analysis is necessary. Actions associated with blank failures are listed in Table 4.

9.2 Laboratory Control Sample (LCS) / LCS Duplicate

A Laboratory Control Sample (LCS) and an LCS Duplicate (LCSD) is extracted with each analytical batch. The LCS consists of an aliquot of a clean (control) matrix similar to the sample matrix and of the same weight or volume. The LCS is spiked with all target analytes. The concentrations of the spiking solutions are listed in Table 2. The recovery and RPD acceptance criteria are listed in Table 3. If any recovery criteria are not met, the extract should be reanalyzed. If the criteria are still not met, the entire batch should be re-extracted, unless the recoveries are high and the associated samples are non-detect. If this is not possible, due to insufficient sample or holding time exceedance, the analyst must write up the failure on a narrative sheet for inclusion in the client report. Actions associated with LCS/LCSD failures are listed in Table 4.

9.3 Initial Calibration Verification (ICV)

Refer to Section 10.2.7

9.4 Continuing Calibration Verification (CCV)

Refer to Section 10.4

9.5 Matrix Spike (MS)/MS Duplicate

A matrix spike/matrix spike duplicate pair is extracted and analyzed for each batch of 20 or less samples only upon client request. MS and MSDs are field samples spiked with a known quantity of the target analyte(s). They are prepared by taking additional sample aliquots of the same weight or volume and adding the appropriate amounts of surrogate and spiking solutions. The spike compounds and levels are listed in Table 2. The recovery and RPD acceptance criteria are listed in Table 3. If the recovery criteria are not met, but are met in the LCS, the

failure may be attributed to sample matrix. Actions associated with MS/MSD failure are listed in Table 4.

9.6 Laboratory Duplicate (DUP)

A duplicate sample is extracted and analyzed upon Client request for each batch of 20 or less samples. Duplicates are laboratory selected replicate samples, prepared by taking an additional sample aliquot of the same weight or volume of a sample. The % RPD criteria are listed in Table 3. If the %RPD is not met, the failure may be attributed to sample matrix effects and must be noted on a narrative sheet for inclusion in the client report. Actions associated with duplicate failures are listed in Table 4.

For samples with a state of origin of New Jersey, a MS and MSD/DUP must be extracted for every twenty samples within a 24hr period.

9.7 Extraction Surrogates

All extracted samples and associated QC are spiked with surrogates at the levels listed in Table 2. The laboratory must evaluate surrogate recovery data from individual samples and QC samples versus the surrogate control limits for both columns listed in Table 3. If the surrogate limits are not met, the extract should be reanalyzed to determine if the failure was due to an instrument problem. If the criteria are still not met, the affected samples should be re-extracted to confirm that the failure was due to sample matrix. If matrix effect is confirmed, this must be noted on a narrative sheet for inclusion in the client report.

9.8 Method Sequence

Typical Initial Calibration (each level has to be identified with the standard lot number)

1. Instrument Prime
2. Blank
3. Std Level 1
4. Std Level 2
5. Std Level 3
6. Std Level 4
7. Std Level 5
8. Std Level 6
9. Initial Calibration Verification Standard (ICV)
10. Initial Calibration Verification Standard (ICV)

Typical Daily Sequence:

1. Instrument Prime
2. Blank
3. Herbicide Continuing Calibration Standard **(identified with the standard lot number**)
4. Extraction Blank
5. Laboratory Control Sample
6. Laboratory Control Sample Duplicate
7. Matrix Spike (Upon Client Request)
8. Duplicate/Matrix Spike Duplicate (Upon Client Request)
9. Samples (10 field samples)
10. Repeat 3 – 9 (as needed)

10. Procedure

10.1 Equipment Set-up

The dual-column / dual-detector approach involves the use of the columns listed in section 7.2. The columns are connected to an Y-split or similar or dual injection GC, and separate electron capture detectors. Alpha typical GC conditions are listed below but may be altered as long as method performance criteria are met.

Temperature 1:	80 °C	**Detector temperature:**	350 °C
Ramp 1:	15°C/minute	**Carrier gas:**	Hydrogen
Temperature 2:	200°C	**Carrier flow:**	2.5 mL/min
Ramp 2:	20°C/minute	**Carrier mode:**	Constant flow
Temperature 3:	280°C	**Makeup gas:**	Nitrogen
Hold Time:	3 minutes	**Total detector flow:**	55 mL/min
Injector Temperature:	250°C		
Injector Mode:	Split		
Injector Flow:	36.5 mL/min		
Septum Purge Flow:	24 mL/min		
Split Flow:	10 mL/min		
Split Ratio:	4:1		
Injection Volume	1 µL		

10.2 Initial Calibration

10.2.1 Prepare calibration standards using the procedures in Section 8.5 and Table 2. The calibration standards are aliquoted into autosampler vials and capped prior to loading onto the autosampler tray. The calibration standards are analyzed and the curve is calculated prior to sample analysis.

10.2.2 Establish the GC operating conditions by loading the appropriate GC method. Typical instrument conditions are listed in section 10.1. The same operating conditions are used for calibrations and sample analyses. Create the analytical sequence using the Agilent Chemstation data acquisition software. Record the calibration standard, unique lot number (PP#) and analyst's initials in the analytical sequence list.

10.2.3 A 1µL injection volume of each calibration standard is typically used. Other injection volumes may be employed, provided that the analyst can demonstrate adequate sensitivity for the compounds of interest. The same injection volume must be used for all standards and samples.

10.2.4 Column adsorption may be a problem when the GC has not been used for a day or more or after system maintenance. The GC column may be primed (or deactivated) by injecting a Herbicides standard mixture approximately 20 times more concentrated than the mid-concentration standard. Inject this standard mixture prior to beginning the initial calibration or calibration verification.

Alternately, the system may be primed by baking at the final analytical temperature for approximately 30 minutes.

Several analytes may be observed in the injection just following system priming. Always run an instrument blank after system priming.

10.2.5 Calibration Factors

Internal standard calibration techniques are employed in this method.

10.2.5.1 Internal Standard Procedure. In each standard, calculate the response factor (RF) for each analyte, the average RF, and the relative standard deviation (RSD) of the RFs, using the Enviroquant data processing software. The calculations are performed automatically, using the formulae listed in Alpha's Quality Manual.

10.2.6 Initial Calibration Criteria

- If the **RSD for an analyte is < 20%,** then the response of the instrument for this compound is considered linear over the range and the mean calibration factor (Avg. RF) can be used to quantitate sample results.

- If the **RSD for any analyte is > 20%**, then linearity through the origin cannot be assumed. The mean response factor cannot be used for quantitation. An alternative calculation may be done by the use of **linear regression** or **quadratic regression** (minimum of six ICAL points are needed and regression must be weighted inversely proportional to concentration) as long as the **correlation coefficient is >0.990**. If both of these quantitation methods fail criteria for any compound in the initial calibration, then the system must be reevaluated and a new calibration curve must be analyzed. If quadratic regression is used for calibration, this must be noted in the laboratory narrative. The regression equation cannot be forced through the origin. The equation for linear regression may be found in Alpha's Quality Manual.

- **MCP requirement:** If linear or non-linear regression is used, RL must to be verified by recalculating concentrations in the lowest calibration standard using the final calibration curve. Recoveries must be **70-130%.**

- Minimum of five standards must be used for the linear regression and minimum of six for non-linear regression.

- Percent Relative Error (%RE): For linear and quadratic fit compounds, the %RE must be calculated for the standard at or near the midpoint and at the lowest level of the initial calibration. The %RE between the calculated and expected concentration of an analyte must be ≤ 30%, otherwise recalibration is necessary.

10.2.7 Initial Calibration Verification

An Initial Calibration Verification standards must be run immediately after each initial calibration, near the midpoint of the curve. The standards must be prepared using a second source that is different than the source used for the initial calibration. (Standards listed in Section 8.6). The **%D** has to be within **20%** (**15% for CT RCP**) when compared to the mean response factor from the initial calibration.

10.2.8 Retention Time Windows

- The retention time windows used for the identification of target analytes is ± 0.03 minutes. These criteria have been adopted from the EPA CLP Statement of Work (OLM04.2). It has been found that these limits work well, being wide enough to eliminate false-negatives while being tight enough to eliminate false-positives. Windows that are calculated using the procedure recommended in Method 8000 tend to be very narrow, creating the risk of false negative results.
- The windows listed above are used as guidance, however the experience of the analyst weighs heavily in the interpretation of the chromatograms. For example, it has been observed that certain oil matrices can cause the retention times to shift more dramatically. Additionally, if any positive results are questionable and at a sufficiently high concentration, GC/MS analysis is used for confirmation.

10.3 Sample Processing

10.3.1 The same GC operating conditions used for the initial calibration must be employed for sample analyses, including sample injection volume.

10.3.2 Tentative identification of an analyte occurs when a peak from a sample extract falls within the retention time window for the compound. Each tentative identification is confirmed using a second GC column of dissimilar stationary phase. In particularly difficult matrices, confirmation by GC/MS may be advisable.

10.3.3 The concentration reported for an identified target analyte in an extract is calculated using the Enviroquant data processing software. The Enviroquant methods have been configured to utilize the quantitation formulas found in Alpha's Quality Manual. Proper quantitation requires the appropriate selection of a baseline from which the peak area or height can be determined. See the Manual Integration SOP for integration guidelines. Also refer to Section 11 for calculations.

10.3.3.1 If the responses exceed the calibration range of the system, dilute the extract and reanalyze.

10.3.4 The laboratory must report **HIGHER** of the two results unless obvious interference is present on one of the columns.

10.3.4.1 The **Relative Percent Difference (RPD)** should be 40 or lower. If the RPD exceeds 40, this will be denoted with a P flag. If the RPD exceedance is due to interference, the lower of the dual column values can be reported with I and P flags.

10.3.5 If compound identification or quantitation is precluded due to interference (e.g. broad, rounded peaks or ill-defined baselines are present) cleanup of the extract may be needed. If instrument problems are suspected, rerun the extract on another instrument to determine if the problem results from analytical hardware or

the sample matrix. Refer to the extraction SOPs for the procedures to be followed in sample cleanup.

10.3.6 GC/MS Confirmation

GC/MS confirmation may be used in conjunction with either single-column or dual-column analysis if the concentration is sufficient for detection by GC/MS.

10.4 Continuing Calibration

10.4.1 Verify calibration each **12-hours** shift by injecting Continuing Calibration standard prior to conducting any sample analyses. A calibration standard must also be injected at intervals of **not less than once every 10 filed samples.**

A bracketing CCV is not required with the use of internal standard calibration method with the exception of samples ran under CT RCP method.

10.4.2 The Response Factor (for internal standard compounds) for each analyte to be quantitated must not exceed a **± 20% difference (± 15% for MCP and CT RCP**) when compared to the initial calibration curve. The Enviroquant data processing software automatically calculates the %D for all analytes according to the formula in Alpha's Quality Manual.

If this criterion is exceeded, inspect the gas chromatographic system to determine the cause and perform whatever maintenance is necessary before verifying calibration and proceeding with sample analysis.

10.4.3 If routine maintenance does not return the instrument performance to meet the QC requirements based on the last initial calibration, then a new initial calibration must be performed. Due to the large number of analytes present, allowances may be made for a CF or RF that drifts out high, as long as there are no positive hits for that particular analyte in any of the associated samples.

10.5 Internal Standard

The use of internal standard calibration does not require that all sample results be bracketed with CCV standard. However, when internal standard calibration is used, the retention times of internal standards and the area response of internal standards should be checked for each analysis.

10.5.1 **IS in CCAL** – The measured area of the internal standard must be no more than + 50% different from the average area calculated during initial calibration (-50 to 150%).

10.5.2 **IS in samples** - The measured area of the internal standard must be no more than -50% to +100% different from the area calculated from opening CCV (-50 to 200%)

Retention time shifts of more than 30 sec from the retention time of the most recent calibration standard are cause for concern and must be investigated.

10.6 Preventive Maintenance

- Routine preventive maintenance should be performed to maintain GC system performance. This includes periodic replacement of injector septa, replacement of injector liner(s), and replacement of injector seals. All maintenance is noted in individual Instrument Maintenance Logbooks.
- Other Maintenance: ECD detectors may become contaminated, requiring bake out at elevated temperatures, (no greater than 375℃) or repair by the manufacturer.

11. Data Evaluation, Calculations and Reporting

Herbicides are calculated as described in Section 11.1, 11.2, and reported in µg/L or µg/Kg units. After performing technical data review, validating that all QC criteria have been met and confirming all positive hits, the data report is sent electronically to the LIMS computer for generation of the client report. Two levels of review of the data in the LIMS system are preferred prior to release of data. These reviews include analyst review and review by the Department Supervisor or other trained analyst.

11.1 Aqueous Calculation

$$\mu g/L = \frac{(A_s)\,(C_{IS})\,(D)\,(V_f)}{(A_{IS})\,(\overline{RF})\,(V_s)\,(1000)}$$

Where:

A_s = Peak area of analyte
A_{IS} = Peak area of Internal Standard
C_{IS} = Concentration of IS (µg/L)
D = Dilution factor (D = 1 for no dilution)
V_f = Final extract volume (mL)
Vs = Initial volume extracted (mL)

$\overline{RF}$ = Mean response factor

11.2 Soil/Solid Calculation

$$\mu g/Kg = \frac{(A_s)\,(C_{IS})\,(D)\,(V_f)}{(A_{IS})\,(\overline{RF})\,(W_s)\,(1000)}$$

Where:

A_s = Peak area of analyte
A_{IS} = Peak area of Internal Standard
C_{IS} = Concentration of IS (µg/L)
D = Dilution factor (D = 1 for no dilution)
V_f = Final extract volume (mL)
Ws = Initial weight extracted (g)

$\overline{RF}$ = Mean response factor

11.2.1 Response Factor Calculation

$$RF = \frac{(A_s)\,(C_{IS})}{(A_{IS})\,(C_s)}$$

Where:

A_s = Peak area of analyte
A_{IS} = Peak area of Internal Standard
C_s = Concentration of analyte (µg/L)
C_{IS} = Concentration of IS (µg/L)

11.3 Molecular Weight Correction

In addition, conversion factors for the molecular weights have been listed for all analytes reported under EPA Method 8151.

The calibration is performed using the methyl ester compounds; therefore the calculation of the concentration includes a correction for the molecular weight of the methyl ester versus the acid herbicide.

Derivatized herbicides are used for the standard curve, and they are supplied as methyl esters as opposed to acid herbicide form which is used for the LCS. The difference between the acid form and the methyl ester is + 14 (i.e. In Derivatization, a $-CH_3$ group replaces the -H, (15-1 = 14)). The factors used for correction (listed in the Table below) vary for each herbicide and are applied to the standard concentration at each level of the calibration within the target processing software.

Example: 2,4-D

2,4-D MW = 221.04 2,4-D Methyl ester MW = 235.06

If you spike 10 ug of 2,4-D, and derivatized it, you end up with 10.634 ug of 2,4-D Methyl ester that you are measure, as you've stripped the -H and added a -CH3, increasing the molecular weight. The true value for the spike is 10 ug as the acid herbicide, and 10.634 ug as the methyl ester. So a spike of 10 ug of acid, would measure 10.634 ug of the methyl ester to get 100% recovery. The true value for the spike would be 10.634 as methyl ester, which you use to divide your measured value by.

If measuring recoveries, the value of the 10 ug of the methyl ester, would be 10 ug measured (as methyl ester)/10.634 ug spiked (as methyl ester) = 94.04%.

If, on the other hand you want to convert your final result using a correction factor, you would use the MW of the acid/MW of the ester (221.04/235.06 = 0.94).

Conversion Factors applied in EQ software:

Parameter	CAS No.[a]	MOL WT.	WT as methyl ester	Conversion Factor
2,4-D [1, 2, 3]	94-75-7	221.04	235.06	0.94
2,4-DB	94-82-6	326.18	340.18	0.96
2,4,5-TP (silvex) [1, 2, 3]	93-72-1	269.51	283.51	0.95
2,4,5-T [1, 2]	93-76-5	255.48	269.48	0.95
Dalapon	75-99-0	142.96	156.96	0.91
Dicamba	1918-00-9	221.04	235.04	0.94
Dichloroprop	120-36-5	235.06	249.06	0.94
Dinoseb	88-85-7	240.21	254.21	0.95
MCPA	94-74-6	200.62	214.62	0.93
MCPP	93-65-2	214.65	228.65	0.94

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

Refer to Section 10 for specific corrective actions.

13. Method Performance

13.1 Method Detection Limit Study (MDL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the MDL, LOD, and/or LOQ as outlined in Qualtrax Document ID 1732. These studies performed by the laboratory are maintained on file for review.

13.2 Demonstration of Capability Studies

Refer to Alpha SOP/08-12 for further information regarding IDC/DOC Generation.

13.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

14. Pollution Prevention and Waste Management

Refer to Alpha's Chemical Hygiene Plan and Waste Management and Disposal SOP for further pollution prevention and waste management information.

15. Referenced Documents

- Chemical Hygiene Plan
- Qualtrax ID 1732 MDL/LOQ Generation
- Qualtrax ID 1739 IDC/DOC Generation
- Qualtrax ID 1728 Waste Management and Disposal SOP

TABLE 4

QC FAILURE ACTION PLAN

Blank Failures	Failure Situation	Action(s)
Surrogate Failure	1 of 2 high or low	Report as is
	Both high	Report as is
	Both low, samples are non-detect with passing surrogates	Report as is
	Both low, samples have hits and/or failing surrogates	Revial/rerun Re-extract if still failing
IS Failure	IS not present (less than 10% recovery)	Add IS Rerun
	IS out high or low	Revial/rerun Re-extract if still failing
Contamination	Below RL; sample(s) non-detect, below RL, or concentration 10 times or more above the blank	Report as is
	Below RL, sample(s) concentration above RL	See team leader/manager
	Above RL, sample(s) concentration 10 times or more above the blank	Report as is
	Above RL with non-detect sample(s)	Report as is
	Above RL, sample(s) concentration less than 10 times above the blank and volume available	Revial/rerun Re-extract if contamination still present
	Above RL, sample(s) concentration less than 10 times above the blank and no volume available	Revial/rerun B-flag affected data

LCS/LCSD Failures	Failure Situation	Action(s)
Surrogate Failure	1 of 2 high or low	Report as is
	Both high or low	Report as is
IS Failure	IS not present (less than 10% recovery)	Add IS Rerun
	IS out high or low	Revial/rerun Re-extract if still failing
Spike Failure	Spike compounds out high and sample(s) are non-detect with passing surrogates	Report as is
	Spike compounds out high and sample(s) have hits	Revial/rerun Re-extract if still high
	Spike compounds out low	Revial/rerun Re-extract if still low
	RPD failure	Report as is

MS/MSD/DUP Failures	Failure Situation	Action(s)
Surrogate Failure	(MS/MSD) 1 of 2 high or low	Report as is
	(MS/MSD) Both high or low	Report as is
	(DUP) 1 or more high, parent sample non-detect	Report as is
	(DUP) 1 of 2 low, parent sample matches	Report as is
	(DUP) 1 or more low, parent sample doesn't match	Revial/rerun Re-extract if still failing
IS Failure	IS not present (less than 10% recovery)	Add IS Rerun
	IS out high or low	Revial/rerun Re-extract if still failing
Spike Failure (MS/MSD only)	Compounds out high or low due to sample matrix or hits	Report as is
	Compounds out high or low due to extraction error	Revial/rerun Re-extract if still failing
	RDP failure	Report as is

Chromium, Hexavalent

1. Scope and Application

Matrices: This method is applicable for the determination of hexavalent chromium in natural or treated water or in a soil or solid matrix.

Definitions: See Alpha Analytical Quality Manual Appendix A

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one of the following laboratory personnel before performing the modification: Area Supervisor, Laboratory Services Manager, Laboratory Director, or Quality Assurance Officer.

This method is restricted to use by or under the supervision of analysts experienced in the operation of the Spectrophotometer and in the interpretation of Spectrophotometric data. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

The hexavalent chromium concentration of U.S. drinking waters has been reported to vary between 3 and 40µg/L with a mean of 3.2µg/L. Chromium salts are used extensively in industrial processes and may enter a water supply through the discharge of wastes. Chromate compounds frequently are added to cooling water for corrosion control. Chromium may exist in water supplies in both the hexavalent and the trivalent state although the trivalent form rarely occurs in potable water.

2. Summary of Method

This procedure measures only hexavalent chromium (Cr^{6+}). The hexavalent chromium is determined colorimetrically by reaction with diphenylcarbazide in acid solution. A very sensitive red-violet color of unknown composition is produced, and its absorbance is measured photometrically at 540nm.

2.1 Method Modifications from Reference

The coloring reagent used for the standards in the calibration curve and for the samples is made by dissolving 1 gram of 1,5-diphenylcarbazine in 250mL of acetone, whereas the reference method 7196A dissolves 1 gram in 200mL of acetone.

Alpha uses a smaller sample volume for analysis; therefore reagent volumes are reduced accordingly.

Alpha doesn't perform Blank correction;

2.5 cm (not 1cm) absorption cell is used for water samples to increase sensitivity.

Soil samples with failed soluble or insoluble spikes will be analyzed for PH and ORP to check if sample has reducing condition. If reducing condition confirm then lab will not Reprep asnd reanalyze samples with failed insoluble and soluble spikes

3. Reporting Limits

The RDL reported is 0.01mg/L for 50mL of an aqueous sample. The RDL reported is 0.8mg/Kg for 2.5g of a soil/solid sample. The RDLs are not adjusted for % Moisture.

4. Interferences

4.1 Background Color

Turbidity and background sample color are removed by filtering the sample through a 0.45µm filter. In cases when filtration alone is not sufficient, background interference can be subtracted out by adding all reagents to the sample except diphenylcarbazide solution, measuring the background absorbance, and then subtracting this value from the colored sample absorbance value.

4.2 Other Metals

The reaction with diphenylcarbazide is nearly specific for chromium. Hexavalent molybdenum and mercury salts will react to form color with the reagent but the intensities are much lower than that for chromium at the specified pH. Concentrations as high as 200 mg/L of Mo or Hg can be tolerated. Vanadium interferes strongly but concentrations up to 10 times that of chromium will not cause trouble. Potential interference from permanganate is eliminated by prior reduction with azide. Iron in concentrations greater than 1mg/L may produce a yellow color but the ferric ion (Fe^{3+}) color is not strong and no difficulty is encountered normally if the absorbance is measured photometrically at the appropriate wavelength. Interfering amounts of molybdenum, vanadium, iron, and copper can be removed by extraction of the cupferrates of these metals into chloroform ($CHCl_3$). A procedure for this extraction is provided in the reference but do not use it unless necessary because residual cupferron and $CHCl_3$ in the aqueous solution complicate the later oxidation. Therefore, follow the extraction by additional treatment with acid fuming to decompose these compounds.

4.3 Reducing/oxidizing tendency of sample matrix

When analyzing a sample digest for total Cr(VI), it is appropriate to determine the reducing/oxidizing tendency of each sample matrix, if the matrix spike for that sample matrix has failed the quality control acceptance criteria for this method. Determination of the Reducing/oxidizing potential for failing matrix spike samples can be accomplished by characterization of each sample for additional parameters, such as pH (Method 9045) and Oxidation Reduction Potential (ORP) (ASTM 1498-93 –aqueous samples). Method 9045 (Section 7.2 of Method 9045) is referenced as the preparatory method for soil samples. The ORP and temperature probes are inserted directly into the soil slurry derived from the pH analysis. The displayed ORP value is allowed to equilibrate and the resulting measurement is recorded. Analysis of these parameters establishes the tendency of Cr(VI) to exist or not exist in the unspiked sample(s) and assists in the interpretation of QC data for matrix spike recoveries outside conventionally accepted criteria for total metals.

4.4 Soluble Cr(III) concentration

For waste materials or soils containing soluble Cr(III) concentrations greater than four times the laboratory Cr(VI) reporting limit, Cr(VI) results obtained using this method may be biased high due to method-induced oxidation. The addition of Mg^{2+} in a phosphate buffer to the alkaline extraction solution has been shown to suppress this oxidation. If an analytical method for Cr(VI) is used that can correct for possible method induced oxidation/reduction, then the Mg^{2+} addition is optional. The presence of soluble Cr(III) can be approximated by extracting the sample with deionized water.

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound must be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available.Hexachrome is toxic and suspected carcinogen. A reference file of material data handling sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

Samples are collected in plastic or glass containers with teflon-lined caps. Sample containers must not contain any stainless steel. Separate container has to be provided for MCP HexCr (see MCP addendum)

6.2 Sample Preservation

Samples are unpreserved and refrigerated at 4 ± 2 °C.

6.3 Sample Shipping

No special shipping requirements.

6.4 Sample Handling

Aqueous samples must be analyzed within 24 hours of collection.

Soil and solid samples must be digested within 30 days of collection. The extracts must be analyzed within 168 hours (7 days) after extraction.

7. Equipment and Supplies

7.1 Spectrophotometer: Genesys 10 Vis or equivalent: for use at 540nm, with a light path of 1cm or longer.

7.2 100 ml digestion cups

7.3 pH Meter: Calibrated.

7.4 Volumetric flasks: 1000mL and 100mL.

7.5 Filtration apparatus.

7.6 0.45µm Membrane filters.

7.7 Hot block Model # SC151 with Stir Base Stirring device (part #SC160)

7.8 Balance.

7.9 Thermometers.

7.10 Volumetric pipets: various volumes.

7.11 50mL Centrifuge Tubes.

7.12 100mL Graduated cylinder

7.13 pH paper range 1-14.

7.14 Centrifuge

8. Reagents and Standards

8.1 1000ppm Stock Hexavalent Chromium Solution (for calibration and LCS): Commercial purchase. Expire upon manufacturer's expiration date. Use different lots for calibration and LCS.

8.2 1ppm Working Standard Hexavalent Chromium Solution (for calibration): Dilute 1.00mL stock chromium solution (Section 8.1) to 1000mL with DI. Store at room temperature. Expires three months from the date of preparation.

8.3 10ppm Working Standard Hexavalent Chromium Solution (for LCS/ICV): Dilute 1.00mL stock chromium solution (Section 8.1) to 100mL with DI. Store at room temperature. Expires six months from the date of preparation

8.4 Nitric acid, HNO_3, concentrated. Do not use if has a yellow tinge. Expires upon manufacturer's expiration date.

8.5 Nitric Acid, 50%: Into a 500mL volumetric flask, dilute 250mL of Concentrated Nitric Acid with 250mL of DI water. Expires six months from the date of preparation.

8.6 Sulfuric acid, H_2SO_4, concentrated.

8.7 Sulfuric acid, H_2SO_4, 10%: Dilute 50mL concentrated H2SO4 to 500mL with DI water. Expires six months from the date of preparation.

8.8 Diphenylcarbazide solution: Dissolve 1.0g 1,5-diphenylcarbazide (1,5-diphenylcarbo-hydrazide) in 250mL acetone. Store in a plastic bottle cover with aluminum foil or away from light. Discard when solution becomes discolored. Prepare fresh weekly.

8.9 Sodium carbonate: Na_2CO_3, anhydrous, analytical reagent grade. Store at 20 – 25°C in a tightly sealed container.

8.10 Sodium hydroxide: NaOH, analytical reagent grade. Store at 20 – 25°C in a tightly sealed container.

8.11 Magnesium Chloride: $MgCl_2$ (anhydrous), analytical reagent grade. 392.18mg $MgCl_2$ is equivalent to 100mg Mg^{2+}. Store at 20 – 25°C in a tightly sealed container. As an alternate, use 0.8366g $MgCl_2 \cdot 6\ H_2O$.

8.11.1 Magnesium Chloride solution: Dissolve 84g of $MgCl_2 \cdot 6\ H_2O$ in 100mL of DI. Store at 20 – 25°C in a tightly sealed container. Expires six months from the date of preparation.

8.12 Phosphate Buffer:

8.12.1 K_2HPO_4: Analytical reagent grade.

8.12.2 KH_2PO_4: Analytical reagent grade.

8.12.3 0.5M K_2HPO_4 / 0.5M KH_2PO_4 buffer: Dissolve 87.09g K_2HPO_4 and 68.04g KH_2PO_4 into 700mL of DI water. Transfer to a 1L volumetric flask and dilute to volume. (When prepared accordingly, the buffer solution has an approximate pH value of 7.)Record pH

in the reagent log book. Store at 20 – 25°C in a tightly sealed container. Expire one year from prep.

8.13 Lead Chromate: $PbCrO_4$, analytical reagent grade. Store under dry conditions at 20 – 25°C in a tightly sealed container. Expires upon manufacturer's expiration date.

8.13.1 Soil matrix insoluble spiking solution: Add 10 – 20mg $PbCrO_4$ (Section 8.12) to a separate aliquot of sample. This spike is used to evaluate the dissolution during the digestion process.

8.14 Digestion solution: Dissolve 20.0 ± 0.05g NaOH and 30.0 ± 0.05g Na_2CO_3 in deionized water in a one-liter volumetric flask and dilute to the mark. Store the solution in a tightly capped polyethylene bottle at 20 – 25 °C and prepare fresh monthly. The pH of the digestion solution must be checked before using. The pH must be 11.5 or greater; if not, discard.

8.15 Potassium Dichromate, $K_2Cr_2O_7$, spiking solution (1000mg/L Cr (VI)): Commercial purchase. Expire upon manufacturer's expiration date.

8.15.1 100mg/L Cr (VI): Add 10.0mL of the 1000mg/L $K_2Cr_2O_7$ spiking solution (Section 8.15) to a 100mL volumetric flask and dilute to volume with deionized water. Mix well.

8.15.2 5ppm: To a 100mL volumetric flask, add 5mL of 100ppm spiking solution (Section 8.15.1), bring to volume with DI.

8.15.3 Soil sample soluble spike: Add 1 ml of 1000mg/L Cr (VI) spiking solution (Section 8.15) to 2.5g of sample.

8.15.4 Post spike soil sample: Add 1 ml of 100mg/L Cr(VI) solution (section 8.15.1) to 25 ml extracted sample.

8.15.5 Aqueous sample spike: Add 1ml of 5 ppm (section 8.15.2) to 50 ml of sample**.**

8.16 ICV and CCV Standards: Commercially prepared solution of known hexavalent chromium concentration. A Certificate of Analysis is kept on file. This solution is diluted with DI to a concentration 0.2 ppm on each day of use

8.17 Acetone: Analytical reagent grade.

8.18 Ottawa Sand

8.19 SRM HexCr standard: ERA QC-Cat#921. Expires upon manufacturer's expiration date

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

9.1 Blank(s)

One preparation blank is digested and analyzed per batch of 20 samples or less for method 3500. Method 7196: batch size is 10 samples or less. The concentration of the Blank must be less than the RDL, or one-tenth the regulatory limit or action level, whichever is greater, otherwise the entire batch must be redigested and reanalyzed.
Method Blanks consist of DI water for liquid samples or 2.5g of Ottawa sand for soil samples.

The ICB consists of DI water that has been colored and analyzed as per Section 10.3.4. Results must be less than the RDL, otherwise another ICB is colored and analyzed. It failure continues, a new calibration curve is generated (Section 10.1).

9.2 Laboratory Control Sample (LCS)

One LCS is prepared and analyzed per batch of 20 samples or less for method 3500. Method 7196: batch size is 10 samples or less.

The LCS for aqueous samples consists of the ICV (Section 10.2). LCS recovery for liquids must be within 85 – 115%, otherwise the entire sample batch must be reanalyzed.

For solids samples, a soluble LCS and insoluble LCS must be digested per batch of 20 samples or less (Refer to Section 10.3.3.1) LCS recovery for solids must be within 80 – 120%, otherwise the sample batch must be redigested and reanalyzed.

Note: SRM HexCr standard made by ERA is used for soil LCS: use 0.2-0.5 g, based on certified value. Expires upon manufacturer's expiration date.

9.3 Initial Calibration Verification (ICV)

Refer to Section 10.2

9.4 Continuing Calibration Verification (CCV)

Refer to Section 10.4

9.5 Matrix Spike

9.5.1 Aqueous samples

One sample per delivery group per batch of 20 samples (method 3500) or 10 samples (method 7196) or less is required to be spiked.

Example: If a batch consists of 6 liquid samples (3 wastewater from Client A and 3 wastewater from Client B), then one wastewater from Client A and one wastewater from Client B each require spiking.

The spike is prepared by adding 1mL of 5ppm aqueous spiking solution (Section 8.15.2) to 50mL of sample. Spike recovery must be within 85 – 115. If spike recovery is outside of the range, adjust sample pH to 8.5 then add 1 ml of 5 ppm spiking solution and reanalyze. If spike recovery still outside of the range, then dilute sample and retest both diluted sample and spiked diluted sample. Report sample results at the dilution for which the spike recovered at 85 – 115%.

Sample dilutions can be made with DI, up to 200X or up to the client's specified detection limits.

If interferences remain after dilutions, and spike recovery is still less than 85% for aqueous samples, refer to Section 10.3.5.

9.5.2 Soil / solid matrix samples

Two spikes per batch of 10 samples or less are required; one with a soluble spike and one with an insoluble spike (Section 10.3.3.1). The acceptance range for spike recovery is 75 – 125%. If recoveries are not within the specified limits, then samples will be analyzed for PH and ORP to confirm matrix interference. If samples have reducing condition then a re-digestion of the sample and matrix spikes will not be needed..

For NJ-HexCr packages: If recoveries are not within the specified limits, then the matrix spike(s) and the associated samples must be re-homogenized/re-digested/re-analyzed. If upon reanalysis, it is found that the recoveries are acceptable, then the data is submitted with the new spike results. If it is found that the recoveries are still unacceptable upon redigestion, then it is assumed that the sample matrix is suspect and the pH (SOP 2203) and ORP (SOP 2237) are measured at once for the sample that was spiked. (for NJ HexCr method). For MCP method, pH and ORP are measured within 24h of sample collection.

If prior knowledge of an interfering sample matrix is known, then matrix spike duplicates (MSD) are set for the soluble and insoluble matrix spikes, along with the pH and ORP analyses for the samples to be spiked. Failure of the MS/MSD will verify that the sample matrix interferes with the digestion and will not necessitate a re-digestion of the sample and matrix spikes.

SOP addendum must be checked for NJ HexCr and MCP HexCr methods for additional actions.

9.6 Laboratory Duplicate

Analyze one sample in duplicate per batch of 20 samples (method 3500) or 10 samples (method 7196) or less. The %RPD must be $\leq$ 20% for aqueous samples and $\leq$ 20% for solid samples, if both the original sample and the duplicate results are greater than or equal to four times the reporting limit. A control limit of ± the laboratory reporting limit is used when either the original sample result or the duplicate sample result is less than four times the laboratory reporting limit.

9.7 Method-specific Quality Control Samples

Not applicable.

9.8 Method Sequence

- Sample preparation (digestion and/or pH adjustment and filtration)
- Coloring procedure
- Analysis on Spectrophotometer
- Verification
- Calculation

10. Procedure

10.1 Equipment Set-up

10.1.1 A calibration curve is generated at a minimum of once per year, as follows:

10.1.1.1 **For Liquid**: Pipet the following volumes of the 1ppm working standard (Section 8.2) into separate 50mL volumetric flasks: 0.25 ml, 0.5 ml, 1 ml, 2.5 ml, 5 ml, 10 ml and 25 ml. Bring each to volume with DI to give the following concentrations respectively: 0.005ppm, 0.01ppm, 0.02 ppm, 0.05 ppm, 0.10ppm, 0.20ppm and 0.50ppm. Include a 50mL DI blank and proceed with subsequent treatment of the standards in the same manner as samples (Section 10.3.2).

10.1.1.2 **For Soil**: Prepare five 100 ml digestion cups, add 1 ml of Magnesium Chloride solution (8.11.1) into each cup, then pipet following volumes of the 10 ppm working standard (section 8.3) into separate digestion cups:0 ml, 0.1mL, 1.0mL, 5.0 ml and 10mL. To all digestion cups add 50 ml of digestion solution and 0.5 ml of phosphate buffer. Proceed to soil/solid digestion and extraction procedure(sections 10.3.3.2 to 10.3.3.7)

10.1.1.3 Develop color for standards and blank as in Section 10.3.4.

10.1.1.4 Construct a calibration curve by plotting the absorbance values against mg/L hexavalent chromium. An acceptable curve must have a calibration coefficient of $\geq$ 0.995. This calibration curve is valid for one year, unless failure of an ICV requires construction of a new calibration curve. For method 3500: analyze RL verification standard (at 0.01 mg/l) following calibration. % recovery must be within +/-30% from true value.

Note: see MCP-HexCr and NJ-HexCr addendum for frequency of calibrations for MCP and NJ sites.

10.2 Initial Calibration

A non-digested, colored ICV (Section 8.16) (from a different source than was used for the calibration standards) must be recovered between 85 – 115%. If these criteria are not met, then the ICV is re-analyzed. If failure repeats, then the ICV is re-made and re-analyzed. If failure continues, prepare a new calibration curve (Section 10.1). See Section 12 for corrective actions.

10.3 Equipment Operation and Sample Processing

10.3.1 Treatment of sample: If interfering amounts of molybdenum, vanadium, copper, or iron are present, then follow the removal procedures as stated in the reference method.

10.3.2 Aqueous Samples:

Samples containing sediment, floating or suspended matter, or turbidity are filtered through a 0.45µm membrane filter prior to pH adjustment. If background interferences persist, measure an absorbance reading before adding diphenylcarbazide reagent (Section 10.3.4) and correct the absorbance of the final colored solution by subtracting the absorbance measured previously.

Proceed to Section 10.3.4.

10.3.3 Solid / soil sample digestion and extraction procedure:

10.3.3.1 **Samples:** Thoroughly mix the sample and weigh 2.5g +/- 0.1g into a 100 ml digestion cup. Add 1 ml of $MgCl_2$ solution.

10.3.3.2 **Blank:** Weigh 2.5g Ottawa Sand into a 100ml digestion cup, add 1 ml of $MgCl_2$ solution.

10.3.3.3 **Insoluble LCS:** Add 0.2-0.5 g of SRM (ERA catalog # 921) and 1 ml of $MgCl_2$ solution.

10.3.3.4 **Soluble LCS:** Weigh 2.5g Ottawa Sand into a 100ml digestion cup, add 1 ml of $MgCl_2$ solution and 1.0mL 1000ppm $K_2Cr_2O_7$. (Section 8.15).

10.3.3.5 **Matrix Spike, insoluble:** Thoroughly mix the sample and weigh 2.5g into a 100 ml digestion cup. Add 1 ml of $MgCl_2$ solution and 0.01 – 0.02g $PbCrO_4$ (Section 8.13.1).

Matrix Spike, soluble: Thoroughly mix the sample and weigh 2.5g into a 100mL digestion cup. Add 1 ml of $MgCl_2$ solution and 1.0mL 1000ppm $K_2Cr_2O_7$. (Section 8.15).

To all samples and QC samples, add 50mL of digestion solution (8.14) and 0.5mL of phosphate buffer (Section 8.12.3).

10.3.3.6 Stir the sample on a stir plate (unheated) for at least 5 minutes.

10.3.3.7 Place samples on hot block with Stirring base; heat samples for 1 hour at 90 – 95 °C (after temperature reached 90°C)

10.3.3.8 While still stirring, allow to cool to room temperature. Transfer the contents of the digestion vessel to 50 ml centrifuge tube then centrifuge for 6 minutes .Pour centrifuged solution back to original cup. Save the solid centrifuged material from the matrix spikes for possible later analysis for assessing low Cr (VI) recoveries. Store the centrifuged solid at 4 ±2°C.

10.3.3.9 While constantly stirring, very slowly add 50% HNO_3 (Section 8.4) to the centrifuged liquid to carefully adjust the pH to 7.5 ± 0.5. If the pH drops below 7.0, discard the solution and re-digest.

10.3.3.10 Remove the stir-bar and rinse keeping rinsate in the cup, and transfer quantitatively to a 100mL volumetric flask, 100 ml graduated cylinder, or 100mL digestion cup. Bring to volume with DI.

10.3.3.11 Proceed with coloring and analysis as described in Section 10.3.4.

10.3.4 Color development and measurement:

Place 45mL of sample or standard solution into a 50mL centrifuge tube. Adjust to pH 2 ± 0.5 with 10% H_2SO_4 (Section 8.7). Record pH on excel format. Add 1mL Diphenylcarbazide solution (Section 8.8) and adjust to 50mL with DI water. Mix and let stand 5 – 10 minutes for full color development.

Set the spectrophotometer to zero at 540 nm, utilizing the colored reagent blank in a 1cm absorption cell for soil samples and 2.5 cm absorption call for waters. Next, transfer a suitable portion of each colored standard solution or sample to a 1cm absorption cell for soils and 2.5 cm absorption cell for waters. Measure and record each absorbance at 540nm. Determine mg/L chromium present by reference to the calibration curve (Section 10.1.1.3).

10.3.4.1 Dilute samples volumetrically with DI water if they are more concentrated than the highest standard in the calibration curve.

10.3.4.2 When necessary samples precipitate poured off for analysis.

10.3.5 Verification of Samples

10.3.5.1 For aqueous and soil samples, verification is required to ensure that neither a reducing condition nor a chemical interference is affecting color development. This is accomplished by analyzing a second 10mL aliquot of the pH adjusted filtrate of the soluble spike. 1mL of 100ppm $K_2Cr_2O_7$ solution (Section 8.15.1) is added to the filtrate and analyzed. To verify the absence of an interference, the spike recovery must be between 85% and 115%.

If the spike recovery is less than 85%, the presence of an interference or reducing condition is verified. Client Services must be notified and a narrative included on the final report that indicates “verification of this sample indicates the presence of a reducing condition or a chemical interference that could affect the results”.

10.3.5.2 If addition of the spike extends the concentration beyond the calibration curve, the analysis solution must be diluted with a blank solution and the calculated results adjusted accordingly.

10.3.5.3 If the result of verification indicates a suppressive interference, the sample must be diluted and reanalyzed.

10.3.5.4 If the interference persists after sample dilution then an alternative method must be considered. See the Inorganics Supervisor for further instruction.

Aqueous samples with acidic extracts that yield recoveries of less than 85% are re-tested to determine if the low spike recovery is due to the presence of residual reducing agent. This determination is performed by first making an aliquot of the extract alkaline (pH 8.0-8.5) using 1N NaOH. The pH is recorded in the laboratory notebook. This aliquot is respiked and analyzed. If a spike recovery of 85-115% is obtained on the alkaline aliquot of an acidic extract that initially was found to contain less than 5 mg/L Cr(VI), one can conclude that the analytical method has been verified.

10.3.5.5 If the spike recovery is still below 85%, then the presence of reducing agent is confirmed. Client Services must be notified and a narrative included on the final report that indicates “verification of this sample indicates the presence of a reducing condition or a chemical interference that could affect the results”.

10.4 Continuing Calibration

The calibration curve must be verified after every 10 samples or less, with a recovery of 85 – 115% of a non-digested, colored ICV/CCV standard (Section 8.16). If these criteria are not met, then the CCV is re-analyzed. If failure repeats, then the CCV is re-made and re-analyzed. If failure continues, prepare a new calibration curve (Section 10.1). See Section 12 for corrective actions.

10.5 Preventive Maintenance

The Spectrophotometer is calibrated on a semi-annual basis by an instrument service company. Records are kept on file.

11. Data Evaluation, Calculations and Reporting

For aqueous samples:

$$\text{mg } Cr^{+6}/L = \left[\frac{\text{absorbance} - \text{y-intercept}}{\text{slope}}\right] \times \text{dilution}$$

For solid samples:

$$\text{mg } Cr^{+6}/Kg = \left[\frac{\text{absorbance} - \text{y-intercept}}{\text{slope}}\right] \times \left[\frac{\text{dilution x 0.1L (final volume)}}{\text{weight (Kg) of sample}}\right]$$

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

Holding time exceedence, improper preservation and observed sample headspace are noted on the nonconformance report form.

Perform routine preventative maintenance following manufacturer's specification. Record all maintenance in the instrument logbook.

Review of standards, blanks and standard response for acceptable performance occurs for each batch of samples. Record any trends or unusual performance on a nonconformance action form.

If the ICV or LCS recovery falls outside the designated acceptance range, the laboratory performance is judged to be out of control, and the problem must be immediately identified and corrected. The analytical result in the unspiked samples is suspect and is only reported for regulatory compliance purposes with the appropriate nonconformance action form. Immediate corrective action includes reanalyzing all affected samples by using any retained sample before the expiration of the holding time.

Failure of the LCS for method 3060A requires that the entire sample batch be re-digested and re-analyzed.

If the method blank for method 3060A is greater than the reporting limit, then the following action must be taken. Samples that are non-detect may be reported, and the method blank result is narrated on the final report. If the sample concentration is greater than 10X the concentration of the method blank, then the sample may be reported, and the method blank is narrated on the final report. If the sample(s) concentration are above the reporting limit, but are not greater than 10X the concentration of the method blank, then those samples must be re-digested and re-analyzed. In this case, it is not necessary to submit a narrative unless there is a problem with the hold time, or there is not enough sample to re-digest. The Client Services Department must be made aware of the situation, and if the data is released then the method blank non-conformance is narrated.

The ICV for the analysis must have a recovery of 85-115%. If the ICV fails, it must be re-made and re-analyzed. If the failure persists, then a new calibration curve is constructed.

The ICB for the analysis must be below the detection limit for the analysis. If the ICB fails this requirement, then fresh blank must be colored and analyzed, if this does not solve the problem then a new calibration curve must be constructed.

If the CCV or the CCB fail, pour out a fresh aliquot of CCV and CCB and re-color and re-analyze. If the CCV or the CCB does not pass, then construct a new calibration curve and re-analyze the samples that followed the last acceptable CCV/CCB.

A duplicate result that is outside of the controls limits for this method must be narrated. The sample must be examined to determine the cause of the poor duplication. If it is determined that the poor duplication was due to analyst technique, then the sample and its duplicate are re-digested and re-analyzed. Otherwise, narrate the non-conformance on the final report.

If the matrix spike (aqueous samples) falls outside of the acceptable range of the method, then the analyst must go to the verification (section 10.3.5) part of this method. Poor spike recoveries must be narrated on the final report. Upon Client authorization, hexachromes with poor spike recoveries can be analyzed for total chromium by ICP-AES (Method 6010). The sample must be processed according to the Total Chromium procedure employed and the digestion procedure necessary. Clients will be invoiced for the Total Chromium analysis. Solids and soils digested under 3060A that have failing matrix spike recoveries must be re-digested and re-analyzed to determine if the failure is do to poor technique or the sample matrix. If upon reanalysis, it is found that the recoveries are acceptable, then the data is submitted with the new spike results. If it is found that the recoveries are still unacceptable upon redigestion, then it is assumed that the sample matrix is suspect The pH and ORP results are evaluated against the Eh/pH Phase Diagram (Figure 1) for MCP or NJ HexCr, and the result (reducing or oxidizing) is included in a sample narrative explaining the poor spike recovery.

13. Method Performance

13.1 Method Detection Limit Study (MDL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the MDL, LOD, and/or LOQ as outlined in Alpha SOP/1732. These studies performed by the laboratory are maintained on file for review.

13.2 Demonstration of Capability Studies

Refer to Alpha SOP/1734,1739 for further information regarding IDC/DOC Generation.

13.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

14. Pollution Prevention and Waste Management

Refer to Alpha's Chemical Hygiene Plan and Waste Management and Disposal SOP for further pollution prevention and waste management information.

1. Scope and Application

Matrices: Water and other aqueous samples (surface and saline waters, groundwaters, domestic and industrial wastes), soil/sediment samples,and tissues.

Definitions: Refer to Alpha Analytical Quality Manual.

Hydride generation Atomic Fluorescence Spectroscopy (HGAFS) determines trace metal concentrations in solution.

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one or more of the following laboratory personnel before performing the modification: Area Supervisor, Department Supervisor, Laboratory Director, or Quality Assurance Officer.

This method is restricted to use by or under the supervision of analysts experienced in the operation of the Mercury analyzer and in the interpretation of Mercury Analyzer data. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

Selenium, Se	7782-49-2

2. Summary of Method

Atomic fluorescence is an element specific, highly sensitive atomic spectrometric Technique, that when coupled to hydride generation, provides extremely high sensitivity for hydride forming elements.

The formation of hydrides is usually carried out by the addition of a reducing agent, in this case, sodium borohydride, to an acidified solution of the analyte. The newly formed hydride is then passed together with any excess hydrogen gas directly to a miniature flame where the hydride species dissociate to form free atoms. The free atoms that formed are excited by an intense excitation source. This source is a Boosted Discharge Hollow Cathode Lamp. The excited atoms are then focused onto the flame and the resultant fluorescence is measured using an interference filter and a photomultiplier tube detection system.

2.1 Method Modifications from Reference

Sediments and tissues may be digested and analyzed using HGAF..

3. Reporting Limits

See Table I in Section 16 for reporting limits.

4. Interferences

This technique is prone to interferences by transition metals, but this should not be significant on natural samples. Recovery tests should be preformed.

There are two oxidation states for Inorganic Arsenic; As (V) and As (III). All arsenic species have to be converted to the As (III) state before generating hydrides.

Physical interferences are effects associated with the sample which may change rate in which the gaseous hydride is purged from solution. If physical interferences are present, they may be reduced by diluting the sample.

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material safety data sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

Care must be taken when handling all liquid samples, digestates, and standards since they are preserved to a pH <2.

Never look directly into the boosted discharge hollow cathode lamp, due to the intense UV radiation produced.

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

Aqueous total samples: The volume of sample required is dependent on the analyses requested. Typically, a 500 mL of sample is collected in plastic or glass containers.

Aqueous dissolved samples: Samples may be field filtered and preserved.

Solid samples: A minimum of 10.0 grams of sample must be collected in a glass jar.

6.2 Sample Preservation

Aqueous total samples: Samples are preserved with 2 mL of 1:1 nitric acid per liter of sample (pH $\leq$ 2) at time of collection. Samples that cannot be acid preserved at the time of collection because of sampling limitations or transport restrictions should be acidified with nitric acid to a pH $\leq$ 2 upon receipt at the laboratory. Following acidification, the sample must be held for a minimum 16 hours before pouring an aliquot for sample digestion.

6.3 Sample Shipping

No special shipping requirements.

6.4 Sample Handling

Aqueous dissolved samples: If the laboratory is required to filter the samples, the sample must be filtered through a 0.45-µm membrane filter. Glass or plastic filtering apparatus must be acid rinsed to avoid possible contamination. A plastic apparatus must be used when determination of boron or silica is critical. Use a portion of the filtered sample to rinse the filter flask, discard this portion and collect the required volume of filtrate. Immediately following filtration acidify the filtrate with nitric acid to a pH $\leq$ 2.

All samples: The samples can be stored at room temperature or can be refrigerated and maintained at 4°$\pm$2°C until digestion and analysis. All samples must be analyzed within 6 months from date of collection.

The use of laboratory equipment and chemicals exposes the analyst to several potential hazards. Good laboratory techniques and safety practices shall be followed at all times. Eating, drinking, smoking, or the application of cosmetics is not permitted in the laboratory area. Horseplay of any kind is prohibited. Pipetting by mouth is not permitted. All Personal Protective Equipment (PPE) must be removed before leaving the laboratory area and befor entering the employee lounge or eating area. Always wash your hands before leaving the laboratory. All relevant Material Safety Data Sheets (MSDSs) are kept alphabetically in the centrally located file storage, in the common area outside of the Information Technology (IT) offices.

Approved PPE, which includes Safety Glasses, Gloves and Lab Coats, must be worn at ***all*** times when handling samples, reagents, chemicals, or when in the vicinity of others handling these items, so that dermal contact is avoided. All standards, reagents, and solvents shall be handled under a hood using the proper PPE. All flammable solvents must be kept in the flammable storage cabinet, and returned to the cabinet immediately after use. When transporting chemicals, use a secure transporting devise and/or secondary outer container. Chemical storage is properly segregated and adequately ventilated to reduce the possibility of

hazardous reactions. Chemical storage in work areas shall be kept to a minimum. Storage on bench tops or other work surfaces, except temporary, is not permitted.

Spilled samples, solvents, reagent, and water must be cleaned up from bench tops, instruments and autosampler surfaces immediately. A spill is considered a quantity of hazardous material if it is two times greater than the normal working volume. Concentrated solvents, acids or bases present a moderate to extreme hazard to the skin and mucous membranes. If contact with the skin occurs, immediately flush with large volumes of water. In the case of acidic/basic spills, the *Spill Kit* located in each laboratory shall be utilized before attempting to cleanup the spill. Although procedures are designed to minimize the possibility of an accident, all injuries or accidents, regardless of the nature or severity, are to be reported to the Department Manager Supervisor immediately. If an employee discovers a potentially unsafe condition, this must be reported to the Department Manager Supervisor immediately. No employee should feel compelled to work in a situation where they do not feel entirely informed, trained, or safe.

Analytical instrumentation poses the unique possibility of exposure to high voltages. Other than the *routine* instrument maintenance, as listed in the front of every Instrument Maintenance Logbook, at no time shall an instrument operator attempt to maintenance an instrument alone, or without the proper training, supervision or instruction. Caution must always be used in the presence of moving parts (autosamplers) and hot surfaces (injection ports).

Compressed gas cylinders shall only be moved with the dolly supplied for this specific purpose. The cap must be on the cylinder while it is being moved. The tank must be secured when in its final position. All spent tanks are to be returned in the same manner, and secured until removed by the vendor. Liquid argon or nitrogen represents a potential cryogenic hazard and safe-handling procedures must be used at all times.

7. Equipment and Supplies

7.1 PSA 10.055 MILLENNIUM EXCALIBUR: The PSA Millennium Excalibur Atomic Fluorescence Analyzer equipped with a PC loaded with instrument software and PSA 20.400 autosampler. The instrument is connected to a source of high-purity, Mercury free argon regulated to 50 PSI.

7.2 Santoprene Peristaltic Pump tubing: Green/Green (PSA part number M025T002 or equivalent) for sample, blank and autosampler rinse. Grey/Grey (PSA part number M055T005 or equivalent) for sodium borohydride.

7.3 Compressed Argon

7.4 Air Displacement pipetters: Eppendorf brand or equivalent digital pipettes capable of delivering volumes ranging from 0.1 to 5000 µL with an assortment of high quality disposable pipette tips.

7.5 15-mL plastic AS-91 Autosampler tubes

7.6 Glassware for Digestion: Pre-cleaned 50mL disposable polyethylene screw cap digestion tubes.

7.7 Analytical balance: Capable of accurate measurement to the nearest 0.01 g.

8. Reagents and Standards

Deionized (DI) water is ASTM Type II laboratory reagent grade water or better (*i.e.,* Type I). The Barnstead NANO-pure system provides Type I water used in the preparation of samples and standards. ACS Trace Metal grade chemicals shall be used in all tests. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination. If the purity of a reagent is in question, analyze for contamination. If the concentration is less than the MDL then the reagent is acceptable.

8.1 Hydrochloric acid (HCL), concentrated. ACS reagent grade, Fisher number A508-212, or equivalent. Lots should be checked for purity prior to use and the results stored in a reagent check logbook.

8.2 10% (vol/vol) Hydrochloric acid. Prepare by adding 200 mL of concentrated hydrochloric acid to 2000 mL reagent water in a clean glass bottle.

8.3 20% (vol/vol) Hydrochloric acid. Prepare by adding 200mL of concentrated hydrochloric acid to 1L of reagent water in a plastic bottle.

8.4 5% (wt/vol) Potassium Iodide(KI)/Ascorbic Acid. Prepare by adding 5 g solid KI (Fisher ACS Grade) 5 g solid ascorbic acid (ACS grade) to 100 ml DI water.

8.5 0.7% Sodium Borohydride Sodium Hydroxide. Prepare by adding 2.0 g sodium hydroxide (ACS grade) to 500 ml DI, add 3.5 g sodium borohydride (reagent grade) and mix thoroughly.

8.6 Single element stock solutions: Stock solutions for the following elements are typically maintained in the laboratory or ordered as necessary. These are normally purchased as 1000 mg/L standards from Fisher Scientific or equivalent.

8.6.1 Arsenic

8.6.2 Selenium

8.7 Intermediate Working Standard Solutions

Intermediate Working Standard solutions are prepared from certified vendor Stock Standard solutions and include those analytes listed above. Vendor sources are subject to change and equivalent solutions may be used. Standards can be prepared as multi-element or single element standards as needed.

Stock standards used to prepare the calibration standards and calibration verification standard are typically diluted 1:1000 to prepare an intermediate working standard. These preparations are recorded in the laboratory standards preparation log and noted as below.

8.7.1 Intermediate Calibration Standard C-(Date)-H(element): The intermediate standard used to prepare the calibration standards is identified as C (calibration) – Date (date prepared) – H (hydride) element (As, Se etc.). These standards are typically diluted in the same matrix as the stock standard, i.e. 2% Nitric acid and are prepared approximately every two weeks or as needed. Add 0.05 ml of stock

1000 mg/L standard to 50 ml vial.

8.7.2 Calibration Standards C-(Date)-H(element)#: Calibration standards are prepared from the Intermediate Standard and identified as C (calibration) – Date (date prepared) – H (hydride) element (As, Se etc.) # (The first set of standards prepared from the Intermediate standard would be #1). Calibration standards are prepared with each batch of samples using the same reagents.

8.7.3 Intermediate Calibration Verification Standard I-(Date)-H(element): The intermediate standard used to prepare the calibration standards is identified as I (initial calibration verification) – Date (date prepared) – H (hydride) element (As, Se etc.). These standards are typically diluted in the same matrix as the stock standard, i.e. 2% Nitric acid and are prepared approximately every two weeks or as needed. Add 0.05 ml of stock 1000 mg/L standard to 50 ml vial.

8.7.4 Calibration Verification Standards I-(Date)-H(element)#: Calibration standards are prepared from the Intermediate Standard and identified as I (initial calibration verification) – Date (date prepared) – H (hydride) element (As, Se etc.) # (The first set of standards prepared from the Intermediate standard would be #1). The calibration verification standard is prepared with each batch samples using the same reagents.

8.8 Daily Calibration Standards

An Initial Calibration Curve is prepared for each level and is described below. Typically a four point curve is prepared including a high level standard at or near the linear range of the analysis (STD4), a low level standard that confirms the reporting limit (STD1), and a calibration blank (STD0), is used. See Table II for a list of the initial calibration concentrations. Calibration standards are prepared to matrix match standards to samples.

Standards must be pre-reduced prior to hydride generation analysis to put the analyte in the oxidation state which most readily forms a volatile hydride. These oxidation states are As^{3+} and Se^{4+}. Arsenic requires the KI/Ascorbic acid solution and selenium requires concentrated acid and heating.

For arsenic standards preparation, add 15 ml concentrated hydrochloric acid and 2.5 ml of the KI/Ascorbic acid solution to 50 ml tubes and add standards as stated below. Arsenic may be analyzed after a minimum of four hours standing at room temperature.

For selenium standards preparation, add 5 ml of concentrated acid to 50 ml tubes and add standards as stated below. Heat standards to 90°C for 30 minutes.

8.8.1 STD0 (Calibration Blank): Calibration Blank: Bring reagents to 50 ml with DI water.

8.8.2 STD1 (Reporting Limit Standard): Add 25 µL of intermediate standard to 50 ml digestion tube containing reagents and bring to volume with DI water. The final concentration of each element is 0.5 µg/L.

Note: For a reporting limit standard of 0.1 µg/L, dilute intermediate 1000 µg/L standard 1:10, add 50 µL and brig to final volume of 50 ml.

8.8.3 STD2: Add 100 µL of intermediate standard to 50 ml digestion tube containing reagents and bring to volume with DI water. The final concentration of each element is 2.0 µg/L.

8.8.4 STD3: Add 250 µL of intermediate standard to 50 ml digestion tube containing

reagents and bring to volume with DI water. The final concentration of each element is 5.0 μg/L.

Note: This standard may be used as the high standard in the calibration curve for 0.1 μg/L reporting limit analyses.

8.8.5 STD4: Add 500 µL of intermediate standard to 50 ml digestion tube containing reagents and bring to volume with DI. The final concentration of each element is 10.0 μg/L.

8.9 The Initial calibration verification (ICV) and continuing calibration verification (CCV). The ICV and CCV standards are prepared from sources separate from the initial calibration curve and are used to verify the initial calibration curve throughout the analytical sequence. See Table II for a list of the ICV/CCV concentrations. To prepare this solution add 250 µL of the separate source intermediate standard to 50 ml digestion tube containing reagents and bring to volume with DI water. The final concentration of each element is 5.0 μg/L.

Note: If 5.0 μg/L standard is used for the highest calibration standard, use 0.1 ml of the separate source intermediate standard and bring to a final volume of 50 ml to prepare a 2.0 μg/L ICV.

The Calibration blank (STD0), initial and continuing calibration blanks (ICB and CCB) are the analysis of the matrix diluent and are analyzed prior to the initial calibration curve and after the ICV and CCVs, respectively.

8.10 Calibration blank (STD0), initial and continuing calibration blanks (ICB and CCB): The blanks are the analysis of the matrix diluent and are analyzed prior to the initial calibration curve and after the ICV and CCVs, respectively.

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

Quality control (QC) samples are necessary to monitor both the sample digestion and analysis procedures.

9.1 Blank(s)

9.1.1 Method Blank

A method blank must be analyzed once per every 20 samples or per metals digestion batch, whichever is more frequent.

Metal concentrations must not be detectable in the method blank at values greater than the reporting limit.

Corrective Action: May repeat analysis once. Digestion of the method blank and all associated samples must be performed until the method blank for the out of control metal is in control. Samples cannot be analyzed until an acceptable method blank analysis is obtained. Exceptions may be made with approval of the Department Manager if the samples associated with an out of control method blank are below the reporting limit for

the affected metal or if the concentrations of the affected metal are greater than 10x the blank level in the samples. In such cases, the sample results are accepted without corrective action for the high method blank result. The client must be notified in the project narrative associated with the sample results.

9.1.2 Initial Calibration Blank (ICB)

An ICB must be analyzed immediately following the ICV.

The ICB concentration must not be greater than the reporting limit.

Corrective Action: May repeat analysis once to see if an analytical error occurred. If the ICB still exceeds the control limits, re-calibrate the instrument and re-analyze a fresh blank.

9.1.3 Continuing Calibration Blank (CCB)

A CCB must be analyzed immediately after every CCV.

The CCB concentration must not be greater than the reporting limit.

Corrective Action: May repeat analysis once to see if an analytical error occurred. If the CCB still exceeds the control limits, re-calibrate and/or re-analyze a fresh blank. All samples associated with the out of control metals in the CCB must be re-analyzed (since the last acceptable CCB). Exceptions may be made with approval of the Department Manager if the samples associated with the out of control method blank are non-detect for the affected metals or if sample concentrations for the affected metals are greater than 10x the blank levels. In such cases, the sample results are accepted without corrective action for the high CCB and the client is notified in a project narrative associated with the sample results.

9.2 Laboratory Control Sample (LCS)

The LCS is from a second source to verify the accuracy of the digestion and analytical procedures. The LCS is digested along with the samples. An LCS must be digested and analyzed once per every 20 samples or per metals digestion batch, whichever is more frequent.

The acceptable recovery QC limits are 80%-120% for an aqueous LCS.

Corrective Action: May repeat analysis once to see if an analytical error has occurred. If the LCS recovery is still out of control, re-digest and re-analyze the LCS and all associated samples. Samples cannot be analyzed until an acceptable LCS is obtained. Exceptions may be made with approval of the Department Manager if the samples associated with the out of control LCS are also associated with a matrix spike that is in control. This is an acceptable measure of accuracy of the digestion and analytical procedures. An explanation of this out of control LCS recovery must be included in the project narrative to the client and the sample data reported with the acceptable MS results as batch QC.

9.3 Initial Calibration Verification (ICV)

The initial calibration verification check standard is from a second source to verify the accuracy of the standard curve. The concentration of the ICV is at approximately the mid-level of the calibration curve.

The acceptable recovery QC limits for the ICV is 85-115%.

Corrective Action: May repeat analysis once to see if an analytical error occurred. If the ICV still exceeds the control limits, re-calibrate the instrument.

9.4 Continuing Calibration Verification (CCV)

A CCV must be analyzed at a minimum of every 10 samples and at the close of an analytical sequence. The concentration of the CCV is at approximately the mid-level of the calibration curve. This standard monitors instrument performance throughout the duration of the analytical sequence.

The acceptable recovery QC limits for the CCV is 85-115%.

Corrective Action: May repeat analysis once to see if an analytical error occurred. If the CCV still exceeds the control limits, re-calibrate and re-analyze all samples since the last acceptable CCV.

9.5 Matrix Spike

A matrix spike must be performed once per 20 samples and is from a second source to verify the accuracy of the digestion and analytical procedures. When project specifications dictate, a Matrix Spike Duplicate (MSD) may also need to be performed at the same frequency as the MS.

The acceptable recovery QC limits for a MS/MSD is 75%-125% for both the solid and aqueous MS/MSD pair. Calculate the %RPD as in Section 9.6 when analyzing a MS/MSD pair. The acceptable %RPD is ± 20%.

Corrective Action: May repeat analysis once to see if an analytical error has occurred. If the % recovery or %RPD still exceeds the control limits and the LCS is compliant; include a project narrative with the results to client noting that there may be potential matrix effects on the accuracy or precision of the affected metals results as evidenced by matrix spike recovery or %RPD outside of QC limits.

9.6 Laboratory Duplicate

Duplicate analyses (matrix duplicate) must be performed once per 20 samples (5% frequency). Acceptable relative percent difference (RPD) for duplicate analysis is ± 20 % for both aqueous and solid matrices. Acceptance criterion is not applicable to sample concentrations less than 5 times the reporting limit. Calculate RPD as follows:

$$RPD = \frac{R1 - R2}{\frac{[R1 + R2]}{2}} \times 100$$

Corrective Action: May repeat analysis once to see if an analytical error has occurred. If the % RPD still exceeds the control limits; include a project narrative with the results to client noting that there may be potential matrix effects on the precision of the affected metals results as evidenced by the matrix duplicate RPD exceedance.

9.7 Method-specific Quality Control Samples

9.7.1 CRI Standard Check Sample (Reporting Limit Standard)

This solution is used to verify instrument sensitivity at the reporting limit. This standard is routinely analyzed as the lowest standard in the initial calibration curve, or STD1, see Section 8.8.2. When included in the initial calibration curve, the curve must meet the criteria for linearity (r = 0.995). When project specifications dictate, the CRI can be analyzed separately from the initial calibration. The concentration of the CRI when analyzed as a separate check from the initial calibration curve, is equivalent to the

reporting limit for each element in STD1, see Table II. See Sections 10.3.1 for preparation details. This check standard, when analyzed, follows the ICV and ICB.

The CRI Check sample, when analyzed per client specifications, must be analyzed at the beginning of an analytical run . This solution verifies the accuracy at the low end of the calibration curve.

Results for the analyte in the CRI solution must be within 50-150% recovery criteria.

Corrective Action: May repeat analysis once to see if an analytical error occurred. If the CRI solutions still exceed the control limits, re-calibrate and/or re-analyze a fresh CRI solution. All samples associated with the out of control metals in the CRI must be re-analyzed (since the last acceptable CRI check sample).

9.8 Method Sequence

The following outlines the general analytical sequence:

Initial calibration curve (Total of 4 standards and a calibration blank)
ICV
ICB
CRI – If required
Method Blank
LCS
Sample analysis (samples 1-6)
CCV
CCB
Sample analysis (7-16)
CCV
CCB
Sample analysis (17-26)
CCV
CCB

10. Procedure

10.1 Equipment Set-up

Samples are prioritized by the Metals Department Manager or Preparation Group Leader for digestion based on hold time and client due date. The analyst must be familiar with instrument software and hardware as described in the user manuals supplied with the instrument, and have a completed IDC on file (Section 13.2) prior to any sample analysis.

The reductant, sample and reagent blank are introduced into the system by the use of a peristaltic pump, which in turn makes up the continuous flow vapor generator. When turning on the instrument, check the tubing for ware, check the pump and the three lines (reductant, sample and blank) for flow.

The Millenium Excalibur should be turned on and allowed to warm up for no less than 20 minutes. Be sure the correct cathode lamp is being used. The peristaltic pumps should be put on idle mode for warm up. Make the appropriate fresh solutions (Sodium Borohydride, 10% HCl, and 20% HCl as needed). In the software, check that the carrier and dryer gases are registering.

At this time, load the autosampler tray with the calibration standards and samples, and create the run sequence. Also check the waste drum, and be sure there is room left for the run's waste. Take the pumps off of idle mode, and light the flame and let the lamp warm up for about 5 minutes.

10.2 Equipment Operation and Sample Processing

Power is turned on to the instrument, autosampler, PC and argon gas supply. Peristaltic pump windings are inspected for wear and replaced if necessary. The winding clips are relaxed in between usage. The instrument manufacturer suggests that the pump tubing be changed once per week.

The sodium borohydride solution is introduced via the grey/grey pump tubing, 10% HCl is attached to the green/green autosampler rinse and the rinse blank line is also a green/green tubing immersed in DI. The autosampler probe line is attached to a green/green pump tubing. The pumps are turned on in the software and flow checked to insure that solutions are delivered to the mixing valve.

After initializing the Millennium software, the instrument is turned on via the software and allowed to warm up for 30 minutes. The analysis method is selected as well as the autosampler template. The hydride methods are set up in the software which specifies delay, read and rinse times as well as pump speeds. Autosampler templates are set up for each method specifying calibration standard, QC standards and positions on the autosamlper rack. Once sample ID's have been typed in, the file is saved as the login number.

A data file is opened and saved as "WGnumber".

Put pumps manually on regular speed, light the lamp and allow to warm up for 5 minutes.

Initiate sample analysis by clicking on the start button on the analysis page. If a sample concentration is greater than the highest standard concentration of the calibration curve, dilute the digestate with the same matrix as was used for the calibration blank, and reanalyze.

Following analysis, the data file is exported to the LIMS on the O:Metals\Millennium drive for data processing. The instrument and autosampler are then rinsed with DI water.

10.3 Initial Calibration

A series of calibration standards are prepared for the initial calibration curve as described in Section 8.8. The preparation date of these standards, the initials of the analyst, the lot number of the source material, stock concentrations, volumes used, final volumes, final concentrations and manufacturer must be recorded in the metals standard preparation logbook.

Calibrate the instrument using the calibration standards listed in Section 8.16. The system must be flushed with a rinse solution and carrier solution (10% HCl) between each standard to protect against potential carry-over. The calibration curve consists of a blank and four standards. Refer to Section 9.8 which outlines the general analytical sequence.

A linear least squares regression calibration curve is selected for the hydride methods.

A four point calibration curve is performed if the CRI standard is not analyzed.

The correlation coefficient must be $\geq$0.995.

Corrective Action: Re-calibrate until criteria are met

10.3.1 Aqueous Sample Preparation

Digests of Sediments (3050B) and Tissues(3051) can be analyzed by this method. Total aqueous, dissolved samples, digests of aqueous and solid samples must be pre-reduced prior to hydride generation analysis to put the analyte in the oxidation state which most readily forms a volatile hydride. These oxidation states are As^{3+} and Se^{4+}. Arsenic requires the KI/Ascorbic acid solution and selenium requires concentrated acid and heating.

For arsenic sample preparation, add 15 ml concentrated hydrochloric acid and 2.5 ml of the KI/Ascorbic acid solution to 50 ml vials, then add 25 ml of sample. This solution must set for a minimum of four hours before bringing to a final volume of 50 ml with DI water for arsenic analysis. If sample dilution is required, cook extra diluent with samples.

Note: If aliquots from acid digestion of soils/sediments,tissues or waters are being analyzed, it is advisable to check the pH of the sample following addition of the sodium borohydride solution to insure that the pH is between 5 and 7.

For selenium sample preparation, add 5 ml of concentrated acid to 50 ml vials and add 45 ml of sample. Heat samples to 90°C for 30 minutes. If sample dilution is required, cook extra diluent with samples.

10.3.1.1 **Preparation Blank:** Add same reagents as sample preparation and add DI water instead of sample. Prepare as sample.

10.3.1.2 **LCS:** Add same reagents as sample preparation and add DI water instead of sample. Add 0.25mL of intermediate standard. Prepare as sample.

10.3.1.3 **Matrix Spike:** Add same reagents as sample preparation and add aliquot of sample. Add 0.25mL of intermediate standard. Prepare as sample.

10.3.2 Sample Analysis

10.3.2.1 Flush the system with the rinse blank. Analyze the CCV and the CCB after each 10 samples and at the end of the analytical sequence. The rinse solution is normally 10% HCl (8.2).

10.3.2.2 The CRI (if required) must be analyzed at the beginning of an analytical run.

The CRI analysis is not performed if a calibration standard is prepared at the reporting limit and included in the initial calibration curve and if not specifically requested by the client. The calibration curve must always meet the criteria for linearity (r = 0.995).

10.3.2.3 Target analytes detected above the calibration range must be diluted and re-analyzed. See Section 12.0 for all Quality Control frequencies and criteria

10.4 Continuing Calibration

Periodically and at he end of the analysis, CCV standards (see 9.4) and CCB standards (see 9.1.3) are analyzed.

10.5 Preventative Maintenance

Inspect pump windings for signs of wear and replace (recommended at least monthly). Clean gas/liquid separator periodically when appears coated with yellow film (rinse with 30% KOH solution and DI). Change dryer tube annually.

11. Data Evaluation, Calculations and Reporting

11.1 Primary and Secondary Review

This analysis review form is used by the analyst and secondary reviewer to note passing/failing QC standards and to record any other comments as communication for reporting sample results.
All metal results are reportable without qualification if analytical holding times are met, preservation (including pH and cooler temperatures) are met, and all QC criteria defined in the table below are met. If any of the below QC parameters are not met, all associated samples must be evaluated for re-analysis. See Section 9 for additional QC discussion including corrective actions for any QC outliers.

QC Parameter	Acceptance Criteria
Initial Calibration Curve	R $\geq$ 0.995
Method Blank	< reporting limit
Laboratory Control Sample	80-120%R for solid and aqueous
Matrix Duplicate	20%RPD for results <5x reporting limit
Matrix Spike	75-125%R for solid and aqueous
Matrix Spike Duplicate (if requested)	75-125%R for solid and aqueous; and 20% RPD
Initial and Continuing Calibration Verification	85-115%R
Initial and Continuing Calibration Blank	< reporting limit
CRI (Reporting Limit Check)	50-150% R (DoD = 80-120%R)

11.2 Calculations

The metal results are calculated as follows:

As:

$$\text{Metal result in } \mu g/L = \frac{C \times B}{A} \times DF$$

where:

A = Initial sample volume in mL, typically 25 mL
B = Digestate final volume in mL, typically 50 mL
C = Concentration of sample from instrument read-out in µg/L
DF = Dilution Factor

Se:

$$\text{Metal result in } \mu g/L = \frac{C \times B}{A} \times DF$$

where:

A = Initial sample volume in mL, typically 45 mL
B = Digestate final volume in mL, typically 50 mL
C = Concentration of sample from instrument read-out in µg/L
DF = Dilution Factor

All metal results must be reported to three significant figures.
For solid samples: C x B x DF divided by grams in dry weight.

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

If non-compliant metals results are to be reported, the Department Manager and/or the Laboratory Director must approve the reporting of these results. The laboratory Project Manager shall be notified, and may chose to relay the non-compliance to the client, for approval, or other corrective action, such as re-sampling and re-analysis. The analyst or Department Manager performing the secondary review initiates the project narrative, and the narrative must clearly document the non-compliance and provide a reason for acceptance of these results.

13. Method Performance

13.1 Method Detection Limit Study (MDL)

The laboratory follows the procedure to determine the MDL, LOD, and/or LOQ as outlined in Alpha SOP/08-05. These studies performed by the laboratory are maintained on file for review.

13.2 Demonstration of Capability Studies

Refer to Alpha SOP/08-12 for further information regarding IDC/DOC Generation.

13.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

14. Pollution Prevention and Waste Management

Refer to Alpha's Chemical Hygiene Plan and Hazardous Waste and Sample Disposal SOP for further pollution prevention and waste management information.

15. Referenced Documents

Stock Standard Preparation

Calibration Stock Standard – Dilute 0.05 ml of 1000 mg/L standard to 50 ml in 2% HNO_3 to make 1000 ug/L standard.

ICV Stock Standard – Dilute 0.05 ml of 1000 mg/L to 50 ml in 2% HNO_3 to make 1000 ug/L standard.

STD0 Add 15 ml Conc. HCl, 2.5 ml 5% KI/5% Ascorbic Acid, bring to 50 ml final volume with DI, wait 4 hours minimum.

STD1 (0.5 ug/L) Add 15 ml Conc. HCl, 2.5 ml 5% KI/5% Ascorbic Acid, **0.025 ml stock standard**, bring to 50 ml with DI, wait 4 hours minimum

STD2 (2 ug/L) Add 15 ml Conc. HCl, 2.5 ml 5% KI/5% Ascorbic Acid, **0.10 ml stock standard**, bring to 50 ml with DI, wait 4 hours minimum

STD3 (5 ug/L) Add 15 ml Conc. HCl, 2.5 ml 5% KI/5% Ascorbic Acid, **0.25 ml stock standard**, bring to 50 ml with DI, wait 4 hours minimum

STD4 (10 ug/L) Add 15 ml Conc. HCl, 2.5 ml 5% KI/5% Ascorbic Acid, **0.50 ml stock standard**, bring to 50 ml with DI, wait 4 hours minimum

ICV (5 ug/L) Add 15 ml Conc. HCl, 2.5 ml 5% KI/5% Ascorbic Acid, **0.25 ml ICV stock**, bring to 50 ml with DI, wait 4 hours minimum

Sample Preparation in 10 ml autosampler tubes

Add 15 ml Conc. HCL to Digestion tubes and 2.5 ml 5% KI/5% Ascorbic Acid

Add 0.25 ml of 1000 ug/L stock to LCS and matrix spike sample

Add 25 ml of sample and mix, wait 4 hours minimum, bring up to a 50 mL final volume with DI water.

Ignitability of Solids

Reference Method: **Method 1030**, Rev. 0, December 1996 (Modified)

Reference: SW-846, Test Methods for Evaluating Solid Waste: Physical/Chemical Methods, EPA SW-846, Update III, 1997.

1. Scope and Application

Matrices: Solids including pastes, powders, granular material, soils, clay and solids that can be cut into strips.

Definitions: See Alpha Laboratories Quality Manual Appendix A

This method may be used to meet certain regulatory applications; with respect to the characteristic of ignitability in CFR 261.21, this method may be used, but is not required, to determine whether a solid waste “when ignited, burns so vigorously and persistently that is creates a hazard.” If it is impractical to perform the test because the physical form of the sample, generator knowledge should be used to determine the ignitability hazard posed by the material.

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one of the following laboratory personnel before performing the modification: Area Supervisor, Laboratory Services Manager, Laboratory Director, or Quality Assurance Officer.

This method is restricted to use by or under the supervision of trained analysts. Each analyst must demonstrate the ability to generate acceptable results with this method by completing the record of training.

2. Summary of Method

In a preliminary test, the test material is formed into an unbroken strip or powder train 250mm in length. An ignition source is applied to one end of the test material to determine whether combustion will propagate along 200mm of the strip within a specified time period. Materials that propagate burning along a 200mm strip within the specified time period are then subjected to a burning rate test. Materials that do not ignite or propagate combustion as described above do not require further testing.

In the burning rate test, the burning time is measured over a distance of 100mm and the rate of burning is determined. Lab doesn’t perform Burning rate test and will proceed to Flashpoint analysis by Flash test EPA 1010. SOP 2227

2.1 Method Modifications from Reference

A high temperature gas torch is utilized as the flame source. Lab is using modified method. Lab doesn’t proceed to the burning rate test if sample ignites during preliminary test.

3. Reporting Limits

There is no reporting limit for this analysis. Results are reported as either Negative or Positive. Refer to Section 11 for data reporting.

4. Interferences

Particle size of test material can affect not only the burning rate, but also the ignition of the material. Therefore particle size of the test material should be the same for each test run. Report the particle size of the test material in a simple descriptive format (e.g. fine powder, sand, coarse granular).

Temperature of some test material such as sulfur powder affects the burning rate. For reproducible results, all tests must be performed at approximately the same initial temperature (ambient room or laboratory temperature).

All tests must be carried out inside a fume hood with the test apparatus situated perpendicular (90°) to the direction of the airflow. Airflow parallel (0°) to the test apparatus results in non-reproducible burning rates.

The rate of airflow through the fume hood affects the burning rate. Too high an airflow will distort the flame and retard its horizontal propagation. The optimum airflow is within the range of 0.7 – 1 meter per second.

Materials that are moisture sensitive (i.e. readily absorb moisture from the air) should be tested as quickly as possible after removal from the sample container. All materials should be tested as received by the laboratory.

5. Health and Safety

Each sample should be treated as a potential health hazard. From this viewpoint, exposure must be reduced to the lowest possible level by whatever means available. References to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents. These practices include, but are not limited to, the use of: laboratory coat, safety glasses, and latex or nitrile gloves, and/or heat resistant gloves. Use caution when operating the high temperature torch. Also use caution in handling the ceramic plate after heating the sample, as it remains hot.

Prior to starting the preliminary test, all sample materials must be tested to determine if that material is explosive or extremely flammable. Use a very small portion of material (1 gram or less). ***If the sample displays explosivity or extreme flammability, do not continue this test.***

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

Sample containers should be completely filled and tightly sealed to preserve sample integrity.

6.2 Sample Preservation

No sample preservation is required.

6.3 Sample Shipping

No special shipping requirements.

6.4 Sample Handling

All samples are tested as received unless requested otherwise. Sample aliquots should be tested as soon as possible after removal from the sample container (i.e. samples must not be allowed to dry or absorb moisture for excessive periods or to lose volatiles). Allow samples to equilibrate to the ambient laboratory temperature in the sample container.

7. Equipment and Supplies

7.1 Ceramic Tile: Low heat conducting, non-combustible and impervious with marks indicating 80mm, 180mm, 200mm and 250mm along the test path. Any material capable to withstand high temperatures that have marks indicating 80mm, 180mm, 200mm and 250mm can be used.

7.2 Powder Train Mold: For molding powdered and granular materials for the burn rate test. The material of construction can be aluminum, brass, stainless steel or plastic. The mold is 250mm in length and has a triangular cross-section, with a width of 20mm, and a depth of 10mm as measured from the bottom of the triangular opening to where the sides meet. On both sides of the mold, in the longitudinal direction, two sheets are mounted as lateral limitations that extend 2mm beyond the upper edge of the triangular cross-section.

7.3 High temperature gas torch: A 6 to 7cm flame, with a minimum diameter of 5mm capable of attaining a temperature of at least 1000 °C. MAPP gas is its fuel source.

7.4 Stop watch.

7.5 Thermocouple: To measure the temperature of the gas flame

7.6 Thermometer: To measure initial temperature of material (i.e. room temperature).

7.7 Anemometer: To measure airflow in the fume hood.

7.8 Fume Hood.

8. Reagents and Standards

No special reagents are required to conduct this test.

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

9.1 Blank(s)

9.2 Laboratory Control Sample (LCS)

Not applicable.

9.3 Initial Calibration Verification (ICV)

Not applicable.

9.4 Continuing Calibration Verification (CCV)

Not applicable.

9.5 Matrix Spike

Not applicable.

9.6 Laboratory Duplicate

Not applicable

9.7 Method-specific Quality Control Samples

Not applicable.

9.8 Method Sequence

- Perform preliminary screening test:
  - Prepare test strip or powder train
  - Light flame and measure temperature
    - If it does not burn within specified time, sample is considered a negative, nonflammable solid. Test is complete.
    - If it does burn within specified time, sample is considered Positive for the preliminary screening test. Stop analysis.
- Contact supervisor or team leader; in order to switch method from Ignitability to Flash point.
- Refer to SOP 2227 for Flash point analysis

10.Procedure

10.1 Equipment Set-up

Safety Test: Prior to starting the preliminary test, all sample materials must be tested to determine if that material is explosive or extremely flammable. Use a very small portion of material (1 gram or less). ***If the sample displays explosivity or extreme flammability, do not continue this test.***

10.2 Initial Calibration

Not applicable.

10.3 Equipment Operation and Sample Processing

10.3.1 Preliminary Screening Test

10.3.1.1 The preliminary ignitability test is conducted on all waste materials.

10.3.1.2 Place a platform (brick, stone, or other flame-resistant tile) in a fume hood about 20cm (or 8 inches) from the front of the hood in an area of laminar airflow. Position the sample perpendicular to the airflow. The airflow across the perpendicular axis of the sample should be sufficient to prevent fumes from escaping into the laboratory and should not be varied during the test. The air velocity should be approximately 0.7 meters/second. Measure and record the air velocity by using the anemometer (Section 7.7).

10.3.1.3 On the platform, prepare the test material in its “as received” form by forming an unbroken strip or powder train of sample 250mm long by 20mm wide by 10mm high on the platform. Position the sample perpendicular to the airflow. Use the mold (Section 7.3) to form the material as in Section 10.3.2.1 if appropriate.

10.3.1.4 Light the gas torch. Measure and record the temperature of the flame (tip of the flame) by a thermocouple (Section 7.6). The temperature of the flame must be at least 1000 °C.

10.3.1.5 Apply the tip of the flame to one end of the sample strip. Measure the propagation of combustion with the ceramic tile (Section 7.1). The test period will depend on the sample matrix as follows:

10.3.1.5.1 Non-Metallic Waste, Soils, Clays: Hold the flame tip on the sample strip until the sample ignites or for a maximum of 2 minutes. If combustion occurs, begin timing with a stopwatch and note whether the combustion propagates up to the 200mm mark within the 2-minute test period.

10.3.1.5.2 Metal or Alloy Powders: Hold the flame tip on the sample strip until the sample ignites or for a maximum of 5 minutes. If combustion occurs, begin timing with a stopwatch and note whether the combustion propagates up to the 200mm mark within the 20-minute test period.

10.3.1.6 If waste does not ignite and propagate combustion by either burning with open flame or by smoldering along the 200mm of sample strip within the 2 minute test period (or 20 minute test period for metal powders), the waste is not considered flammable and no further testing is required.

10.3.1.7 If the waste propagates burning of 200mm of the test strip within the 2-minute test period (20 minute test period for metals), test should be stopped and analysis should be switched to Flashpoint test (SOP 2227)

10.4 Continuing Calibration

Not applicable.

10.5 Preventive Maintenance

The ceramic plate and train mold must be cleaned after each sample.

11. Data Evaluation, Calculations and Reporting

Open ELN and include the following information for each sample:

Test Material Information:

- Date of test:
- Description of material: e.g. powder or paste, metallic or non-metallic
- Particle size: e.g. fine powder, granular, sand, etc.
- If the preliminary screening test (Section10.3.1) was negative, the result for the sample is Not Ignitable (reported as “NI”) and no further data is required.

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

Holding time exceedence and improper preservation are noted on the Sample Delivery Group Form and/or Nonconformance Report form. Project manager also have to be notified.

If sample cannot be analyzed using Ignitability method, project manager has to be notified and customer has to be contacted. If matrix of the sample is not appropriate for Ignitability analysis then LIMS product may be changed to Flashpoint product in order to provide customer with accurate data. Project manager/customer have to be notified and project manager has to approve this change.

Supervisor and project manager have to be notified if there is not a sufficient amount of sample provided for analysis.

13. Method Performance

13.1 Method Detection Limit Study (MDL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the MDL, LOD, and/or LOQ as outlined in Alpha SOP/1732. These studies performed by the laboratory are maintained on file for review.

This study is not applicable to this method.

13.2 Demonstration of Capability Studies

Refer to Alpha SOP/1739 for further information regarding IDC/DOC Generation.

These studies are not applicable to this method.

13.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

14. Pollution Prevention and Waste Management

Refer to Alpha's Chemical Hygiene Plan and Waste Management and Disposal SOP for further pollution prevention and waste management information.

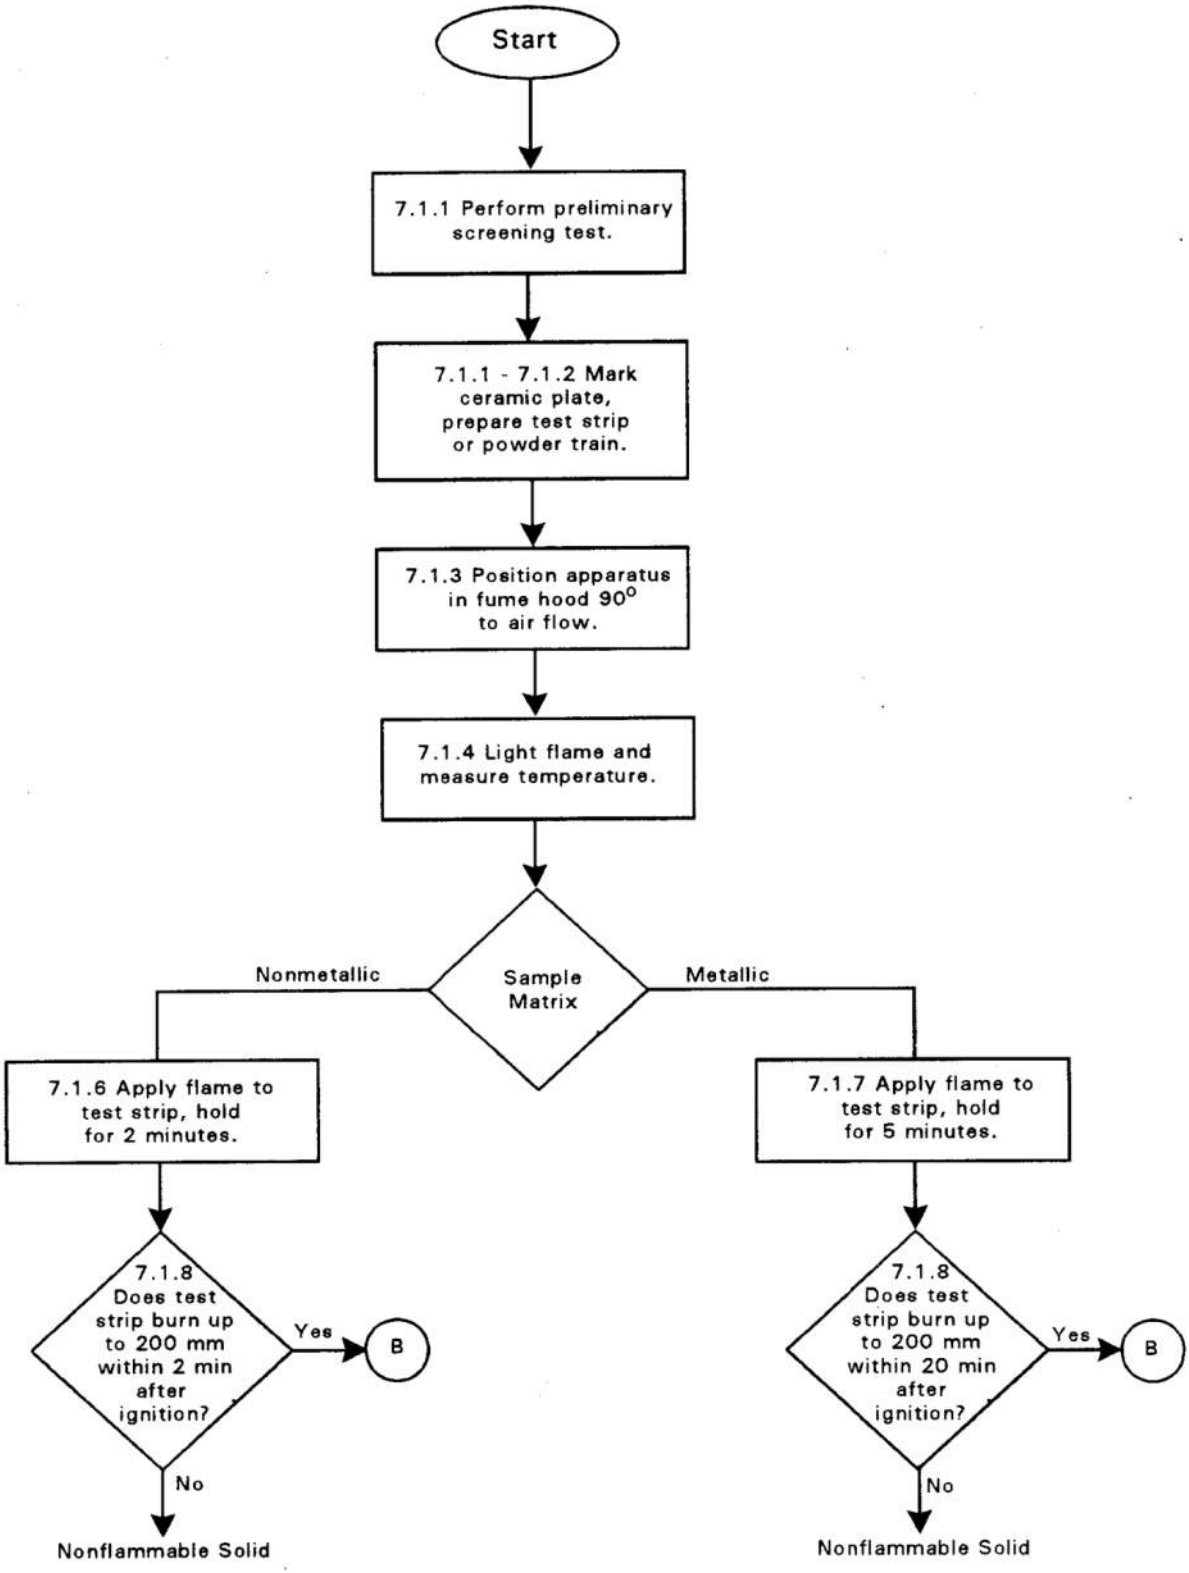
Flowchart – Ignitability of Solids Method 1030



Inductively Coupled Plasma - Mass Spectrometry 6020B

Reference: **Method 6020B,** Test Methods for Evaluating Solid Waste: Physical/Chemical Methods, EPA SW-846, Revision V, July 2014.

1. Scope and Application

Matrices: Groundwaters, aqueous samples, industrial waste, soils, sludges, sediments, and other solid wastes.

Definitions: Refer to Alpha Analytical Quality Manual.

Inductively coupled plasma-mass spectrometry (ICP-MS) is applicable to the determination of sub µg/L concentrations of a large number of elements in water samples, waste extracts or digestates.

ICP-MS has been applied to the determination of over 60 elements in various matrices. Elements for which EPA has determined the acceptability of Method 6020 in a mulit-laboratory study on solid wastes are listed below and in Table 1.

If method 6020 is used to determine any analyte not listed in Table 1 below, it is the responsibility of the analyst to demonstrate the accuracy and precision of the method in the waste to be analyzed. The analyst is always required to monitor potential sources of interferences and take appropriate action to ensure data of known quality.

Use of this method is restricted to spectroscopists who are knowledgeable in the recognition and in the correction of spectral, chemical, and physical interferences in ICP-MS.

An appropriate internal standard is required for each analyte determined by ICP-MS. Recommended Internal standards are ^{6}Li, ^{45}Sc, ^{89}Y, ^{103}Rh, ^{115}In, ^{159}Tb, ^{165}Ho, and ^{209}Bi. The Lithium internal standard must have an enriched abundance of 6Li, so that interference from Lithium native to the sample is minimized. Other elements may need to be used as internal standards when samples contain significant amounts of the recommended internal standards. The internal standard used in this method is as follows: ^{6}Li, ^{45}Sc, ^{74}Ge, ^{103}Rh, ^{115}In, ^{159}Tb, ^{175}Lu, ^{209}Bi.

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one or more of the following laboratory personnel before performing the modification: Area Supervisor, Department Supervisor, Laboratory Director, or Quality Assurance Officer.

This method is restricted to use by or under the supervision of analysts experienced in the operation of the ICP-MS and in the interpretation of ICP-MS data. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

Table 1

Parameter	CAS		Parameter	CAS

Iron	7439-89-6		Vanadium	7440-62-2
Lead	7439-92-1		Zinc	7440-66-6

2. Summary of Method

When dissolved constituents are required, samples must be filtered and acid-preserved prior to analysis. No digestion is required prior to analysis for dissolved elements in water samples. Acid digestion prior to filtration and analysis is required for groundwater, aqueous samples, industrial waste, soils, sludge's, sediments, and other solid wastes for which total (acid-leachable) elements are required.

Method 6020 describes the multi-elemental determination of analytes by ICP-MS. The method measures ions produced by a radio-frequency inductively coupled plasma. Analyte species originating in a liquid are nebulized and the resulting aerosol transported by argon gas into the plasma torch. The ions produced are entrained in the plasma gas and introduced, by means of an interface, into the mass spectrometer. The ions produced in the plasma are sorted according to their mass-to-charge ratio and quantified with a channel electron multiplier. Interferences must be assessed and valid corrections applied or the data flagged to indicate a problem. Interference correction must include compensation for background ions contributed by the plasma gas, reagents, and constituents of the sample matrix.

2.1 Method Modifications from Reference

This method is performed in a 1% Nitric Acid matrix for the calibration curve and standards and a 2% Nitric Acid matrix for the rinse.

3. Reporting Limits

Instrument detection limits, sensitivities, and linear ranges will vary with the matrices, instrumentation and operating conditions. In relatively simple matrices, detection limits will generally be below 20 µg/L. Table 2 contains the list of Reporting Limits.

4. Interferences

4.1 Isobaric Elemental Interference

Isobaric elemental interferences in ICP-MS are caused by isotopes of different elements forming atomic ions with the same nominal mass-to-charge ratio (m/z). A data system must be used to correct for these interferences. This involves determining the signal for

another isotope of the interfering element and subtracting the appropriate signal from the analyte isotope signal. Since commercial ICP-MS instruments nominally provide unit resolution at 10% of the peak height, very high ion currents at adjacent masses can also contribute to ion signals at the mass of interest. Although this type of interference is uncommon, it is not easily corrected, and samples exhibiting a significant problem of this type could require resolution improvement, matrix separation, or analysis using another verified and documented isotope, or use of another method.

4.2 Isobaric Molecular and Doubly Charged Ion Interference

Isobaric molecular and doubly-charged ion interferences in ICP-MS are caused by ions consisting of more than one atom or charge, respectively. Most isobaric interferences that could affect ICP-MS determinations have been identified in the literature. Examples include $ArCl^+$ ions on the ^{75}As signal and MoO^+ ions on the Cadmium isotopes. While the approach used to correct for molecular isobaric interferences is demonstrated below using the natural isotope abundances form the literature, the most precise coefficients for an instrument can be determined form the ratio of the net isotope signals observed for a standing solution at a concentration providing suitable (<1 percent) counting statistics. Because the ^{35}Cl natural abundance of 75.77 percent is 3.13 times the ^{37}Cl abundance of 24.23 percent, the chloride correction for arsenic can be calculated (approximately) as follows (where the $^{38}Ar^{37}Cl^+$ contribution at m/z 75 is a negligible 0.06 percent of the $^{40}Ar^{35}Cl^+$ signal):

Corrected arsenic signal (using natural isotopes abundances for coefficient approximations) = (m/z 75 signal) – (3.13) (m/z 77 signal) + (2.73) (m/z) (82 signal), (where the final term adjust for any selenium contribution at 77 m/z)

Note: Arsenic values can be biased high by this type of equation when the net signal at m/z 82 is caused by ions other than $^{82}Se^+$, (e.g. $^{81}BrH^+$ from bromine waste)

Similarly, corrected cadmium signal (using natural isotopes abundances for coefficient approximations) = (m/z 114 signal) – (0.027) (m/z 118 signal) – (1.63) (m/z 108 signal), (where the last two terms adjust for any tin or MoO^+ contributions at m/z 114).

> **Note:** Cadmium values will be biased low by this type of equation when $^{92}ZrO^+$ ions contribute at m/z 108, but use of the m/z 111 for Cd is even subject to direct ($^{94}ZrOH^+$) and indirect ($^{90}ZrO^+$) additive interferences when Zr is present
>
> **Note**: As for the arsenic equation above, the coefficients in the Cd equation are for only illustrative purposes. The most appropriate coefficients for an instrument can be determined from the ratio of the net isotope signals observed for a standard solution at a concentration providing suitable (<1 percent) counting precision.

The accuracy of these types of equations is based upon the constancy of the OBSERVED isotopic ratios for the interfering species. Corrections that presume a constant fraction of a molecular ion relative to the “parent” ion have not been found to be reliable, e.g. oxide levels can vary. If a correction for an oxide ion is based upon the ratio of parent –to-oxide ion intensities, the correction must be adjusted for the degree of outside formation by the use of an appropriate oxide internal standard previously demonstrated to form a similar level of oxide as the interferant. This type of correction has been reported for oxide-ion corrections using ThO^+/Th for the determination of rare earth elements. The use of aerosol desolvation and/or mixed plasmas has been shown to greatly reduce molecular interferences. These techniques can be used provided that method detection limits, accuracy, and precision requirements for analysis of the samples can be met.

4.3 Physical Interference

Physical interferences are associated with the sample nebulization and transport processes as well as with ion-transmission efficiencies. Nebulization and transport processes can be affected if a matrix component causes a change in surface tension or viscosity. Changes in matrix composition can cause significant signal suppression or enhancement. Dissolved solids can deposit on the nebulizer tip of a pneumatic nebulizer and on the interface skimmers (reducing the orifice size and the instrument performance). Total solid levels below 0.2% (2,000mg/L) have been currently recommended to minimize solid deposition. An internal standard can be used to correct for the physical interferences, if it is carefully matched to the analyte so that the two elements are similarly affected by the matrix change. When the intensity level of an internal standard is less than 30 percent or greater than 120 percent of the intensity of the first standard used during calibration, the sample must be reanalyzed after a fivefold (1+4) or greater dilution has been performed.

4.4 Memory Interference

Memory interferences can occur when there are large concentration differences between samples or standards which are analyzed sequentially. Sample deposition on the sampler and skimmer cones, spray chamber design, and the type of nebulizer affect the extent of the memory interferences which are observed. The rinse period between samples must be long enough to eliminate significant memory interferences.

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material safety data sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

Only Polyethylene or fluorocarbon (PFA or TFE) containers are recommended. Alpha uses polyethylene bottles. 0.5L is the recommended size.

6.2 Sample Preservation

Samples for total metals are preserved with (1:1) Nitric Acid to a pH<2.

Samples for soluble metals must be preserved with (1:1) Nitric Acid to a pH of <2 **after** filtration through a 0.45 um filter.

6.3 Sample Shipping

No specific requirements.

6.4 Sample Handling

Samples that are to be analyzed for soluble metals, and have not been field filtered, must be filtered through a 0.45um filter as soon as possible. Samples are then preserved with 1:1 Nitric Acid to a pH<2, and then held for 18 hours. After the 18 hours the pH must be re-checked. If

after 18 hours the pH is still >2, then the sample must be re-acidified and held again for 18 hours. If the pH is till >2 after this 18 hour period, then the Inorganics Manager must be told.

Samples preserved with Nitric Acid to a pH<2, and are not being analyzed for Mercury, have a hold time of 6 months.

Samples are stored at room temperature

7. Equipment and Supplies

7.1 Thermo Q and RQ ICP-MS:

The MS features dual extraction lenses and a compound ion lens system that ensures a mass range from Li-U (masses 6-240). It also features the enhanced RAPID (Right Angle Positive Ion Deflection) lens technology (90° ion optics done right) for separation of ions and neutrals. Simultaneous analog/PC detector with real time multi-channel analyzer electronics provides >9 orders of dynamic range suitable for both steady state and transient signal analysis. The software is Qtegra which provides integrated plug-ins for autosamplers, autodiluters and one click instrument set up: with a single mouse click, the iCAP Q is taken into operate mode, tested and, where necessary intelligently autotuned and/or calibrated to meet the protocol.

7.2 CETAC ASX-510 Autosampler: Delivers sample and internal standard to the torch

7.3 Thermo X-series II ICP-MS

The Innovative Protective Ion Extraction and Infinity II ion optics, based upon a hexapole design with chicane ion deflector, provides low background specification coupled with a userinterchangeable Xt interface and Xs interface. High-performance quadrupole analyzer is pumped by a novel split flow turbo pump backed by a single rotary. Simultaneous analog/PC detector with real time multi-channel analyzer electronics provides >8 orders of dynamic range suitable for both steady state and transient signal analysis. Instrument and accessories are fully computer controlled by the PlasmaLab software. Peltier spray chamber cooling provides enhanced performance for outstanding signal /background.

7.4 Edwards E2M28 and Sogevac 40 Rotary Pumps

7.5 Neslab M-75 Chiller: Cools the torch and the MS

7.6 Eppendorf pipets: Accurate means to make trace standards

8. Reagents and Standards

8.1 Nitric Acid (HNO_3), Trace metals grade: 18M Concentrated Redistilled

8.2 1% Nitric Acid (v/v): 10mL of 18M HNO_3 diluted to 1L using Type I water

8.3 Type I De-Ionized Water

8.4 Calibration Standard: Multiple Element Standard, purchased (Table 4) and diluted. Store at room temperature. Expires upon manufacturer's specified date. Prepare as needed if confirmed with the ICV solution made fresh daily.

8.5 Internal Standard: Multiple Element Standard, purchased (Table 8). Store at room temperature. Expires upon manufacturer's specified date.

8.6 Tune Stock: Multiple Element Standard, purchased (Table 9). 100.0 ug/L solution of each ^{7}Li ^{9}Be, ^{58}Ce, ^{59}Co, ^{115}In, ^{137}Ba and ^{208}Pb, and ^{238}U.

8.7 ICV: Multiple Element Standard, second source from calibration standard (Section 8.4) purchased and diluted (Table 10). Concentrations are near but not at the mid-point of the calibration Prepare fresh daily.

8.8 CCV: Multiple Element Standard, purchased (Table 11) and diluted. Store at room temperature. Concentrations are at or near the mid-point of the calibration. Expires upon manufacturer's specified date.

8.9 SIC: High-Purity Standards Cat. #ICP-MS-ICS-2 A stock. Dilute 5 mL to 50 mL (Table 12). Store at room temperature. Prepare fresh weekly.

8.10 LDR Check Solution: A multiple element or single element solution run at a point above the highest calibration standard under the same calibration used to quantify the associated sample data. The LDR check must be within +/-10% of the true value of each element of interest and be within +/- 50% of the sample concentration to be consider valid.

8.11 Lower Limit of Quantitation (LLOQ) check standard: The laboratory should establish the LLOQ as the lowest point of quantitation which, in most cases, is the lowest concentration in the calibration curve. See section 12.16.

8.12 Argon Gas: 0.9995 or better grade. High capacity tank plumbed into the lab.

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

9.1 Blank(s)

Three types of blanks are required for the analysis. The calibration blank, which is also the ICB/CCB, is used in establishing the calibration curve. The ICB/CCB is used to monitor carryover, signal noise, and drift. The method blank is used to monitor for possible contamination resulting from the sample preparation procedure. The rinse blank is used to flush the system between all samples and standards. See Section 12.3 for Corrective Action.

9.1.1 The Calibration blank, Initial Calibration Blank and the Continuing Calibration Blank consists of the same concentration of the same acid used to prepare the final dilution of the calibrating solutions of the analytes. This is a 1% HNO_3 solution (v/v) in Type I deionized water along with the selected concentrations of internal standard element for each of the analytes. The Calibration Blank is analyzed before the standards are analyzed. The Initial Calibration Blank must follow the Initial Calibration Verification standard (ICV) and the Continuing Calibration Blank must follow the Continuing Calibration Verification standard (CCV). These must be analyzed at a frequency of every 10 or less samples and at the end of the analytical run. The ICB must be no greater than ½ the LLOQ for any analyte; The CCB must be no greater than the LLOQ for any analyte See Section 12.11 for Corrective Action.

9.1.2 The method (or reagent) blank must be carried through the complete preparation procedure and contain the same volumes of reagents as the sample solutions. Method blanks are generally considered to be acceptable if target analyte

concentrations are less than the LLOQ or are less than project-specific requirements. Blanks may contain analyte concentrations greater than acceptance limits if the associated samples in the batch are unaffected (i.e. targets are not present in samples or sample concentrations are ≥10X the blank). Other criteria may be used depending on the needs of the project. See Section 12.8 for Corrective Action.

9.1.3 The rinse blank consists of HNO_3 (1% or 2%) (v/v) in reagent water. Prepare a sufficient quantity to flush the system between standards and samples.

9.2 Laboratory Control Sample (LCS)

The Laboratory Control Sample (LCS) must be analyzed for each analyzed for each analyte using the same sample preparations, analytical methods and QA/QC procedures employed for the test samples. One LCS must be prepared and analyzed for each sample batch at a frequency of one LCS for each 20 samples or less. Aqueous LCS recoveries must be 80-120%, and soil LCS recoveries must be within the SRM limits. See Sections 12.9 and 12.10 for Corrective Actions.

9.3 Initial Calibration Verification (ICV)

The ICV must have a recovery that is within ±10% of the true value. The ICV and must contain all of the elements that are calibrated. The ICV is an independent source other than those standards used for the calibration of the instrument. The ICV must be analyzed following the calibration.

9.4 Continuing Calibration Verification (CCV)

The CCV must have a recovery that is within ±10% of the true value. The CCV must be analyzed at a frequency of 10 samples or less and at the end of the analytical run.

9.5 Matrix Spike

Analyze one matrix spike per twenty or less analytical samples. The recovery of the matrix spike must be between 75 – 125%. Calculate percent recovery using Section 11.2.

9.5.1 **Dilution Test:** If the analyte concentration is sufficiently high (minimally, a factor of 25 above the lower limit of quantitation after dilution), an analysis of a 1:5 dilution must agree within ± 20% of the original determination. Elements that fail the dilution test are reported as estimated values.

9.5.2 **Post Digestion Spike Addition:** If the sample concentrations are insufficient to perform a dilution test a post digestion spike added to a portion of a prepared sample, or its dilution for the elements failing the matrix spike recoveries must be run, recovery limits equal to 75% to 125% of the known spike value. If the spike is not recovered within the specified limits If the post-digestion recovery fails to meet the acceptance criteria, the sample results must be reported as estimated values

9.6 Laboratory Duplicate

Analyze one duplicate sample for every matrix in a batch at a frequency of one matrix duplicate for every 20 samples. Calculate RPD under section 11.3.

A control limit of 20% RPD must not be exceeded for analyte values greater than 100 times the instrument detection limit (Section 13.3). See Section 12.14 for Corrective Action.

9.7 Method-specific Quality Control Samples

9.7.1 Internal Standards

The intensities of all internal standards must be monitored for every analysis. If the intensity of any internal standard applied to a sample falls below 70% of the intensity of that internal standard in the initial calibration standard, a significant matrix effect must be suspected.

Under these conditions, the established lower limit of quantitation has degraded and the correction ability of the internal standardization technique becomes questionable. The following procedure is followed -- First, make sure the instrument has not drifted by observing the internal standard intensities in the nearest calibration blank.

If the low internal standard intensities are also seen in the nearest calibration blank, terminate the analysis, correct the problem, recalibrate, verify the new calibration, and reanalyze the affected samples. If drift has not occurred, matrix effects need to be removed by dilution of the affected sample. The sample should be diluted fivefold (1+4) and reanalyzed with the addition of appropriate amounts of internal standards. If the first dilution does not eliminate the problem, this procedure must be repeated until the internal-standard intensities rise to the minimum 70% limit. Reported results must be corrected for all dilutions.

9.7.2 Interference Check Standards

Verify the magnitude of elemental and molecular-ion isobaric interferences and the adequacy of any corrections at the beginning of an analytical run or once every 12 hours, whichever is more frequent. Do this by analyzing the SIC check (8.9). Refer to Section 4.0 for a discussion on interferences and potential solutions to those interferences if additional guidance is needed. SIC must be below 2X LLOQ for all non-spiked elements of interest. See Section 12.8 for Corrective Action

9.7.3 Low Level Verification Standard (LLV)

The low level standard analyzed should quantitate to within 80-120% of the true value.

9.7.4 Mid Level Verification Standard (MLV)

The mid-level standard analyzed should quantitate to within 90-110% of the true value.

10. Procedure

10.1 Equipment Set-up

10.1.1 Sample Preparation

Prior to analysis, samples which require total (acid-leachable) values must be digested using appropriate sample preparation methods, such as Methods 3005A, 3015, 3051 and 3050B.

10.1.2 Tuning the instrument on from Stand By

- Tighten the peristaltic pump windings for the sample, Internal standard and spray chamber drain.
- Turn on the Argon gas supply and chiller.

Thermo Q and RQ:

- Turn on the computer and monitor. Start the Qtegra software. On the front instrument tab select the ON button, select OK. The fully automatic system will advance to ignition, torch box alignment and start the sample introduction system.
- Allow the instrument to warm up for **30 minutes.**

Thermo X-series II:

- Turn on the computer and monitor. Start the Plasmalab software. On the front instrument tab select the ON button. A message box will ask if to advance from vacuum to start up, select OK. The fully automatic system will advance to ignition, torch box alignment and start the sample introduction system.
- Allow the instrument to warm up for **30 minutes.**

10.1.3 Tuning

After the 30 minute warm up period has passed, a daily tune must be performed and a report generated.

Thermo X-series II and Thermo Q:

Select autotune, introduce the Tune A solution The Instrument stock tune solution (Table 9) is a 10 µg/L, Tune A is a 10 fold dilution. Run the autotune after a minimum 40 second uptake delay.

From the drop down menu select Run Performance Check (x –series), icon (Q) with the sample probe in Tune A solution. After completion of the performance check, select print and the file will be save to the archive. Upon successfully passing the performance check the instrument is ready for calibration.

Typical values of tuning parameters

Parameter	Typical Conditions	Adjustment
RF Power (W)	1300	1200 to 1600
Sampling Depth (mm)	6	4 to 8
Carrier gas (L/min)	1.2	0.8 to 1.3
Makeup gas (L/min)	0	0 to 0.4
Peri-pump 1 (rps)	0.1	0.06 TO 0.15
S/C Temp (°C)	2	Normally used at 2 °C
Extraction	-150	-200 to -100
Extraction	-70	-150 to -10
Einzel 1.3 (V)	-100	-130 to -40
Einzel 2(V)	7	-20 to +70
Omega Bias (V)	-35	-40 to 0
Omega (+)(V)	5	0 to +30
RF Power (W)	1300	1200 to 1600

Typical value of Sensitivity and RSD (Using the normal torch)

Mass	Counts / 10ppb Integ. Time = 0.1 sec	RSD
^{7}Li	>6400	<5%
^{89}Y	>16000	<5%
^{205}Tl	>9600	<5%

10.2 Initial Calibration

Mixed calibration standard solutions are prepared by diluting the stock-standard solutions to levels within the linear range for the instrument in a solvent consisting of 5% HNO_3 (v/v) in reagent water. The calibration standard solutions must contain a suitable concentration of an appropriate internal standard for each analyte. Internal standards are added at the time of analysis using a second channel of the peristaltic pump and an appropriate mixing manifold. Generally, an internal standard must be no more than 50amu removed from the analyte. Alpha employs the following internal standards: ^{6}Li, ^{45}Sc, ^{74}Ge, ^{103}Rh, ^{115}In, ^{159}Tb, ^{175}Lu, ^{209}Bi. Lithium is excluded when analyzing for ^{6}Li/^{7}Li.

Prior to preparing the mixed standards, each stock solution must be analyzed separately to determine possible spectral interferences or the presence of impurities. Care must be taken when preparing the mixed standards that the elements are compatible and stable. Transfer the mixed standard solutions to freshly acid-cleaned HPLC bottles for storage. Fresh mixed standards must be prepared as needed with the realization that concentrations can change upon aging. Calibration standards must be initially verified using a quality control standard (ICV), and monitored daily for stability.

Calibrate the instrument for the analytes of interest (recommended isotopes for the analytes in Table 1 are provided in Table 3), using the calibration blank (Section 9.1.1) and the set of 4 standards (see Table 4.). The analytical range brackets an RDL of 0.2 µg/L to 120 µg/L with the exceptions of Fe, K, Na, Ca and Mg which bracket the range of 10µg/L to 12,000µg/L. All solutions

and standards are prepared in a 1% Nitric Acid matrix. The calibration is defined as the calibration blank and four standards. The only standards that may be discarded in the calibration are the first standard (the low standard) and the fourth standard (the high standard). The only instance when the standard may be discarded is if the linearity of the element in question does not meet the correlation coefficient acceptance criteria of 0.995 or greater. No mid-level standards are ever discarded. The LDR is defined by the LDR standard run within the same calibration and recovered with +/- 10% of the true value of each element and within +/- 50% of the sample concentration, no sample is to exceed 90% of the top LDR standard or a dilution must be performed. All standards, QC samples and samples are to be integrated three times and then averaged. The calibration block is part of the analytical sequence and includes an ICV, ICB, LLV, MLV immediately following the analysis of the calibration standards. The calibration block can also contain a pause so that the analyst can evaluate the calibration prior to sample analysis. The routine calibration sequence is as follows:

Blank #1
Cal blank
0.2 µg/L std (10 µg/L Fe, K, Na, Ca, Mg)
1.0 µg/L std (100 µg/L Fe, K, Na, Ca, Mg)
10.0 µg/L std (1000 µg/L Fe, K, Na, Ca, Mg)
120 µg/L std (12,000 µg/L Fe, K, Na, Ca, Mg)

The quality control standard is the Initial Calibration Verification solution (ICV), which must be prepared in the same acid matrix as the calibration standards. This solution must be an independent standard near but not at the midpoint of the instrument calibration. An independent standard is defined as a standard composed of analytes from a source other than that used for the standards for instrument calibration.

Immediately after the calibration has been established, the calibration must be verified and documented for every analyte by the analysis of the Initial Calibration Verification solution (ICV) (Section 8.7). The calibration is verified if the solution is within the 10% of the true value (Table 10) for each element. See Section 12 for corrective action if the ICV fails. The ICB (9.1.1) is analyzed immediately following the ICV. The ICB must be no greater than the ½ LLOQ for any analyte. See Sections 12 for Corrective Actions.

10.3 Equipment Operation and Sample Processing

10.3.1 Spectral Interference Check Solution

The interference check solution (SIC) is prepared to contain known concentrations of interfering elements that will demonstrate the magnitude of interference and provide an adequate test of any corrections.

Chloride in the SIC provides a means to evaluate software corrections for chloride-related interferences such as $^{35}Cl^{16}O^{+}$ on $^{51}V^{+}$ and $^{40}Ar^{35}Cl^{+}$ on $^{75}As^{+}$.

Iron is used to demonstrate adequate resolution of the spectrometer for the determination of manganese.

Molybdenum serves to indicate oxide effects on cadmium isotopes.

The other components are present to evaluate the ability of the measurement system to correct for various molecular-ion isobaric interferences. The ICS is used to verify that the interference levels are corrected by the data system within quality control limits. The ICSA solution (Section 8.8) contains 20,000mg/L of Cl^{-}, 3,000 mg/L of Ca, 2,500 mg/L of Fe and Na, 2,000 mg/L of C, 1,000 mg/L of Al, K , Mg, P, S and 20 mg/L of Mo and Ti.

The non-target analytes for the SIC should have a recovery less than 2x LLOQ. Narrate nonconformance.

10.3.2 Sample Analysis and Continuing Calibration Verification

The default sample table on the instrument will include the ICV, ICB, LLV, MLV, SIC, samples and CCV and CCB. After the initial Instrument QC has been analyzed and passed, then 10 samples will be analyzed. After the tenth sample has been analyzed, a CCV and a CCB will be analyzed. Analysis of standards and samples must only take place when the instrument has come to equilibrium (typically after 30 minutes after plasma ignition). All masses which could affect data quality must be monitored to determine potential effects from matrix components on the analyte peaks. The recommended isotopes to be monitored are listed in Table 3. When the analysis is ready to start, flush the system with the rinse blank solution (Section 9.1.3) until the signal levels return to the method's level of quantitation (usually about 30 seconds) before the analysis of each sample. Nebulize each sample until a steady-state signal is achieved (usually in about 30 seconds) prior to collecting the data. Analyze the Continuing Calibration Verification solution (CCV) (Section 8.7) and the continuing Calibration blank (Section 9.1.1) at a frequency of at least once per ten analytical samples, and at the end of the analytical run. Dilute and reanalyze samples that are more concentrated than the linear range (or species needed for a correction) or measure an alternate less-abundant isotope if calibrated. The linearity at the alternate mass must be confirmed by appropriate calibration.

10.4 Preventive Maintenance

The scheduled maintenance is automatically tracked by the run time log for the following parameters. A message will appear on the computer screen reminding the analyst that a piece of maintenance must be performed. An electronic log, along with a maintenance notebook is kept. Below is a list what needs to be performed:

1. Check rough pump oil
2. Replace rough pump oil
3. Replace mist filter 4
4. Clean the extraction lenses
5. Clean the skimmer cone
6. Clean the sampling cone
7. Clean the nebulizer

11. Data Evaluation, Calculations and Reporting

The quantitative values are reported in appropriate units directly from the instrument: micrograms per liter (µg/L) for aqueous samples and milligrams per kilograms (mg/Kg) for solid samples. If dilutions were performed, the appropriate corrections must be applied to the sample values.

11.1 It is required that results for solids be reported on a dry weight basis as follows:

A separate determination of percent solids is performed by the Wet Chemistry Department and the result is loaded in the **LIMS**. To retrieve the result in the LIMS, go to **"Status"** and type in the sample ID. Click the sample number that is part of that sample ID, and click the product that says **TS-S**. The percent solids for the sample is there. LIMS will automatically

correct the sample for percent solids after the metals analysis has been **Final Metals Reviewed.** This is the calculation:

$$\text{Concentration (dry weight) (mg/kg)} = \frac{C \times V}{W \times S}$$

Where:
C= Digest Concentration (mg/L)
V= Final volume in Liters after sample preparation
W= Weight in Kg of wet sample
$S = \frac{\%\text{Solids}}{100}$

Calculations must include appropriate interference corrections (see Section 4.1 for examples), internal-standard normalization, and the summation of signals at 206, 207, and 208 m/z for Lead (to compensate for any differences in the abundances of these isotopes between samples and standards).

11.2 Calculate Percent Recovery for the Matrix Spike corrected for concentrations measured in the unfortified sample. Percent recovery is calculated using the following equation:

$$\%\ \text{Recovery} = \frac{(Cm - C)}{s} \times 100$$

Where:
Cm = measured in the fortified sample
C = measured native sample concentration
S = concentration equivalent of spike added to sample

11.3 Calculate the Relative Percent Difference (RPD) for each Duplicate of the initial quantitated concentration (IC) and duplicate quantitated concentration (Dc) using the following formula:

$$RPD = \frac{|(IC - Dc)|}{\{(IC + Dc) / 2\}} \times 100$$

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

Holding time exceedances, improper preservation and observed sample headspace are noted on the nonconformance report form.

Perform routine preventative maintenance following manufacturer's specification. Record all maintenance in the instrument logbook.

Review of standards, blanks and standard response for acceptable performance occurs for each batch of samples. Record any trends or unusual performance on a nonconformance action form

12.1 The performance check standard is included in the tuning solution. Ce and Ba are included with the tuning solution and monitor the formation of oxides and the effect of doubly-charged ions

respectively. If the solution fails >3% (Section 10.1.3) then instrument maintenance must be performed and the solution re-run.

12.2 For the Tune to pass, the mass calibration for the three tune elements (Section 10.1.3) must not differ by more than 0.1 amu from the true value and the resolution must be <0.9 amu full width at 10% peak height. Furthermore the RSD for the three tune elements must be <5% If any of these criteria fail then the mass calibration must be adjusted to the correct value. This is done by re-optimizing the instrument conditions and re-tuning.

12.3 The results of the calibration blank (Section 9.1.1) must be less than the LLOQ for each element. If this is not the case, the reason for the out-of-control condition must be found and corrected, and affected samples must be reanalyzed. If the laboratory consistently has concentrations greater than 3 times the LLOQ, the LLOQ may be indicative of an estimated LLOQ and must be re-evaluated.

12.4 Calibration is performed after the tune passes. A five point calibration is performed (Section 9.3). If more than three points are to be used for the calibration, then the resultant curve must have a correlation coefficient (cc) of 0.995 or greater. If the cc is <0.995, then the instrument must be re-optimized and re-calibrated. The calibration must define the working linear range of the curve. The reporting RL must be the low standard, and the upper linear range must be defined by the high standard.

12.5 The ICV (Section 9.3) is performed immediately after an acceptable calibration has been produced. The acceptable range for this standard is 90-110%. If this standard fails then the analysis must be stopped and the instrument re-calibrated, and the ICV re-analyzed. Analysis cannot continue until this standard passes.

12.6 The CCV (Section 9.4) is performed at a frequency of 10 samples or less and at the end of the analytical run. The acceptable range for this standard is 90-110%. If this standard fails it can be rerun once. If it continues to fail the instrument is re-calibrated, and the CCV re-analyzed. Analysis cannot continue until this standard passes. All samples run after the last passing CCV must be rerun for the CCV failures.

12.7 The ICB (Section 9.1.1) must be performed immediately after the ICV. The ICB must be ½ LLOQ. If the ICB fails then the analysis is terminated, sources of contamination are checked for, and the instrument is re-calibrated and the ICV and ICB are re-analyzed.

12.8 The Spectral Interference Check Solution (Section 9.7.2) monitor how well the system is correcting for interference. The target non-spiked elements in SIC must be below 2X LLOQ for those elements in question. If the recovery of this solution is outside of the control limits, the non-compliance must be narrated. There is no corrective action required because instrument corrections are based on natural isotope abundances that cannot be changed. If the IS is in compliance then the data is acceptable.

12.9 The Method (Preparation) Blank (Section 9.1.2) must be less than the LLOQ for all of the elements that are being analyzed. If the element in question is non-detect, and the method blank is positive then the corrective action is a narration on the final report. If the samples associated with the method blank have “hits”, and they are 10x greater than the method blank, then the corrective action is a narration on the final report. If the method blank is not less than the RL, and the associated samples have results that are greater than the RL but less than 10x the method blank, then the samples must be re-digested and re-analyzed.

12.10 If the LCS (Section 9.2) fails, then all samples associated with that batch must be re-digested and re-analyzed. (Massachusetts recognizes that if the MS passes and the LCS fails then the data can be accepted. Narrate then non-compliance. This is only for MCP projects).

12.11 Failure of the CCB (9.1.1) rerun once, if continued failure evaluate the data; if associated sample results are greater than 10x CCB level then the results are acceptable. Otherwise, recalibrate and re-analyze all samples since last compliant CCB.

12.12 If the dilution test (Section 9.5.1) fails, then an interference may be suspected. There is no corrective action to be applied. Report all elements as estimated on the final report if the sample concentration is 25x LLOQ.

12.13 If the Post–Digestion Spike (Section 9.5.2) fails, then matrix interference may be suspected and a dilution should be performed to confirm. Report all elements as estimated on the final report.

12.14 Failure of the duplicate sample (Section 9.6) must be investigated. If the sample is found to be non-homogeneous or less than 5 x the LLOQ then the non-compliance must be narrated on the final report.

12.15 If the Internal Standards (Section 9.7.1) fail the acceptance criteria, then dilute the samples until the IS passes. If the criteria are still not met, then terminate the analysis, re-calibrate, verify the new calibration, and reanalyze all of the affected samples. If IS continues to fail at dilutions, seek an alternate technology to analyze the affected samples.

12.16 The LLOQ is initially verified by the analysis of at least 7 replicate samples, spiked at the LLOQ and processed through all preparation and analysis steps of the method. The mean recovery and relative standard deviation of these samples provide an initial statement of precision and accuracy at the LLOQ. In most cases the mean recovery should be +/- 35% of the true value and RSD should be < 20%. In-house limits may be calculated when sufficient data points exist. Monitoring recovery of LLOQ over time is useful for assessing precision and bias.

Ongoing LLOQ verification, at a minimum, is on a quarterly basis to validate quantitation capability at low analyte concentration levels. This verification may be accomplished either with clean control material (e.g., reagent water, method blanks. Optimally, the LLOQ should be less than the desired regulatory action levels based on the stated project-specific requirements.

13. Data Evaluation, Calculations and Reporting

13.1 If dilutions were performed, the appropriate factors must be applied to sample values. All results must be reported with up to three significant figures.

13.2 Soil samples

Soil samples are calculated as follows:

$$A = \frac{\text{Sample weight (grams)}}{\text{Final Volume (mL)}}$$

$$B \text{ (concentration in mg/Kg)} = \frac{\text{Concentration of analyte (mg/L)}}{A}$$

13.2.1 Dry weight correction

The LIMS calculates the dry weight correction, however it is calculated as follows:

$$\text{Final concentration in mg/Kg dry weight} = \frac{B}{\%\ \text{Solids}}$$

13.3 Liquid samples

Liquid samples are calculated as follows:

$$\text{Dilution Factor} = \frac{\text{Final Volume (mL)}}{\text{Sample Volume (mL)}}$$

Final concentration in mg/L = Concentration of analyte (mg/L) x Dilution Factor

13.4 Calculations for Hardness

The method for determining hardness is to compute it from the results of separate determinations of Calcium and Magnesium on aqueous samples.

13.4.1 Total Hardness

Total Hardness, mg equivalent CaCO3/L = [2.497 (Ca, mg/L)] + [4.118 (Mg, mg/L)]

13.4.2 Calcium Hardness

Calcium Hardness, mg equivalent CaCO3/L = [2.497 (Ca, mg/L)]

14. Method Performance

14.1 Detection Limit Study (DL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the DL, LOD, and/or LOQ as outlined in Alpha SOP ID 1732 unless superseded in the SOP. These studies performed by the laboratory are maintained on file for review

14.2 Demonstration of Capability Studies

14.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

14.2.2 Continuing (DOC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples

14.3 Instrument Detection Limits (IDLs)

Instrument detection limits (IDLs) are useful means to evaluate the instrument noise level and response changes over time for each analyte from a series of reagent blank analyses to obtain a calculated concentration. They are not to be confused with the lower limit of quantitation, nor should they be used in establishing this limit. It may be helpful to compare the calculated IDLs to the established lower limit of quantitation, however, it should be understood that the lower limit of quantitation needs to be verified.

Instrument Detection limits (in µg/L) can be estimated by calculating the average of the standard deviations of the three runs on three non-consecutive days from the analysis of a reagent blank solution with seven consecutive measurements per day. Each measurement must be performed as though it were a separate analytical sample (i.e. each measurement must be followed by a rinse and/or any other procedure normally performed between the analysis of separate samples). IDLs should be determined at least once using new equipment, after major instrument maintenance such as changing the detector, and/or at a frequency designated by the project and a record of time and date kept in the instrument maintenance log book.

15. Pollution Prevention and Waste Management

Refer to Alpha's Chemical Hygiene Plan and Hazardous Waste Management and Disposal SOP for further pollution prevention and waste management information.

Table 4 Calibration Standards

Multi-element standard (Section 8.4) containing the following:

High Range Elements (HR): 1000 mg/L of the following: Fe, K, Ca, Na, Mg, Sr

Low Range Elements (LR): 10 mg/L of the following: Ag, Al, As, Ba, Be, Cd, Co, Cr, Cu, Mn, Mo, Ni, Pb, Sb, Se, Tl, V, Zn, Th, U

All Calibration Standards are purchased in 5% HNO3, Tr HF (v/v).
Lithium is analyzed with a single standard curve matching the levels listed below for the routine curve.

Standard #1 (0.2 µg/L LR, 20 ug/L HR): Dilute Standard #3: 1.0 mL to 50mL final volume 1% HNO_3 (v/v).

Standard #2 (1.0 µg/L LR, 100 ug/L HR): Dilute Standard #3: 5.0 mL to 50mL final volume 1% HNO_3 (v/v).

Standard #3 (10.0 µg/L LR, 1000 ug/L HR): Dilute 0.05 mL to 50mL final volume 1% HNO_3 (v/v).

Standard #4 (60.0 µg/L LR, 1000 ug/L HR): Dilute 0.3 mL to 50mL final volume 1% HNO_3 (v/v).

Standard #5 (120.0 µg/L LR, 12000 ug/L HR): Dilute 0.6 mL to 50mL final volume 1% HNO_3 (v/v).

Table 5: Recommended Isotopes for Selected Elements

Mass	Element of Interest
27	Aluminum
121, **123**	Antimony

24, **25**, **26**	Magnesium (I)
55	Manganese
98, 96, 92, **97**, 94, (108)[a]	Molybdenum (I)
58, **60**, 62, **61**, 64	Nickel
39	Potassium (I)
103	Rhodium (IS)
45	Scandium (IS)
80, **78**, **82**, **86**, **77**, 74	Selenium
107, **109**	Silver
23	Sodium (I)
159	Terbium (IS)
205, 203	Thallium
51, **50**	Vanadium
120, **118**	Tin (I)
89	Yttrium (IS)
64, **66**, **68**, **67**, 70	Zinc

NOTE: Method 6020 is recommended for only those analytes listed in Table 1. Other elements are included in this Table because they are potential interferents (I) in the determination of recommended analytes, or because they are commonly used internal standards (IS). Isotopes are listed in descending order of natural abundance. The most useful isotopes are underlined and in boldface, although certain matrices may require the use of alternative isotopes.

[a] These masses are also useful for interference correction (Section 4.2)

[b] Internal standard must be enriched in the 6Li isotope. This minimizes interference from indigenous Li

Table 8 Internal Standard

Multiple Element Standard, purchased (Section 8.5), 100mg/L of ^{6}Li, ^{45}Sc, ^{74}Ge, ^{103}Rh, ^{115}In, ^{159}Tb, ^{175}Lu, ^{209}Bi

Working Internal Standard (IS) Solution (1 mg/L solution) Dilute 10.0 mL to 1L final volume 1% HNO_3 (v/v).

Table 9 Tune Solution

Tune Solution: 100 ug/L multi-element standard, purchased for ^{7}Li ^{9}Be, ^{58}Ce ^{59}Co, ^{115}In, ^{137}Ba and ^{208} Pb, ^{238}U in 1% HNO_3 (v/v) (Section 8.6).

Working Tune Solution: Dilute 1.0 mL of 100 ug/L multi-element standard for ^{7}Li ^{9}Be, ^{58}Ce ^{59}Co, ^{115}In, ^{137}Ba and ^{208}Pb, ^{238}U with 1% HNO_3 (v/v) to 100mL final volume. This will give a final concentration of these metals at 1.0µg/L.

Table 10 ICV Solution

Multiple Element Standard, purchased (Section 8.7):

1000mg/L of K, Na, Ca, Mg, Fe, Sr
10mg/L of Ag, Al, As, Ba, Be, Cd, Co, Cr, Cu, Mn, Mo, Ni, Pb, Sb, Se, Tl, V, An, Th, U

Working ICV Solution: Dilute 1.0 mL with 0.25% HNO_3 (v/v) to 50mL final volume. This will give the following concentrations:

5000µg/L of K, Na, Ca, Mg, Fe, Sr

50µg/L of Ag, Al, As, Ba, Be, Cd, Co, Cr, Cu, Mn, Mo, Ni, Pb, Sb, Se, Tl, V, An, Th, U

Table 11 CCV Solution

Multi-element standard (Section 8.4) containing the following:

High Range Elements (HR): 1000 mg/L of the following: Fe, K, Ca, Na, Mg, Sr

Low Range Elements (LR): 10 mg/L of the following: Ag, Al, As, Ba, Be, Cd, Co, Cr, Cu, Mn, Mo, Ni, Pb, Sb, Se, Tl, V, Zn, Th, U

All Standards are purchased in 5% HNO3, Tr HF (v/v).

60.0 µg/L LR, **1000 ug/L** HR: Dilute 0.3 mL to 50mL final volume 1% HNO_3 (v/v).

Table 12 Spectral Interference Check Solutions

SIC, High-Purity Standards Cat. #ICP-MS-ICS-2 A (Section 8.8):

20000 mg/L of Cl^- **3000 mg/L Ca**
2500 mg/L Fe, Na
2000 mg/L of C
1000 mg/L of Al, K, Mg, P, S
20 mg/L of Mo, Ti

Working SIC Solution: Dilute 5 mL of High-Purity Standards Cat. #ICP-MS-ICS-2 A, with 1% HNO_3 (v/v) to 50mL final volume. This will give the following concentrations:

2000 mg/L of Cl^-
300 mg/L Ca
250 mg/L Fe, Na
200 mg/L of C
100 mg/L of Al, K, Mg, P, S
2 mg/L of Mo, Ti

Table 13
Interference Correction Equations

Correction equations are in the form: corrected signal for mass X=(signal from mass X) ± (signal from mass Y)*(correction factor).

Inductively Coupled Plasma - Mass Spectrometry 6020B

Reference: **Method 6020B,** Test Methods for Evaluating Solid Waste: Physical/Chemical Methods, EPA SW-846, Revision V, July 2014.

1. Scope and Application

Matrices: Groundwaters, aqueous samples, industrial waste, soils, sludges, sediments, and other solid wastes.

Definitions: Refer to Alpha Analytical Quality Manual.

Inductively coupled plasma-mass spectrometry (ICP-MS) is applicable to the determination of sub µg/L concentrations of a large number of elements in water samples, waste extracts or digestates.

ICP-MS has been applied to the determination of over 60 elements in various matrices. Elements for which EPA has determined the acceptability of Method 6020 in a mulit-laboratory study on solid wastes are listed below and in Table 1.

If method 6020 is used to determine any analyte not listed in Table 1 below, it is the responsibility of the analyst to demonstrate the accuracy and precision of the method in the waste to be analyzed. The analyst is always required to monitor potential sources of interferences and take appropriate action to ensure data of known quality.

Use of this method is restricted to spectroscopists who are knowledgeable in the recognition and in the correction of spectral, chemical, and physical interferences in ICP-MS.

An appropriate internal standard is required for each analyte determined by ICP-MS. Recommended Internal standards are ^{6}Li, ^{45}Sc, ^{89}Y, ^{103}Rh, ^{115}In, ^{159}Tb, ^{165}Ho, and ^{209}Bi. The Lithium internal standard must have an enriched abundance of 6Li, so that interference from Lithium native to the sample is minimized. Other elements may need to be used as internal standards when samples contain significant amounts of the recommended internal standards. The internal standard used in this method is as follows: ^{6}Li, ^{45}Sc, ^{74}Ge, ^{103}Rh, ^{115}In, ^{159}Tb, ^{175}Lu, ^{209}Bi.

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one or more of the following laboratory personnel before performing the modification: Area Supervisor, Department Supervisor, Laboratory Director, or Quality Assurance Officer.

This method is restricted to use by or under the supervision of analysts experienced in the operation of the ICP-MS and in the interpretation of ICP-MS data. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

Table 1

Parameter	CAS		Parameter	CAS
Aluminum	7429-90-5		Magnesium	7439-95-4
Antimony	7440-36-0		Manganese	7439-96-5
Arsenic	7440-38-2		Lithium	7439-93-2
Barium	7440-39-3		Molybdenum	7439-98-7
Beryllium	7440-41-7		Nickel	7440-02-0
Cadmium	7440-43-9		Potassium	7440-09-7
Calcium	7440-70-2		Selenium	7782-49-2
Chromium	7440-47-3		Silver	7440-22-4
Cobalt	7440-48-4		Sodium	7440-23-5
Copper	7440-50-8		Thallium	7440-28-0
Iron	7439-89-6		Vanadium	7440-62-2
Lead	7439-92-1		Zinc	7440-66-6

2. Summary of Method

When dissolved constituents are required, samples must be filtered and acid-preserved prior to analysis. No digestion is required prior to analysis for dissolved elements in water samples. Acid digestion prior to filtration and analysis is required for groundwater, aqueous samples, industrial waste, soils, sludge's, sediments, and other solid wastes for which total (acid-leachable) elements are required.

Method 6020 describes the multi-elemental determination of analytes by ICP-MS. The method measures ions produced by a radio-frequency inductively coupled plasma. Analyte species originating in a liquid are nebulized and the resulting aerosol transported by argon gas into the plasma torch. The ions produced are entrained in the plasma gas and introduced, by means of an interface, into the mass spectrometer. The ions produced in the plasma are sorted according to their mass-to-charge ratio and quantified with a channel electron multiplier. Interferences must be assessed and valid corrections applied or the data flagged to indicate a problem. Interference correction must include compensation for background ions contributed by the plasma gas, reagents, and constituents of the sample matrix.

2.1 Method Modifications from Reference

This method is performed in a 1% Nitric Acid matrix for the calibration curve and standards and a 2% Nitric Acid matrix for the rinse.

3. Reporting Limits

Instrument detection limits, sensitivities, and linear ranges will vary with the matrices, instrumentation and operating conditions. In relatively simple matrices, detection limits will generally be below 20 µg/L. Table 2 contains the list of Reporting Limits.

4. Interferences

4.1 Isobaric Elemental Interference

Isobaric elemental interferences in ICP-MS are caused by isotopes of different elements forming atomic ions with the same nominal mass-to-charge ratio (m/z). A data system must be used to correct for these interferences. This involves determining the signal for

another isotope of the interfering element and subtracting the appropriate signal from the analyte isotope signal. Since commercial ICP-MS instruments nominally provide unit resolution at 10% of the peak height, very high ion currents at adjacent masses can also contribute to ion signals at the mass of interest. Although this type of interference is uncommon, it is not easily corrected, and samples exhibiting a significant problem of this type could require resolution improvement, matrix separation, or analysis using another verified and documented isotope, or use of another method.

4.2 Isobaric Molecular and Doubly Charged Ion Interference

Isobaric molecular and doubly-charged ion interferences in ICP-MS are caused by ions consisting of more than one atom or charge, respectively. Most isobaric interferences that could affect ICP-MS determinations have been identified in the literature. Examples include $ArCl^+$ ions on the ^{75}As signal and MoO^+ ions on the Cadmium isotopes. While the approach used to correct for molecular isobaric interferences is demonstrated below using the natural isotope abundances form the literature, the most precise coefficients for an instrument can be determined form the ratio of the net isotope signals observed for a standing solution at a concentration providing suitable (<1 percent) counting statistics. Because the ^{35}Cl natural abundance of 75.77 percent is 3.13 times the ^{37}Cl abundance of 24.23 percent, the chloride correction for arsenic can be calculated (approximately) as follows (where the $^{38}Ar^{37}Cl^+$ contribution at m/z 75 is a negligible 0.06 percent of the $^{40}Ar^{35}Cl^+$ signal):

Corrected arsenic signal (using natural isotopes abundances for coefficient approximations) = (m/z 75 signal) – (3.13) (m/z 77 signal) + (2.73) (m/z) (82 signal), (where the final term adjust for any selenium contribution at 77 m/z)

Note: Arsenic values can be biased high by this type of equation when the net signal at m/z 82 is caused by ions other than $^{82}Se^+$, (e.g. $^{81}BrH^+$ from bromine waste)

Similarly, corrected cadmium signal (using natural isotopes abundances for coefficient approximations) = (m/z 114 signal) – (0.027) (m/z 118 signal) – (1.63) (m/z 108 signal), (where the last two terms adjust for any tin or MoO^+ contributions at m/z 114).

> **Note:** Cadmium values will be biased low by this type of equation when $^{92}ZrO^+$ ions contribute at m/z 108, but use of the m/z 111 for Cd is even subject to direct ($^{94}ZrOH^+$) and indirect ($^{90}ZrO^+$) additive interferences when Zr is present
>
> **Note**: As for the arsenic equation above, the coefficients in the Cd equation are for only illustrative purposes. The most appropriate coefficients for an instrument can be determined from the ratio of the net isotope signals observed for a standard solution at a concentration providing suitable (<1 percent) counting precision.

The accuracy of these types of equations is based upon the constancy of the OBSERVED isotopic ratios for the interfering species. Corrections that presume a constant fraction of a molecular ion relative to the “parent” ion have not been found to be reliable, e.g. oxide levels can vary. If a correction for an oxide ion is based upon the ratio of parent –to-oxide ion intensities, the correction must be adjusted for the degree of outside formation by the use of an appropriate oxide internal standard previously demonstrated to form a similar level of oxide as the interferant. This type of correction has been reported for oxide-ion corrections using ThO^+/Th for the determination of rare earth elements. The use of aerosol desolvation and/or mixed plasmas has been shown to greatly reduce molecular interferences. These techniques can be used provided that method detection limits, accuracy, and precision requirements for analysis of the samples can be met.

4.3 Physical Interference

Physical interferences are associated with the sample nebulization and transport processes as well as with ion-transmission efficiencies. Nebulization and transport processes can be affected if a matrix component causes a change in surface tension or viscosity. Changes in matrix composition can cause significant signal suppression or enhancement. Dissolved solids can deposit on the nebulizer tip of a pneumatic nebulizer and on the interface skimmers (reducing the orifice size and the instrument performance). Total solid levels below 0.2% (2,000mg/L) have been currently recommended to minimize solid deposition. An internal standard can be used to correct for the physical interferences, if it is carefully matched to the analyte so that the two elements are similarly affected by the matrix change. When the intensity level of an internal standard is less than 30 percent or greater than 120 percent of the intensity of the first standard used during calibration, the sample must be reanalyzed after a fivefold (1+4) or greater dilution has been performed.

4.4 Memory Interference

Memory interferences can occur when there are large concentration differences between samples or standards which are analyzed sequentially. Sample deposition on the sampler and skimmer cones, spray chamber design, and the type of nebulizer affect the extent of the memory interferences which are observed. The rinse period between samples must be long enough to eliminate significant memory interferences.

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material safety data sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

Only Polyethylene or fluorocarbon (PFA or TFE) containers are recommended. Alpha uses polyethylene bottles. 0.5L is the recommended size.

6.2 Sample Preservation

Samples for total metals are preserved with (1:1) Nitric Acid to a pH<2.

Samples for soluble metals must be preserved with (1:1) Nitric Acid to a pH of <2 **after** filtration through a 0.45 um filter.

6.3 Sample Shipping

No specific requirements.

6.4 Sample Handling

Samples that are to be analyzed for soluble metals, and have not been field filtered, must be filtered through a 0.45um filter as soon as possible. Samples are then preserved with 1:1 Nitric Acid to a pH<2, and then held for 18 hours. After the 18 hours the pH must be re-checked. If

after 18 hours the pH is still >2, then the sample must be re-acidified and held again for 18 hours. If the pH is till >2 after this 18 hour period, then the Inorganics Manager must be told.

Samples preserved with Nitric Acid to a pH<2, and are not being analyzed for Mercury, have a hold time of 6 months.

Samples are stored at room temperature

7. Equipment and Supplies

7.1 Thermo Q and RQ ICP-MS:

The MS features dual extraction lenses and a compound ion lens system that ensures a mass range from Li-U (masses 6-240). It also features the enhanced RAPID (Right Angle Positive Ion Deflection) lens technology (90° ion optics done right) for separation of ions and neutrals. Simultaneous analog/PC detector with real time multi-channel analyzer electronics provides >9 orders of dynamic range suitable for both steady state and transient signal analysis. The software is Qtegra which provides integrated plug-ins for autosamplers, autodiluters and one click instrument set up: with a single mouse click, the iCAP Q is taken into operate mode, tested and, where necessary intelligently autotuned and/or calibrated to meet the protocol.

7.2 CETAC ASX-510 Autosampler: Delivers sample and internal standard to the torch

7.3 Thermo X-series II ICP-MS

The Innovative Protective Ion Extraction and Infinity II ion optics, based upon a hexapole design with chicane ion deflector, provides low background specification coupled with a userinterchangeable Xt interface and Xs interface. High-performance quadrupole analyzer is pumped by a novel split flow turbo pump backed by a single rotary. Simultaneous analog/PC detector with real time multi-channel analyzer electronics provides >8 orders of dynamic range suitable for both steady state and transient signal analysis. Instrument and accessories are fully computer controlled by the PlasmaLab software. Peltier spray chamber cooling provides enhanced performance for outstanding signal /background.

7.4 Edwards E2M28 and Sogevac 40 Rotary Pumps

7.5 Neslab M-75 Chiller: Cools the torch and the MS

7.6 Eppendorf pipets: Accurate means to make trace standards

8. Reagents and Standards

8.1 Nitric Acid (HNO_3), Trace metals grade: 18M Concentrated Redistilled

8.2 1% Nitric Acid (v/v): 10mL of 18M HNO_3 diluted to 1L using Type I water

8.3 Type I De-Ionized Water

8.4 Calibration Standard: Multiple Element Standard, purchased (Table 4) and diluted. Store at room temperature. Expires upon manufacturer's specified date. Prepare as needed if confirmed with the ICV solution made fresh daily.

8.5 Internal Standard: Multiple Element Standard, purchased (Table 8). Store at room temperature. Expires upon manufacturer's specified date.

8.6 Tune Stock: Multiple Element Standard, purchased (Table 9). 100.0 ug/L solution of each ^{7}Li ^{9}Be, ^{58}Ce, ^{59}Co, ^{115}In, ^{137}Ba and ^{208}Pb, and ^{238}U.

8.7 ICV: Multiple Element Standard, second source from calibration standard (Section 8.4) purchased and diluted (Table 10). Concentrations are near but not at the mid-point of the calibration Prepare fresh daily.

8.8 CCV: Multiple Element Standard, purchased (Table 11) and diluted. Store at room temperature. Concentrations are at or near the mid-point of the calibration. Expires upon manufacturer's specified date.

8.9 SIC: High-Purity Standards Cat. #ICP-MS-ICS-2 A stock. Dilute 5 mL to 50 mL (Table 12). Store at room temperature. Prepare fresh weekly.

8.10 LDR Check Solution: A multiple element or single element solution run at a point above the highest calibration standard under the same calibration used to quantify the associated sample data. The LDR check must be within +/-10% of the true value of each element of interest and be within +/- 50% of the sample concentration to be consider valid.

8.11 Lower Limit of Quantitation (LLOQ) check standard: The laboratory should establish the LLOQ as the lowest point of quantitation which, in most cases, is the lowest concentration in the calibration curve. See section 12.16.

8.12 Argon Gas: 0.9995 or better grade. High capacity tank plumbed into the lab.

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

9.1 Blank(s)

Three types of blanks are required for the analysis. The calibration blank, which is also the ICB/CCB, is used in establishing the calibration curve. The ICB/CCB is used to monitor carryover, signal noise, and drift. The method blank is used to monitor for possible contamination resulting from the sample preparation procedure. The rinse blank is used to flush the system between all samples and standards. See Section 12.3 for Corrective Action.

9.1.1 The Calibration blank, Initial Calibration Blank and the Continuing Calibration Blank consists of the same concentration of the same acid used to prepare the final dilution of the calibrating solutions of the analytes. This is a 1% HNO_3 solution (v/v) in Type I deionized water along with the selected concentrations of internal standard element for each of the analytes. The Calibration Blank is analyzed before the standards are analyzed. The Initial Calibration Blank must follow the Initial Calibration Verification standard (ICV) and the Continuing Calibration Blank must follow the Continuing Calibration Verification standard (CCV). These must be analyzed at a frequency of every 10 or less samples and at the end of the analytical run. The ICB must be no greater than ½ the LLOQ for any analyte; The CCB must be no greater than the LLOQ for any analyte See Section 12.11 for Corrective Action.

9.1.2 The method (or reagent) blank must be carried through the complete preparation procedure and contain the same volumes of reagents as the sample solutions. Method blanks are generally considered to be acceptable if target analyte

concentrations are less than the LLOQ or are less than project-specific requirements. Blanks may contain analyte concentrations greater than acceptance limits if the associated samples in the batch are unaffected (i.e. targets are not present in samples or sample concentrations are ≥10X the blank). Other criteria may be used depending on the needs of the project. See Section 12.8 for Corrective Action.

9.1.3 The rinse blank consists of HNO_3 (1% or 2%) (v/v) in reagent water. Prepare a sufficient quantity to flush the system between standards and samples.

9.2 Laboratory Control Sample (LCS)

The Laboratory Control Sample (LCS) must be analyzed for each analyzed for each analyte using the same sample preparations, analytical methods and QA/QC procedures employed for the test samples. One LCS must be prepared and analyzed for each sample batch at a frequency of one LCS for each 20 samples or less. Aqueous LCS recoveries must be 80-120%, and soil LCS recoveries must be within the SRM limits. See Sections 12.9 and 12.10 for Corrective Actions.

9.3 Initial Calibration Verification (ICV)

The ICV must have a recovery that is within ±10% of the true value. The ICV and must contain all of the elements that are calibrated. The ICV is an independent source other than those standards used for the calibration of the instrument. The ICV must be analyzed following the calibration.

9.4 Continuing Calibration Verification (CCV)

The CCV must have a recovery that is within ±10% of the true value. The CCV must be analyzed at a frequency of 10 samples or less and at the end of the analytical run.

9.5 Matrix Spike

Analyze one matrix spike per twenty or less analytical samples. The recovery of the matrix spike must be between 75 – 125%. Calculate percent recovery using Section 11.2.

9.5.1 **Dilution Test:** If the analyte concentration is sufficiently high (minimally, a factor of 25 above the lower limit of quantitation after dilution), an analysis of a 1:5 dilution must agree within ± 20% of the original determination. Elements that fail the dilution test are reported as estimated values.

9.5.2 **Post Digestion Spike Addition:** If the sample concentrations are insufficient to perform a dilution test a post digestion spike added to a portion of a prepared sample, or its dilution for the elements failing the matrix spike recoveries must be run, recovery limits equal to 75% to 125% of the known spike value. If the spike is not recovered within the specified limits If the post-digestion recovery fails to meet the acceptance criteria, the sample results must be reported as estimated values

9.6 Laboratory Duplicate

Analyze one duplicate sample for every matrix in a batch at a frequency of one matrix duplicate for every 20 samples. Calculate RPD under section 11.3.

A control limit of 20% RPD must not be exceeded for analyte values greater than 100 times the instrument detection limit (Section 13.3). See Section 12.14 for Corrective Action.

9.7 Method-specific Quality Control Samples

9.7.1 Internal Standards

The intensities of all internal standards must be monitored for every analysis. If the intensity of any internal standard applied to a sample falls below 70% of the intensity of that internal standard in the initial calibration standard, a significant matrix effect must be suspected.

Under these conditions, the established lower limit of quantitation has degraded and the correction ability of the internal standardization technique becomes questionable. The following procedure is followed -- First, make sure the instrument has not drifted by observing the internal standard intensities in the nearest calibration blank.

If the low internal standard intensities are also seen in the nearest calibration blank, terminate the analysis, correct the problem, recalibrate, verify the new calibration, and reanalyze the affected samples. If drift has not occurred, matrix effects need to be removed by dilution of the affected sample. The sample should be diluted fivefold (1+4) and reanalyzed with the addition of appropriate amounts of internal standards. If the first dilution does not eliminate the problem, this procedure must be repeated until the internal-standard intensities rise to the minimum 70% limit. Reported results must be corrected for all dilutions.

9.7.2 Interference Check Standards

Verify the magnitude of elemental and molecular-ion isobaric interferences and the adequacy of any corrections at the beginning of an analytical run or once every 12 hours, whichever is more frequent. Do this by analyzing the SIC check (8.9). Refer to Section 4.0 for a discussion on interferences and potential solutions to those interferences if additional guidance is needed. SIC must be below 2X LLOQ for all non-spiked elements of interest. See Section 12.8 for Corrective Action

9.7.3 Low Level Verification Standard (LLV)

The low level standard analyzed should quantitate to within 80-120% of the true value.

9.7.4 Mid Level Verification Standard (MLV)

The mid-level standard analyzed should quantitate to within 90-110% of the true value.

10. Procedure

10.1 Equipment Set-up

10.1.1 Sample Preparation

Prior to analysis, samples which require total (acid-leachable) values must be digested using appropriate sample preparation methods, such as Methods 3005A, 3015, 3051 and 3050B.

10.1.2 Tuning the instrument on from Stand By

- Tighten the peristaltic pump windings for the sample, Internal standard and spray chamber drain.
- Turn on the Argon gas supply and chiller.

Thermo Q and RQ:

- Turn on the computer and monitor. Start the Qtegra software. On the front instrument tab select the ON button, select OK. The fully automatic system will advance to ignition, torch box alignment and start the sample introduction system.
- Allow the instrument to warm up for **30 minutes.**

Thermo X-series II:

- Turn on the computer and monitor. Start the Plasmalab software. On the front instrument tab select the ON button. A message box will ask if to advance from vacuum to start up, select OK. The fully automatic system will advance to ignition, torch box alignment and start the sample introduction system.
- Allow the instrument to warm up for **30 minutes.**

10.1.3 Tuning

After the 30 minute warm up period has passed, a daily tune must be performed and a report generated.

Thermo X-series II and Thermo Q:

Select autotune, introduce the Tune A solution The Instrument stock tune solution (Table 9) is a 10 µg/L, Tune A is a 10 fold dilution. Run the autotune after a minimum 40 second uptake delay.

From the drop down menu select Run Performance Check (x –series), icon (Q) with the sample probe in Tune A solution. After completion of the performance check, select print and the file will be save to the archive. Upon successfully passing the performance check the instrument is ready for calibration.

Typical values of tuning parameters

Parameter	Typical Conditions	Adjustment
RF Power (W)	1300	1200 to 1600
Sampling Depth (mm)	6	4 to 8
Carrier gas (L/min)	1.2	0.8 to 1.3
Makeup gas (L/min)	0	0 to 0.4
Peri-pump 1 (rps)	0.1	0.06 TO 0.15
S/C Temp (°C)	2	Normally used at 2 °C
Extraction	-150	-200 to -100
Extraction	-70	-150 to -10
Einzel 1.3 (V)	-100	-130 to -40
Einzel 2(V)	7	-20 to +70
Omega Bias (V)	-35	-40 to 0
Omega (+)(V)	5	0 to +30
RF Power (W)	1300	1200 to 1600

Typical value of Sensitivity and RSD (Using the normal torch)

Mass	Counts / 10ppb Integ. Time = 0.1 sec	RSD
^{7}Li	>6400	<5%
^{89}Y	>16000	<5%
^{205}Tl	>9600	<5%

10.2 Initial Calibration

Mixed calibration standard solutions are prepared by diluting the stock-standard solutions to levels within the linear range for the instrument in a solvent consisting of 5% HNO_3 (v/v) in reagent water. The calibration standard solutions must contain a suitable concentration of an appropriate internal standard for each analyte. Internal standards are added at the time of analysis using a second channel of the peristaltic pump and an appropriate mixing manifold. Generally, an internal standard must be no more than 50amu removed from the analyte. Alpha employs the following internal standards: ^{6}Li, ^{45}Sc, ^{74}Ge, ^{103}Rh, ^{115}In, ^{159}Tb, ^{175}Lu, ^{209}Bi. Lithium is excluded when analyzing for ^{6}Li/^{7}Li.

Prior to preparing the mixed standards, each stock solution must be analyzed separately to determine possible spectral interferences or the presence of impurities. Care must be taken when preparing the mixed standards that the elements are compatible and stable. Transfer the mixed standard solutions to freshly acid-cleaned HPLC bottles for storage. Fresh mixed standards must be prepared as needed with the realization that concentrations can change upon aging. Calibration standards must be initially verified using a quality control standard (ICV), and monitored daily for stability.

Calibrate the instrument for the analytes of interest (recommended isotopes for the analytes in Table 1 are provided in Table 3), using the calibration blank (Section 9.1.1) and the set of 4 standards (see Table 4.). The analytical range brackets an RDL of 0.2 µg/L to 120 µg/L with the exceptions of Fe, K, Na, Ca and Mg which bracket the range of 10µg/L to 12,000µg/L. All solutions

and standards are prepared in a 1% Nitric Acid matrix. The calibration is defined as the calibration blank and four standards. The only standards that may be discarded in the calibration are the first standard (the low standard) and the fourth standard (the high standard). The only instance when the standard may be discarded is if the linearity of the element in question does not meet the correlation coefficient acceptance criteria of 0.995 or greater. No mid-level standards are ever discarded. The LDR is defined by the LDR standard run within the same calibration and recovered with +/- 10% of the true value of each element and within +/- 50% of the sample concentration, no sample is to exceed 90% of the top LDR standard or a dilution must be performed. All standards, QC samples and samples are to be integrated three times and then averaged. The calibration block is part of the analytical sequence and includes an ICV, ICB, LLV, MLV immediately following the analysis of the calibration standards. The calibration block can also contain a pause so that the analyst can evaluate the calibration prior to sample analysis. The routine calibration sequence is as follows:

Blank #1
Cal blank
0.2 µg/L std (10 µg/L Fe, K, Na, Ca, Mg)
1.0 µg/L std (100 µg/L Fe, K, Na, Ca, Mg)
10.0 µg/L std (1000 µg/L Fe, K, Na, Ca, Mg)
120 µg/L std (12,000 µg/L Fe, K, Na, Ca, Mg)

The quality control standard is the Initial Calibration Verification solution (ICV), which must be prepared in the same acid matrix as the calibration standards. This solution must be an independent standard near but not at the midpoint of the instrument calibration. An independent standard is defined as a standard composed of analytes from a source other than that used for the standards for instrument calibration.

Immediately after the calibration has been established, the calibration must be verified and documented for every analyte by the analysis of the Initial Calibration Verification solution (ICV) (Section 8.7). The calibration is verified if the solution is within the 10% of the true value (Table 10) for each element. See Section 12 for corrective action if the ICV fails. The ICB (9.1.1) is analyzed immediately following the ICV. The ICB must be no greater than the ½ LLOQ for any analyte. See Sections 12 for Corrective Actions.

10.3 Equipment Operation and Sample Processing

10.3.1 Spectral Interference Check Solution

The interference check solution (SIC) is prepared to contain known concentrations of interfering elements that will demonstrate the magnitude of interference and provide an adequate test of any corrections.

Chloride in the SIC provides a means to evaluate software corrections for chloride-related interferences such as $^{35}Cl^{16}O^{+}$ on $^{51}V^{+}$ and $^{40}Ar^{35}Cl^{+}$ on $^{75}As^{+}$.

Iron is used to demonstrate adequate resolution of the spectrometer for the determination of manganese.

Molybdenum serves to indicate oxide effects on cadmium isotopes.

The other components are present to evaluate the ability of the measurement system to correct for various molecular-ion isobaric interferences. The ICS is used to verify that the interference levels are corrected by the data system within quality control limits. The ICSA solution (Section 8.8) contains 20,000mg/L of Cl^{-}, 3,000 mg/L of Ca, 2,500 mg/L of Fe and Na, 2,000 mg/L of C, 1,000 mg/L of Al, K , Mg, P, S and 20 mg/L of Mo and Ti.

The non-target analytes for the SIC should have a recovery less than 2x LLOQ. Narrate nonconformance.

10.3.2 Sample Analysis and Continuing Calibration Verification

The default sample table on the instrument will include the ICV, ICB, LLV, MLV, SIC, samples and CCV and CCB. After the initial Instrument QC has been analyzed and passed, then 10 samples will be analyzed. After the tenth sample has been analyzed, a CCV and a CCB will be analyzed. Analysis of standards and samples must only take place when the instrument has come to equilibrium (typically after 30 minutes after plasma ignition). All masses which could affect data quality must be monitored to determine potential effects from matrix components on the analyte peaks. The recommended isotopes to be monitored are listed in Table 3. When the analysis is ready to start, flush the system with the rinse blank solution (Section 9.1.3) until the signal levels return to the method's level of quantitation (usually about 30 seconds) before the analysis of each sample. Nebulize each sample until a steady-state signal is achieved (usually in about 30 seconds) prior to collecting the data. Analyze the Continuing Calibration Verification solution (CCV) (Section 8.7) and the continuing Calibration blank (Section 9.1.1) at a frequency of at least once per ten analytical samples, and at the end of the analytical run. Dilute and reanalyze samples that are more concentrated than the linear range (or species needed for a correction) or measure an alternate less-abundant isotope if calibrated. The linearity at the alternate mass must be confirmed by appropriate calibration.

10.4 Preventive Maintenance

The scheduled maintenance is automatically tracked by the run time log for the following parameters. A message will appear on the computer screen reminding the analyst that a piece of maintenance must be performed. An electronic log, along with a maintenance notebook is kept. Below is a list what needs to be performed:

1. Check rough pump oil
2. Replace rough pump oil
3. Replace mist filter 4
4. Clean the extraction lenses
5. Clean the skimmer cone
6. Clean the sampling cone
7. Clean the nebulizer

11. Data Evaluation, Calculations and Reporting

The quantitative values are reported in appropriate units directly from the instrument: micrograms per liter (µg/L) for aqueous samples and milligrams per kilograms (mg/Kg) for solid samples. If dilutions were performed, the appropriate corrections must be applied to the sample values.

11.1 It is required that results for solids be reported on a dry weight basis as follows:

A separate determination of percent solids is performed by the Wet Chemistry Department and the result is loaded in the **LIMS**. To retrieve the result in the LIMS, go to **"Status"** and type in the sample ID. Click the sample number that is part of that sample ID, and click the product that says **TS-S**. The percent solids for the sample is there. LIMS will automatically

correct the sample for percent solids after the metals analysis has been **Final Metals Reviewed.** This is the calculation:

$$\text{Concentration (dry weight) (mg/kg)} = \frac{C \times V}{W \times S}$$

Where:
C= Digest Concentration (mg/L)
V= Final volume in Liters after sample preparation
W= Weight in Kg of wet sample
$S = \frac{\%\text{Solids}}{100}$

Calculations must include appropriate interference corrections (see Section 4.1 for examples), internal-standard normalization, and the summation of signals at 206, 207, and 208 m/z for Lead (to compensate for any differences in the abundances of these isotopes between samples and standards).

11.2 Calculate Percent Recovery for the Matrix Spike corrected for concentrations measured in the unfortified sample. Percent recovery is calculated using the following equation:

$$\%\ \text{Recovery} = \frac{(Cm - C)}{s} \times 100$$

Where:
Cm = measured in the fortified sample
C = measured native sample concentration
S = concentration equivalent of spike added to sample

11.3 Calculate the Relative Percent Difference (RPD) for each Duplicate of the initial quantitated concentration (IC) and duplicate quantitated concentration (Dc) using the following formula:

$$RPD = \frac{|(IC - Dc)|}{\{(IC + Dc) / 2\}} \times 100$$

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

Holding time exceedances, improper preservation and observed sample headspace are noted on the nonconformance report form.

Perform routine preventative maintenance following manufacturer's specification. Record all maintenance in the instrument logbook.

Review of standards, blanks and standard response for acceptable performance occurs for each batch of samples. Record any trends or unusual performance on a nonconformance action form

12.1 The performance check standard is included in the tuning solution. Ce and Ba are included with the tuning solution and monitor the formation of oxides and the effect of doubly-charged ions

respectively. If the solution fails >3% (Section 10.1.3) then instrument maintenance must be performed and the solution re-run.

12.2 For the Tune to pass, the mass calibration for the three tune elements (Section 10.1.3) must not differ by more than 0.1 amu from the true value and the resolution must be <0.9 amu full width at 10% peak height. Furthermore the RSD for the three tune elements must be <5% If any of these criteria fail then the mass calibration must be adjusted to the correct value. This is done by re-optimizing the instrument conditions and re-tuning.

12.3 The results of the calibration blank (Section 9.1.1) must be less than the LLOQ for each element. If this is not the case, the reason for the out-of-control condition must be found and corrected, and affected samples must be reanalyzed. If the laboratory consistently has concentrations greater than 3 times the LLOQ, the LLOQ may be indicative of an estimated LLOQ and must be re-evaluated.

12.4 Calibration is performed after the tune passes. A five point calibration is performed (Section 9.3). If more than three points are to be used for the calibration, then the resultant curve must have a correlation coefficient (cc) of 0.995 or greater. If the cc is <0.995, then the instrument must be re-optimized and re-calibrated. The calibration must define the working linear range of the curve. The reporting RL must be the low standard, and the upper linear range must be defined by the high standard.

12.5 The ICV (Section 9.3) is performed immediately after an acceptable calibration has been produced. The acceptable range for this standard is 90-110%. If this standard fails then the analysis must be stopped and the instrument re-calibrated, and the ICV re-analyzed. Analysis cannot continue until this standard passes.

12.6 The CCV (Section 9.4) is performed at a frequency of 10 samples or less and at the end of the analytical run. The acceptable range for this standard is 90-110%. If this standard fails it can be rerun once. If it continues to fail the instrument is re-calibrated, and the CCV re-analyzed. Analysis cannot continue until this standard passes. All samples run after the last passing CCV must be rerun for the CCV failures.

12.7 The ICB (Section 9.1.1) must be performed immediately after the ICV. The ICB must be ½ LLOQ. If the ICB fails then the analysis is terminated, sources of contamination are checked for, and the instrument is re-calibrated and the ICV and ICB are re-analyzed.

12.8 The Spectral Interference Check Solution (Section 9.7.2) monitor how well the system is correcting for interference. The target non-spiked elements in SIC must be below 2X LLOQ for those elements in question. If the recovery of this solution is outside of the control limits, the non-compliance must be narrated. There is no corrective action required because instrument corrections are based on natural isotope abundances that cannot be changed. If the IS is in compliance then the data is acceptable.

12.9 The Method (Preparation) Blank (Section 9.1.2) must be less than the LLOQ for all of the elements that are being analyzed. If the element in question is non-detect, and the method blank is positive then the corrective action is a narration on the final report. If the samples associated with the method blank have “hits”, and they are 10x greater than the method blank, then the corrective action is a narration on the final report. If the method blank is not less than the RL, and the associated samples have results that are greater than the RL but less than 10x the method blank, then the samples must be re-digested and re-analyzed.

12.10 If the LCS (Section 9.2) fails, then all samples associated with that batch must be re-digested and re-analyzed. (Massachusetts recognizes that if the MS passes and the LCS fails then the data can be accepted. Narrate then non-compliance. This is only for MCP projects).

12.11 Failure of the CCB (9.1.1) rerun once, if continued failure evaluate the data; if associated sample results are greater than 10x CCB level then the results are acceptable. Otherwise, recalibrate and re-analyze all samples since last compliant CCB.

12.12 If the dilution test (Section 9.5.1) fails, then an interference may be suspected. There is no corrective action to be applied. Report all elements as estimated on the final report if the sample concentration is 25x LLOQ.

12.13 If the Post–Digestion Spike (Section 9.5.2) fails, then matrix interference may be suspected and a dilution should be performed to confirm. Report all elements as estimated on the final report.

12.14 Failure of the duplicate sample (Section 9.6) must be investigated. If the sample is found to be non-homogeneous or less than 5 x the LLOQ then the non-compliance must be narrated on the final report.

12.15 If the Internal Standards (Section 9.7.1) fail the acceptance criteria, then dilute the samples until the IS passes. If the criteria are still not met, then terminate the analysis, re-calibrate, verify the new calibration, and reanalyze all of the affected samples. If IS continues to fail at dilutions, seek an alternate technology to analyze the affected samples.

12.16 The LLOQ is initially verified by the analysis of at least 7 replicate samples, spiked at the LLOQ and processed through all preparation and analysis steps of the method. The mean recovery and relative standard deviation of these samples provide an initial statement of precision and accuracy at the LLOQ. In most cases the mean recovery should be +/- 35% of the true value and RSD should be < 20%. In-house limits may be calculated when sufficient data points exist. Monitoring recovery of LLOQ over time is useful for assessing precision and bias.

Ongoing LLOQ verification, at a minimum, is on a quarterly basis to validate quantitation capability at low analyte concentration levels. This verification may be accomplished either with clean control material (e.g., reagent water, method blanks. Optimally, the LLOQ should be less than the desired regulatory action levels based on the stated project-specific requirements.

13. Data Evaluation, Calculations and Reporting

13.1 If dilutions were performed, the appropriate factors must be applied to sample values. All results must be reported with up to three significant figures.

13.2 Soil samples

Soil samples are calculated as follows:

$$A = \frac{\text{Sample weight (grams)}}{\text{Final Volume (mL)}}$$

$$B \text{ (concentration in mg/Kg)} = \frac{\text{Concentration of analyte (mg/L)}}{A}$$

13.2.1 Dry weight correction

The LIMS calculates the dry weight correction, however it is calculated as follows:

$$\text{Final concentration in mg/Kg dry weight} = \frac{B}{\%\ \text{Solids}}$$

13.3 Liquid samples

Liquid samples are calculated as follows:

$$\text{Dilution Factor} = \frac{\text{Final Volume (mL)}}{\text{Sample Volume (mL)}}$$

Final concentration in mg/L = Concentration of analyte (mg/L) x Dilution Factor

13.4 Calculations for Hardness

The method for determining hardness is to compute it from the results of separate determinations of Calcium and Magnesium on aqueous samples.

13.4.1 Total Hardness

Total Hardness, mg equivalent CaCO3/L = [2.497 (Ca, mg/L)] + [4.118 (Mg, mg/L)]

13.4.2 Calcium Hardness

Calcium Hardness, mg equivalent CaCO3/L = [2.497 (Ca, mg/L)]

14. Method Performance

14.1 Detection Limit Study (DL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the DL, LOD, and/or LOQ as outlined in Alpha SOP ID 1732 unless superseded in the SOP. These studies performed by the laboratory are maintained on file for review

14.2 Demonstration of Capability Studies

14.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

14.2.2 Continuing (DOC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples

14.3 Instrument Detection Limits (IDLs)

Instrument detection limits (IDLs) are useful means to evaluate the instrument noise level and response changes over time for each analyte from a series of reagent blank analyses to obtain a calculated concentration. They are not to be confused with the lower limit of quantitation, nor should they be used in establishing this limit. It may be helpful to compare the calculated IDLs to the established lower limit of quantitation, however, it should be understood that the lower limit of quantitation needs to be verified.

Instrument Detection limits (in µg/L) can be estimated by calculating the average of the standard deviations of the three runs on three non-consecutive days from the analysis of a reagent blank solution with seven consecutive measurements per day. Each measurement must be performed as though it were a separate analytical sample (i.e. each measurement must be followed by a rinse and/or any other procedure normally performed between the analysis of separate samples). IDLs should be determined at least once using new equipment, after major instrument maintenance such as changing the detector, and/or at a frequency designated by the project and a record of time and date kept in the instrument maintenance log book.

15. Pollution Prevention and Waste Management

Refer to Alpha's Chemical Hygiene Plan and Hazardous Waste Management and Disposal SOP for further pollution prevention and waste management information.

Table 4 Calibration Standards

Multi-element standard (Section 8.4) containing the following:

High Range Elements (HR): 1000 mg/L of the following: Fe, K, Ca, Na, Mg, Sr

Low Range Elements (LR): 10 mg/L of the following: Ag, Al, As, Ba, Be, Cd, Co, Cr, Cu, Mn, Mo, Ni, Pb, Sb, Se, Tl, V, Zn, Th, U

All Calibration Standards are purchased in 5% HNO3, Tr HF (v/v).
Lithium is analyzed with a single standard curve matching the levels listed below for the routine curve.

Standard #1 (0.2 µg/L LR, 20 ug/L HR): Dilute Standard #3: 1.0 mL to 50mL final volume 1% HNO_3 (v/v).

Standard #2 (1.0 µg/L LR, 100 ug/L HR): Dilute Standard #3: 5.0 mL to 50mL final volume 1% HNO_3 (v/v).

Standard #3 (10.0 µg/L LR, 1000 ug/L HR): Dilute 0.05 mL to 50mL final volume 1% HNO_3 (v/v).

Standard #4 (60.0 µg/L LR, 1000 ug/L HR): Dilute 0.3 mL to 50mL final volume 1% HNO_3 (v/v).

Standard #5 (120.0 µg/L LR, 12000 ug/L HR): Dilute 0.6 mL to 50mL final volume 1% HNO_3 (v/v).

89	Yttrium (IS)
64, **66**, **68**, **67**, 70	Zinc

NOTE: Method 6020 is recommended for only those analytes listed in Table 1. Other elements are included in this Table because they are potential interferents (I) in the determination of recommended analytes, or because they are commonly used internal standards (IS). Isotopes are listed in descending order of natural abundance. The most useful isotopes are underlined and in boldface, although certain matrices may require the use of alternative isotopes.

[a] These masses are also useful for interference correction (Section 4.2)

[b] Internal standard must be enriched in the 6Li isotope. This minimizes interference from indigenous Li

Table 8 Internal Standard

Multiple Element Standard, purchased (Section 8.5), 100mg/L of ^{6}Li, ^{45}Sc, ^{74}Ge, ^{103}Rh, ^{115}In, ^{159}Tb, ^{175}Lu, ^{209}Bi

Working Internal Standard (IS) Solution (1 mg/L solution) Dilute 10.0 mL to 1L final volume 1% HNO_3 (v/v).

Table 9 Tune Solution

Tune Solution: 100 ug/L multi-element standard, purchased for ^{7}Li ^{9}Be, ^{58}Ce ^{59}Co, ^{115}In, ^{137}Ba and ^{208} Pb, ^{238}U in 1% HNO_3 (v/v) (Section 8.6).

Working Tune Solution: Dilute 1.0 mL of 100 ug/L multi-element standard for ^{7}Li ^{9}Be, ^{58}Ce ^{59}Co, ^{115}In, ^{137}Ba and ^{208}Pb, ^{238}U with 1% HNO_3 (v/v) to 100mL final volume. This will give a final concentration of these metals at 1.0µg/L.

Table 10 ICV Solution

Multiple Element Standard, purchased (Section 8.7):

1000mg/L of K, Na, Ca, Mg, Fe, Sr
10mg/L of Ag, Al, As, Ba, Be, Cd, Co, Cr, Cu, Mn, Mo, Ni, Pb, Sb, Se, Tl, V, An, Th, U

Working ICV Solution: Dilute 1.0 mL with 0.25% HNO_3 (v/v) to 50mL final volume. This will give the following concentrations:

5000µg/L of K, Na, Ca, Mg, Fe, Sr

50µg/L of Ag, Al, As, Ba, Be, Cd, Co, Cr, Cu, Mn, Mo, Ni, Pb, Sb, Se, Tl, V, An, Th, U

Table 11 CCV Solution

Multi-element standard (Section 8.4) containing the following:

High Range Elements (HR): 1000 mg/L of the following: Fe, K, Ca, Na, Mg, Sr

Low Range Elements (LR): 10 mg/L of the following: Ag, Al, As, Ba, Be, Cd, Co, Cr, Cu, Mn, Mo, Ni, Pb, Sb, Se, Tl, V, Zn, Th, U

All Standards are purchased in 5% HNO3, Tr HF (v/v).

60.0 µg/L LR, **1000 ug/L** HR: Dilute 0.3 mL to 50mL final volume 1% HNO_3 (v/v).

Table 12 Spectral Interference Check Solutions

SIC, High-Purity Standards Cat. #ICP-MS-ICS-2 A (Section 8.8):

20000 mg/L of Cl^- **3000 mg/L Ca**
2500 mg/L Fe, Na
2000 mg/L of C
1000 mg/L of Al, K, Mg, P, S
20 mg/L of Mo, Ti

Working SIC Solution: Dilute 5 mL of High-Purity Standards Cat. #ICP-MS-ICS-2 A, with 1% HNO_3 (v/v) to 50mL final volume. This will give the following concentrations:

2000 mg/L of Cl^-
300 mg/L Ca
250 mg/L Fe, Na
200 mg/L of C
100 mg/L of Al, K, Mg, P, S
2 mg/L of Mo, Ti

Low Level Mercury Determination by Purge and Trap Cold Vapor Atomic Fluorescence Technique (CVAF) Using CETAC M-8000

References: **Method 1631, Rev. E,** Mercury in Water by Oxidation, Purge and Trap, and Cold Vapor Atomic Fluorescence Spectrometry. U.S. EPA Office of Water, Office of Science and Technology. August 2002. EPA-821-R-02-019.

Appendix to Method 1631, Total Mercury in Tissue, Sludge, Sediment, and Soil by Acid Digestion and BrCl Oxidation, January 2001. EPA-821-R-01-013

Determination of Mercury in Seawater at Sub-Nanogram per Liter Levels. Bloom, N.S. and E.A. Crecilius, Marine Chemistry, 14, 49-59. 1983.

1. Scope and Application

Matrices: The method is applicable to total and dissolved mercury in aqueous samples, tissue, sludge, sediment and soil.

Definitions: Refer to Alpha Analytical Quality Manual.

Three procedures for the analysis of mercury by cold vapor atomic fluorescence spectrometry are discussed in this SOP.

Method 1631 for aqueous samples

This procedure utilizes a bromine chloride digestion. Samples are then decolorized using hydroxylamine hydrochloride (optional) and analyzed following reduction with stannous chloride. Elemental mercury is then purged from solution and collected on a gold trap. The trap is heated to desorb mercury and analyzed by atomic fluorescence spectrometry. The reporting limit is 0.5 ng/L and the linear range of the analysis is 100 ng/L which may be extended with dilution.

Method 1631 for tissue (digestion II as outlined in Appendix to 1631)

This procedure is preferred for matrices containing organic materials, such as sludge and plant and animal tissues. An aliquot of sample is digested with HNO_3/H_2SO_4. The digestate is diluted with BrCl solution to destroy any remaining organic material. The reporting limit is 0.001 mg/Kg assuming 0.5g sample and 100% solids.

Method 1631 for sediment and soil (digestion I as outlined in Appendix to 1631)

This procedure is preferred for geological materials and is capable of rapid and compete dissolution of inorganic mercury. A sample aliquot is digested with HCl/HNO3 followed by addition of BrCl to destroy any organic material. The reporting limit is 0.001 mg/Kg assuming 0.5g sample and 100% solids.

Parameter	CAS
Mercury (Hg)	7439-97-6

2. Summary of Method

Mercury is determined by cold vapor atomic fluorescence spectrometry following digestion with an acidic bromine chloride solution. Bromine chloride is prepared by mixing potassium bromide with potassium bromate solutions with hydrochloric acid producing a yellow solution. Bromine chloride is known to oxidize inorganic and organomercury compounds.

If a yellow color does not persist after addition of bromine chloride then additional solution must be added until a yellow color persists. The same volume of bromine chloride solution is added to all samples, the method blank, LCS and standards. After digestion is complete, 12% hydroxylamine hydrochloride solution may be added (not required) to the sample, the sample shaken and allowed to stand for 5 minutes. As samples are diluted 1:10 at the instrument, there is adequate stannous chloride to reduce both the BrCl and mercury to Hg^0.

Samples and standards are placed in the autosampler rack and analyzed by cold vapor atomic fluorescence spectrometry at a wavelength of 253.7 nm.

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one or more of the following laboratory personnel before performing the modification: Area Supervisor, Department Supervisor, Laboratory Director, or Quality Assurance Officer.

This method is restricted to use by or under the supervision of trained analysts. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

2.1 Method Modifications from Reference

New perfluoropolymer lined 250 mL bottles are used for aqueous sample collection for Method 1631E. These bottles are rinsed two times with Type I water, filled with DI water and 1 mL 0.2N BrCl and leached overnight. The bottles are rinsed two more times and placed in a new plastic bag for use. This cleaning procedure has been determined to be adequate through analysis of bottles blanks prepared for at least each lot of bottles.

3. Reporting Limits

The mercury aqueous is 0.0005 μg/L Method 1631.

The soil/sediment/tissue RL is 0.001 mg/Kg.

4. Interferences

4.1 Gold, silver and iodide are known interferences. An iodide test is performed on all samples suspected or known to contain iodide. Samples positive for iodide are pre-reduced with stannous chloride to clarify the brown color, analysis should proceed immediately.

4.1.1 Place about 15 to 20 drops of the sample solution into cup and add 8 to 10 drops of the 1 mol/L silver nitrate solution. The formation of a yellow precipitate represents a positive test for iodide.

4.1.2 Prepare a starch solution by dissolving 1g of soluble starch in 100mL of distilled water.

4.1.3 Place about 20 drops of the sample solution in a test tube and add 1 to 2 drops of sodium hypochlorite (household bleach). The sample should turn brownish-red if iodide is present.

4.1.4 Shake the test tube and add 4 or 5 drops of starch solution. A dark blue coloration upon addition of the starch confirms the presence of iodide.

It may be necessary to clean the analytical system with 4N HCl following analysis of a sample with high iodide concentrations (typically greater than 30 mg/L).

4.2 Sulfide concentrations up to 24 mg/L produce no interference problems.

4.3 High concentrations of gold and silver in a sample may suppress mercury reduction.

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material safety data sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

The use of laboratory equipment and chemicals exposes the analyst to several potential hazards. Good laboratory techniques and safety practices shall be followed at all times. Eating, drinking, smoking, or the application of cosmetics is not permitted in the laboratory area. Horseplay of any kind is prohibited. Pipetting by mouth is not permitted. All Personal Protective Equipment (PPE) must be removed before leaving the laboratory area and before entering the employee lounge or eating area. Always wash your hands before leaving the laboratory. All relevant Material Safety Data Sheets (MSDSs) are kept alphabetically in the centrally located file storage, in the common area outside of the Information Technology (IT) offices.

Approved PPE, which includes Safety Glasses, Gloves and Lab Coats, must be worn at ***all*** times when handling samples, reagents, chemicals, or when in the vicinity of others handling these items, so that dermal contact is avoided. All standards, reagents and solvents shall be handled under a hood using the proper PPE. All flammable solvents must be kept in the flammable storage cabinet, and returned to the cabinet immediately after use. When transporting chemicals, use a secure transporting devise and/or secondary outer container. Chemical storage is properly segregated and adequately ventilated to reduce the possibility of hazardous reactions. Chemical storage in work areas shall be kept to a minimum. Storage on bench tops or other work surfaces, except temporary, is not permitted.

Spilled samples, solvents, reagents, and water must be cleaned up from bench tops, instruments and autosampler surfaces immediately. A spill is considered a quantity of hazardous material if it is two times greater than the normal working volume. Concentrated solvents, acids or bases present a moderate to extreme hazard to the skin and mucous membranes. If contact with the skin occurs, immediately flush with large volumes of water. In the case of acidic/basic spills, the *Spill Kit* located in each laboratory shall be utilized before attempting to cleanup the spill. Although procedures are

designed to minimize the possibility of an accident, all injuries or accidents, regardless of the nature or severity, are to be reported to the Department Manager Supervisor immediately. If an employee discovers a potentially unsafe condition, this must be reported to the Department Manager Supervisor immediately. No employee should feel compelled to work in a situation where they do not feel entirely informed, trained, or safe.

Analytical instrumentation poses the unique possibility of exposure to high voltages. Other than the *routine* instrument maintenance, as listed in the front of every Instrument Maintenance Logbook, at no time shall an instrument operator attempt to maintenance an instrument alone, or without the proper training, supervision or instruction. Caution must always be used in the presence of moving parts (autosamplers) and hot surfaces (injection ports).

Compressed gas cylinders shall only be moved with the dolly supplied for this specific purpose. The cap must be on the cylinder while it is being moved. The tank must be secured when in its final position. All spent tanks are to be returned in the same manner, and secured until removed by the vendor. Liquid argon or nitrogen represents a potential cryogenic hazard and safe-handling procedures must be used at all times.

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

Aqueous samples collected for Methods 1631 are collected in pre-cleaned fluoropolymer bottles with tightly fitting fluoropolymer caps. Atmospheric mercury is known to diffuse through polyethylene bottles at levels below 0.05 µg/L.

Fluoropolymer bottles supplied by the laboratory for sample collection by Methods 1631 must be tested prior to sampling. 5% of a new lot of bottles are tested by adding DI water and 0.25 mL of BrCl and letting stand overnight. Mercury concentrations in the bottles must be less than 0.5 ng/L.

Sediments and tissues are collected in amber glass jars.

6.2 Sample Preservation

Samples collected for Methods 1631 may be preserved with 5 mL/L of 12 N HCl or 5 mL/L of BrCl solution (Section 8.8) if only total Hg is being analyzed. Sample preservation at the laboratory is recorded in the Sample Preservation/Filtration Log Book in the Metals Laboratory.

Samples collected and preserved under these conditions are stable for 90 days for Method 1631E.

6.3 Sample Shipping

No special sample shipping requirements. Typical shipping procedures may be found in the Alpha Sample Receipt & Login SOP (08-01).

6.4 Sample Handling

Samples may be stored at room temperature in the laboratory. It is suggested that the sample containers for samples being analyzed by Methods 1631 be stored in new polyethylene bags until analysis to prevent possible contamination.

7. Equipment and Supplies

7.1 Instrument: CETAC M-8000 equipped with a PC loaded with instrumental software,. The instrument is connected to a source of high-purity, mercury free argon regulated to 15 PSI.

7.2 Santoprene Peristaltic Pump Tubing: Various tubing sizes for reagent pump and autosampler rinse pump.

7.3 Glassware for Digestion: Pre-cleaned 50mL disposable polyethylene screw cap digestion tubes.

7.4 Other: Adjustable Eppendorf pipettes and replacement tips.

8. Reagents and Standards

ACS Trace Metal grade chemicals shall be used in all tests. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination. If the purity of a reagent is in question, analyze for contamination. If the concentration is less than the MDL then the reagent is acceptable.

Solutions below expire yearly unless noted and are stored at room temperature.

8.1 Deionized (DI) water: The Barnstead NANO-pure system provides Type I water used in the preparation of samples and standards.

8.2 Hydrochloric acid, concentrated (HCl): ACS reagent grade, Fisher #A508-212, or equivalent. Lots should be checked for purity prior to use and the results stored in a reagent check log book.

8.3 Nitric acid, concentrated (HNO_3): ACS reagent grade, Fisher #A509-212, or equivalent. Lots should be checked for purity prior to use and the results stored in a reagent check log book.

8.3.1 2% HCl/2%HNO_3: Add 20mL concentrated HCl and 20mL concentrated HNO_3 to approximately 500mL DI and bring to 1L with DI. Larger volumes are prepared in a similar manner.

8.3.2 10% HNO_3: Add 100 concentrated HNO_3 to approximately 500mL DI and bring to 1L with DI. Larger volumes are prepared in a similar manner.

8.4 Hydroxylamine hydrochloride ($NH_2OH{\cdot}HCl$): ACS reagent grade, VWR #HX0770-1, or equivalent. Reagent expires 4 years from date received.

8.4.1 12% Hydroxylamine Hydrochloride solution: Add 12g Hydroxylamine hydrochloride ($NH_2OH{\cdot}HCl$) per 100 mL of DI. Prepare in 125 mL fluorocarbon lined bottle. Prepare every 6 months or as needed.

8.5 Stannous Chloride ($SnCl_2{\cdot}H_2O$): ACS reagent grade, Fisher #T142-500, or equivalent. Reagent expires 4 years from date received.

8.5.1 10% Stannous Chloride/7% HCl Solution: Add 100g $SnCl_2$ and 70 mL concentrated HCl to 500mL DI, dilute to 1 L with DI. Solution is stable for 3 days. Solution is purged with argon at 2L/minute for 30 minutes to remove Hg impurities if necessary.

8.6 Potassium Bromate ($KBrO_3$): ACS grade, Fisher #P207-250. Bake in muffle furnace at 250°C for 8 hours to remove mercury impurities if necessary. Reagent expires 4 years from date received.

8.7 Potassium Bromide (KBr): ACS grade, Fisher #P205-500. Bake in muffle furnace at 250°C for 8 hours to remove mercury impurities if necessary. Reagent expires 5 years from date received.

8.8 Bromine Chloride (0.2N BrCl) Solution: Prepare in BOD bottle or fluoropolymer bottle under fume hood by adding 2.7g KBr and 3.8g $KBrO_3$ to 250mL concentrated HCl and mix. Solution will turn yellow. **Free Halogens are generated from this solution. Seal bottle when taking out of fume hood.** Prepare every 6 months or as needed.

8.9 0.07N Bromine Chloride (BrCl) Solution: Prepare in BOD bottle or fluoropolymer bottle under fume hood by diluting 300 mL of 0.2N BrCl to 1000mL DI. **Seal bottle when taking out of fume hood.** Prepare every 6 months or as needed.

8.10 0.02N Bromine Chloride (BrCl) Solution: Prepare in BOD bottle or PEF bottle under fume hood by diluting 100 mL of 0.2N BrCl to 1000mL DI. **Seal bottle when taking out of fume hood.** Prepare every 6 months or as needed.

8.11 HNO_3/H_2SO_4 Solution: In a hood, slowly add 300 mL of concentrated H2SO4 to 700 mL of concentrated HNO3 in a fluoropolymer bottle. Prepare every 6 months or as needed.

8.12 Stock and Working Standards: Store standards at room temperature out of direct light. All stock and working calibration standards expiration dates are based on manufacturer expiration date or one year from date received.

8.12.1 1000 mg/L Stock Calibration Mercury Standard: Ultra Scientific #ICP-080, or equivalent.

8.12.1.1 1000µg/L Working Standard: Prepare by adding 0.1 mL of 1000 mg/L stock to a 100 mL volumetric flask containing 2% HCl. Bring to volume with DI water and pour into brown bottle. This standard is identified as **C-date-V** in the Mercury Standards Preparation Log.

8.12.1.2 100 µg/L Intermediate Standard: Prepare by adding 1 mL of the 1000 µg/L working standard to 15 mL graduated centrifuge tube containing 2% HCl. Bring to 10 ml final volume with DI water. This intermediate standard is used for calibration standards preparation and then discarded.

8.12.1.3 5 µg/L Working Standard: Prepare by adding 0.25 mL of 1000 µg/L working standard to a 50 mL graduated screw cap centrifuge tube containing 2% HCl. Bring to 50 mL final volume with DI water. This standard is identified as **C-date-VS** in the Mercury Standards Preparation Log.

8.12.2 1000 mg/L Stock ICV Mercury Standard: Inorganic Ventures #CGHG-1, or equivalent.

8.12.2.1 1000 µg/L ICV Working Standard: Prepare by adding 0.1 mL of 1000 mg/L ICV stock to a 100 mL volumetric flask containing 2% HCl. Bring to volume with DI water and pour into brown bottle. This standard is identified as **I-date-V** in the Mercury Standards Preparation Log.

8.12.2.2 5 µg/L ICV Working Standard: Prepare by adding 0.25 mL of 1000 µg/L working standard to a 50 mL graduated screw cap centrifuge tube containing 2% HCl. Bring to 50 mL final volume with DI water. This standard is identified as **I-date-VS** in the Mercury Standards Preparation Log.

8.13 Calibration and Calibration Check Standards: Store standards at room temperature out of direct light.

Calibration and calibration check standards are prepared in 50 ml polypropylene (or equivalent) screw cap digestion tubes containing about 50 mL of DI water and 0.5 mL of BrCl(Section 8.8) solution. The STD0 consists of 50mL DI and 0.5mL BrCl solution.

After addition of the working standard, calibration standards are brought to 50mL final volume with DI water and optionally decolorized with 0.1 mL of hydroxylamine hydrochloride solution (Section 8.4.1). If sample preparation required additional quantities of BrCl to maintain a yellow color, then the same amount of BrCl is added to calibration and calibration check standards.

8.13.1 Standards Preparation for Method 1631

Standard ID	Vol. 5 µg/L Standard (Section 8.12.1.3) (mL)	Vol. STD5 (mL)	Final Concentration (µg/L)
STD0	-	-	0.0
STD1	-	0.25	0.0005
STD2	0.05	-	0.005
STD3	0.25	-	0.025
STD4	0.5	-	0.050
STD5	1.0	-	0.100
ICV,CCV,MS Section 8.12.2.2)	0.05	-	0.005

8.14 Argon Gas: Ultra-high purity

8.15 1M Silver Nitrate solution: purchased

8.16 Soluble starch

8.17 Chlorine Bleach: Clorox brand or equivalent (6% sodium hypochlorite)

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

9.1 Blanks

9.1.1 Method Blank

A method blank must be prepared once per every 20 samples or per digestion batch, whichever is more frequent. Prepare with same reagents as in the sample digests where applicable.

Mercury must not be detectable in the method blank at a concentration greater than the reporting limit.

For samples analyzed by Method 1631E, The mercury concentration in the Method Blank must be less than 0.5 ng/L or not to exceed one third of the regulatory limit if the data are to be used for regulatory purposes.

Corrective Action: May reanalyze once to determine if analytical error has occurred. Digestion of the method blank and all associated samples must be performed until the blank is in control. Samples cannot be analyzed until an acceptable method blank analysis is obtained. Exceptions may be made with approval of the Metals Department Manager, Laboratory Director or QAO, if the samples associated with the out of control method blank are non-detect for the elements of interest, or if sample concentrations are greater than 10x the blank levels. In such cases, the sample results are accepted without corrective action for the high method blank and the client is notified in a project narrative associated with the sample results.

9.1.2 Initial Calibration Blank (ICB)

An initial calibration blank must be analyzed immediately following the ICV(See 9.4).

An initial calibration blank may be analyzed immediately following calibration for Method 1631E.

Mercury must not be detectable in the ICB at a concentration greater than the reporting limit.

Corrective Action: May reanalyze once to determine if analytical error has occurred. If the concentration still exceeds the acceptance limit, stop and recalibrate the instrument. Samples cannot be analyzed until an acceptable ICB analysis is obtained. Exceptions may be made with approval of the Metals Department Manager, Laboratory Director or QAO, if the samples associated with the out of control blank are non-detect for mercury, or if sample concentrations are greater than 10x the blank levels. In such cases, the sample results are accepted without corrective action for the high blank and the client is notified in a project narrative associated with the sample results.

Note: The ICB is equivalent to a Reagent Blank for Method 1631E. The mercury concentration in the Reagent Blank is not to exceed 0.2 ng/L or one third of the regulatory limit.

9.1.3 Continuing Calibration Blank

A continuing calibration blank must be analyzed immediately following the CCV (see 9.5).

Mercury must not be detectable in the CCB at a concentration greater than the reporting limit.

Corrective Action: May reanalyze once to determine if analytical error has occurred. If the concentration still exceeds the acceptance limit, stop, recalibrate the instrument and reanalyze all associated samples. Samples cannot be analyzed until an acceptable CCB analysis is obtained. Exceptions may be made with approval of the Metals Department Manager, Laboratory Director or QAO, if the samples associated with the out of control blank are non-detect for the elements of interest, or if sample concentrations are greater than 10x the blank levels. In such cases, the sample results are accepted without corrective action for the high

method blank and the client is notified in a project narrative associated with the sample results.

Note: The CCB is equivalent to a Method Blank for Method 1631E. Three Method Blanks must be analyzed with each batch.

9.2 Initial Precision and Recovery (IPR) for Soil/Sediment and Tissue

IPR is a one time initial demonstration of performance. Four aliquots of the appropriate reference matrix(Teflon chips for soil/sediment and chicken breast for tissue) spiked with 4.0 ng of Hg. The average % recovery must be 75-125% and the RSD between the replicates <20%.

9.3 LCS/Ongoing Precision and Recovery (OPR) for Soil/Sediment and Tissue

OPR/LCS is a test of the analytical system including prep. Analyze one aliquot of appropriate reference matrix spiked with 4.0 ng of Hg. Recovery must be 70-130%.

LCS/OPR for aqueous samples, recovery must be 77-123%

Corrective Action: Analysis according to the method may be repeated once to see if an analytical error has occurred. If the concentration still exceeds the acceptance limit, stop and recalibrate the instrument. Samples cannot be analyzed until an acceptable OPR analysis is obtained.

9.4 Initial Calibration Verification (ICV)

An initial calibration verification standard from a source different from that used to calibrate the instrument must be analyzed immediately following calibration as an independent check of instrument performance. Nominal acceptance limits are 85% - 115% of the true value.

Corrective Action: Analysis according to the method may be repeated once to see if an analytical error has occurred. If the concentration still exceeds the acceptance limit, stop and recalibrate the instrument. Samples cannot be analyzed until an acceptable ICV analysis is obtained.

9.5 Continuing Calibration Verification (CCV)

A continuing calibration verification standard must be analyzed after analysis of no more than 10 samples as an on-going check of instrument performance. Nominal acceptance limits are 85% - 115% of the true value.

Corrective Action: Analysis according to the method may be repeated once to see if an analytical error has occurred. If the concentration still exceeds the acceptance limit, stop, recalibrate the instrument and reanalyze all associated samples. Results cannot be accepted until an acceptable CCV analysis is obtained. Exceptions may be made with approval of the Metals Department Manager, Laboratory Director or QAO, if the samples associated with a high recovery CCV are non-detect. In such cases, the sample results are accepted without corrective action for the high CCV recovery and the client is notified in a project narrative associated with the sample results.

9.6 Matrix Spike/Matrix Spike Duplicate

An MS/MSD pair must be analyzed at a frequency of 1 per 10 samples. Spike samples at level in IPR/OPR (4.0 ng Hg for sediment/tissue, 0.005ug/L for aqueous). MS/MSD recovery criteria

70-130% and RPD <30% for sediment/tissue, 71-125% and RPD 24% for aqueous samples.

Corrective Action: For sediment/tissue, if MS/MSD fail and sample concentration is > ½ the spike concentration, the MS/MSD must be spiked at 2-5X the sample concentration and reanalyzed.

If the %RPD between the MS and MSD is not acceptable, a narrative is submitted with the data for inclusion on the final report.

9.7 Laboratory Duplicate

Duplicate analyses (matrix or sample duplicate) must be performed once per 20 samples 5% frequency), or per digestion batch, whichever is more frequent.

Acceptable relative percent differences (RPD) of duplicates is ≤20%. Acceptance criterion is not applicable to sample concentrations less than 5 times the reporting limit. Calculate the RPD as follows:

$$RPD = \frac{R1 - R2}{\frac{[R1 + R2]}{2}} \times 100$$

where:

R1 = sample Replicate #1
R2 = sample Replicate #2

Corrective Action: Include a project narrative.

9.8 Standard Reference Materials

Digest and analyze an appropriate reference material for the matrix, (animal tissue/plant tissue/soil/sediment). Recommended SRMs:

Soil/solid – ERA D076 (Metals in Soil) or equivalent

Sediment – NIST 2702 (Marine Sediment)

Plant tissue – NIST 1515 (Apple Leaves)

Animal tissue – NIST 2976 (Mussel tissue) or Tort-2 (Lobster tissue)

One SRM per batch must be analyzed and pass acceptance criteria

Corrective Action: Analysis according to the method may be repeated once to see if an analytical error has occurred. If the concentration still exceeds the acceptance limit, stop, recalibrate the instrument and reanalyze all associated samples. Results cannot be accepted until an acceptable SRM analysis is obtained. Exceptions may be made with approval of the Metals Department Manager, Laboratory Director or QAO, if the samples associated with a high recovery SRM are non-detect. In such cases, the sample results are accepted without corrective action for the high SRM recovery and the client is notified in a project narrative associated with the sample results.

9.9 Method-specific Quality Control Samples

Method 1631 requires that three calibration or system blanks be analyzed with the mean blank concentration used to blank correct all Data.

The average blank must be less than one third of the regulatory limit or 0.5 ng/L with the RSD less than <0.1 ng/L if the data is to be used for regulatory purposes.

Method 1631 requires that the recovery of mercury from the low calibration standard be within the range of 75% -125%.

The RSD of the mean calibration factor must be less than or equal to 15%.

9.10 Method Sequence

- Initial Calibration

- CCB

10. Procedure

10.1 Equipment Set-up

Samples are prioritized by the Metals Department Manager or Preparation Group Leader for digestion based on hold time and client due date. The analyst must be familiar with instrument software and hardware as described in the user manuals supplied with the instrument, and have a completed IDC on file (Section 13.2) prior to any sample analysis.

10.1.1 Digestion I (Tissue/Sludge)

To a 50mL digestion tube, weigh 0.5 to 1.5 grams of material. Use less material if high organic content is expected.

Spike the OPR and MS/MSD samples with 0.08 mL of 5 ug/L intermediate (Section 8.12.2.2)

To each sample, add 10.0 mL of HNO3/H2SO4 (Section 8.11). Loosely cap with a watch glass. Carbohydrate based samples may react violently, allow these type of samples to react at room temperature for 4 hours prior to heating.

Place samples into digestion block. Monitor samples and remove from heat if excessive foaming occurs. Reflux for 2-3 hours.

After digestion, dilute samples with 0.02N BrCl (Section 8.10) and mix thoroughly. Allow samples to oxidize organic mercury for 4 hours prior to analysis.

Diluted digestates may be stored up to one year in glass or fluoropolymer containers.

10.1.2 Digestion II (Soil/Sediment)

To a 50mL digestion tube, weigh 0.5-1.5 grams of sample. Samples may be sieved if necessary to assure homogeneity.

Spike the OPR and MS/MSD samples with 0.08 mL of 5 ug/L intermediate (Section 8.12.2.2).

In a hood, add 8.0 mL concentrated HCl, then add 2.0 mL concentrated HNO_3. Allow to digest at room temperature for at least 4 hours, preferably overnight.

Dilute the digestate to 50 mL with 0.07N BrCl and shake thoroughly. Samples may be filtered through a 0.45µm filter or centrifuged for 20 minutes at 3000 RPM.

Diluted digestates may be stored up to one year in glass or fluoropolymer containers.

10.1.3 Aqueous Samples

To a 50mL digestion tube, add 50mL of sample and 0.25 mL of BrCl solution (Section 8.8). The sample should remain a yellow color. If not, add more BrCl solution to all samples, the Method Blank, LCS and all samples until yellow color persists.

Spike the MS/MSD and LCS with 0.05 L of 5ug/L Working Standard (Section 8.12.2.2).

Let stand for 12 hours and decolorize(optional) with 0.05mL of 12% hydroxylamine solution (Section 8.4.1).

10.2 Initial Calibration

The instrument is calibrated prior to sample analysis and at least once every 24 hours. Refer to Section 8.13 for the preparation of calibration standards for each determinative method.

For Method 1631, all standards and sample signals are blank corrected using the mean of the three calibration blanks analyzed at the beginning of the run. The instrument software calculates a mean calibration factor, calibration factor RSD and a recovery of the low calibration standard. The RSD of the mean calibration factor must be ≤ 15% and the recovery of the low calibration standard must be within the 75% - 125% range.

10.3 Equipment Operation and Sample Processing

Power is turned on to the instrument, autosampler, PC and argon gas supply. Peristaltic pump tubing is inspected for wear and replaced if necessary.

10.3.1 STARTUP

Instrument startup (cold start).

Power up M-8000 and autosampler and open the QuickTrace software. If system is to be used for analysis in the ppb range a minimum of 15 minutes warm-up time is required. If system is to be run in the ppt range a minimum of 30 minutes warm-up time is required.

Instrument startup (warm start). *The instrument and auto-sampler are on and stable. It is ok to leave the units powered up with the lamp and gas off.*
Place the auto-sampler rinse tubing into the rinse bottle(2%HCl/2%HNO_3)(Section 8.3.2). Turn on the lamp and carrier gas. A minimum 15-minute warm-up time is required.

Verify that the sample capillary (inlet insert) is 0.5mm above the Gas/liquid separator (GLS) center post.

Open vents on waste container.

Inspect peristaltic pump tubing for flat spots replace if necessary. Place the peristaltic pump tubing in their appropriate shoes and bridge stops. Do not lock shoe clamps at this time.

Open instrument controls and start auto-sampler rinse pump if not already operating (click pump on and probe down).

Place the SnCl2 capillary in the 10%$SnCl_3$/7% HCl (Section 8.5.1). and start the peristaltic pump at desired pump speed, which will usually match the method speed.

Lock down the peristaltic shoe clamps.

Inspect liquid flows. The GLS drain should be flowing smoothly with no build up or pulsing of liquid. The waste line from the peristaltic pump to the waste container should be liquid/gas etc… with no vibration. If this is not the case upon inspection, stop immediately and change GLS drain line and or waste line. The autosampler rinse station should have a convex liquid bubble adhering to the sample probe. If this is not the case, check that the rinse reservoir supply tubes are immersed in the rinse. If they are then check the rinse pump and pump tubing. Replace the tubing if necessary.

Wet the GLS center post. In instrument controls set the GLS gas flow to high and pump speed to 100%, pinch the drain line prior to the tee on the peristaltic pump drain tubing inlet side, let two or three bubbles go to the top of the GLS center post. Release the drain line and allow the liquid level to restore itself to normal operating levels before continuing to the next step. If the liquid does not bubble and the over flow sensor activates then clear the overflow and retry.

Connect the GLS exhaust tube (Nafion) or soda lime tubing to the GLS.

Place reagent capillaries in the reagent bottles.

Open the appropriate worksheet and verify that the gas flow and pump speed in the worksheet matches what is listed in >instrument>M-8000 controls, if the flow and speed are not the same make the necessary change in instrument controls or click the auto set icon on the menu bar. This will stabilize the instrument before auto zeroing and running a peak profile.

Zero the M-8000 using the auto zero.

If major maintenance was performed since the last start up perform the following check: Peak profile a standard with a minimum peak area response of 200K and verify the baseline is stable and the sample peak falls within the method integration times. Perform the necessary maintenance to meet this before proceeding with calibration and analysis.

Initiate sample analysis by clicking on the start button on the analysis page. If a sample concentration is greater than the highest standard concentration of the calibration curve, dilute the digestate and reanalyze.

10.3.2 SHUTTING DOWN:

Place the SnCl2 capillary in a beaker of 10% HNO3 and cap the SnCl2 bottle.

Rinse the system for a minimum of ten minutes with acid flowing.

Place the reagent capillaries in a beaker of DI water and rinse the system for one minute.

Raise sample probe via >instrument>auto-sampler controls (click probe up and pump off).

Remove reagent capillaries from DI water.

Allow the drain and waste lines to run completely dry.

Turn off peristaltic pump via >instrument>M-8000>pump off.

Release peristaltic shoe clamps and release the pump tubing from their bridge stops, release and relax peristaltic pump tubing.

Close vents on waste container.

Disconnect the GLS exhaust line (Nafion) or soda lime tubing from the GLS.

Turn off gas and lamp >instrument>M-8000>controls (note: you may want to turn off main supply gas at the Dewar or cylinder source).

If you are going to use the instrument the next day or in the near future, leave the software on the page >instrument>M-8000 controls>auto-sampler. It will then be ready for a warm start.

If you are not going to be using the instrument in the near future then exit the QuickTrace software and turn off the autodiluter, autosampler and M-8000 and pump.

The analysis method is selected and the autosampler template is selected. Once sample ID's have been typed in, the file is saved as the LIMS workgroup number.

Following analysis, the data file is exported to the LIMS on the O:Metals\CETAC drive for data processing.

10.4 Continuing Calibration

Periodically and at the end of the analysis, CCV standards (Section 9.5) and CCB standards (Section 9.1.3) are analyzed.

10.5 Preventive Maintenance

Inspect pump tubing for signs of wear and replace (recommended at least monthly). Clean gas/liquid separator as needed. Change dryer tube annually.

11. Data Evaluation, Calculations and Reporting

All results for the metals elements of interests are reportable without qualification if digestion and analytical holding times are met, preservation (including cooler temperatures) are met, all QC criteria defined in the table below are met, and matrix interference is not suspected during digestion or analysis of the samples

Sample concentrations for Method 1631 using the CETAC M-8000 are calculated based on peak area.

Sample concentrations are calculated as follows:

Sample Concentration = $((A_s - A_{mcb}) * (V_f/V_i) * DF)/CFm$

Where:

A_s = sample peak height or area
A_{mcb} = Mean calibration blank peak height or area
V_f = Final volume from preparation
V_i = Initial volume from preparation
DF = dilution factor
CFm = mean calibration factor for the calibration curve

Note: The final volume from the sample preparation would reflect any changes in volume due to BrCl added to sample.

QC Parameter	Acceptance Criteria
Method Blank	< reporting limit
OPR/LCS (sediment/tissue)	70-130% Recovery
OPR/LCS (aqueous)	77-123% Recovery
SRM (sediment/tissue)	% Recovery limits are specific to each SRM
Matrix Duplicate	≤ 20% RPD
Matrix Spike	70-130% Recovery(sediment/tissue) 71-125% Recovery (aqueous)
Matrix Spike Duplicate	≤ 30% RPD, 70-130% Recovery (sediment/tissue) ≤ 24% RPD, 71-125% Recovery (aqueous)

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

Section 9 outlines sample batch QC acceptance criteria. If non-compliant results are to be reported, the Metals Department Manager and/or the Laboratory Director must approve the reporting of these results. The laboratory Project Manager shall be notified, and may chose to relay the non-compliance to the client for approval, or other corrective action, such as re-sampling and re-analysis. The instrument analyst or Department Manager performing the secondary analytical review initiates a project narrative, and the narrative must clearly document the non-compliance and provide a reason for acceptance of these results.

13. Method Performance

13.1 Method Detection Limit Study (MDL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the MDL, LOD, and/or LOQ as outlined in Alpha SOP 1732. These studies performed by the laboratory are maintained on file for review.

13.2 Demonstration of Capability Studies

Refer to Alpha SOP 1739 for further information regarding IDC/DOC Generation.

13.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

13.3 Instrument Detection Limits

The instrument detection limit (IDL) is the smallest signal above the background noise that an instrument can detect. The IDL can be calculated taking the average of the standard deviations for three measurements of a reagent blank solution analyzed on three analytical runs on three non-consecutive days. Seven consecutive measurements must be taken per

day. The IDL samples are not required to go through sample digestion. Each measurement must be performed as though it were a separate sample.

14. Pollution Prevention and Waste Management

The *Hazardous Waste and Sample Disposal* SOP (1797), must be referenced for disposal of used standards, solvents, acids, reagents or other chemicals.

Once sample batches have completed digestion, the sample containers are stored in the metals lab and held for 30 days. If there is no sample remaining in the sample collection bottle, it may be rinsed and thrown away.

Once the samples have been held for 30 days, any aqueous sample remaining must be disposed in a 55-gallon drum labeled “Corrosive Liquid”.

Once satisfactory inorganic element results have been generated, the digestates are held for 30 days, or longer if specified by a client contract, then discarded into a 55-gallon drum labeled “Corrosive Liquid”.

All reagent waste generated during digestion must be stored in satellite containers in the metals preparation laboratory.

Once the reagent waste satellite containers are full, they must be emptied into 55-gallon drums marked “Corrosive Liquid”.

Refer to Alpha’s Chemical Hygiene Plan and Waste Management and Disposal SOP for further pollution prevention and waste management information.

Mercury Determination in Aqueous Samples by Cold Vapor Atomic Fluorescence Technique (CVAF)

References: **Method 7474,** Mercury in Sediment and Tissues by Atomic Flourescence Spectrometry. SW-846, Test Methods for Evaluating Solid Waste: Physical/Chemical Methods, EPA SW-846, Revision 0, February 2007.

1. Scope and Application

Matrices: The method is applicable to total and dissolved mercury in aqueous samples.

Definitions: Refer to Alpha Analytical Quality Manual.

Three procedures for the analysis of mercury by cold vapor atomic fluorescence spectrometry are discussed in this SOP.

Lab Method 7474 (modified)

This method utilizes a bromine chloride digestion. Samples are then decolorized using hydroxylamine hydrochloride and analyzed following reduction with stannous chloride. Elemental mercury is then purged from solution and analyzed by atomic fluorescence spectrometry. The reporting limit is 0.1 µg/L and the linear range of the analysis is 5 µg/L.

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one or more of the following laboratory personnel before performing the modification: Area Supervisor, Department Supervisor, Laboratory Director, or Quality Assurance Officer.

This method is restricted to use by or under the supervision of analysts experienced in the operation of the Mercury Analyzer and in the interpretation of Mercury data. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

Parameter	CAS
Mercury (Hg)	7439-97-6

2. Summary of Method

Mercury in aqueous samples is determined by cold vapor atomic fluorescence spectrometry following digestion with an acidic bromine chloride solution. Bromine chloride is prepared by mixing potassium bromide with potassium bromate solutions with hydrochloric acid producing a yellow solution. Bromine chloride is known to oxidize inorganic and organomercury compounds. Samples are digested by adding 5 ml of bromine chloride per liter of sample. Samples are allowed to digest for a minimum of 15 minutes.

If a yellow color does not persist after addition of bromine chloride then additional solution must be added until a yellow color persists. The same volume of bromine chloride solution is added to all samples, the method blank, LCS and standards. After digestion is complete, 12% hydroxyl amine

hydrochloride solution is added to the sample, the sample shaken and allowed to stand for 5 minutes. Additional hydroxyl amine hydrochloride is added if the yellow color from the bromine chloride solution persists.

Following stannous chloride reduction, samples and standards are placed in the autosampler rack and analyzed by cold vapor atomic fluorescence spectrometry at a wavelength of 253.7 nm.

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one or more of the following laboratory personnel before performing the modification: Area Supervisor, Department Supervisor, Laboratory Director, or Quality Assurance Officer.

This method is restricted to use by or under the supervision of trained analysts. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability, analyzing a proficiency test sample and completing the record of training.

After initial demonstration, ongoing demonstration is based on acceptable laboratory performance of at least a quarterly laboratory control sample or acceptable performance from an annual proficiency test sample. A major modification to this procedure requires demonstration of performance. The identification of major method modification requiring performance demonstration is directed by the Quality Assurance Officer and/or Laboratory Director on a case-by-case basis.

2.1 Method Modifications from Reference

Method 7474 is a test method for the analysis of mercury in Soil/Sediments and tissues. A reduced gain setting is used for decreased instrumental sensitivity for samples not requiring low level reporting limits (<0.1 µg/L).

The procedure used to prepare the bromine chloride solution has been modified from the method reference to that used in EPA method 1631E, 2002. There is no impact to the data as indicated by the performance of PT samples.

3. Reporting Limits

The mercury aqueous RL is 0.05 µg/L by Method 7474 Modified.

4. Interferences

4.1 Gold, silver and iodide are known interferences. Samples with iodide concentrations greater than 3 mg/L are pre-reduced with stannous chloride to clarify the brown color. It may be necessary to clean the analytical system with 4N HCl following analysis of a sample with iodide concentrations greater than 30 mg/L.

4.2 Sulfide concentrations up to 24 mg/L produce no interference problems.

4.3 High concentrations of gold and silver in a sample may suppress mercury reduction.

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material safety data sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

The use of laboratory equipment and chemicals exposes the analyst to several potential hazards. Good laboratory techniques and safety practices shall be followed at all times. Eating, drinking, smoking, or the application of cosmetics is not permitted in the laboratory area. Horseplay of any kind is prohibited. Pipetting by mouth is not permitted. All Personal Protective Equipment (PPE) must be removed before leaving the laboratory area and before entering the employee lounge or eating area. Always wash your hands before leaving the laboratory. All relevant Material Safety Data Sheets (MSDSs) are kept alphabetically in the centrally located file storage, in the common area outside of the Information Technology (IT) offices.

Approved PPE, which includes Safety Glasses, Gloves and Lab Coats, must be worn at ***all*** times when handling samples, reagents, chemicals, or when in the vicinity of others handling these items, so that dermal contact is avoided. All standards, reagents and solvents shall be handled under a hood using the proper PPE. All flammable solvents must be kept in the flammable storage cabinet, and returned to the cabinet immediately after use. When transporting chemicals, use a secure transporting devise and/or secondary outer container. Chemical storage is properly segregated and adequately ventilated to reduce the possibility of hazardous reactions. Chemical storage in work areas shall be kept to a minimum. Storage on bench tops or other work surfaces, except temporary, is not permitted.

Spilled samples, solvents, reagents, and water must be cleaned up from bench tops, instruments and autosampler surfaces immediately. A spill is considered a quantity of hazardous material if it is two times greater than the normal working volume. Concentrated solvents, acids or bases present a moderate to extreme hazard to the skin and mucous membranes. If contact with the skin occurs, immediately flush with large volumes of water. In the case of acidic/basic spills, the *Spill Kit* located in each laboratory shall be utilized before attempting to cleanup the spill. Although procedures are designed to minimize the possibility of an accident, all injuries or accidents, regardless of the nature or severity, are to be reported to the Department Manager Supervisor immediately. If an employee discovers a potentially unsafe condition, this must be reported to the Department Manager Supervisor immediately. No employee should feel compelled to work in a situation where they do not feel entirely informed, trained, or safe.

Analytical instrumentation poses the unique possibility of exposure to high voltages. Other than the *routine* instrument maintenance, as listed in the front of every Instrument Maintenance Logbook, at no time shall an instrument operator attempt to maintenance an instrument alone, or without the proper training, supervision or instruction. Caution must always be used in the presence of moving parts (autosamplers) and hot surfaces (injection ports).

Compressed gas cylinders shall only be moved with the dolly supplied for this specific purpose. The cap must be on the cylinder while it is being moved. The tank must be secured when in its final position. All spent tanks are to be returned in the same manner, and secured until removed by the

vendor. Liquid argon or nitrogen represents a potential cryogenic hazard and safe-handling procedures must be used at all times.

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

Samples collected for Method 7474 Modified are collected in polyethylene bottles. Bottle size will vary with project requirements.

6.2 Sample Preservation

Aqueous samples collected for Method 7474 Modified are preserved at pH ≤ 2 with 2 mL/L of 1:1 HNO_3.

Samples collected and preserved under these conditions are stable for 28 days for Method 7474.

6.3 Sample Shipping

No special sample shipping requirements. Typical shipping procedures may be found in the Alpha Sample Receipt & Login SOP (1559).

6.4 Sample Handling

Samples may be stored at room temperature in the laboratory.

7. Equipment and Supplies

7.1 Instrument: The PSA Millennium Merlin Atomic Fluorescence Analyzer equipped with a PC loaded with instrumental software, and PSA 20.400 autosampler. The instrument is connected to a source of high-purity, mercury free argon regulated to 50 PSI.

7.2 Santoprene Peristaltic Pump Tubing: Green/Green (PSA part number M025T002 or equivalent) for sample, blank and autosampler rinse, Grey/Grey (PSA part number M055T005 or equivalent) for stannous chloride.

7.3 Glassware for Digestion: Pre-cleaned 50mL disposable polyethylene screw cap digestion tubes. Rinse two times with DI water before use.

7.4 Other: Adjustable Eppendorf pipettes and replacement tips.

8. Reagents and Standards

ACS Trace Metal grade chemicals shall be used in all tests. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening

the accuracy of the determination. If the purity of a reagent is in question, analyze for contamination. If the concentration is less than the MDL then the reagent is acceptable.

Solutions below expire yearly unless noted and are stored at room temperature.

8.1 Deionized (DI) water: The Barnstead NANO-pure system provides Type I water used in the preparation of samples and standards.

8.2 Hydrochloric acid, concentrated (HCl): ACS reagent grade.

8.2.1 10% HCl: Add 100mL concentrated HCl to approximately 500mL DI and bring to 1L with DI. Larger volumes are prepared in a similar manner.

8.3 Nitric acid, concentrated (HNO_3): ACS reagent grade.

8.4 Hydroxylamine hydrochloride ($NH_2OH{\cdot}HCl$): ACS reagent grade. Reagent expires 4 years from date received.

8.4.1 12% Hydroxylamine Hydrochloride solution: Add 12g Hydroxylamine hydrochloride ($NH_2OH{\cdot}HCl$) per 100 mL of DI. Prepare in 125 mL fluorocarbon lined bottle.

8.5 Stannous Chloride ($SnCl_2{\cdot}H_20$): ACS reagent grade. Reagent expires 4 years from date received.

8.5.1 2% Stannous Chloride Solution: Add 20g to 1L of 10% HCl. Prepare daily. Solution is purged with argon at 2L/minute for 30 minutes to remove Hg impurities if necessary.

8.6 Potassium Bromate ($KBrO_3$): ACS grade. Bake in muffle furnace at 150°C for 8 hours to remove mercury impurities if necessary. Reagent expires 4 years from date received.

8.7 Potassium Bromide (KBr): ACS grade. Bake in muffle furnace at 150°C for 8 hours to remove mercury impurities if necessary. Reagent expires 5 years from date received.

8.8 Bromine Chloride (BrCl) Solution: Prepare in BOD bottle under fume hood by adding 2.7g KBr and 3.8g $KBrO_3$ to 250mL of concentrated HCl and mix. Solution will turn yellow. **Free Halogens are generated from this solution. Seal bottle when taking out of fume hood.** Prepare every 6 months or as needed.

8.9 Stock and Working Standards: Store standards at room temperature out of direct light. All stock and working calibration standards expiration dates are based on manufacturer expiration date or one year from date received.

8.9.1 1000 mg/L Stock Calibration Mercury Standard: Ultra Scientific #ICP-080, or equivalent.

8.9.1.1 1000µg/L Working Standard: Prepare by adding 0.1 mL of 1000 mg/L stock to a 100 mL volumetric flask containing 2% HCl. Bring to volume with DI water and pour into brown bottle. This standard is identified as **C-date-V** in the Mercury Standards Preparation Log.

8.9.1.2 100 µg/L Intermediate Standard: Prepare by adding 1 mL of the 1000 µg/L working standard to 15 mL graduated centrifuge tube containing 2% HCl. Bring to 10 ml final volume with DI water. This intermediate standard is used for calibration standards

preparation and then discarded.

8.9.1.3 5 µg/L Working Standard: Prepare by adding 0.25 mL of 1000 µg/L working standard to a 50 mL graduated screw cap centrifuge tube containing 2% HCl. Bring to 50 mL final volume with DI water. This standard is identified as **C-date-VS** in the Mercury Standards Preparation Log.

8.9.2 1000 mg/L Stock ICV Mercury Standard: Inorganic Ventures #CGHG-1, or equivalent.

8.9.2.1 1000 µg/L ICV Working Standard: Prepare by adding 0.1 mL of 1000 mg/L ICV stock to a 100 mL volumetric flask containing 2% HCl. Bring to volume with DI water and pour into brown bottle. This standard is identified as **I-date-V** in the Mercury Standards Preparation Log.

8.9.2.2 5 µg/L ICV Working Standard: Prepare by adding 0.25 mL of 1000 µg/L working standard to a 50 mL graduated screw cap centrifuge tube containing 2% HCl. Bring to 50 mL final volume with DI water. This standard is identified as **I-date-VS** in the Mercury Standards Preparation Log.

8.10 Calibration and Calibration Check Standards: Store standards at room temperature out of direct light.

Calibration and calibration check standards are prepared in 50 ml polypropylene (or equivalent) screw cap digestion tubes containing approximately 25 mL of DI water and 0.25 mL of BrCl solution. The STD0 consists of 50mL DI and 0.25mL BrCl solution.

After addition of the working standard, calibration standards are brought to 50mL final volume with DI water, wait 15 minutes and decolorized with 0.050 mL of hydroxylamine hydrochloride solution (Section 8.4). If sample preparation required additional quantities of BrCl to maintain a yellow color, then the same amount of BrCl is added to calibration and calibration check standards (Section 10.3).

8.10.1 Standards Preparation for Method 7474 Modified

Standard ID	Vol. 1000 µg/L Standard (Section 8.9.1.1) (mL)	Vol. 100 µg/L Standard (Section 8.9.1.2) (mL)	Final Concentration (µg/L)
STD0	-	-	0.0
STD1	-	0.025	0.05
STD2	-	0.05	0.1
STD3	-	0.25	0.5
STD4	0.1	-	2.0
STD5	0.25	-	5.0
ICV,CCV,MS **(Section 8.9.2.1)**	0.125	-	2.5

8.11 Argon Gas: Ultra-high purity

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

9.1 Blanks

9.1.1 Method Blank

A method blank must be prepared once per every 20 samples or per digestion batch, whichever is more frequent.

Mercury must not be detectable in the method blank at a concentration greater than the reporting limit.

Corrective Action: May reanalyze once to determine if analytical error has occurred. Digestion of the method blank and all associated samples must be performed until the blank is in control. Samples cannot be analyzed until an acceptable method blank analysis is obtained. Exceptions may be made with approval of the Metals Department Manager, Laboratory Director or QAO, if the samples associated with the out of control method blank are non-detect for the elements of interest, or if sample concentrations are greater than 10x the blank levels. In such cases, the sample results are accepted without corrective action for the high method blank and the client is notified in a project narrative associated with the sample results.

9.1.2 Initial Calibration Blank (ICB)

An initial calibration blank must be analyzed immediately following the ICV (see 9.3).

Mercury must not be detectable in the ICB at a concentration greater than the reporting limit.

Corrective Action: May reanalyze once to determine if analytical error has occurred. If the concentration still exceeds the acceptance limit, stop and recalibrate the instrument. Samples cannot be analyzed until an acceptable ICB analysis is obtained. Exceptions may be made with approval of the Metals Department Manager, Laboratory Director or QAO, if the samples associated with the out of control blank are non-detect for mercury, or if sample concentrations are greater than 10x the blank levels. In such cases, the sample results are accepted without corrective action for the high blank and the client is notified in a project narrative associated with the sample results.

9.1.3 Continuing Calibration Blank

A continuing calibration blank must be analyzed immediately following the CCV (see 9.4).

Mercury must not be detectable in the CCB at a concentration greater than the reporting limit.

Corrective Action: May reanalyze once to determine if analytical error has occurred. If the concentration still exceeds the acceptance limit, stop, recalibrate the instrument and reanalyze all associated samples. Samples cannot be analyzed until an acceptable CCB analysis is obtained. Exceptions may be made with approval of the Metals Department Manager, Laboratory Director or QAO, if the samples associated with the out of control blank are non-detect for the elements

of interest, or if sample concentrations are greater than 10x the blank levels. In such cases, the sample results are accepted without corrective action for the high method blank and the client is notified in a project narrative associated with the sample results.

9.2 Laboratory Control Sample (LCS)

Laboratory control sample (LCS) must be prepared once per every 20 samples or per digestion batch, whichever is more frequent, and spiked with a solution prepared from a second source or lot number, other than the source used to verify the accuracy of the standard curve for the determinative analytical method. The LCS contains the target element, and is digested along with the samples as verification of the accuracy of the entire digestion procedure.

The LCS must be recovered within 80-120% of the true value.

Corrective Action: Analysis according to the method may be repeated once to see if an analytical error has occurred. If the LCS recovery is still out of control, re-prepare and re-analyze the LCS and all associated samples. Samples cannot be reported until an acceptable LCS is obtained. Exceptions may be made with approval of the Metals Department Manager, Laboratory Director or QAO, if the samples associated with the out of control LCS are also associated with a matrix spike that is in control. This is an acceptable measure of accuracy of the digestion and analytical procedures. An explanation of the out of control LCS recovery must be included in the project narrative to the client and the sample data reported noting the acceptable MS results as batch QC.

9.3 Initial Calibration Verification (ICV)

An initial calibration verification standard from a source different from that used to calibrate the instrument (see 8.9.2) must be analyzed immediately following calibration as an independent check of instrument performance. Nominal acceptance limits are 90% - 110% for Method 7474.

Corrective Action: Analysis according to the method may be repeated once to see if an analytical error has occurred. If the concentration still exceeds the acceptance limit, stop and recalibrate the instrument. Samples cannot be analyzed until an acceptable ICV analysis is obtained. Exceptions may be made with approval of the Metals Department Manager, Laboratory Director or QAO, if the samples associated with a high recovery ICV are non-detect. In such cases, the sample results are accepted without corrective action for the high ICV recovery and the client is notified in a project narrative associated with the sample results.

9.4 Continuing Calibration Verification (CCV)

A continuing calibration verification standard must be analyzed after analysis of no more than 10 samples as an on-going check of instrument performance. Nominal acceptance limits are 90% - 110% for Method 7474.

Corrective Action: Analysis according to the method may be repeated once to see if an analytical error has occurred. If the concentration still exceeds the acceptance limit, stop, recalibrate the instrument and reanalyze all associated samples. Results cannot be accepted until an acceptable CCV analysis is obtained. Exceptions may be made with approval of the Metals Department Manager, Laboratory Director or QAO, if the samples associated with a high recovery CCV are non-detect. In such cases, the sample results are accepted without corrective

action for the high CCV recovery and the client is notified in a project narrative associated with the sample results.

9.5 Matrix Spike

A matrix spike (MS) sample must be performed once per 20 samples (5% frequency), or per digestion batch, whichever is more frequent. The MS contains the target element.

The MS must be recovered within 80%-120%.

A matrix spike duplicate (MSD) is performed upon client request and must meet the same recovery criteria as the MS. The %RPD between the MS and MSD must be ≤20%.

Corrective Action: Analysis according to the appropriate method may be repeated once to see if an analytical error has occurred. If the % recovery still exceeds the control limits and the LCS is compliant; include a project narrative with the results to client noting that there may be potential matrix effects on the accuracy of the reported results as evidenced by MS recovery outside of QC limits.

9.6 Laboratory Duplicate

Duplicate analyses (matrix or sample duplicate) must be performed once per 20 samples 5% frequency), or per digestion batch, whichever is more frequent.

Acceptable relative percent differences (RPD) of duplicates is ≤20%. Acceptance criterion is not applicable to sample concentrations less than 5 times the reporting limit. Calculate the RPD as follows:

$$RPD = \frac{R1 - R2}{\frac{[R1 + R2]}{2}} \times 100$$

where:

R1 = sample Replicate #1
R2 = sample Replicate #2

Corrective Action: Analysis may be repeated once to see if an analytical error has occurred. If the % RPD still exceeds the control limits; include a project narrative with the results to client noting that there may be potential matrix effects on the precision of the reported metals results as evidenced by the matrix duplicate %RPD exceedance.

9.7 Method Sequence

10. Procedure

10.1 Equipment Set-up

Samples are prioritized by the Metals Department Manager or Preparation Group Leader for digestion based on hold time and client due date. The analyst must be familiar with instrument software and hardware as described in the user manuals supplied with the instrument, and have a completed IDC on file (Section 13.2) prior to any sample analysis.

10.1.1 Method 7474 (Modified) Sample Preparation

To a 50mL digestion tube, add 50mL of sample and 0.25 mL of BrCl solution (Section 8.8). The sample should remain a yellow color. If not, add more BrCl solution to all samples, the Method Blank, LCS and all samples until yellow color persists.

Spike the MS and LCS with 0.125mL of 5ug/L Working Standard (Section 8.9.1.3).

Let stand for 15 minutes and decolorize with 0.05mL of 12% hydroxylamine solution (Section 8.4.1).

10.2 Initial Calibration

The instrument is calibrated prior to sample analysis and at least once every 24 hours. Refer to Section 8.10 for the preparation of calibration standards for each determinative method. The peak height mode is selected in the method for calibration purposes. Peak area mode is also an option in the method for determining sample concentration and may be used if the analyst determines that it is necessary.

A linear least squares regression calibration curve is selected for methods 7474.

In all cases, a correlation coefficient ≥ 0.995 is required before the analysis of samples can begin.

An ICV (see 9.3) and ICB (see 9.1.2) are analyzed after calibration

10.3 Equipment Operation and Sample Processing

Power is turned on to the instrument, autosampler, PC and argon gas supply. Peristaltic pump windings are inspected for wear and replaced if necessary. The winding clips are relaxed in between usage. The instrument manufacturer suggests that the pump tubing be changed once per week.

The stannous chloride solution (Section 8.5) is attached to the grey/grey pump tubing, 10% HCl (Section 8.2.1) is attached to the green/green autosampler rinse and DI is attached to the green/green rinse blank. The autosampler probe line is attached to a green/green pump tubing. The pumps are turned on in the software and flow checked to insure that solutions are delivered to the mixing valve.

After initializing the Millennium software, the instrument is turned on via the software and allowed to warm up for 30 minutes. The analysis method is selected and the autosampler template is selected. Methods 7474 is set up in the software which specifies delay, read and rinse times as well as pump speeds. Autosampler templates are set up for each method specifying calibration standard, QC standards and positions on the autosampler rack. Once sample ID's have been typed in, the file is saved as the ETR number.

A data file is opened and saved as "WGnumber".

Initiate sample analysis by clicking on the start button on the analysis page. If a sample concentration is greater than the highest standard concentration of the calibration curve, dilute the digestate with the same matrix as was used for the calibration blank, and reanalyze.

Following analysis, the data file is exported to the LIMS on the O:Metals\Millennium drive for data processing. The instrument and autosampler are then rinsed with DI water.

10.4 Continuing Calibration

Periodically and at the end of the analysis, CCV standards (see 9.4) and CCB standards (see 9.1.3) are analyzed.

10.5 Preventive Maintenance

Inspect pump windings for signs of wear and replace (recommended at least monthly). Clean gas/liquid separator periodically when appears coated with yellow film (rinse with 30% KOH solution and DI). Change dryer tube annually.

11. Data Evaluation, Calculations and Reporting

All results for the metals elements of interests are reportable without qualification if digestion and analytical holding times are met, preservation (including cooler temperatures) are met, all QC criteria defined in the table below are met, and matrix interference is not suspected during digestion or analysis of the samples. If any of the below QC parameters are not met, all associated samples must be evaluated for re-extraction and/or re-analysis.

The instrument software calculates sample concentrations based on the signal peak height, the calibration curve. Sample concentrations for Method 7474 are calculated as follows:

Sample Concentration = $(A_s / Cf) * (V_f / V_i) * DF$

Where:

A_s = sample peak height or area
V_f = Final volume from preparation
V_i = Initial volume from preparation
DF = dilution factor
Cf = calibration factor for the calibration curve

Note: The final volume from the sample preparation would reflect any changes in volume due to BrCl added.

QC Parameter	Acceptance Criteria
Method Blank	< reporting limit
Laboratory Control Sample	80%-120% Recovery
Matrix Duplicate	≤ 20% RPD
Matrix Spike	75% - 125% Recovery 80%- 120% for Method 7474
Matrix Spike Duplicate (if needed)	≤ 20% RPD, 75% - 125% Recovery 80% - 120% for Method 7474

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

Section 9 outlines sample batch QC acceptance criteria. If non-compliant results are to be reported, the Metals Department Manager and/or the Laboratory Director must approve the reporting of these results. The laboratory Project Manager shall be notified, and may chose to relay the non-compliance to the client for approval, or other corrective action, such as re-sampling and re-analysis. The instrument analyst or Department Manager performing the secondary analytical review initiates a project narrative, and the narrative must clearly document the non-compliance and provide a reason for acceptance of these results.

13. Method Performance

13.1 Method Detection Limit Study (MDL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the MDL, LOD, and/or LOQ as outlined in Alpha SOP/1732. These studies performed by the laboratory are maintained on file for review.

13.2 Demonstration of Capability Studies

13.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

13.3 Instrument Detection Limits

The instrument detection limit (IDL) is the smallest signal above the background noise that an instrument can detect. The IDL can be calculated taking the average of the standard deviations for three measurements of a reagent blank solution analyzed on three analytical

runs on three non-consecutive days. Seven consecutive measurements must be taken per day. The IDL samples are not required to go through sample digestion. Each measurement must be performed as though it were a separate sample.

14. Pollution Prevention and Waste Management

The *Hazardous Waste and Sample Disposal* SOP (1797), must be referenced for disposal of used standards, solvents, acids, reagents or other chemicals.

Once sample batches have completed digestion, the sample containers are stored in the metals lab and held for 30 days. If there is no sample remaining in the sample collection bottle, it may be rinsed and thrown away. It must be noted in the *Internal COC* that there is no sample remaining in the bottle, and the bottle was discarded.

Once the samples have been held for 30 days, any aqueous sample remaining must be disposed in a 55-gallon drum labeled “Corrosive Liquid”.

Once satisfactory inorganic element results have been generated, the digestates are held for 30 days, or longer if specified by a client contract, then discarded into a 55-gallon drum labeled “Corrosive Liquid”.

All reagent waste generated during digestion must be stored in satellite containers in the metals preparation laboratory.

Once the reagent waste satellite containers are full, they must be emptied into 55-gallon drums marked “Corrosive Liquid”.

Refer to Alpha’s Chemical Hygiene Plan and Waste Management and Disposal SOP for further pollution prevention and waste management information.

Mercury in Liquid Waste

(Automated Cold-Vapor Technique)

Reference Method No.: **EPA 7470A**

Reference: SW-846, Test Methods for Evaluating Solid Waste: Physical/Chemical Methods, EPA SW-846, Update II, September 1994.

1. Scope and Application

Matrices: Method 7470 is a cold-vapor atomic absorption procedure approved for determining the concentration of mercury in mobility-procedure extracts, aqueous wastes, and ground waters. (Method 7470 can also be used for analyzing certain solid and sludge-type wastes; however, Method 7471 is usually the method of choice for these waste types.) All samples must be subjected to an appropriate dissolution step prior to analysis.

Definitions: See Alpha Laboratories Quality Manual Appendix A.

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one or more of the following laboratory personnel before performing the modification: Area Supervisor, Department Supervisor, Laboratory Director, or Quality Assurance Officer.

This method is restricted to use by or under the supervision of analysts experienced in the operation of the Mercury Analyzer and in the interpretation of Mercury data. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

2. Summary of Method

Prior to analysis, the liquid samples must be prepared according to the procedure discussed in this method.

Method 7470, a cold-vapor atomic absorption technique, is based on the absorption of radiation at 253.7-nm by mercury vapor. The mercury is reduced to the elemental state and aerated from solution in a closed system. The mercury vapor passes through a cell positioned in the light path of an atomic absorption spectrophotometer. Absorbance (peak height) is measured as a function of mercury concentration.

2.1 Method Modifications from Reference

2.1.1 A smaller sample sized is prepared, and therefore proportionately less reagent volumes are used.

2.1.2 The original method does not address the automated instrument procedure.

3. Reporting Limits

The typical reporting limit for Mercury is 0.0002mg/L. This satisfies Massachusetts, GW1 and GW 2 criteria. Connecticut mobility criteria for SPLP is 0.0004mg/L, Rhode Island is 0.002mg/L, and the Drinking Water reporting limit is 0.0002mg/L.

4. Interferences

Potassium permanganate is added to eliminate possible interference from sulfide. Concentrations as high as 20 mg/L of sulfide as sodium sulfide do not interfere with the recovery of added inorganic mercury from reagent water.

Copper has also been reported to interfere; however, copper concentrations as high as 10 mg/L had no effect on recovery of mercury from spiked samples.

Seawaters, brines, and industrial effluents high in chlorides require additional permanganate (as much as 25 mL) because, during the oxidation step, chlorides are converted to free chlorine, which also absorbs radiation of 253.7 nm. Care must therefore be taken to ensure that free chlorine is absent before the mercury is reduced and swept into the cell. This may be accomplished by using an excess of hydroxylamine sulfate reagent (25 mL). Both inorganic and organic mercury spikes have been quantitatively recovered from seawater by using this technique.

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material safety data sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

Mercury compounds are highly toxic if swallowed, inhaled, or absorbed through the skin. Analysis is conducted under a laboratory exhaust hood. The analyst must wear chemical resistant gloves when handling concentrated mercury standards.

The acidification of samples containing reactive materials may result in the release of toxic gases, such as cyanides or sulfides. Therefore, the acidification of samples is to be conducted under a laboratory exhaust hood.

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

Samples are collected in either glass or plastic containers.

6.2 Sample Preservation

Samples are preserved with HNO_3 to a pH of <2.

6.3 Sample Shipping

No special shipping requirements.

6.4 Sample Handling

Samples are stored under refrigeration at 4 ± 2°C and analyzed as soon as possible after collection. The samples have a 28-day holding time from the time of collection.

7. Equipment and Supplies

Instrumentation:

Perkin Elmer FIMS 100 Atomic absorption spectrophotometer: Use instrument settings recommended by the manufacturer. The PE FIMS is designed specifically for the measurement of mercury using the cold-vapor technique with BOC (background offset correction) performed by a survey scan prior to each sample introduction. PE S10 autosampler is coupled to the instrument.

Cetac M-6100 Atomic absorption spectrophotometer: Use instrument settings recommended by the manufacturer. This instrument employs a reference cell off-set correction and full automation through the CETAC software. A Cetac ASX-260 autosampler is coupled to the instrument.

Nippon Instrument model# RA-4300A analyzer with integrated 80 position autosampler:

The instrument adds a stannous chloride (II) solution to the sample post digestion, the divalent mercury ion (Hg2+) is reduced to zero-valent metallic mercury and turns into mercury gas by bubbling. Hg2++SnCl2 → Hg0 ↑
After removing the acid mist and water vapor generated by bubbling with an electronic cooling unit, the instrument measures the absorbance of mercury at 253.7 nm absorption wavelength. It measures the known mercury amount, creates a calibration curve, and then calculates the mercury amount from the absorbance.

7.1 Graduated cylinder: Rinse once with 50% HNO_3 and then rinse with reagent water prior to use.

7.2 Volumetric Flasks, Class A, various volumes: Rinse once with 50% HNO_3 and then rinse with reagent water prior to use.

7.3 Heating Block: Environmental Express HotBlock, 48 position capacity, able to maintain 95˚C +/-3.

7.4 50 mL Digestion Tubes: Polypropylene, graduated.

7.5 50 mL Digestion Tube Rack: 48 position, racklock

7.6 Pump tubing: Environmental Express, three stop and two in various IDs.

7.7 PTFE membranes: Whatman TE37 disks.

7.8 Dilution vials: 20mL capacity, used to prepare analytical dilutions.

7.9 Low Dust Laboratory Wipes

7.10 Compressed Air

7.11 Whatman 41 filter paper or equivalent

8. Reagents and Standards

8.1 Reagent Water: Reagent water is DI water shown to be interference free. All references to water in this method will refer to reagent water unless otherwise specified.

8.2 Sulfuric acid (H_2SO_4), concentrated: Reagent grade. Store at room temperature in an appropriately designated acid cabinet.

8.3 Hydrochloric acid, concentrated: Trace Metal grade. Store at room temperature in an appropriately designated acid cabinet.

8.4 Carrier, Hydrochloric Acid, 3%: This is the ***carrier*** for the Instrument. In a 1L volumetric flask, add 30mL concentrated trace grade HCl (Section 8.3). Bring to volume with reagent water. Store at room temperature, prepare daily as needed.

8.5 Reductant, Stannous Chloride in 3% HCl: This is the ***reductant*** for the Instrument. In a 1L volumetric flask, add 30mL concentrated trace grade HCl and 11g $SnCl_2 \cdot 2H_20$. Mix to dissolve the solid and bring to volume with reagent water. Store at room temperature, prepare daily as needed.

8.6 Nitric acid (HNO_3), concentrated: Trace metal grade of low mercury content. If a high reagent blank is obtained, it may be necessary to distill the nitric acid. Store at room temperature in an appropriately designated acid cabinet.

8.7 Sodium chloride-hydroxylamine hydrochloride solution: Dissolve 12 g of sodium chloride and 12 g of hydroxylamine hydrochloride in reagent water and dilute to 100mL. Store at room temperature. Expires one month from date of preparation.

8.8 Potassium permanganate, mercury-free, 5% solution (w/v): Dissolve 5 g of potassium permanganate in 100 mL of reagent water. Store at room temperature. Expires one month from date of preparation.

8.9 Potassium persulfate, 5% solution (w/v): Dissolve 5 g of potassium persulfate in 100 mL of reagent water. Store at room temperature. Expires one month from date of preparation.

8.10 Mercury Stock Standard, 1000ppm: Purchased from a commercial source with a certificate of analysis. Purchase three different sources. Store at room temperature. Expires upon manufacturer's specification.

8.11 Mercury Stock Calibration Standard, 10ppm: To a 100mL volumetric flask, add 5mL of concentrated HNO_3, 2.5mL of concentrated H_2SO_4 and 1000ppm Mercury Stock Standard (Section 8.10, use one source). Bring to volume with reagent water. Store at room temperature. Expires one month from date of preparation.

8.12 Mercury Working Calibration Standard / Matrix Spike Solution, 0.1ppm: To a 100mL volumetric flask, add 5mL of concentrated HNO_3, 2.5mL of concentrated H_2SO_4 and 1mL of 10ppm Mercury Stock Standard (Section 8.11). Bring to volume with reagent water. Store at room temperature. Make fresh daily.

8.13 Mercury Calibration Standards: All calibration standards are prepared daily.

8.13.1 0 ppm Calibration Standard: Add 10 mL of reagent water to a polypropylene digestion vessel. This aliquot may be used for the CCB. Another separate aliquot is prepared in the same manner for use as the ICB and diluent for sample dilutions.

8.13.2 **0.0002ppm Calibration Standard:** Add 10 mL of reagent water to a polypropylene digestion vessel. Pipet 0.05 mL of 0.1ppm Mercury Working Stock (Section 8.12) to the digestion vessel. Bring to a final volume of 25 mL.

8.13.3 **0.001ppm Calibration Standard:** Add 10 mL of reagent water to a polypropylene digestion vessel. Pipet 0.25 mL of 0.1ppm Mercury Working Stock (Section 8.12) to the digestion vessel. Bring to a final volume of 25 mL.

8.13.4 **0.002ppm Calibration Standard** Add 10 mL of reagent water to a polypropylene digestion vessel. Pipet 0.5 mL of 0.1ppm Mercury Working Stock (Section 8.12) to the digestion vessel. Bring to a final volume of 25 mL.

8.13.5 **0.005ppm Calibration Standard/Continuing Calibration Verification Standard:** Add 10 mL of reagent water to a polypropylene digestion vessel. Pipet 1.25 mL of 0.1ppm Mercury Working Stock (Section 8.12) to the digestion vessel. Bring to a final volume of 25 mL.

8.13.6 **0.010ppm Calibration Standard / Post Analytical Spike Solution:** Add 10 mL of reagent water to a polypropylene digestion vessel. Pipet 2.5 mL of 0.1ppm Mercury Working Stock (Section 8.12) to the digestion vessel. Bring to a final volume of 25 mL.

8.13.7 **0.020ppm Calibration Standard / Post Analytical Spike Solution:** Add 10 mL of reagent water to a polypropylene digestion vessel. Pipet 5.0 mL of 0.1ppm Mercury Working Stock (Section 8.12) to the digestion vessel. Bring to a final volume of 25 mL.

8.14 Mercury Stock LCS Standard, 10ppm: To a 100mL volumetric flask add 25mL of reagent water and 5mL of concentrated HNO_3 (Section 8.6). Add 1mL of 1000ppm Mercury Stock Standard (Section 8.10). Bring to volume with reagent water. Store at room temperature. Expires one month from date of preparation.

8.15 Mercury Working LCS Standard, 0.1ppm: To a 100mL volumetric flask add 25mL of reagent water and 5mL concentrated HNO_3 (Section 8.6). Add 1mL of 10ppm Stock LCS Standard (Section 8.14). Bring to volume with reagent water. Store at room temperature. Expires one week from date of preparation.

8.16 Mercury LCS Standard, 0.001ppm: Prepare daily with each batch of samples. To a 50mL digestion vessel add 10mL of reagent water Add 0.25 mL of 0.1ppm Working LCS Standard (Section 8.15). Bring to a final volume of 25mL and carry through entire digestion process as in Section 10.1.1.

8.17 Mercury Stock ICV Standard, 10ppm: To a 100mL volumetric flask add 25mL of reagent water and 5mL of concentrated HNO_3 (Section 8.6). Add 1mL of 1000ppm Mercury Stock Standard (Section 8.10-use alternate source than that used for both the calibration standards and the LCS Stock Standard). Bring to volume with reagent water. Store at room temperature. Expires one month from date of preparation.

8.18 Mercury Working ICV Standard, 0.3ppm: To a 100mL volumetric flask add 25mL of reagent water and 5mL of concentrated HNO_3 (Section 8.6). Add 3mL of 10ppm Stock ICV Standard (Section 8.5). Bring to volume with reagent water. Store at room temperature. Expires one week from date of preparation.

8.19 Mercury ICV Standard, 0.003ppm: Prepare daily with each batch of samples. To a 25mL digestion vessel add 10mL of reagent water. Add 0.25mL of 0.3ppm Working ICV Standard (Section 8.18). Bring to a 25mL final volume with reagent water and carry through entire digestion process as in Section 10.1.1..

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

9.1 Blank(s)

The ICB, CCB, and Method Blank: A 25mL aliquot of 0ppm calibration standard brought through the preparation procedure as outlined in Section 10.1.1 . Blank results must be <RL. See Section 12.1 for corrective action. An ICB is analyzed after the initial calibration or re-calibration. The CCB is analyzed at every 10 sample injection interval. Method Blank is analyzed once per batch of samples; batch consists of 20 samples.

9.2 Laboratory Control Samples (LCS)

The LCS Standard consists of a 0.001ppm Mercury LCS Standard (Section 8.16). This standard is brought through the preparation procedure as outlined in Section 10.1.1. The LCS Standard must be recovered within ± 20% of the true value. See Section 12.3 for corrective action. The LCS Standard is analyzed once per batch of samples. A batch consists of 20 samples.

9.3 Initial Calibration verification (ICV)

The ICV Standard consists of a 25mL aliquot of 0.003ppm Mercury ICV Standard (Section 8.19). The ICV must be recovered within 10% of the true value. See Section 12.2 for corrective action.

9.4 Continuing Calibration Verification (CCV)

The CCV Standard consists of a 0.010ppm calibration standard (Section 8.13.3). The CCV must be recovered within 20% of the true value. See Section 12.2 for corrective action.

9.5 Matrix Spike

A matrix spike is analyzed once per batch of samples. A batch consists of 20 samples for monitoring wells, surface waters, influents and effluents. Prepare the matrix spike at 0.005ppm by adding 1.25mL of 0.1ppm Mercury Stock Standard (Section 8.3) to 25mL of the selected QC sample. The final concentration of the matrix spike is 0.005mg/L.

The matrix spike sample is brought through the preparation procedure as outlined in Section 10.1. A matrix spike is analyzed once per batch of samples. A batch consists of 20 samples for monitoring wells and surface waters. The recovery of the matrix spike must be between 75 – 125% (using the calculation in Section 11.2).

If the recovery of the matrix spike is out of range, a post-analytical spike is analyzed. Prepare the post analytical spike by adding 5mL of 0.010ppm Calibration Standard / Post Analytical Spike Solution (Section 8.1.6) and 5mL of the sample digestate to a 50mL centrifuge tube for a final concentration of 0.005mg/L. Analyze the post spike as outlined in Section 10.3.5.

Calculate the post spike concentration as follows:

Post Analytical Spike Sample Concentration (mg/L) =

[Sample Concentration (mg/L) x (0.5)] + 0.005mg/L

The percent recovery of the post-analytical spike must be between 75 – 125%. See Section 12.4 for corrective action.

9.6 Laboratory Duplicate

A sample is analyzed in duplicate once per batch of samples. A batch consists of 20 samples for monitoring wells and surface waters. The RPD between the sample and its duplicate must be 20% or less (using the calculation in Section 11.3), See Section 12.5 for corrective action.

9.7 Method-specific Quality Control Samples

Not applicable.

9.8 Method Sequence

- Calibration Blank
- 0.0002 ppm Calibration Standard
- 0.0005 ppm Calibration Standard
- 0.001 ppm Calibration Standard
- 0.002 ppm Calibration Standard
- 0.010 ppm Calibration Standard
- 0.020 ppm Calibration Standard

- Etc.

10. Procedure

10.1 Equipment Set-up

10.1.1 Preparation and Digestion

Samples, Standards and All Batch QC

Transfer 25mL of well-homogenized sample (or an aliquot of the sample diluted to 25mL with reagent water) or standards (Sections 8.13.1 through 8.13.7, 8.16 and 8.19) to a 50mL centrifuge tube.

Add 1.25mL of concentrated H_2SO_4 (Section 8.2), 0.625mL of concentrated HNO_3 (Section 8.6), Add 3.75mL of Potassium Permanganate Solution, shake and add additional portions of potassium permanganate solution (if necessary) to all samples and QC, until the purple color persists for at least 15 min. (Section 8.8). Add 2mL of Potassium Persulfate Solution (Section 8.9), and heat samples for 2 hours in a 95°C +/-3

heating block. Cool, and add 1.5mL of Sodium Chloride-Hydroxylamine hydrochloride solution (Section 8.7).
Filter the sample if needed to remove any sediment or particulate.

Analyze samples and the digested calibration standards (Sections 8.13.1 through 8.13.7) are used in Section 9.2 to generate a calibration curve.

10.2 Initial Calibration

Construct a calibration curve by plotting the absorbances of prepared standards (Section 10.1.1) versus micrograms of mercury. Determine the peak height of the unknown from the absorbance maxima on the spectrometer, and read the mercury value from the standard curve. (See Section 11.)

The curve correlation coefficient (cc) must be greater than or equal to 0.995 in order for the curve to be linear. If the correlation coefficient is less than 0.995, find and correct the problem. When the problem has been corrected, re-analyze either the previous standards or new standards. When the curve has generated an acceptable cc then the analysis can continue with the ICV/ICB.

10.3 Equipment Operation and Sample Processing

Sample and standard analysis:

10.3.1 Instrument Setup

10.3.1.1 Turn the instrument on. The autosampler will initialize itself.

10.3.1.2 Choose the instrument software from the desktop menu. The autosampler will initialize again.

FIMS 100 NOTE: The instrument must be turned on before the application is started. Otherwise, an error message will result.

10.3.1.3 Enter the appropriate fields for sample identification, and data storage.

10.3.1.4 Fill the carrier and reductant bottles.

10.3.1.4.1 The Carrier is 3% HCl (Section 8.6).

10.3.1.4.2 The Reductant is 1.1% $SnCl_2$ in 3% HCl (Section 8.5).

10.3.1.5 Allow the instrument to warm up while clearing samples. Samples that are cloudy or with particulate present after clearing must be filtered through Whatman 41 filter paper (Section 7.11) before analysis.

10.3.1.6 Place carrier uptake line and reductant uptake line.

10.3.1.7 Load carrier and reductant lines into pump magazines

10.3.1.8 Load the two waste lines into the pump magazines below the roller.

10.3.1.9 Lock the magazines into place.

FIMS100 only:

10.3.1.10 Remove the cap from the liquid/vapor separator and wipe dry with a Lab Wipe (Section 7.9). Compressed air (Section 7.10) through the vapor transfer line to dry it out.

10.3.1.11 Place a PTFE membrane (Section 7.7), rough side up, in the liquid/vapor separator; replace the cap and reattach the vapor transfer line to the sample absorption cell.

10.3.1.12 Adjust the gas flow by turning the black knob below the air flow meter to obtain a reading of just over 50.

10.3.2 Calibration and Sample Analysis

10.3.2.1 The instrument will now run the calibration standards; verify a CC of 0.995 or better before proceeding with the ICV and ICB. Ten analytical samples, a CCV and CCB, ten analytical samples, CCV, CCB, etc. The CCBs and CCVs must be recovered within the proper ranges (Sections 9.4 and 9.1.3) for analysis to continue.

10.3.2.2 If the sample result is beyond 90% of the concentration of the highest point on the calibration curve or LDR study used to establish the linear range, dilute the sample extract with a portion of one of the prepared blanks (ICB, CCB or PBS) to produce an analytical result that is within the range.

10.3.3 Instrument Shut Down

10.3.3.1 When analysis is complete place reagent uptake lines in a beaker of reagent water.

10.3.3.1.1 Continue to run the pumps for several minutes to flush reagents out of the lines.

10.3.3.1.2 Continue to run the pumps for several minutes to flush reagents out of the lines.

10.3.3.2 Pull the reagent uptake lines out of the reagent water beaker to allow the pump to draw air through the lines.

10.3.3.3 Unlock the top and bottom pump magazines and remove tubing from the magazines.

10.3.3.4 Exit from the software application.

10.3.3.4.1 Dump the samples and instrument waste in the Metals/WetChem waste drum located in the transfer room.

10.4 Continuing Calibration

Continuing calibration verification samples are analyzed after every 10 samples in the sample run, as outlined in Section 10.3.5.

10.5 Preventative Maintenance

Preventative maintenance is conducted per the manufacturer's instructions. All preventative maintenance is recorded in the Instrument Maintenance Logbook.

11. Data Evaluation, Calculations and Reporting

11.1 Calculate Mercury concentration

Calculate Mercury concentration from the daily calibration curve. The curve is generated utilizing a straight-line equation defined as:

$$A = k_1 + k_2C$$

Where:

A = Average peak height of the sample/standard integrations
C = Sample/Standard Concentration, µg/L
k_1 = y-intercept
k2 = slope

The instrument will plot peak height against concentration (µg/L). The result is generated in µg/L . This value is divided by 1000 to convert the units to mg/L. If the sample is diluted (DF), the result is multiplied by the DF to generate the final result.

Result, mg/L = (concentration, µg/L) x (1mg/1000µg) x (DF)

11.2 Matrix Spike Calculation

Calculate percent recovery for the Matrix Spike corrected for concentrations measured in the unfortified sample. Percent recovery is calculated using the following equation:

$$\% \text{ Recovery} = \frac{(Cm - C)}{s} \times 100$$

Where:

Cm = measured Mercury in the fortified sample
C = measured native mercury sample concentration
S = concentration equivalent of spike added to sample

11.3 Relative Percent Difference (RPD) Calculation

Calculate the Relative Percent Difference (RPD) for each Duplicate of the initial quantitated concentration (IC) and duplicate quantitated concentration (Dc) using the following formula:

$$RPD = \frac{|(IC - Dc)|}{\{(IC + Dc) / 2\}} \times 100$$

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

12.1 Method Blank Failure: When a prep blank mercury level constitutes 10% or more of analyte level determined for any sample in the batch, or is greater than 2.2x the MDL value (whichever is greater), the associated samples in the batch must be redigested (Section 10.1).

For method blanks that have concentrations greater than the RL, the data is rejected and the associated samples sent back for redigestion unless the associated sample concentrations are greater than 10x the blank concentration. In this case the blank is narrated and the results are reported without qualification.

12.2 ICV / CCV Failure: If the ICV %Recovery is outside of acceptance criteria, the ICV is reinjected. If the %Recovery is outside the acceptance criteria, the analysis is terminated until the problem is found and corrected. If the CCV %Recovery is outside of acceptance criteria, the CCV is reinjected. If the % Recovery is still outside the acceptance criteria, all samples analyzed since the last acceptable CCV must be reanalyzed following correction of the problem.

12.3 LCS Failure: If the LCS is not recovered within acceptance criteria, the LCS is reinjected. If the % Recovery is still outside the acceptance criteria, either recalibrate and rerun or the associated batch and another LCS must be redigested (Section 10.1).

12.4 Matrix Spike / Post Digestion Spike Failure: If the recovery of the matrix spike is outside of the acceptance criteria, a post digestion spike is performed (Section 9.54). If the post digestion spike is outside of 75 – 125%, a narrative must be included with the data. (Section 10.1).

12.5 Duplicate Failure: If the RPD between the sample and its duplicate is greater than 20%, visually evaluate the sample matrix. If the matrix appears problematic, the sample digestate may be diluted and reanalyzed, or a narrative included with the data to explain the matrix problem.

13. Method Performance

13.1 Method Detection Limit Study (MDL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the MDL, LOD, and/or LOQ as outlined in Alpha SOP 1732. These studies performed by the laboratory are maintained on file for review.

13.2 Demonstration of Capability Studies

Refer to Alpha SOP 1739 for further information regarding IDC/DOC Generation.

13.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

14. Pollution Prevention and Waste Management

Refer to Alpha's Chemical Hygiene Plan and Waste Management and Disposal SOP for further pollution prevention and waste management information.

15. Referenced Documents

Mercury Determination in Tissue and Soil/Sediment Samples by Cold Vapor Atomic Fluorescence Technique (CVAF)

References: **Method 7474,** Mercury in Sediment and Tissues by Atomic Fluorescence Spectrometry. SW-846, Test Methods for Evaluating Solid Waste: Physical/Chemical Methods, EPA SW-846, Revision 0, 2007.

Method 7471B, Mercury in Solid or Semisolid Waste (Manual Cold Vapor Technique). SW-846, Test Methods for Evaluating Solid Waste: Physical/Chemical Methods, EPA SW-846, Revision 2, February 2007.

1. Scope and Application

Matrices: The method is applicable to total mercury in tissue and soil/sediment samples.

Definitions: Refer to Alpha Analytical Quality Manual.

Two procedures for the analysis of mercury by cold vapor atomic fluorescence spectrometry are discussed in this SOP.

Mercury in Tissues - This method utilizes a microwave digestion followed by bromine chloride oxidation. Samples are then decolorized using hydroxylamine hydrochloride and analyzed following reduction with stannous chloride. Elemental mercury is then purged from solution and analyzed by atomic fluorescence spectrometry.

Mercury in Soil/Sediments - This method utilizes a hot plate digestion with aqua regia followed by bromine chloride oxidation. Samples are then decolorized using hydroxylamine hydrochloride and analyzed following reduction with stannous chloride. Elemental mercury is then purged from solution and analyzed by atomic fluorescence spectrometry.

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one or more of the following laboratory personnel before performing the modification: Area Supervisor, Department Supervisor, Laboratory Director, or Quality Assurance Officer.

This method is restricted to use by or under the supervision of analysts experienced in the operation of the Mercury analyzer and in the interpretation of Mercury data. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

Parameter	CAS
Mercury	7439-97-6

2. Summary of Method

Mercury in tissue samples is determined by cold vapor atomic fluorescence spectrometry from an aliquot of a microwave digestion (see SOP 2150; method 3051). A 10 mL aliquot of the digest is

added to a 50 mL screw cap polyethylene digestion tube along with 2 mL of an acidic bromine chloride solution. Bromine chloride is prepared by mixing potassium bromide with potassium bromate solutions with hydrochloric acid producing a yellow solution. Bromine chloride is known to oxidize inorganic and organomercury compounds. If a yellow color does not persist after addition of bromine chloride, then additional solution must be added until a yellow color persists. The same volume of bromine chloride solution is added to all samples and standards. This solution is allowed to stand for at least 15 minutes. After digestion is complete, bring to 50 mL, add 0.4 mL of 12% hydroxyl amine hydrochloride solution and shake. Additional hydroxyl amine hydrochloride is added if the yellow color from the bromine chloride solution persists.

Samples and standards are placed in the autosampler rack for analysis following stannous chloride reduction and analysis by cold vapor atomic fluorescence spectrometry at a wavelength of 253.7 nm.

Mercury in soil/sediment samples is determined by cold vapor atomic fluorescence spectrometry from a hot plate digestion utilizing aqua regia. A 0.5 – 1 g wet sediment aliquot is added to a 50 mL screw cap polyethylene digestion tube along with 5 mL of DI water, 3.75 mL concentrated HCl and 1.25 mL of concentrated HNO_3. Samples are heated on the hot block for 2 minutes and allowed to cool. 25 mL of Di water are then added, the samples placed back on the hot block and heated for 30 minutes. The samples are then cooled and brought to 50 mL with DI water. A 10 mL aliquot of the digest is added to a 50 mL digestion tube along with 2 mL of an acidic bromine chloride solution. If a yellow color does not persist after addition of bromine chloride then additional solution must be added until a yellow color persists. The same volume of bromine chloride solution is added to all samples and standards. This solution is allowed to stand for at least 15 minutes. After digestion is complete, bring to 50 mL, add 0.4 mL of 12% hydroxyl amine hydrochloride solution and shake. Additional hydroxyl amine hydrochloride is added if the yellow color from the bromine chloride solution persists.

Samples and standards are placed in the autosampler rack for analysis following stannous chloride reduction and analyzed by cold vapor atomic fluorescence spectrometry at a wavelength of 253.7 nm.

2.1 Method Modifications from Reference

Method 7474 calls for a microwave digestion for both tissues and soils/sediments with nitric and hydrochloric acids. The method has been modified for tissues to use an aliquot of a microwave digest utilizing nitric acid only. The method has been modified for soils/sediments to use a hot block digestion similar to that used for Method 7471B but without the addition of potassium permanganate. The change allows for more rapid preparation of samples and yields equivalent data to the reference method as indicated by the performance of PT samples.

Bromate/Bromide solution has been modified from the method reference.

3. Reporting Limit

The Reporting limit for mercury in tissues is 0.05 µg/L (0.0125 mg/kg) and the linear range of the analysis is 5 µg/L (1.25 mg/kg).

The Reporting limit for mercury in soil/sediment is 0.05 µg/L (0.0125 mg/kg) and the linear range of the analysis is 5 µg/L (1.25 mg/kg).

4. Interferences

4.1 Gold, silver and iodide are known interference.

4.1.1 High concentrations of gold and silver in a sample may suppress mercury reduction.

4.1.2 Samples with iodide concentrations greater than 3 mg/L should be pre-reduced with stannous chloride to clarify the brown color. It may be necessary to clean the analytical system with 4N HCl following analysis of a sample with iodide concentrations greater than 30 mg/L.

4.1.3 Sulfide concentrations up to 24 mg/L produce no interference problems.

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material safety data sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

The use of laboratory equipment and chemicals exposes the analyst to several potential hazards. Good laboratory techniques and safety practices shall be followed at all times. Eating, drinking, smoking, or the application of cosmetics is not permitted in the laboratory area. Horseplay of any kind is prohibited. Pipetting by mouth is not permitted. All Personal Protective Equipment (PPE) must be removed before leaving the laboratory area and before entering the employee lounge or eating area. Always wash your hands before leaving the laboratory. All relevant Material Safety Data Sheets (MSDSs) are kept alphabetically in a centrally located file storage.

Approved PPE, which includes Safety Glasses, Gloves and Lab Coats, must be worn at ***all*** times when handling samples, reagents, chemicals, or when in the vicinity of others handling these items, so that dermal contact is avoided. All standards, reagents and solvents shall be handled under a hood using the proper PPE. All flammable solvents must be kept in the flammable storage cabinet, and returned to the cabinet immediately after use. When transporting chemicals, use a secure transporting device and/or secondary outer container. Chemical storage is properly segregated and adequately ventilated to reduce the possibility of hazardous reactions. Chemical storage in work areas shall be kept to a minimum. Storage on bench tops or other work surfaces, except temporary, is not permitted.

Spilled samples, solvents, reagents, and water must be cleaned up from bench tops, instruments and autosampler surfaces immediately. A spill is considered a quantity of hazardous material if it is moderate to extreme hazard to the skin and mucous membranes. If contact with the skin occurs, immediately flush with large volumes of water. In the case of acidic/basic spills, the *Spill Kit* located in each laboratory shall be utilized before attempting to cleanup the spill. Although procedures are designed to minimize the possibility of an accident, all injuries or accidents, regardless of the nature or severity, are to be reported to the Department Manager Supervisor immediately. If an employee discovers a potentially unsafe condition, this must be reported to the Department Manager Supervisor immediately. No employee should feel compelled to work in a situation where they do not feel entirely informed, trained, or safe.

Analytical instrumentation poses the unique possibility of exposure to high voltages. Other than the *routine* instrument maintenance, as listed in the front of every Instrument Maintenance Logbook, at no time shall an instrument operator attempt to maintenance an instrument alone, or without the proper training, supervision or instruction. Caution must always be used in the presence of moving parts (autosamplers) and hot surfaces (injection ports).

Compressed gas cylinders shall only be moved with the dolly supplied for this specific purpose. The cap must be on the cylinder while it is being moved. The tank must be secured when in its final position. All spent tanks are to be returned in the same manner, and secured until removed by the vendor. Liquid argon or nitrogen represents a potential cryogenic hazard and safe-handling procedures must be used at all times.

All additional company safety practices shall be followed at all times as written in the *Chemical Hygiene Plan.*

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

A minimum of 10g of sample must be collected in a pre-cleaned 2oz or 4oz glass jar with a Teflon lined screw cap.

6.2 Sample Preservation

No preservatives are used. See Section 6.4.

6.3 Sample Shipping

No special sample shipping requirements.

6.4 Sample Handling

Samples are stored at 4°C $\pm$ 2°C. The hold time for soil/sediment and tissue samples is 28 days. Sediment and tissue samples may be stored frozen at -20°C $\pm$ 10°C. The hold time for solid samples stored frozen may be extended unless specifically noted by project or client requirements.

7. Equipment and Supplies

Instrument:

7.1 PSA Millennium Merlin Atomic Fluorescence Analyzer equipped with a PC loaded with instrumental software, and PSA 20.400 autosampler. The instrument is connected to a source of high-purity, mercury free argon regulated to 50 PSI.

7.2 Santoprene Peristaltic Pump Tubing: Green/Green (PSA part number M025T002 or equivalent) for blank and autosampler rinse, Grey/Grey (PSA part number M055T005 or equivalent) for sample and stannous chloride.

7.3 Electric Hot Plate: Adjustable and capable of maintaining a temperature of 90-95°C equipped with graphite carbon blocks that each have 36 positions to hold the sample tubes.

NOTE: Hotplate/Block temperatures are monitored regularly using NIST calibrated and traceable thermometers. If any thermometer is suspected to not be reading the temperatures correctly, it is replaced with another certified thermometer.

7.4 CEM Mars 6 Xpress Microwave Oven: Equipped with temperature control sensors and high pressure perfluoropolymer vessels.

7.5 Digestion Tubes: 50mL disposable polyethylene screw cap digestion tubes.

7.6 Other: Adjustable Eppendorf pipettes and replacement tips

8. Reagents and Standards

ACS Trace Metal grade chemicals shall be used in all tests. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination. If the purity of a reagent is in question, analyze for contamination. If the concentration is less than the MDL then the reagent is acceptable.

Solutions below expire six months from preparation unless noted.

Stock standard solutions are stored in a cabinet, out of direct light

8.1 Deionized (DI) water: The Barnstead NANO-pure system provides Type I water used in the preparation of samples and standards.

8.2 Hydrochloric acid, concentrated (HCl): ACS reagent grade Hydrochloric acid (1:1 HCl) - Add 500mL concentrated HCl to 400mL DI water and dilute to 1L. 10% HCl – Add 100 mL concentrated HCl to approximately 500 mL DI and bring to 1 L with DI. Lots should be checked for purity prior to use and the results stored in a reagent check log book.

8.3 Nitric acid, concentrated (HNO_3): ACS reagent grade Nitric Acid (1:1 HNO_3) - Add 500mL concentrated HNO_3 to 400mL DI water and dilute to 1L. Prepare 1% Nitric Acid by diluting 1mL of concentrated HNO_3 up to 100mL in DI water. Lots should be checked for purity prior to use and the results stored in a reagent check log book.

8.4 Hydroxylamine hydrochloride ($NH_2OH{\cdot}HCl$): ACS reagent grade. Prepare 12% solution by adding 12 g per 100 mL of DI.

8.5 Stannous Chloride ($SnCl_2{\cdot}H_20$): ACS reagent grade. Prepare 2% solution by adding 20 g to 1L of 10% HCl. Prepare daily. Solution may be purged with argon at 2 L/minute for 30 minutes to remove Hg impurities.

8.6 Potassium Bromate ($KBrO_3$): ACS grade. May be baked in muffle furnace at 250°C for 8 hours to remove mercury impurities.

8.7 Potassium Bromide (KBr): ACS grade. May be baked in muffle furnace at 250°C for 8 hours to remove mercury impurities.

8.8 Bromine Chloride (BrCl): Prepare in a BOD bottle under a fume hood by adding 5.4 g KBr and 7.6 g $KBrO_3$ to 500mL of concentrated HCl and mix. Final concentration is 0.2N. Solution will turn yellow. **Free Halogens are generated from this solution. Seal the bottle when taking out of fume hood.**

8.9 Stock and Working Standards:

The 1000 µg/L working standards must be prepared in the same manner as samples. These standards are then diluted to make calibration and calibration check standards. After preparation, the 1000 µg/L working standards can be used for one week.

8.9.1 1000 mg/L Stock Calibration Mercury Standard. Purchased.

8.9.1.1 1000 µg/L Working Standard for Tissues: Prepare by adding 0.05mL of 1000 mg/L stock to a microwave digestion vessel containing 10mL of concentrated HNO_3. This standard is digested along with samples according to Method 3051 (SOP 2150). The standard is then brought to a 50mL final volume with DI water in a screw cap digestion tube.

8.9.1.2 1000 µg/L Working Standard for Soils/Sediments: Prepare by adding 0.05 mL of 1000 mg/L stock (Section 8.9.1) to a 50 mL screw cap digestion tube containing 5 mL of DI water, 1.25 mL of concentrated HNO_3 and 3.75 mL of concentrated HCl. This standard is digested along with samples. The standard is then brought to a 50 mL final volume with DI water.

8.9.1.3 100 µg/L Intermediate Standard: Prepare by adding 0.1 mL of the 1000 µg/L working standard (Section 8.9.1.1 or 8.9.1.2) to 0.9 mL DI water. This intermediate standard is used for calibration standards preparation and then discarded.

8.9.1.4 10 µg/L Intermediate Standard: Prepare by adding 0.1 mL of the 100 µg/L working standard (Section 8.9.1.3) to 0.9 mL DI. This intermediate standard is used for calibration standards preparation and then discarded.

8.9.1.5 5 µg/L Intermediate Standard: Prepare by adding 0.25 mL of the 1000 µg/L working standard (Section 8.9.1.1 or 8.9.1.2) to 50 mL graduated digestion tube containing 2% HCl. Bring to 50 mL final volume.

8.9.2 1000 mg/L Stock ICV Mercury Standard: Purchased.

8.9.2.1 1000 µg/L ICV Working Standard for Tissues: Prepare by adding 0.05 mL of 1000 mg/L stock to a microwave digestion vessel containing 10 mL of concentrated HNO_3. This standard is digested along with samples according to Method 3051 (SOP-2150). The standard is then brought to a 50 mL final volume with DI water in a screw cap digestion tube.

8.9.2.2 1000 µg/L ICV Working Standard for Soils/Sediments: Prepare by adding 0.05 mL of 1000 mg/L stock to a 50 mL screw cap digestion tube containing 5 mL of DI water, 1.25 mL of concentrated HNO_3 and 3.75 mL of concentrated HCl. This standard is digested along with samples. The standard is then brought to a 50 mL final volume with DI water.

8.9.2.3 5 µg/L Intermediate Standard: Prepare by adding 0.25 mL of the 1000 µg/L working standard (Section 8.9.2.1 or 8.9.2.2) to 50 mL graduated digestion tube containing 2% HCl. Bring to 50 mL final volume.

8.9.2.4 1000 µg/L LCS and Matrix Standard for Tissues and Soils/Sediments: Prepare by adding 0.1 mL of 1000 mg/L stock (8.9.2) to a 100 mL volumetric flask containing 2% HCL.

8.10 Calibration and Calibration Check Standards

8.10.1 Standards Preparation for Method 7474 Tissues

To 50 mL screw cap digestion tubes, add 10 mL of DI water and 2 mL of concentrated HNO3. Add the volumes of each standard as indicated in the table below, 2 mL of BrCl solution and bring to 50 mL. The same volume of the 1000 µg/L ICV stock is added to the preparation batch LCS and matrix spike sample.

If more than 2 mL of BrCl solution was added to samples to maintain the yellow color, add the same amount to standards. 0.2 mL of 12% hydroxyl amine hydrochloride is added to each vial and shaken. The yellow color should disappear.

8.10.2 Standards Preparation for Method 7474 Soils/Sediments

To 50 mL screw cap digestion tubes, add 10 mL of DI water, 0.75 mL of concentrated HCl and 0.25 mL of concentrated HNO_3. Add the volumes of each standard as indicated in the table below, 2 mL of BrCl solution and bring to 50 mL. The same volume of the 1000 µg/L ICV stock is added to the preparation batch LCS and matrix spike sample.

If more than 2 mL of BrCl solution was added to samples to maintain the yellow color, add the same amount to standards. 0.2 mL of 12% hydroxyl amine hydrochloride is added to each vial and shaken. The yellow color should disappear.

8.10.3 Calibration, Calibration Check Standards, LCS and Matrix Spike

Calibration and calibration check standards are prepared by adding standard volumes to vials prepared for tissues and soils/sediments as designated in the following table:

Standard ID	Vol. 1000 µg/L (mL) (Sec. 8.9.1.1 or 8.9.1.2)	Vol. 100 µg/L (mL) (Sec. 8.9.1.3)	Vol. 10 µg/L (mL) (Sec. 8.9.1.4)	Final Concentration (µg/L)
STD0	-	-	-	0.0
STD1	-	-	0.25	0.05
STD2	-	0.05	-	0.1
STD3	-	0.25	-	0.5
STD4	0.1	-	-	2.0
STD5	0.25	-	-	5.0
ICV, CCV	0.125 (Sec. 8.9.2.1 or 8.9.2.2)			2.5
LCS, MS	0.125 (Sec. 8.9.2.4)			2.5

Lower detection limits and analytical reporting limits may be required at times for some samples. Lower limits are attained by increasing the instrumental gain from 10 to 100 and by calibrating using lower concentration standards. Calibration standards and the LCS and MS are prepared as in the following table:

Standard ID	Vol. 5 µg/L Standard (Section 8.9.1.1 through .5) (mL)	Final Concentration (µg/L)
STD0	-	0.000
STD1	0.05	0.005
STD2	0.10	0.010
STD3	0.20	0.020
STD4	0.50	0.050
STD5	1.0	0.100
STD6	2.0	0.200
ICV,CCV,LCS, MS	1.0	0.100

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

9.1 Blanks

9.1.1 Method Blank

A method blank must be prepared once per every 20 samples or per digestion batch, whichever is more frequent.

Mercury must not be detectable in the method blank at a concentration greater than the reporting limit.

Corrective Action: Analysis according to the appropriate analytical SOP may be repeated once to see if an analytical error has occurred. Digestion of the method blank and all associated samples must be performed until the blank is in control. Samples cannot be analyzed until an acceptable method blank analysis is obtained. Exceptions may be made with approval of the Metals Department Manager, Laboratory Director or QAO, if the samples associated with the out of control method blank are non-detect for the elements of interest, or if sample concentrations are greater than 10x the blank levels. In such cases, the sample results are accepted without corrective action for the high method blank and the client is notified in a project narrative associated with the sample results.

9.1.2 Initial Calibration Blank (ICB)

An initial calibration blank must be analyzed immediately following the ICV (see 9.3).

Mercury must not be detectable in the ICB at a concentration greater than the reporting limit.

Corrective Action: May reanalyze the standard once. If the concentration still exceeds the acceptance limit, stop and recalibrate the instrument. Samples cannot be analyzed until

an acceptable ICB analysis is obtained. Exceptions may be made with approval of the Metals Department Manager, Laboratory Director or QAO, if the samples associated with the out of control blank are non-detect for mercury, or if sample concentrations are greater than 10x the blank levels. In such cases, the sample results are accepted without corrective action for the high blank and the client is notified in a project narrative associated with the sample results.

9.1.3 Continuing Calibration Blank

A continuing calibration blank must be analyzed immediately following the CCV (see 9.4).

Mercury must not be detectable in the CCB at a concentration greater than the reporting limit.

Corrective Action: May reanalyze the standard once. If the concentration still exceeds the acceptance limit, stop, recalibrate the instrument and reanalyze all associated samples. Samples cannot be analyzed until an acceptable CCB analysis is obtained. Exceptions may be made with approval of the Metals Department Manager, Laboratory Director or QAO, if the samples associated with the out of control blank are non-detect for the elements of interest, or if sample concentrations are greater than 10x the blank levels. In such cases, the sample results are accepted without corrective action for the high method blank and the client is notified in a project narrative associated with the sample results.

9.2 Laboratory Control Sample (LCS)

Laboratory control sample (LCS) must be prepared once per every 20 samples or per digestion batch, whichever is more frequent, and spiked with a solution prepared from a second source or lot number, other than the source used to verify the accuracy of the standard curve for the determinative analytical method. The LCS contains all target elements of interest, and is digested along with the samples as verification of the accuracy of the entire digestion procedure.

The acceptable recovery QC limits are 80 – 120%. The recovery limits are continuously monitored and documented in-house through control charts. The *Control Limit Generation* SOP (1734) provides details explaining how control charts are generated and used for quality control.

Corrective Action: Analysis according to the appropriate analytical SOP may be repeated once to see if an analytical error has occurred. If the LCS recovery is still out of control, re-prepare and re-analyze the LCS and all associated samples. Samples cannot be reported until an acceptable LCS is obtained. Exceptions may be made with approval of the Metals Department Manager, Laboratory Director or QAO, if the samples associated with the out of control LCS are also associated with a matrix spike that is in control. This is an acceptable measure of accuracy of the digestion and analytical procedures. An explanation of the out of control LCS recovery must be included in the project narrative to the client and the sample data reported noting the acceptable MS results as batch QC.

9.3 Initial Calibration Verification (ICV)

An initial calibration verification standard from a source different from that used to calibrate the instrument (see 8.9.2) must be analyzed immediately following calibration as an independent check of instrument performance. Nominal acceptance limits are 90% - 110% of the true value.

Corrective Action: May reanalyze the standard once. If the concentration still exceeds the acceptance limit, stop and recalibrate the instrument. Samples cannot be analyzed until an

acceptable ICV analysis is obtained. Exceptions may be made with approval of the Metals Department Manager, Laboratory Director or QAO, if the samples associated with a high recovery ICV are non-detect. In such cases, the sample results are accepted without corrective action for the high ICV recovery and the client is notified in a project narrative associated with the sample results.

9.4 Continuing Calibration Verification (CCV)

A continuing calibration verification standard must be analyzed after analysis of no more than 10 samples as an on-going check of instrument performance. Nominal acceptance limits are 90% - 110% of the true value.

Corrective Action: May reanalyze the standard once. If the concentration still exceeds the acceptance limit, stop, recalibrate the instrument and reanalyze all associated samples. Results cannot be accepted until an acceptable CCV analysis is obtained. Exceptions may be made with approval of the Metals Department Manager, Laboratory Director or QAO, if the samples associated with a high recovery CCV are non-detect. In such cases, the sample results are accepted without corrective action for the high CCV recovery and the client is notified in a project narrative associated with the sample results.

9.5 Matrix Spike

A matrix spike (MS) sample must be performed once per 20 samples (5% frequency), or per digestion batch, whichever is more frequent. The MS contains all target elements of interest.

The acceptable % recovery QC limits are 80% – 120%. The % recovery QC limits are continuously monitored and documented in-house through control charts. The *Control Limit Generation* SOP (1734) provides details explaining how control charts are generated and used for quality control.

Corrective Action: Analysis according to the appropriate analytical SOP may be repeated once to see if an analytical error has occurred. If the % recovery still exceeds the control limits and the LCS is compliant, include a project narrative with the results to the client noting that there may be potential matrix effects on the accuracy of the reported results as evidenced by MS recovery outside of QC limits.

9.6 Laboratory Duplicate

Duplicate analyses (matrix or sample duplicate) must be performed once per 20 samples 5% frequency), or per digestion batch, whichever is more frequent.

Acceptable relative percent differences (RPD) of duplicates is $\leq$ 20%. This acceptance criterion is not applicable to sample concentrations less than 5 times the reporting limit. Calculate the RPD as follows:

$$RPD = \frac{R1 - R2}{\frac{[R1 + R2]}{2}} \times 100$$

where:

R1 = sample Replicate #1
R2 = sample Replicate #2

The RPD limits are continuously monitored and documented in-house through control charts. The *Control Limit Generation* SOP (1734) provides details explaining how control charts are generated and used for quality control.

Corrective Action: Analysis may be repeated once to see if an analytical error has occurred. If the % RPD still exceeds the control limits; include a project narrative with the results to client noting that there may be potential matrix effects on the precision of the reported metals results as evidenced by the matrix duplicate %RPD exceedance.

9.7 Method-specific Quality Control Samples

None.

10. Procedure

10.1 Equipment Set-up

Samples are prioritized by the Metals Department Manager or Preparation Group Leader for digestion based on hold time and client due date. The analyst must be familiar with instrument software and hardware as described in the user manuals supplied with the instrument before attempting to perform an analysis.

Power to the instrument, autosampler , PC and the argon gas supply are turned on. Peristaltic pump windings are inspected for wear and replaced if necessary. The winding clips are relaxed in between usage. The instrument manufacturer suggests that the pump tubing be changed once per month or more frequently as needed.

The stannous chloride solution is attached to the grey/grey pump tubing, 10% HCl is attached to the green/green autosampler rinse and DI is attached to the geen/green rinse blank. The

autosampler probe line is attached to a grey/grey pump tubing. The pumps are turned on via the software and the flow is checked to insure that solutions are delivered to the mixing valve.

10.1.1 Sample Preparation

10.1.1.1 Tissues

Tissue samples are prepared by microwave oven assisted acid digestion according to SOP 2150. The LCS and MS are spiked as indicated in the table in 8.10.3.

A 10 mL aliquot of each digest is added to a 50 mL screw cap digestion tube along with 2 mL of BrCl solution. The vial contents should remain a yellow color. If a yellow color does not remain, add more BrCl solution. This solution is allowed to stand for 15 minutes. Bring the vial to 50 mL with DI water . The vials are then decolorized with 0.4 mL of 12% hydroxyl amine hydrochloride and shaken. The yellow color should disappear. If the solution remains yellow, add more hydroxyl amine until the color disappears. Add the same amount to all samples and standards.

10.1.1.2 Soils/Sediment

A 0.5 – 1.0 g wet weight well mixed aliquot of soil/sediment is added to a 50 mL screw cap digestion tube with 5 mL of DI water. The LCS and MS are spiked as indicated in the table in 8.10.3. A 3.75 mL volume of concentrated HCl and 1.25 mL of concentrated HNO_3 are added and the tube placed on the hot block set to 95 ± 3 ^oC for 2 minutes. Samples are allowed to cool and then 25 mL of DI water is added to each vial and placed back on the hot block for 30 minutes.

After cooling bring to a final volume of 50 mL with DI water. Then a 10 mL aliquot of each digest is added to a 50 mL screw cap digestion tube along 2 mL of BrCl solution. The vial contents should remain a yellow color. If a yellow color does not remain, add more BrCl solution. Allow samples to react for 15 minutes. The vials are then decolorized with 0.4 mL of 12% hydroxyl amine hydrochloride, brought to a final volume of 50 mL and shaken. The yellow color should disappear. If the solution remains yellow, add more hydroxyl amine until the color disappears. Add the same amount to all samples and standards.

10.2 Initial Calibration

The instrument is calibrated prior to sample analysis and at least once every 24 hours. A linear least squares regression calibration curve is selected for Method 7474.

In all cases, a correlation coefficient ≥ 0.995 is required before the analysis of samples can begin. The calibration blank is included as a point in the calibration curve.

An ICV (Section 9.3) and ICB (Section 9.1.2) are analyzed after calibration.

10.3 Equipment Operation and Sample Processing

After initializing the Millennium software, the instrument is turned on via the software and allowed to warm up for 30 minutes. The analysis method is selected and the autosampler template is selected. Method 7474 is set up in the software which specifies delay, read and

rinse times as well as pump speeds. An autosampler template is set up specifying calibration standard, QC standards and positions on the autosampler rack. Once sample ID's have been typed in, the file is saved as the Job number.

A Work Group is obtained from LIMS and used as the data file name.

The analysis is initiated by clicking on the start button on the analysis page.

Following analysis, the data file is exported to the LIMS on the O: Metals\Millennium drive for data processing. The instrument and autosampler are then rinsed with DI water and turned off

10.4 Continuing Calibration

Periodically (after no more than 10 samples) and at the end of the analysis, CCV standards (Section 9.4) and CCB standards (Section 9.1.3) are analyzed.

10.5 Preventive Maintenance

Inspect pump tubing for signs of wear and replace monthly or more frequently if necessary.

Clean glass liquid separator when glass appears coated with yellow film.

Replace dryer tube annually.

11. Data Evaluation, Calculations and Reporting

Procedures for data and record management must adhere to the Quality Systems Manual, other subordinate documents covering record keeping, and the *Document Control* SOP (1729). All records must be stored in such a manner as to be safe and accessible for at least 10 years.

The digestion batch bench sheets and other relevant laboratory notebooks must follow the specifications in all record keeping and document control practices.

Sample concentrations are calculated as follows:

Sample Concentration = ((Dc*Df)*Dv)/((Md*(S%/100)*1000))

Where:

Dc = digest Concentration in µg/L
Df = Dilution factor
Dv = Digest volume in mL
Md = Mass of sample digested in g
S% = percent solid of the sample (if reported on wet weight basis then percent solid = 100)

All results are reportable without qualification if digestion and analytical holding times are met, preservation (including cooler temperatures) are met, all QC criteria defined in the table below are met, and matrix interference is not suspected during digestion or analysis of the samples. If any of the below QC parameters are not met, all associated samples must be evaluated for re-extraction and/or re-analysis

QC Parameter	Acceptance Criteria
Method Blank	< reporting limit
Laboratory Control Sample	80%-120% Recovery
Matrix Duplicate	≤ 20% RPD
Matrix Spike	80% - 120% Recovery
Matrix Spike Duplicate (if needed)	≤ 20% RPD, 80% - 120% Recovery

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

Section 9 outlines sample batch QC acceptance criteria. If non-compliant results are to be reported, the Metals Department Manager and/or the Laboratory Director, and the QA Manager must approve the reporting of the results. The laboratory Project Manager shall be notified, and may chose to relay the non-compliance to the client, for approval, or other corrective action, such as re-sampling and re-analysis. The instrument analyst or Department Manager performing the secondary analytical review initiates the project narrative, and the narrative must clearly document the non-compliance and provide a reason for acceptance of these results.

13. Method Performance

13.1 Detection Limit Study (DL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the DL, LOD, and/or LOQ as outlined in Alpha SOP/1732. These studies performed by the laboratory are maintained on file for review.

13.2 Demonstration of Capability Studies

Refer to Alpha SOP/1739 for further information regarding IDC/DOC Generation.

13.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method

13.3 Instrument Detection Limits

The instrument detection limit (IDL) is the smallest signal above the background noise that an instrument can detect. The IDL can be calculated taking the average of the standard deviations for three measurements of a reagent blank solution analyzed on three analytical runs on three non-consecutive days. Seven consecutive measurements must be taken per day. The IDLs are

not required to go through sample digestion. Each measurement must be performed as though it were a separate sample.

14. Pollution Prevention and Waste Management

The *Hazardous Waste and Sample Disposal* SOP (1797) must be referenced for disposal of used standards, solvents, acids, reagents or other chemicals.

Once sample batches have completed digestion, the sample containers are stored in the metals lab and held for 30 days. If there is no sample remaining in the sample collection bottle, it may be rinsed and thrown away. It must be noted in the *Internal COC* that there is no sample remaining in the bottle, and the bottle was discarded.

Once satisfactory results have been generated, the digestates are held for 30 days, or longer if specified by a client contract, then discarded into a 55-gallon drum labeled “Corrosive Liquid”.

All reagent waste generated during digestion must be stored in satellite containers in the metals preparation laboratory.

Once the reagent waste satellite containers are full, they must be emptied into 55-gallon drums marked “Corrosive Liquid”.

Refer to Alpha’s Chemical Hygiene Plan and Waste Management and Disposal SOP for further pollution prevention and waste management information.

Mercury in Solid or Semisolid Waste
(Manual Cold-Vapor Technique)

Reference Method No.: **EPA 7471B**

Reference: SW-846, Test Methods for Evaluating Solid Waste: Physical/Chemical Methods, EPA SW-846, Update III, February 2007.

1. Scope and Application

Matrices: Method 7471 is approved for measuring total mercury (organic and inorganic) in soils, sediments, bottom deposits, and sludge-type materials. All samples must be subjected to an appropriate dissolution step prior to analysis. If this dissolution procedure is not sufficient to dissolve a specific matrix type or sample, then this method is not applicable for that matrix.

Definitions: Refer to Alpha Analytical Quality Manual.

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one or more of the following laboratory personnel before performing the modification: Area Supervisor, Department Supervisor, Laboratory Director, or Quality Assurance Officer.

This method is restricted to use by or under the supervision of analysts experienced in the operation of the Mercury Analyzer and in the interpretation of Mercury data. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability..

2. Summary of Method

Prior to analysis, the solid or semi-solid samples must be prepared according to the procedures discussed in this method.

Method 7471, a cold-vapor atomic absorption method, is based on the absorption of radiation at the 253.7-nm wavelength by mercury vapor. The mercury is reduced to the elemental state and aerated from solution in a closed system. The mercury vapor passes through a cell positioned in the light path of an atomic absorption spectrophotometer. Absorbance (peak height) is measured as a function of mercury concentration.

2.1 Method Modifications from Reference

Alpha analyzes only one 0.3g aliquot of sample. The original method does not address the automated instrument procedure. A reduced volume of sample is digested in disposable digestion tubes on a hot block digestor.

3. Reporting Limits

The reporting limit for this method is 0.08mg/Kg.

4. Interferences

Potassium permanganate is added to eliminate possible interference from sulfide. Concentrations as high as 20 mg/Kg of sulfide, as sodium sulfide, do not interfere with the recovery of added inorganic mercury in reagent water.

Copper has also been reported to interfere; however, copper concentrations as high as 10 mg/Kg had no effect on recovery of mercury from spiked samples.

Samples high in chlorides require additional permanganate (as much as 25 mL) because, during the oxidation step, chlorides are converted to free chlorine, which also absorbs radiation of 253 nm. Care must therefore be taken to ensure that free chlorine is absent before the mercury is reduced and swept into the cell. This may be accomplished by using an excess of hydroxylamine sulfate reagent (25 mL).

Certain volatile organic materials that absorb at this wavelength may also cause interference. A preliminary run without reagents should determine if this type of interference is present.

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material safety data sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

Because mercury vapor is toxic, precaution must be taken to avoid its inhalation.

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

Samples may be collected in plastic or glass containers.

6.2 Sample Preservation

None.

6.3 Sample Shipping

No special shipping requirements.

6.4 Sample Handling

Samples are stored under refrigeration at 4°C and analyzed as soon as possible after collection. The samples have a 28-day holding time from the time of collection.

7. Equipment and Supplies

7.1 Instrumentation:

Perkin Elmer FIMS 100 Atomic absorption spectrophotometer: Use instrument settings recommended by the manufacturer. The PE FIMS is designed specifically

for the measurement of mercury using the cold-vapor technique with BOC (background offset correction) performed by a survey scan prior to each sample introduction. PE S10 autosampler is coupled to the instrument.

Cetac M-6100 Atomic absorption spectrophotometer: Use instrument settings recommended by the manufacturer. This instrument employs a reference cell off-set correction and full automation through the CETAC software. A Cetac ASX-260 autosampler is coupled to the instrument.

Nippon Instrument model# RA-4300A analyzer with integrated 80 position autosampler:

The instrument adds a stannous chloride (II) solution to the sample post digestion, the divalent mercury ion (Hg2+) is reduced to zero-valent metallic mercury and turns into mercury gas by bubbling. $Hg2{+}{+}SnCl2 \rightarrow Hg0 \uparrow$

After removing the acid mist and water vapor generated by bubbling with an electronic cooling unit, the instrument measures the absorbance of mercury at 253.7 nm absorption wavelength. It measures the known mercury amount, creates a calibration curve, and then calculates the mercury amount from the absorbance.

7.2 Hot Block Digestor: Environmental Express, 54 position, capable of maintaining a temperature of 95°C +/-3°C.

7.3 Graduated cylinder. Rinse once with 50% Nitric Acid, then rinse with reagent water prior to use.

7.4 Volumetric Flasks, Class A, various volumes. Rinse once with 50% Nitric Acid, then rinse with reagent water prior to use.

7.5 Polypropylene Digestion Vessels: 50 mL volume, with plastic screw caps

7.6 Pump Tubing: Environmental Express, three stop and two stop tubing in various IDs.

7.7 PTFE membranes: Pall TF1000 disks

7.8 Dilution vials: 20mL capacity, used when making analytical dilutions.

7.9 Laboratory Wipes

7.10 Compressed Air

7.11 Whatman 41 or equivalent filter paper

7.12 Eppendorf pipets: Accurate means to make trace standards

8. Reagents and Standards

8.1 Reagent Water: Reagent water is DI water shown to be interference free. All references to water in this method refer to reagent water unless otherwise specified.

8.2 Aqua regia: Prepare immediately before use by carefully adding three volumes of concentrated HCl to one volume of concentrated HNO_3.

8.3 Concentrated Nitric Acid, (HNO_3): Trace grade. Store at room temperature in the appropriately marked acid cabinet.

8.4 Concentrated Hydrochloric Acid, (HCl): Trace grade. Store at room temperature in the appropriately marked acid cabinet.

8.5 Reductant, Stannous Chloride in 3% HCl: This is the ***reductant*** for the Instrument. In a 1L volumetric flask, add 30mL concentrated trace grade HCl and 11g $SnCl_2 \cdot 2H_20$. Mix to dissolve the solid and bring to volume with reagent water. Store at room temperature, prepare as needed.

8.6 Carrier, Hydrochloric Acid, 3%: This is the ***carrier*** for the instrument. In a 1L volumetric flask, add 30mL concentrated trace grade HCl (Section 8.4). Bring to volume with reagent water. Store at room temperature, prepare as needed.

8.7 Potassium permanganate, mercury-free, 5% solution (w/v): Dissolve 5 g of potassium permanganate in 100 mL of reagent water. Store at room temperature.

8.8 Sodium chloride-hydroxylamine hydrochloride solution: Dissolve 12 g of sodium chloride and 12 g of hydroxylamine hydrochloride in reagent water and dilute to 100 mL. Store at room temperature.

8.9 Mercury stock solution, 1000ppm: This solution is purchased commercially prepared with a certificate of analysis. Three solutions are purchased, each from a different source. Store at room temperature. Expires according to manufacturer's specifications.

8.9.1 10ppm Mercury Stock Standard: To a 100mL volumetric flask, add 5mL of concentrated HNO_3 and 1.0mL of 1000ppm Mercury Stock Solution (Section 8.9). Bring to volume with reagent water. Store at room temperature. Expires one month from date of preparation.

8.9.1.1 0.1ppm Mercury Working Stock / Matrix Spike Solution: To a 500mL volumetric flask, add 5mL of concentrated HNO_3 and 5 mL of 10ppm Mercury Stock Standard (Section 8.9.1). Bring to volume with reagent water. Store at room temperature. Expires one week from date of preparation.

8.9.2 10ppm Mercury ICV Stock Standard: To a 100mL volumetric flask, add 5mL of concentrated HNO_3 and 1.0mL of Mercury Stock Solution (Section 8.9, from an alternate source than that used in Section 8.9.1). Bring to volume with reagent water. Store at room temperature. Expires one month from date of preparation.

8.9.2.1 0.3ppm Mercury ICV Working Stock: To a 100mL volumetric flask, add 5mL of concentrated HNO_3 and 3.0mL of 10ppm Hg ICV Stock Standard (Section 8.9.2). Bring to volume with reagent water. Store at room temperature. Expires one week from date of preparation.

8.9.3 10ppm Mercury LCS Stock Standard: To a 100mL volumetric flask, add 5mL of concentrated HNO_3 and 1.0mL of 1000ppm Mercury Stock Solution (Section 8.9, from an alternate source than that used in Sections 8.9.1 and 8.9.2). Bring to volume with reagent water. Store at room temperature. Expires one month from date of preparation.

8.9.3.1 0.1ppm Mercury LCS Working Stock: To a 100mL volumetric flask, add 5mL of concentrated HNO_3 and 1.0mL of 10ppm Mercury LCS Stock Standard (Section

8.9.3). Bring to volume with reagent water. Store at room temperature. Expires one week from date of preparation.

8.10 SRM: Purchased from ERA in 300-500g lots.

9. Quality Control and Data Assessment

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

9.1 Blank(s)

The Method Blank consists of the 0ppm standard as prepared in Section 10.1.2.1.1. Analyze one Method Blank per analytical batch of twenty samples or less. The Method Blank must be less than the Reporting Limit (RL). See Section 12.1 for corrective action.

9.1.1 PBS

A preparation blank is analyzed once per batch of twenty samples or less. It is prepared in the same manner as the 0ppm standard (Section 10.1.2.1.1). The PBS must be recovered within ± 0.2 µg/L.

9.1.2 ICB

The ICB is analyzed after the ICV, and is prepared in the same manner as the 0ppm standard (Section 10.1.2.1.1). The ICB must be recovered within ± 0.2 µg/L.

9.1.3 CCB

The CCB is analyzed after the CCV. It is prepared in the same manner as the 0ppm standard (Section 10.1.2.1.1). The CCB must be recovered within ± 0.2 µg/L.

9.2 Laboratory Control Sample (LCS)

The LCS is analyzed once per each analytical batch of twenty samples or less. It is prepared in the same manner as in Section 10.1.2.3. The LCS must be recovered within 80 – 120% of the true value. See Section 12.3 for corrective action.

9.3 Initial Calibration Verification (ICV)

The ICV is analyzed after the calibration curve. It is prepared in the manner specified in Section 10.1.2.2. The ICV must be recovered within ± 10% of the true value. See Section 12.2 for corrective action.

9.4 Continuing Calibration Verification (CCV)

The CCV is analyzed after every ten analytical samples. It is prepared in the same manner as the 5.0ppb calibration standard (Section 10.1.2.1.5). The CCV must be recovered within 20% of the true value. See Section 12.2 for corrective action.

9.5 Matrix Spike

Analyze one matrix spike per twenty or less analytical samples. The recovery of the matrix spike must be between 80 – 120%. Calculate percent recovery using Section 11.2.

If the recovery of the matrix spike is out of range, a post-analytical spike is analyzed. Prepare the post analytical spike by adding 1.25mL of 0.020ppm Calibration Standard

(Section 10.1.2.1.6) and 1.25mL of the sample digestate to a 15mL centrifuge tube for a final concentration of 0.0105mg/L. Analyze the post spike as outlined in Section 10.3.

Calculate the post spike concentration as follows:

Post Analytical Spike Sample Concentration (mg/L) =

[Sample Concentration (mg/L) x (0.5)] + 0.010mg/L

The percent recovery of the post-analytical spike must be between 75 – 125%.

See Section 12.4 for corrective action.

9.6 Laboratory Duplicate

Analyze one sample in duplicate per twenty or less analytical samples. The RPD between the sample and its duplicate must be ≤ 20% (as calculated in Section 11.3). See Section 12.5 for corrective action.

9.7 Method-specific Quality Control Samples

None

9.8 Method Sequence

10. Procedure

10.1 Equipment Set-Up

10.1.1 Sample preparation: Weigh a 0.3-g portion of untreated and homogenized sample and place in the bottom of a polypropylene digestion vessel. Record the weight in the laboratory notebook. NOTE: When preparing the batch, include one sample duplicate aliquot to be prepared in the same manner.

Add 2.5 mL of reagent water and 2.5 mL of aqua regia (Section 8.2). Heat 2 min on a hot block at 95°C +/-3°C. Cool; then add 15 mL reagent water, and 7.5 mL potassium permanganate solution (Section 8.7) to the digestion vessel. Wait 15 minutes to be sure the potassium permanganate is not exhausted (purple color disappears), if it does add additional potassium permanganate to all samples and QC until stable. Mix thoroughly and place in the hot block for 30 min at 95°C +/-3°C. Cool and add 3 mL of sodium chloride-hydroxylamine hydrochloride (Section 8.8) to reduce the excess permanganate.

CAUTION: Perform this addition under a hood, as Cl_2 could be evolved.

Bring up to a final volume of 50 mL with reagent water. Continue as described under Section 10.3.1.

10.1.2 Standard preparation: Standard preparation is performed each time samples are digested.

10.1.2.1 Calibration Standards

10.1.2.1.1 0 ppb: Add 10mL of reagent water to a polypropylene digestion vessel. This aliquot may be used for the CCB. Another separate aliquot is prepared for use as the ICB and the diluent for any samples with concentration greater than 90% the highest calibration standard used to determine the linear range.

10.1.2.1.2 0.5ppb: Add 10 mL of reagent water to a polypropylene digestion vessel. Using a volumetric pipet, add 0.25 mL of 0.1ppm Mercury Working Stock (Section 8.9.1.1) to the digestion vesel.

10.1.2.1.3 1.0ppb: Add 10 mL of reagent water to a polypropylene digestion vessel.. Using a volumetric pipet, add 0.5 mL of 0.1ppm Mercury Working Stock (Section 8.9.1.1) to the digestion vessel.

10.1.2.1.4 2.0ppb: Add 10 mL of reagent water to a polypropylene digestion vessel.. Using a volumetric pipet, add 1.0mL of 0.1ppm Mercury Working Stock (Section 8.9.1.1) to the digestion vessel.

10.1.2.1.5 5.0ppb/CCV: Add 10 mL of reagent water to a polypropylene digestion vessel.. Using a volumetric pipet, add 2.5 mL of 0.1ppm Mercury Working Stock (Section 8.9.1.1) to the digestion vessel.

10.1.2.1.6 10ppb: Add 10 mL of reagent water to a polypropylene digestion vessel.Using a volumetric pipet, add 5.0 mL of 0.1ppm Mercury Working Stock (Section 8.9.1.1) to the digestion vessel.

10.1.2.1.7 20ppb: Add 10 mL of reagent water to a polypropylene digestion vessel.Using a volumetric pipet, add 10.0 mL of 0.1ppm Mercury Working Stock (Section 8.9.1.1) to the digestion vessel.

10.1.2.2 ICV Standard, 3.0ppb: This standard is used for calibration verification.

Add 10.0 mL of reagent water to a digestion vessel. Using a volumetric pipet, add 0.5 mL of 0.3ppm Mercury Working Stock (Section 8.9.2.1) to the digestion vessel. Digest the ICV Standard as in Section 10.1.3.

10.1.2.3 LCS Standard, 1.0ppb: This standard is prepared and analyzed with each analytical batch.

Add 5.0mL of reagent water to a digestion vessel. Add 0.15g of SRM (Section 8.10). Digest the LCS Standard as in Section 10.1.3.

10.1.2.4 Matrix Spike, 0.001mg/L: Weigh two aliquots of the sample designated to be the batch matrix spike.

Add 10.0 mL of the reagent water to the digestion vessel containing the weighed sample aliquot. Add a 5 mL aliquot of 0.1ppm Mercury LCS Working Stock (Section 8.9.3.1). Digest the MS as in Section 10.1.3.

10.1.3 Standard Digestion:

To each standard (Sections 10.1.2.1 through 10.1.2.3), add 2.5 mL of reagent water and 2.5 mL of aqua regia (Section 8.2) and heat 2 min on the hot block at 95°C +/- 3°C. Allow the standard to cool; add 15 mL reagent water and 7.5 mL of $KMnO_4$ solution (Section 8.7) to each bottle and return to the hot block for 30 min. Cool and add 3 mL of sodium chloride-hydroxylamine hydrochloride solution (Section 8.8) to reduce the excess permanganate. Bring up to final volume of 50 mL with reagent water, continue as described in Section 10.3.3.

Note: Alternate volumes of standards may be made base on need as long as they are made with the same proportions as describe above.

10.2 Initial Calibration

Construct a calibration curve by plotting the absorbances of prepared standards (Section 10.1.2) versus micrograms of mercury. (See Section 11.1.) Determine the peak height of the unknown from the absorbance maxima on the spectrometer, and read the mercury value from the standard curve.

The curve correlation coefficient (cc) must be greater than or equal to 0.995 in order for the curve to be linear. If the correlation coefficient is less than 0.995, find and correct the problem. When the problem has been corrected, re-analyze either the previous standards or new standards. When the curve has generated an acceptable cc, then the analysis can continue with the ICV/ICB.

Analyze an Initial Calibration Verification Standard (ICV) (Section 9.3), an Initial Calibration Blank sample (ICB) (Section 9.1.2) at the start of the analytical run. The results for the ICV must be within 10% of the true value. If results are outside this range, refer to Section 12.2 for corrective action.

10.3 Equipment Operation and Sample Processing

10.3.1 Instrument Setup

10.3.1.1 Turn the instrument on. The autosampler will initialize itself.

10.3.1.2 Choose the instrument software from the desktop menu. The autosampler will initialize again.

FIMS 100 NOTE: The instrument must be turned on before the application is started. Otherwise, an error message will result.

10.3.1.3 Enter the appropriate fields for sample identification, and data storage.

10.3.1.4 Fill the carrier and reductant bottles.

10.3.1.4.1 The Carrier is 3% HCl (Section 8.6).

10.3.1.4.2 The Reductant is 1.1% $SnCl_2$ in 3% HCl (Section 8.5).

10.3.1.5 Allow the instrument to warm up while clearing samples. Samples that are cloudy or with particulate present after clearing must be filtered through Whatman 41 filter paper (Section 7.11) before analysis.

10.3.1.6 Place carrier uptake line and reductant uptake line.

10.3.1.7 Load carrier and reductant lines into pump magazines

10.3.1.8 Load the two waste lines into the pump magazines below the roller.

10.3.1.9 Lock the magazines into place.

FIMS100 only:

10.3.1.10 Remove the cap from the liquid/vapor separator and wipe dry with a Lab Wipe (Section 7.9). Compressed air (Section 7.10) through the vapor transfer line to dry it out.

10.3.1.11 Place a PTFE membrane (Section 7.7), rough side up, in the liquid/vapor separator; replace the cap and reattach the vapor transfer line to the sample absorption cell.

10.3.1.12 Adjust the gas flow by turning the black knob below the air flow meter to obtain a reading of just over 50.

10.3.2 Calibration and Sample Analysis

10.3.2.1 The instrument will now run the calibration standards; verify a CC of 0.995 or better before proceeding with the ICV and ICB. Ten analytical samples, a CCV and CCB, ten analytical samples, CCV, CCB, etc. The CCBs and CCVs must be recovered within the proper ranges (Sections 9.4 and 9.1.3) for analysis to continue.

10.3.2.2 If the sample result is beyond 90% of the concentration of the highest point on the calibration curve or LDR study used to establish the linear range, dilute the sample extract with a portion of one of the prepared blanks (ICB, CCB or PBS) to produce an analytical result that is within the range.

10.3.3 Instrument Shut Down

10.3.3.1 When analysis is complete place reagent uptake lines in a beaker of DI water.

10.3.3.1.1 Continue to run the pumps for several minutes to flush reagents out of the lines.

10.3.3.1.2 Continue to run the pumps for several more minutes to flush the lines thoroughly with DI water.

10.3.3.2 Pull the reagent uptake lines out of the DI water beaker to allow the pump to draw air completely through the lines.

10.3.3.3 Unlock the top and bottom pump magazines and remove tubing from the magazines.

10.3.3.4 Exit from the software application.

Note: This procedure must be followed every time the instrument is shut down to prevent water or reagents from being draw back into the instrument which can cause severe damage.

10.3.3.4.1 Dump the samples and instrument waste in the Metals/WetChem waste drum located in the transfer room only after all data has been processed through final review and package generation.

10.4 Continuing Calibration

After every 10 samples, analyze a Continuing Calibration Verification Standard (CCV), and a Continuing Calibration Blank sample (CCB). Determine the concentrations from the calibration curve. The results for the CCV must be within 20% of the true value.

10.5 Preventive Maintenance

Preventative maintenance is conducted per the manufacturer's instructions. All preventative maintenance is recorded in the Instrument Maintenance Logbook.

11. Data Evaluation, Calculations and Reporting

11.1 Calculate Mercury Concentration From the Daily Calibration Curve

The curve is generated utilizing a straight-line equation defined as:

$$A = k_1 + k_2C$$

Where:

A = Average peak height of the sample/standard integrations
C = Sample/Standard Concentration, µg/L
k_1 = y-intercept
k2 = slope

The instrument will plot peak height against concentration (µg/L). The result is generated in µg/L. This value is divided by 1000 to convert the units to mg/L. The mg/L units are converted to mg/Kg by multiplying by L/Kg. A dilution factor (DF) is applied if necessary. The Result is then divided by the % Total Solids prior to release to the client.

$$\text{Result, mg/Kg} = (\text{concentration, µg/L}) \times (1\text{mg}/1000\mu\text{g}) \times (\text{DF}) \times (\text{L/Kg})$$

Where:

$$\text{L/Kg} = \frac{\text{Final volume of digestate, in L}}{\text{Weight of original sample, in Kg}}$$

11.2 Calculate Percent Recovery for the Matrix Spike corrected for concentrations measured in the unfortified sample. Percent recovery is calculated using the following equation:

$$\%\ \text{Recovery} = \frac{(Cm - C)}{s} \times 100$$

Where:

Cm = measured Mercury in the fortified sample
C = measured native mercury sample concentration
S = concentration equivalent of spike added to sample

11.3 Calculate the Relative Percent Difference (RPD) for each Duplicate of the initial quantitated concentration (IC) and duplicate quantitated concentration (Dc) using the following formula:

$$RPD = \frac{|(IC - Dc)|}{\{(IC + Dc) / 2\}} \times 100$$

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

12.1 Method Blank Failure

When a prep blank mercury concentration is ≥10% of the mercury concentration determined for any associated sample, or is greater than 2.2x the MDL value (whichever is greater), the entire batch associated with the prep blank must be redigested.

12.2 ICV / CCV Failure

If the ICV %Recovery is outside of acceptance criteria, analysis is terminated until the problem is found and corrected. If the CCV %Recovery is outside of acceptance criteria, all samples analyzed since the last acceptable CCV must be reanalyzed following correction of the problem.

12.3 LCS Failure

If the LCS is not recovered within acceptance criteria, the associated batch and another LCS must be redigested (Section 10.1).

12.4 Matrix Spike/Post Digestion Spike Failure

If the recovery of the matrix spike is outside of the acceptance criteria of 80 – 120%, a post digestion spike is performed (Section 9.5). If the post digestion spike is beyond 75 – 125%, the sample and its spike are redigested (Section 10.1).

12.5 Duplicate Failure

If the RPD between the sample and its duplicate is greater than 20%, visually evaluate the sample matrix. If the sample matrix appears clean, the sample and its duplicate are removed from the batch and redigested (Section 10.1). If the matrix appears problematic, the sample digestate may be diluted and reanalyzed, or a narrative included with the data to explain the matrix problem.

13. Method Performance

13.1 Method Detection Limit Study (MDL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the MDL, LOD, and/or LOQ as outlined in Alpha SOP 1732. These studies performed by the laboratory are maintained on file for review.

13.2 Demonstration of Capability Studies

Refer to Alpha SOP 1739 for further information regarding IDC/DOC Generation.

13.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

14. Pollution Prevention and Waste Management

Refer to Alpha's Chemical Hygiene Plan and Waste Management and Disposal SOP for further pollution prevention and waste management information.

15. Referenced Documents

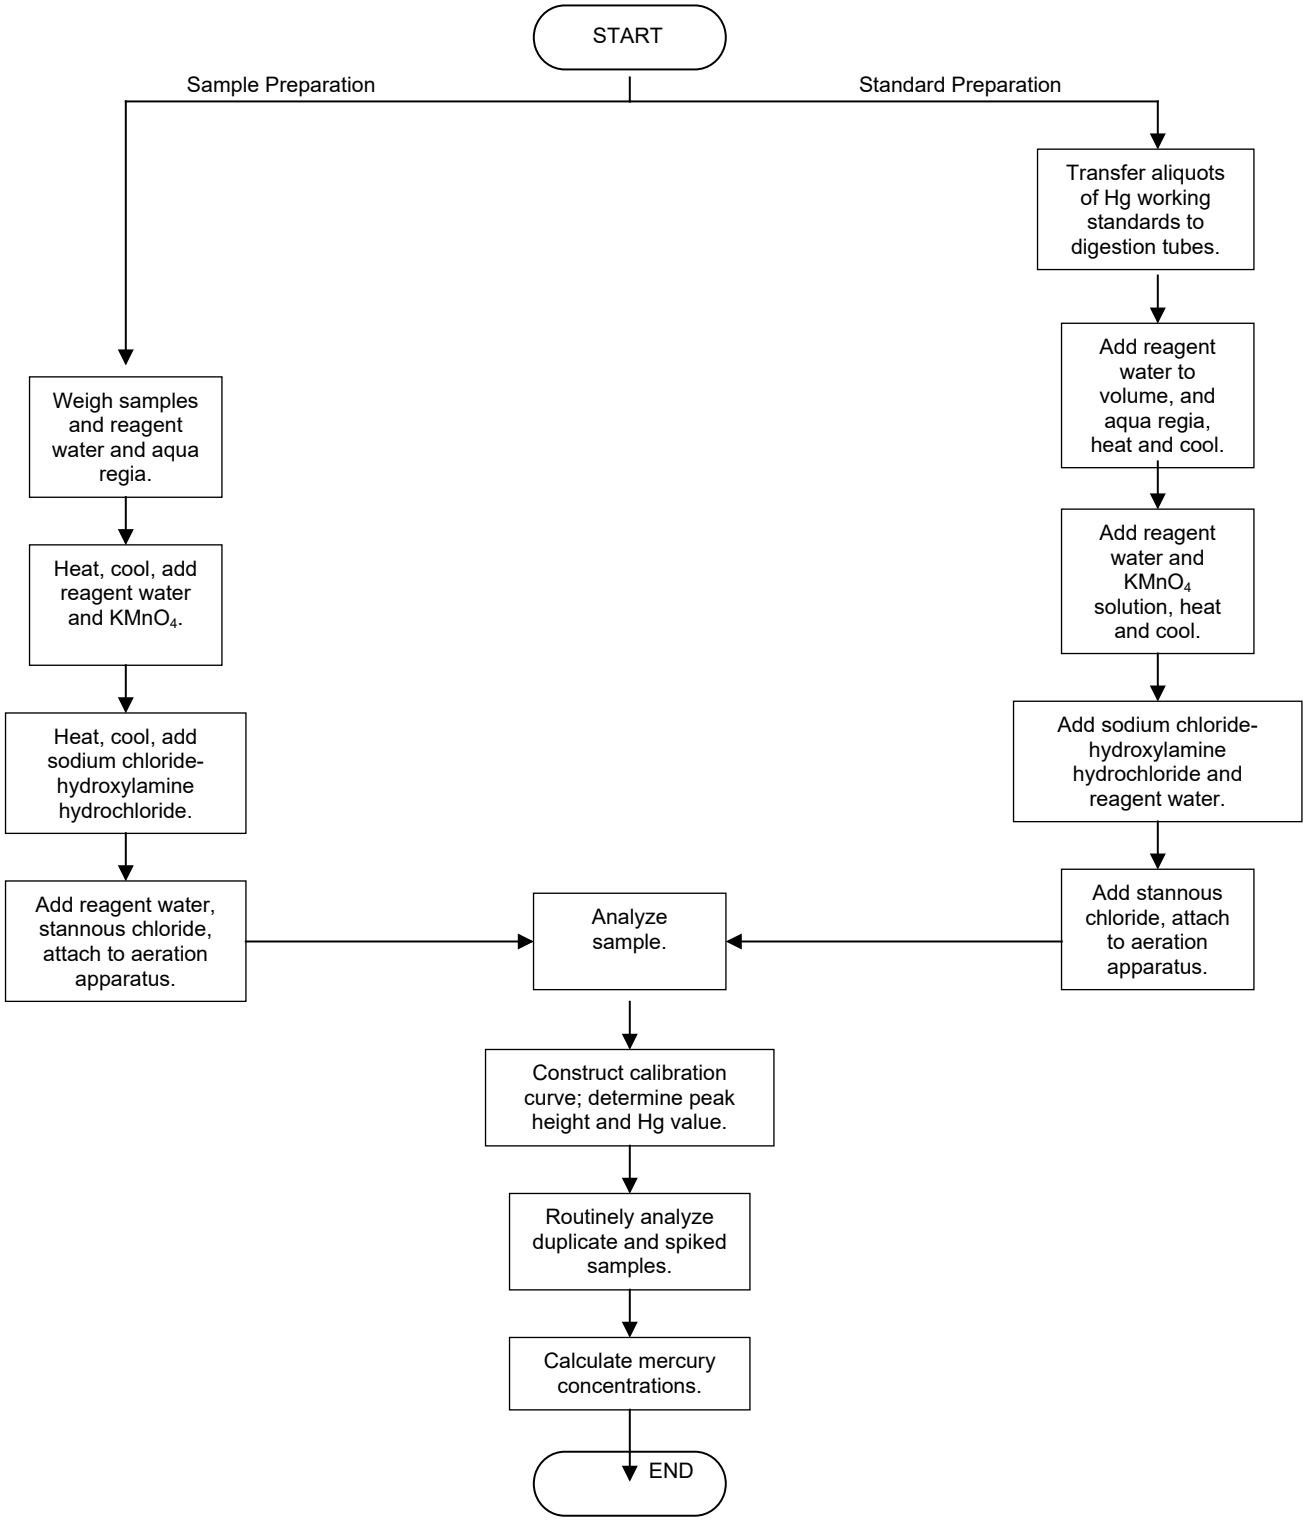
Method 7471B Flow Chart



Mercury Determination in Solids by Cold Vapor Atomic Absorption Technique (CVAA)

References: USEPA, "Method 7471B Mercury in Solid or Semisolid Waste (Manual Cold-Vapor Technique)," in Test Methods for Evaluating Solid Waste, SW846, Revision 2, February 2007

1. Scope and Application

Matrices: This cold-vapor atomic absorption method is applicable to the determination of total mercury (organic and inorganic) in solid samples (soils, sediments and sludges).

Definitions: Refer to Alpha Analytical Quality Manual.

This digestion and analytical procedure measures total mercury (organic & inorganic) in soil, sediment and sludge samples. Mercury can accurately be determined in the range of 0.005 to 0.25 mg/Kg for solid samples that do not require dilution.

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one or more of the following laboratory personnel before performing the modification: Area Supervisor, Department Supervisor, Laboratory Director, or Quality Assurance Officer.

This method is restricted to use by or under the supervision of analysts experienced in the operation of the AA and in the interpretation of AA data. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

Parameter	CAS
Mercury	7439-97-6

2. Summary of Method

A 0.5 to 1.5 gram aliquot of sample is digested in an acidic, oxidizing solution (consisting of Hydrochloric acid, nitric acid, and potassium permanganate) and heated for a total of 32 minutes on a hotplate at 95°C to convert all forms of mercury to inorganic Hg (II). Once the samples have been digested, they are ready for analysis by the cold-vapor atomic absorption technique (CVAA).

The CVAA technique is based on the absorption of radiation at 253.7-nm by mercury vapor. The addition of the hydroxylamine-hydrochloride solution to the digestate, reduces the excess potassium permanganate without reducing the mercury and transforms the oxidized mercury to the insoluble and non-volatile $HgCL_2$. Mercury is then reduced with stannous chloride from $HgCL_2$ to elemental mercury, [Hg (0)]. The elemental mercury is aerated as mercury vapor from the digestate in a closed system where the vapor passes through a cell positioned in the light path of an atomic absorption spectrometer. Absorbance is measured as a function of mercury concentration based on the peak height measured.

2.1 Method Modifications from Reference

Method 7471B specifies use of 300 mL BOD bottles for sample and standard preparation and a final volume of approximately 100 mL. This method has been modified for use of 50 mL plastic digestion tubes. Reagent volumes have been reduced proportionately.

3. Reporting Limits

The mercury solid RL is 0.005 mg/Kg.

4. Interferences

4.1 Potassium permanganate is added to eliminate potential interference from sulfide. Concentrations as high as 20 mg/L of sulfide as sodium sulfide do not interfere with the recovery of inorganic mercury from distilled water.

4.2 High concentrations of copper may cause interference; however copper concentrations as high as 10 mg/L have no effect on the recovery of spiked mercury samples.

4.3 Additional portions of potassium permanganate may need to be added until the purple color persists due to interference from chloride or organic matter. During the oxidation step, chlorides are converted to free chlorine which absorbs radiation at 253.7-nm. Care must be taken to ensure that free chlorine is absent before mercury is reduced to its elemental state and mercury vapor is swept into the cell. This may be accomplished by using additional portions of sodium chloride-hydroxylamine hydrochloride solution.

Note: Chloride interference is not as common in solid matrices as aqueous matrices.

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material safety data sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

5.1 Mercury compounds are highly toxic if swallowed, inhaled, or absorbed through the skin. All digestion and analysis procedures must be conducted in a laboratory exhaust hood.

5.2 Care must be taken when handling all samples, digestates, and standards since they are preserved to a pH <2. In addition, the digestate solutions contain strong oxidizing reagents.

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

A minimum of 10.0 grams of sample must be collected in a glass jar.

6.2 Sample Preservation

The samples must be refrigerated and maintained at 4°±2°C until digestion and analysis.

6.3 Sample Shipping

No special shipping requirements.

6.4 Sample Handling

All solid samples must be analyzed within 28 days from date of collection.

7. Equipment and Supplies

7.1 PSA 10.035 MILLENNIUM MERLIN MERCURY ANALYZER

7.1.1 Lamp: Mercury, low pressure

7.1.2 HP Laser Jet P2015dn or equivalent, compatible with AA and AF software

7.1.3 Millennium AAS Detector:

7.1.4 Pumps: Two variable speed and independently controlled peristaltic pumps to deliver reagent and sample solutions as well as remove waste.

7.1.5 Drying Tube: Gas liquid separator and dryer tube to remove mercury vapor from solution and prevent water vapor from entering the absorption cell.

7.2 Disposable Digestion tubes, 50mL

7.3 Electric Hot Plate- Adjustable and capable of maintaining a temperature of 90-95°C equipped with graphite carbon blocks that each have 36 positions to hold sample tubes. Glassware - Assorted Class A: volumetric flasks, beakers, graduated cylinders and pipettes of appropriate sizes for preparing reagents, standards, and measuring sample volumes.

7.4 Air Displacement pipettes: Digital pipettes capable of delivering volumes ranging from 0.1 to 5000 µL with an assortment of high quality disposable pipette tips.

7.5 Analytical balance: Capable of accurate measurement to the nearest 0.0001 g

7.6 Top-loading balance: Capable of accurate measurement to the nearest 0.01 g

8. Reagents and Standards

ACS Trace Metal grade chemicals shall be used in all tests. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination. If the purity of a reagent is in question, analyze for contamination. If the concentration is less than the MDL then the reagent is acceptable.

Solutions below expire six months from preparation unless noted.

Stock standard solutions are stored in a cabinet, out of direct light

8.1 Deionized (DI) water: The Barnstead NANO-pure system provides Type I water used in the preparation of samples and standards.

8.2 Concentrated hydrochloric acid (HCl). Fisher trace metals grade or equivalent. *(Digestion reagent).* Lots should be checked for purity prior to use and the results stored in a reagent check log book.

8.3 Concentrated nitric acid (HNO_3). Fisher trace metals grade or equivalent. *(Digestion reagent).* Lots should be checked for purity prior to use and the results stored in a reagent check log book.

8.4 Aqua Regia. Mix concentrated HCl and HNO_3 at a ratio of 3:1. *(Digestion reagent)*

8.5 Potassium Permanganate ($KMnO_4$), Fisher P279-500 or equivalent

8.6 5% Solution (w/v) of Potassium Permanganate Solution. Dissolve 50g of $KMnO_4$ in deionized water and dilute to 1L. *(Digestion reagent)*

8.7 Hydroxylamine Hydrochloride ($NH_2OH \bullet HCl$). Fisher H330-500, or equivalent. *(Analytical reagent)*

8.8 Stannous Chloride ($SnCl_2 \bullet 2H_2O$). Fisher T142-500, or equivalent. *(Analytical reagent)*

8.9 Stannous Chloride Reduction Solution (2%). Add 20 g of $SnCl_2 \bullet 2H_2O$ to 100mL of concentrated HCl and dilute to 1L with deionized water. Prepare fresh daily. *(Analytical reagent)*

8.10 HCl Rinse Solution (10%). Dilute 900mL of concentrated HCl to 9L with deionized water. *(Analytical reagent)*

8.11 Sodium Chloride (NaCl). Fisher S271-3, or equivalent. *(Analytical reagent, added to the Hydroxylamine Hydrochloride Solution below)*

8.12 Sodium Chloride-Hydroxylamine Hydrochloride Solution. Dissolve 120g of NaCl and of $NH_2OH \bullet HCl$ in deionized water and dilute to 1L. *(Analytical reagent)*

8.13 1000mg/L Mercury Stock Standard from two different sources. One source is used to prepare the calibration curve (Ultra Scientific ICP-080) and the other is for verification of the calibration curve (Inorganic ventures CGHG1-1). Use the vendor's expiration date. *(Standards preparation)*

8.14 Mercury Working Standards. Three mercury working standards are prepared from successive dilutions of the mercury stock standard and are used to prepare the calibration curve. Acidity of the working standards must be maintained at 1% HCl acid. Add 1mL of concentrated HCl to a 100mL volumetric flask. A 1.0mg/L working standard is prepared by adding 0.1mL of the 1000mg/L Ultra Scientific stock standard to a final volume of 100mL. This standard is diluted 1:10 to make a 0.1mg/L working standard and 1:100 to make a 0.01 mg/L working standard. The 0.1 and 0.01mg/L working standard is diluted prior to preparation of the calibration standards. The 1.0mg/L working standard is prepared monthly. See Section 10.0, for specific details regarding working standard preparations. *(Standards preparation)*

8.15 1.0mg/L LCS and Matrix Spike Solution. Prepare from the 1000 mg/L stock standard (8.13) by adding a 0.1mL aliquot to a final volume of 100mL. This solution is stable for 1 month. *(Spiking Solution)*

8.16 Solid Matrix LCS Standard: Purchased from Environmental Resource Associates (ERA), Catalog #540 Metals in Soil QC Standard, or equivalent.

8.17 Solid Matrix Blank Sample: Purchased from Environmental Resource Associates (ERA), Catalog #058 Blank Soil QC Sample, or equivalent.

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

9.1 Blank

9.1.1 A method blank must be analyzed once per every 20 samples or per mercury digestion batch, whichever is more frequent.

9.1.2 Mercury concentrations must not be detectable in the method blank at values greater than the reporting limit.

9.1.3 Corrective Action: Digestion of the method blank and all associated samples must be performed until the method blank is in control. Samples cannot be analyzed until an acceptable method blank analysis is obtained. Exceptions may be made with approval of the Section Head if the samples associated with the method blank are non-detect for mercury or if the concentration of mercury is greater than 10x the blank level in the samples. In such cases, the sample results are accepted without corrective action for the high method blank result. The client must be notified in the project narrative associated with the sample results.

9.2 Laboratory Control Sample (LCS)

9.2.1 The LCS is digested along with the samples. A LCS must be digested and analyzed once per every 20 samples or per mercury digestion batch, whichever is more frequent.

9.2.2 The acceptable recovery QC limits are 80%-120%. The solid LCS recovery limits are continuously monitored and documented in-house through control charts. The SOP *Control Limit Generation* (1734) provides details explaining how control charts are generated and used for quality control.

9.2.3 Corrective Action: May repeat analysis once to see if an analytical error has occurred. If the LCS recovery is still out of control, re-digest and re-analyze the LCS and all associated samples. Samples cannot be analyzed until an acceptable LCS is obtained. Exceptions may be made with approval of the Section Head if the samples associated with the out of control LCS are also associated with a matrix spike that is in control. This is an acceptable measure of accuracy of the digestion and analytical procedures. An explanation of this out of control LCS recovery must be included in the project narrative to the client and the sample data reported noting the acceptable MS results as batch QC.

9.3 Initial Calibration Verification (ICV)

9.3.1 Initial Calibration Curve

9.3.1.1 The correlation coefficient (r) of the initial calibration curve must be ≥0.995. The initial calibration curve consists of five standards and a blank.

9.3.1.2 Corrective Action: If the correlation coefficient does not exceed 0.995, individual standards or the entire curve may be re-analyzed until the correlation coefficient is in control. If the correlation coefficient is still not in control, the initial calibration curve must be re-prepared and re-analyzed until the correlation coefficient is acceptable.

9.3.2 Initial Calibration Verification (ICV) Check Standard

9.3.2.1 The initial calibration verification check standard must be from a second source or lot number to verify the accuracy of the standard curve. The concentration of the ICV is at approximately the mid-level of the calibration curve.

9.3.2.2 The acceptable recovery QC limits for the ICV is 90%-110%.

9.3.2.3 Corrective Action: May repeat analysis once to see if an analytical error occurred. If the ICV still exceeds the control limits, re-calibrate the instrument.

9.3.3 Initial Calibration Blank (ICB)

9.3.3.1 An ICB must be analyzed immediately following the ICV.

9.3.3.2 The ICB concentration must not be greater than the reporting limit.

9.3.3.3 Corrective Action: May repeat analysis once to see if an analytical error occurred. If the ICB still exceeds the control limits, re-calibrate the instrument and re-analyze a fresh blank.

9.4 Continuing Calibration Verification (CCV)

9.4.1 Continuing Calibration Verification (CCV) Check Standard

9.4.1.1 A CCV must be analyzed at a minimum of every 10 samples and at the close of an analytical sequence. The concentration of the CCV is at approximately the mid-level of the calibration curve. This standard monitors instrument performance throughout the duration of the analytical run.

9.4.1.2 The acceptable recovery QC limits for the CCV is 90%-110%.

9.4.1.3 Corrective Action: May repeat analysis once to see if an analytical error occurred. If the CCV still exceeds the control limits, re-calibrate and re-analyze all samples since the last acceptable CCV.

9.4.2 Continuing Calibration Blank (CCB)

9.4.2.1 A CCB must be analyzed immediately after every CCV.

9.4.2.2 The CCB concentration must not be greater than the reporting limit.

9.4.2.3 Corrective Action: May repeat analysis once to see if an analytical error occurred. If the CCB still exceeds the control limits, re-calibrate and/or re-analyze a fresh blank. All samples associated with the out of control CCB

must be re-analyzed (since the last acceptable CCB). Exceptions may be made with approval of the Section Head if the samples associated with the out of control CCB are non-detect for mercury or if sample concentrations for the affected metals are greater than 10x the blank levels. In such cases, the sample results are accepted without corrective action for the high CCB and the client is notified in a project narrative associated with the sample results.

9.5 Matrix Spike

9.5.1 A matrix spike must be performed once per 20 samples (5% frequency). When project specifications dictate, a Matrix Spike Duplicate (MSD) may also need to be performed at the same frequency as the MS.

9.5.2 The acceptable recovery QC limits is 80%-120% for the solid MS/MSD. For MCP projects the recovery QC limits are 75%-125% for the solid MS/MSD. Calculate MS Recovery as follows:

$$\% \text{ Recovery} = \frac{MS - R1}{MS_{\text{True Value}}} \times 100$$

9.5.3 Calculate the %RPD as in 12.3.2 above when analyzing a MS/MSD pair. The acceptable %RPD is $\leq$ 20%. Both the solid recovery limits and %RPD are continuously monitored and documented in-house through control charts.

9.5.4 Corrective Action: Repeat analysis once to see if an analytical error has occurred. If the % recovery, or %RPD, still exceed the control limits and the LCS is compliant; include a project narrative with the results to the client noting that there may be potential matrix effects on the accuracy or precision of the affected mercury results as evidenced by matrix spike %recovery or %RPD outside of the QC limits.

9.6 Laboratory Duplicate

9.6.1 Duplicate analyses (matrix duplicate) must be performed once per 20 samples (5% frequency).

9.6.2 Acceptable relative percent difference (RPD) for duplicate analysis is $\leq$ 20 % for solid matrices. Acceptance criterion is not applicable to sample concentrations less than 5 times the reporting limit. Calculate RPD as follows:

$$RPD = \frac{R1 - R2}{\frac{[R1 + R2]}{2}} \times 100$$

The RPD limits are continuously monitored and documented in-house through control charts.

9.6.3 Corrective Action: Repeat analysis once to see if an analytical error has occurred. If the % RPD still exceeds the control limits; include a project narrative with the results to client noting that there may be potential matrix effects on the precision of the affected mercury results as evidenced by the matrix duplicate RPD exceedance.

9.7 Method-specific Quality Control Samples

9.7.1 Serial Dilution (SD)

9.7.1.1 Serial dilution of one sample per batch of 20, at a 1:5 dilution, is useful in the assessment of matrix effects, and must be analyzed as needed to assess a new or unusual matrix.

9.7.1.2 The acceptable agreement between the undiluted and diluted results is ± 10%.

9.7.1.3 Corrective Action: May repeat analysis once to see if an analytical error has occurred. If the precision between the results still exceeds the control limits, include a project narrative with the results to the client noting that there may be potential matrix effects on the precision of the affected mercury results as evidenced by the SD outside of the QC limits.

9.7.2 CRA Standard Check Sample

9.7.2.1 The CRA Check sample is typically analyzed as part of the initial calibration curve, however, project specifications may require this to be analyzed at the beginning of the analytical sequence after the ICV and ICB. This solution verifies the accuracy at the low end of the calibration curve.

9.7.2.2 Results for mercury in the CRA solution must be within 70-130% recovery criteria or within project specified acceptance limits.

9.7.2.3 Corrective Action: May repeat analysis once to see if an analytical error occurred. If the CRA solutions still exceed the control limits, re-calibrate and/or re-analyze a fresh CRA solution. All samples associated with the out of control mercury CRA must be re-analyzed.

***NOTE**: The CRA analysis is not preformed if a calibration standard is prepared at the reporting limit and included in the initial calibration curve. The calibration curve must meet the criteria for linearity.*

9.8 Method Sequence

Initial calibration curve (STD0, STD1, etc., to STD5)
ICV
ICB
CRA (if required by the project)
Method Blank (The assigned LIMS batch name)
LCS (The assigned LIMS batch name)
Sample analysis (samples 1-5 including SD, MS and MD samples)
CCV
CCB
Sample analysis (6-15)
CCV
CCB

The CRA analysis is not preformed if a calibration standard is prepared at the reporting limit and included in the initial calibration curve. The calibration curve must meet the criteria for linearity.

10. Procedure

10.1 Equipment Set-up

10.1.1 Digestion Procedure Using Block Digestion

10.1.1.1 Weigh a 0.5 to 1.5g aliquot of well-homogenized sample into the digestion tube. A nominal weight of 0.5-0.6g of each sample is generally sufficient; however an increased amount of wet sample may be used, and depends upon the required reporting limits for the project. See the Section Head or the Project Manager if there are any questions regarding the reporting limits required or the amount of sample to be used.

10.1.1.2 A method blank, LCS, matrix spike sample, and matrix duplicate sample must be digested with each analytical batch at the frequency listed in Section 9, Quality Control. In some instances, the client may request matrix spike duplicate analysis as an alternative to matrix duplicate analysis.

If required, and a blank solid material of a similar matrix type of high enough purity can be obtained to meet required reporting limits, a solid material may be used in the Method Blank preparation to matrix match QC samples and field samples.

If required, a solid LCS may be prepared to matrix match QC samples and field samples.

10.1.1.3 The calibration standards are digested along with the samples.

10.1.1.4 Add 5mL of ASTM Type II laboratory reagent ASTM Type II laboratory reagent and 5 mL Aqua Regia (3:1 HCL to HNO3) to sample and calibration tubes.

10.1.1.5 Spike Laboratory Control Sample and Matrix Spike sample with 0.125mL of the Hg 1 mg/L spiking solution (see 8.14).

10.1.1.6 Heat samples and calibration curve to 95°C +/- 3°C on heated Blocks for 2 minutes, remove from heat, let cool to room temperature, then add 15mL ASTM Type II laboratory reagent grade water.

10.1.1.7 Add 7.50mL of 5% Potassium Permanganate solution, wait 15 minutes.

10.1.1.8 If the purple color dissipates, add additional portions of $KMnO_4$ solution until the purple color persists. Note the additional amount of $KMnO_4$ on the preparation bench sheet. Heat for an additional 30 minutes on heated blocks.

10.1.1.9 Allow the samples and standards to cool. Add 3.0mL of NaCl-NH_2OH•HCl solution to each digestion tube to reduce the excess permanganate. Add deionized water to bring the final volume to 50mL.

10.1.1.10 The digestates are now ready for analysis. The batch must be transferred to the metals instrument room with the project folder, the preparation paperwork and the metals preparation checklist.

10.2 Initial Calibration

A series of five calibration standards are prepared by pipetting suitable volumes of standard solution into 50mL centrifuge tubes. The preparation date of these standards, the initials of the analyst, the lot number of the source material, stock concentrations, volumes used, final volumes, final concentrations, and manufacturer, and expiration date must be recorded in the *Mercury CVAF, Mercury CVAA and Amalgam Working Standards Preparation Logbook*. The

PSA MILLENIUM MERLIN is calibrated using a multi-point calibration curve consisting of a blank and six standards.

10.2.1 The working standards are prepared as follows:

10.2.1.1 Mercury Stock Solution (1000mg/L). See Section 8.13. Check expiration date to ensure the standard has not expired.

10.2.1.2 Mercury Working Standard (1.0mg/L). See Section 8.14. Check expiration date to ensure the standard has not expired.

10.2.1.3 Diluted Mercury Working Standard (0.1mg/L): Dilute 0.1mL of working standard (10.2.1.2) to 1.0mL. This solution must be prepared fresh daily.

10.2.1.4 Diluted Mercury Working Standard (0.01mg/L): Dilute 0.1 mL of working standard (10.2.1.3) to 1.0mL. This solution must be prepared fresh daily.

10.2.1.5 The calibration standards may be prepared in 50mL screw cap plastic digestion tubes. Each tube must contain approximately 25mL of deionized water, which is then spiked with the volume listed in the table below. Prepare a six-point mercury calibration curve daily as follows

Volume of the Working Standard (mL)	Concentration of Working Standard (mg/L)	Concentration of Calibration Standard (µg/L)
0	None	Blank
0.025	0.1	0.05
0.05	0.1	0.1
0.25	0.1	0.5
0.1	1	2
0.25	1	5

10.2.1.6 Digest all standards along with the samples as described in Section 10.1, Equipment Set-up.

10.2.2 The PSA MILLENIUM MERLIN computer will calculate a linear regression, correlation coefficient ("r"), and slope of standard curve. The correlation coefficient must be greater than $\geq$ 0.995 for linearity. The linear regression is computed on a multipoint calibration.

10.3 Equipment Operation and Sample Processing

10.3.1 Before turning the instrument on, unplug and power off on rear panel. Connect the millennium AAS detector, plug back in and power on the back panel. The pump windings must be inspected for wear, rotated and/or changed. Secure the pump windings to the pump. Turn the gas on to 52 P.S.I. Turn on the mercury analyzer and the computer. Allow the instrument to warm up for 30 to 60 minutes.

10.3.2 Place the rinse line in the 10% HCl rinse solution. The $SnCl_2$ line from the instrument must be immersed into the 2% stannous chloride reduction solution.

10.3.3 All standard and sample information is entered into a sample information, or instrument sequence file. The following information is entered: sample ID, dilution and units. A hard copy of the sequence file is printed, given a page number, and becomes part of the permanent instrument run log. After one month, or more if suitable, of mercury analyses, the sequence printouts are bound and given an internal log identification number.

10.3.4 Place the calibration standards and samples onto the autosampler rack in the appropriate positions according to the sample information sequence file.

10.3.5 Begin the run sequence with the initial calibration curve and evaluate it for QC acceptance. Evaluate the ICV, ICB, CRA, Method Blank and LCS for QC acceptance prior to the analysis of the samples. The typical analytical sequence is listed in Section 9.8.

10.3.6 The instrument detection limits (IDLs) may be performed if required by the regulatory program or the client.

10.3.7 Dilute and reanalyze any samples that exceed the linear calibration range for mercury. Report the mercury result from the dilution analysis.

10.3.8 The *Mercury Data Review Checklist* must accompany all acceptable mercury results for primary and secondary review.

10.4 Continuing Calibration

10.4.1 The same time must be elapsed between CCVs and CCBs as is allowed between samples. Analyze the continuing calibration verification (CCV) and the continuing calibration blank (CCB) after each 10 samples and at the end of the analytical sequence.

10.5 Preventive Maintenance

Pump windings should be inspected for wear on a daily basis and replaced when they appear flattened (approximately once per month depending on use). The gas-liquid separator should be cleaned periodically when it appears coated with a yellow film. Add 30% KOH solution and let set for approximately 30 minutes. Rinse with DI water. The dryer tube should be replaced approximately once per year. (Part number H003S001 PS Analytical)

11. Data Evaluation, Calculations and Reporting

11.1 The mercury results are calculated by the following equation:

Solid:

$$\text{Mercury result in mg/Kg} = \frac{C \times B}{A} \times DF \times 1000 \times \frac{100}{\%\ \text{solid}}$$

Where:

A = Initial sample weight in grams, typically 1 gram
B = Digestion final volume in mL, typically 50 mL
C = Concentration of sample from instrument read-out in µg/L
DF = Dilution Factor

11.2 All mercury results must be reported to three significant figures.

11.3 The primary analyst does the batching and data upload into the LIMS system.

11.4 All solids including soils, sediments, and sludges must be reported on a dry-weight basis.

11.5 A secondary review is performed on all.

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

Section 9, Quality Control, defines the corrective actions that must be taken in instances where QC outliers exist.

13. Method Performance

13.1 Detection Limit Study (MDL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the DL, LOD, and/or LOQ as outlined in Alpha SOP/1732. These studies performed by the laboratory are maintained on file for review.

13.2 Demonstration of Capability Studies

Refer to Alpha SOP/1739 for further information regarding IDC/DOC Generation.

13.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

14. Pollution Prevention and Waste Management

Refer to Alpha's Chemical Hygiene Plan and Waste Management and Disposal SOP for further pollution prevention and waste management information.

Inductively Coupled Plasma - Atomic Emission Spectrometry

Reference Method No.: **Method 6010D** SW-846, Test Methods for Evaluating Solid Waste: Physical/Chemical Methods, EPA SW-846, Update V, July, 2014.

SM 2340B, Hardness by Calculation, Standard Methods for the Examination of Water and Wastewater, APHA-AWWA-WPCF, 21st Edition, 1997.

1. Scope and Application

Matrices: Digestates from all matrices.

Definitions: See Alpha Laboratories Quality Manual Appendix A

Inductively coupled plasma-atomic emission spectrometry (ICP-AES) determines trace elements, including metals, in solution. The method is applicable to all of the elements listed in Table 1. All matrices, excluding filtered groundwater samples but including ground water, aqueous samples, TCLP and EP extracts, industrial and organic wastes, soils, sludge, sediments, and other solid wastes, require digestion prior to analysis. Groundwater samples that have been prefiltered and acidified will not need acid digestion unless chemical interferences are suspected. Samples which are not digested are matrix matched with the standards. Refer to Metals Preparation SOPs for the appropriate digestion procedures.

Table 1 lists the elements for which this method is applicable. Detection limits, sensitivity, and the optimum and linear concentration ranges of the elements can vary with the wavelength, spectrometer, matrix and operating conditions. Table 1 lists the recommended analytical wavelengths for the elements in clean aqueous matrices. Table 3 lists the Reported Detection Limits. The reported detection limit data may be used to estimate instrument and method performance for other sample matrices. Elements other than those listed in Table 1 may be analyzed by this method if performance at the concentration levels of interest (see Section 9) is demonstrated.

Users of the method should state the data quality objectives prior to analysis and must document and have on file the required initial demonstration performance data described in the following sections prior to using the method for analysis.

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is made by one of the following laboratory personnel before performing the modification: Area Supervisor, Metals Manager, Laboratory Services Manager, Laboratory Director, or Quality Assurance Officer.

Use of this method is restricted to spectroscopists who are knowledgeable in the correction of spectral, chemical, and physical interferences described in this method. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

.

2. Summary of Method

Prior to analysis, samples must be solubilized or digested using appropriate Sample Preparation Methods. When analyzing groundwater samples for dissolved constituents, acid digestion is not necessary if the samples are filtered and acid preserved prior to analysis.

This method describes multielemental determinations by ICP-AES using sequential or simultaneous optical systems and axial or radial viewing of the plasma. The instrument measures characteristic emission spectra by optical spectrometry. Samples are nebulized and the resulting aerosol is transported to the plasma torch. Element-specific emission spectra are produced by a radio-frequency inductively coupled plasma. The spectra are dispersed by a grating spectrometer, and the intensities of the emission lines are monitored by photosensitive devices. Background correction is required for trace element determination. Background must be measured adjacent to analyte lines on samples during analysis. The position selected for the background-intensity measurement, on either or both sides of the analytical line, will be determined by the complexity of the spectrum adjacent to the analyte line. In one mode of analysis the position used must be as free as possible from spectral interference and must reflect the same change in background intensity as occurs at the analyte wavelength measured. Background correction is not required in cases of line broadening where a background correction measurement would actually degrade the analytical result. The possibility of additional interferences named in Section 4.0 must also be recognized and appropriate corrections made; tests for their presence are described in Section 9.7. Alternatively, users may choose multivariate calibration methods. In this case, point selections for background correction are superfluous since whole spectral regions are processed.

This SOP includes the manual calculations for Total Hardness and Calcium Hardness, according to SM 2340B.

2.1 Method Modifications from Reference

None.

3. Reporting Limits

Refer to Table 3 for method Reporting Limits.

4. Interferences

4.1 Spectral

Spectral interferences are caused by background emission from continuous or recombination phenomena, stray light from the line emission of high concentration elements, overlap of a spectral line from another element, or unresolved overlap of molecular band spectra.

4.1.1 Background emission and stray light can usually be compensated for by subtracting the background emission determined by measurements adjacent to the analyte wavelength peak. Spectral scans of samples or single element solutions in the analyte regions may indicate when alternate wavelengths are desirable because of severe spectral interference. These scans will also show whether the most appropriate estimate of the background emission is provided by an interpolation from measurements on both sides of the wavelength peak or by measured emission on only one side. The locations selected for the measurement of background intensity will be determined by the complexity of the spectrum adjacent to the wavelength peak. The locations used for

routine measurement must be free of off-line spectral interference (interelement or molecular) or adequately corrected to reflect the same change in background intensity as occurs at the wavelength peak. For multivariate methods using whole spectral regions, background scans must be included in the correction algorithm. Off-line spectral interferences are handled by including spectra on interfering species in the algorithm.

4.1.2 To determine the appropriate location for off-line background correction, the user must scan the area on either side adjacent to the wavelength and record the apparent emission intensity from all other method analytes. This spectral information must be documented and kept on file. The location selected for background correction must be either free of off-line interelement spectral interference or a computer routine must be used for automatic correction on all determinations. If a wavelength other than the recommended wavelength is used, the analyst must determine and document both the overlapping and nearby spectral interference effects from all method analytes and common elements and provide for their automatic correction on all analyses. Tests to determine spectral interference must be done using analyte concentrations that will adequately describe the interference. Normally, 100 mg/L single element solutions are sufficient; however, for analytes such as iron that may be found at high concentration, a more appropriate test would be to use a concentration near the upper analytical range limit.

4.1.3 Spectral overlaps may be avoided by using an alternate wavelength or can be compensated by equations that correct for interelement contributions. Instruments that use equations for interelement correction require the interfering elements be analyzed at the same time as the element of interest. When operative and uncorrected, interferences will produce false positive determinations and be reported as analyte concentrations. More extensive information on interferant effects at various wavelengths and resolutions is available in reference wavelength tables and books. Users may apply interelement correction equations determined on their instruments with tested concentration ranges to compensate (off line or on line) for the effects of interfering elements. For multivariate methods using whole spectral regions, spectral interferences are handled by including spectra of the interfering elements in the algorithm. The interferences listed are only those that occur between method analytes. Only interferences of a direct overlap nature are listed. These overlaps were observed with a single instrument having a working resolution of 0.035 nm.

4.1.4 When using inter-element correction equations, the interference may be expressed as analyte concentration equivalents (i.e. false analyte concentrations) arising from 100 mg/L of the interference element. For example, assume that As is to be determined (at 193.696 nm) in a sample containing approximately 10 mg/L of Al. 100 mg/L of Al would yield a false signal for As equivalent to approximately 1.3 mg/L. Therefore, the presence of 10 mg/L of Al would result in a false signal for As equivalent to approximately 0.13 mg/L. The user is cautioned that each instrument may exhibit somewhat different levels of interference. The interference effects must be evaluated for each individual instrument since the intensities will vary.

Major known interferences are Fe, Al, Ca, Mg, V, Ni, Cu, and Cr. To minimize any of these interferences, every analyte is analyzed on each instrument at or near its linear range and corrected for these interferences. This is done on an annual basis, and data is kept on file.

4.1.5 Inter-element corrections will vary for the same emission line among instruments because of differences in resolution, as determined by the grating, the entrance and exit slit widths, and by the order of dispersion. Inter-element corrections will also vary depending upon the choice of background correction points. Selecting a background correction point where an interfering emission line may appear must be avoided when practical. Inter-element corrections that constitute a major portion of an emission signal may not yield accurate data. Users must not forget that some samples may contain uncommon elements that could contribute spectral interferences.

4.1.6 The interference effects must be evaluated for each individual instrument whether configured as a sequential or simultaneous instrument. For each instrument, intensities will vary not only with optical resolution but also with operating conditions (such as power, viewing height and argon flow rate). When using the recommended wavelengths, the analyst is required to determine and document for each wavelength the effect from referenced interferences as well as any other suspected interferences that may be specific to the instrument or matrix. The analyst is encouraged to utilize a computer routine for automatic correction on all analyses.

4.1.7 The primary wavelength for each analyte is based upon the instrument manufacturer's recommendations. An alternate wavelength is chosen if there is an indication of elevated background or overlap of another spectral wavelength. The wavelength for each analyte must be as free from interferences as possible.

4.1.8 If the correction routine is operating properly, the determined apparent analyte(s) concentration from analysis of each interference solution must fall within a specific concentration range around the calibration blank. The concentration range is calculated by multiplying the concentration of the interfering element by the value of the correction factor being tested and divided by 10. If after the subtraction of the calibration blank the apparent analyte concentration falls outside of this range in either a positive or negative direction, a change in the correction factor of more than 10% should be suspected. The cause of the change must be determined and corrected and the correction factor updated. The interference check solutions must be analyzed more than once to confirm a change has occurred. Adequate rinse time between solutions and before analysis of the calibration blank will assist in the confirmation.

4.1.9 When inter-element corrections are applied, their accuracy must be verified, daily, by analyzing the spectral interference check solution. The correction factor or multivariate correction matrices tested on a daily basis. All inter-element spectral correction factors or multivariate correction matrices are verified and updated when an instrumentation change, such as in the torch, nebulizer, injector, or plasma conditions occurs. The standard solution must be inspected to ensure that there is no contamination that may be perceived as a spectral interference.

4.1.10 When inter-element corrections are <u>not</u> used, verification of absence of interferences is required.

4.1.10.1 One method is to use a computer software routine for comparing the determinative data to limits, files for notifying the analyst when an interfering element is detected in the sample at a concentration that will produce either an apparent false positive concentration, (i.e., greater than) the analyte

instrument detection limit, or false negative analyte concentration, (i.e., less than the lower control limit of the calibration blank defined for a 99% confidence interval).

4.1.10.2 Another method is to analyze an Interference Check Solution(s) which contains similar concentrations of the major components of the samples (>10 mg/L) on a continuing basis to verify the absence of effects at the wavelengths selected. These data must be kept on file with the sample analysis data. If the check solution confirms an operative interference that is >20% of the analyte concentration, the analyte must be determined using (1) analytical and background correction wavelengths (or spectral regions) free of the interference, (2) by an alternative wavelength, or (3) by another documented test procedure.

4.2 Physical

Physical interferences are effects associated with the sample nebulization and transport processes. Changes in viscosity and surface tension can cause significant inaccuracies, especially in samples containing high dissolved solids or high acid concentrations. If physical interferences are present, they must be reduced by diluting the sample, using a peristaltic pump, use of an internal standard or by using a high solids nebulizer. Another problem that can occur with high dissolved solids is salt buildup at the tip of the nebulizer, affecting aerosol flow rate and causing instrumental drift. The problem can be controlled by wetting the argon prior to nebulization, using a tip washer, using a high solids nebulizer or diluting the sample. Also, it has been reported that better control of the argon flow rate, especially to the nebulizer, improves instrument performance: this may be accomplished with the use of mass flow controllers. The test described in Section 10.3.4.1 will help determine if a physical interference is present.

4.3 Chemical

Chemical interferences include molecular compound formation, ionization effects, and solute vaporization effects. Normally, these effects are not significant with the ICP technique, but if observed, can be minimized by careful selection of operating conditions (incident power, observation position, and so forth), by buffering of the sample, by matrix matching, and by standard addition procedures. Additionally, if filtered samples are found to have an organic or sulfur like odor they are processed by heating after the addition of the acids to matrix match. Chemical interferences are highly dependent on matrix type and the specific analyte element.

4.4 Memory

Memory interferences result when analytes in a previous sample contribute to the signals measured in a new sample. Memory effects can result from sample deposition on the uptake tubing to the nebulizer and from the build-up of sample material in the plasma torch and spray chamber. The site where these effects occur is dependent on the element and can be minimized by flushing the system with a rinse blank between samples. The possibility of memory interferences must be recognized within an analytical run and suitable rinse times must be used to reduce them. The rinse times necessary for a particular element must be estimated prior to analysis. This may be achieved by aspirating a standard containing elements at a concentration ten times the usual amount or at the top of the linear dynamic range. The aspiration time for this sample must be the same as a normal sample analysis period, followed by analysis of the rinse blank at designated intervals. The length of time required to reduce analyte signals to within a factor of two of the method detection limit must be noted. Until the required rinse time is established, this method suggests a rinse period of at least 60 seconds between samples and standards. If memory interference is suspected, the sample must be reanalyzed after a rinse period of sufficient length. Alternate rinse times may be established by the analyst based upon their DQOs.

4.5 Other Interferences

4.5.1 Users are advised that high salt concentrations can cause analyte signal suppressions and confuse interference tests. If the instrument does not display negative values, fortify the interference check solution with the elements of interest at 0.5 to 1 mg/L and measure the added standard concentration accordingly. Concentrations must be within 20% of the true spiked concentration or dilution of the samples will be necessary. In the absence of measurable analyte, overcorrection could go undetected if a negative value is reported as zero.

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound must be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material data handling sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

Samples are collected in plastic bottles.

6.2 Sample Preservation

If samples are for soluble metals analysis, filtration must take place prior to preservation with 1:1 HNO3 to a pH < 2. Soluble samples must be held at pH < 2 for at least 24 hours prior to digestion if not preserved at the time of filtration. Samples for total metals analysis are preserved with 1:1 HNO3 to a pH < 2. Samples must be pH <2 for at least 24 hours prior to digestion if not preserved at the time of collection.

6.3 Sample Shipping

No special shipping requirements.

6.4 Sample Handling

Samples to be analyzed for soluble metals, that have not been filtered, must be filtered and preserved within 24 hours of sample collection.

Preserved samples have a hold time of 6 months, and are stored at ambient temperature.

7. Equipment and Supplies

7.1 Inductively coupled argon plasma emission spectrometer:

- **Thermo Scientific ICAP Duo 6500 (Trace7)**

7.1.1 Computer-controlled emission spectrometer with background correction.

7.1.2 Radio-frequency generator compliant with FCC regulations.

7.1.3 Optional mass flow controller for argon nebulizer gas supply.

7.1.4 Optional peristaltic pump.

7.1.5 Optional Autosampler.

7.1.6 Argon gas supply - high purity.

7.2 Volumetric flasks of suitable precision and accuracy.

7.3 Volumetric pipets of suitable precision and accuracy.

8. Standards and Reagents

Reagent semiconductor and/or trace grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination. If the purity of a reagent is in question, analyze for contamination. If the concentration of the contamination is less than the MDL then the reagent is acceptable.

8.1 Hydrochloric acid (conc), HCl. Stored at room temperature in acid resistant cabinet. Expiration date if defined by vendor.

8.2 Hydrochloric acid (1:1), HCl. Add 500 mL concentrated HCl to 400 mL DI water and dilute to 1 liter in an appropriately sized beaker. Stored at room temperature in polypropylene bottle, expiration date if defined by vendor..

8.3 Nitric acid (conc), HNO_3. Stored at room temperature in acid resistant cabinet. Expiration date if defined by vendor.

8.4 Nitric acid (1:1), HNO_3. Add 500 mL concentrated HNO_3 to 400 mL DI water and dilute to 1 liter in an appropriately sized beaker. Stored at room temperature in polypropylene bottle, expiration date if defined by vendor..

8.5 Reagent Water. All references to water in the method refer to reagent water unless otherwise specified. Reagent water will be interference free. Refer to Chapter One for a definition of reagent water.

8.6 Standard stock solutions may be purchased or prepared from ultra- high purity grade chemicals or metals (99.99% pure or greater). All stock standards are ordered through ISO and American Association for Lab Accreditation vendors. All standards are in aqueous solutions and are generally at concentrations of 1000ppm and 10,000ppm.

8.7 Mixed calibration standard solutions

Prepare mixed calibration standard solutions by combining appropriate volumes of the stock solutions in volumetric flasks. Add the appropriate types and volumes of acids so that the standards are matrix matched with the sample digestates. Care must be taken when preparing the mixed standards to ensure that the elements are compatible and stable together. Transfer the mixed standard solutions to HDPE or polypropylene bottles for storage. Fresh

mixed standards must be prepared, as needed, with the realization that concentration can change on aging as evidenced by failures in the ICV.

NOTE: If the addition of silver to the recommended acid combination results in an initial precipitation, add 15 mL of water and warm the flask until the solution clears. Cool and dilute to 100 mL with water. For this acid combination, the silver concentration must be limited to 2 mg/L. Silver under these conditions is stable in a tap-water matrix for 30 days. Higher concentrations of silver require additional HCl.
Additionally, sulfur standards are stand-alone single element standards and therefore are not to be combined in a mixed calibration standard solution.

8.8 Blanks

Three types of blanks are required for the analysis for samples. The calibration blank is used in establishing the analytical curve, and the method blank is used to identify possible contamination resulting from varying amounts of the acids used in the sample processing. The rinse blank is used to flush the system between all samples and standards.

8.8.1 The calibration blank is prepared by acidifying reagent water to the same concentrations of the acids found in the standards. Prepare a sufficient quantity to flush the system between standards and samples. The calibration blank will also be used for all initial (ICB) and continuing calibration blank (CCB) determinations (see Sections 10.2 and 10.4). Refer to Section 10.4.1.2 for acceptance criteria and/or corrective actions.

8.8.2 The method blank must contain all of the reagents in the same volumes as used in the processing of the samples. The method blank must be carried through the complete procedure and contain the same acid concentration in the final solution as the sample solution used for analysis. Refer to Section 9.1 for acceptance criteria and/or corrective actions.

8.8.3 The rinse blank consists of HNO_3 (1% or 2%) (v/v) in reagent water. Prepare a sufficient quantity to flush the system between standards and samples.

8.9 The Initial Calibration Verification Standard (ICV) and the Continuing Calibration Verification Standard (CCV)

These ICV is prepared by the analyst by combining compatible elements from a standard source different than that of the calibration standard at a concentration at or near the mid-point of the calibration curve. The CCV is prepared from the same source as the calibration standards and must be at a concentration near the mid-point of the calibration curve.

8.10 Low Level of Quantification, (LLOQ)

The LLOQ is initially verified by the analysis of at least 7 replicate samples, spiked at the LLOQ and processed through all preparation and analysis steps of the method at or below the lowest calibration point. The mean recovery and relative standard deviation of these samples provide an initial statement of precision and accuracy at the LLOQ. In most cases the mean recovery should be +/- 35% of the true value and RSD should be < 20%. In-house limits may be calculated when sufficient data points exist. Monitoring recovery of LLOQ over time is useful for assessing precision and bias.

Ongoing LLOQ verification, at a minimum, is on a quarterly basis to validate quantitation capability at low analyte concentration levels. This verification may be accomplished either with clean control material (e.g., reagent water, method blanks. Optimally, the LLOQ should be less than the desired regulatory action levels based on the stated project-specific requirements.

8.11 Spectral Interference Check Solution

These solutions are prepared to contain known concentrations of interfering elements that will provide an adequate test of the correction factors. Analysts are advised that high salt concentrations can cause analyte signal suppressions and confuse interference tests.

Single element interference checks - At a minimum, single element SIC checks must be performed for the following elements: Aluminum 500mg/L; Boron 50mg/L, Barium, 50mg/L, Calcium 500mg/L; Copper 50mg/L; Iron 200mg/L; Magnesium 500mg/L; Manganese 50mg/L; Molybdenum 20mg/L; Sodium 1000mg/L; Nickel 20mg/L; Selenium 20mg/L; Silicon 200mg/L; Tin 20mg/L; Vanadium 20mg/L; Zinc 20mg/L The absolute value of the concentration observed for any unspiked analyte in the single element SIC checks must be less than two times the analytes' LLOQ.

The concentration of the SIC checks are suggested, but become the highest concentration allowed in a sample analysis, and cannot be higher than the highest established linear range. Samples with concentrations of elements higher than the SIC check must be diluted until the concentration is less than the SIC check solution. Note that reanalysis of a diluted sample is required even if the high concentration element is not required to be reported for the specific sample, since the function of the SIC check is to evaluate spectral interferences on other elements. The single element SIC checks are performed when the instrument is setup and periodically (at least once every 6 months) thereafter.

Mixed element interference check - The mixed element SIC solution is analyzed at least once per day, immediately after the initial calibration. The concentration measured for any target analytes must be less than +/- the LLOQ. If this criterion is not met then sample analysis may not proceed until the problem is corrected, or alternatively the LLOQ may be raised to twice the concentration observed in the SIC solution. The only exceptions are those elements that have been demonstrated to be contaminants in the SIC solutions These may be present up to the concentration documented plus the LLOQ.

Mixed element SIC solution: Aluminum, 500mg/L; Calcium, 500mg/L; Iron, 200mg/L; Magnesium, 500mg/L

8.12 Ongoing Low Level of Quantification, (LLOQ)

Ongoing LLOQ verification, at a minimum, is on a quarterly basis to validate quantitation capability at low analyte concentration levels. This verification may be accomplished either with clean control material (e.g., reagent water, method blanks. Optimally, the LLOQ should be less than the desired regulatory action levels based on the stated project-specific requirements.

8.13 Internal Standard

The internal standard consists of a multi-element solution; each internal standard covers a range of the spectrum (low, middle, or high wavelengths) and the elements within that range.

5.0ug/mL Scandium

3.0ug/mL Yttrium

Note: The standard is used to monitor instrument fluctuations including but not limited to nebulization efficiency, plasma variations, environmental temperature changes, peristaltic pump pulsations, etc. Therefore, the solution used to start an analysis calibration cannot be added to or changed out during analysis without requiring subsequent full recalibration.

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

9.1 Blank(s)

Employ a minimum of one method blank per sample batch to determine if contamination or any memory effects are occurring. A method blank is a volume of reagent water carried through the same preparation process as a sample.

The method blank results must be less than ½ of the LLOQ for all analytes of concern. If the results of the method blank exceed the RDL for any analyte, perform re-analysis of a new aliquot of the method blank.

If the results continue to exceed the RDL, proceed as follows:

If all of the samples for the analyte are non-detected, and the method blank is at or above the RDL, no action is required.

If one or more associated samples for that analyte have positive results at or above the RDL, those samples must be considered to be out of control, and are re-digested and reanalyzed.

9.2 Laboratory Control Sample (LCS)

Analyze one LCSW/SRM per sample batch. A LCS/SRM sample is a spiked volume of reagent water that is brought through the entire preparation and analytical process. The LCSW must have a % Recovery of ± 20% within the actual value or within vendor control limits (95% confidence limits) for the solid SRM.

If the LCSW or SRM % Recovery is outside the acceptable limits as stated in Table 2, or outside any vendor control limits, the LCS is rerun once. If upon reanalysis the LCS is still out of control, the failed analytes are re-prepped and re-analyzed. Otherwise, a nonconformance report form is raised to document the exact problem and this form is then authorized by the QA/QC Director and/or the Laboratory Manager(s).

9.3 Initial Calibration Verification (ICV)

For all analytes and determinations, the laboratory must analyze an ICV (Section 8.9), and a calibration blank (ICB, Section 8.8.1), immediately following daily calibration. The results of the ICV are to agree within 10% of the expected value; if not, re-analyze once, if still failing terminate the analysis, correct the problem, and recalibrate the instrument.

9.4 Continuing Calibration Verification (CCV)

A calibration blank (CCB, Section 8.8.1) and a calibration verification standard (CCV, Section 8.9) must be analyzed after every tenth sample and at the end of the sample run. Analysis of the calibration verification (CCV) must verify that the instrument is within 10% of the calibration with the relative standard deviation < 5% from replicate (minimum of two) integrations.

Immediate corrective action for a failing CCV/CCB includes reanalyzing the failing standard. If the standard passes the second time then the analysis may be continued. The batch sheet is noted. If the standard fails again, instrument maintenance must be performed and the CCV/CCB standard is reanalyzed. If the standard passes, then all samples run after the last passing CCV/CCB pair must be re-analyzed.

If the standard fails after instrument maintenance, the instrument is recalibrated. A new ICV/ICB is performed, and all previous data after the last passing CCV/CCB is reanalyzed.

9.5 Matrix Spike

Analyze matrix spike samples at a frequency of one per matrix batch. The matrix spike is the same solution as used for the LCS (Table 4). A matrix spike sample is a sample brought through the entire sample preparation and analytical process.

9.5.1 The percent recovery is to be calculated as follows:

$$\% \text{ Recovery} = \frac{MS - S}{C} \times 100$$

where:

MS = Matrix Spike value
S = Sample value.
C = Concentration of the Spiking solution.

9.5.2 If the Matrix Spike falls outside of the limits as stated in Table 2, or outside any historical documentation for analytes of interest a post analytical spike is performed for the failed analytes. The same sample from which the MS/MSD aliquots were prepared should be spiked with a post digestion spike at a minimum level of 10 times and a maximum of 100 times the lower limit of quantitation. The acceptable % Recovery of the post analytical spike is 75-125%%. A nonconformance is noted in the LIMS and approved in secondary peer review and/or by the Metals Manager.

9.5.3 If the Post Spike fails the dilution test should be performed**.** If the analyte concentration is sufficiently high (minimally, a factor of 25 above the lower limit of quantitation after dilution), an analysis of a 1:5 dilution should agree within ± 20% of the original determination. If not, then a chemical or physical interference effect should be suspected.

9.6 Laboratory Duplicate

A duplicate sample is analyzed once per matrix batch. This sample is brought through the entire sample preparation and analytical process.

9.6.1 The relative percent difference between duplicate determinations is to be calculated as follows:

$$RPD = \frac{|D_1 - D_2|}{(|D_1 + D_2|)/2} \times 100$$

where:

RPD = relative percent difference.
D_1 = first sample value.
D_2 = second sample value (replicate).

9.6.2 If the Duplicate falls outside of the limits as stated in Table 2, or outside any historical documentation and the concentrations of the failing analytes are less than 5x the RL or a matrix interference is found a nonconformance is noted in the LIMS and approved in secondary peer review and/or by the Metals Manager.

9.7 Method-specific Quality Control Samples

9.7.1 Spectra Interference Check Standard

A mixed check solution is analyzed once daily (section 8.11). One solution (SIC) has only elevated concentrations of Fe, Al, Ca, Mg to ensure no interferences occur. The concentrations of the analytes of interest must have an absolute value of the LLOQ. This solution is analyzed at the beginning of the first analytical run of the day.

The high level interferences are not evaluated for recovery. If the SIC fails take corrective action which may include re-evaluation of the inter-element correction values (IECs) after running single element SIC. The instrument calibration routine must then be performed and confirmed by the ICV/ICB pair and the SIC re-analyzed before proceeding with analysis. Otherwise, the nonconformance issue is raised to the Department Supervisor and/or the QA Department.

9.7.2 Internal Standard

The internal standards are added prior to the nebulizer and corrects for intensity differences in the instrument response between the standard's and sample's matrix. They are monitored for any variation in response during the sample analyses and used to ratio the sample response to the internal standard response of the calibration blank. The ratio is applied to compensate for instrument conditions in the plasma or nebulization caused by the matrix. The internal standard is monitored for 50-150% recovery or laboratory generated control ranges difference from the calibration blank IS response to ensure the proper functioning of the internal standard introduction system and matrix interferences. If an injection falls outside of this acceptance range the sample or QC check is rerun once to check for an introduction error.

If a sample continues to fail it's to be run on successive increasing dilutions until the internal standards associated with the elements of interest are within range. If a QC check fails on the single rerun the analysis is stopped, the root cause investigated, corrected and the instrument re-calibrated/verified. The analysis begins again with all samples that were run after the last acceptable CCV/CCB pair.

9.7.3 LDR Check Solution: A multiple element or single element solution run at a point above the highest calibration standard under the same calibration used to quantify the associated sample data. The LDR check must be within +/-10% of the true value of each element of interest to be considered valid.

9.8 Method Sequence

- Calibration of instrument
- Initial Calibration Verification Standard
- Initial Calibration Blank
- Mixed SIC Solution
- Continuing Calibration Verification Standard
- Continuing Calibration Blank

- 10 samples
- Continuing Calibration Verification Standard
- Continuing Calibration Blank
- 10 Samples
- Continuing Calibration Verification Standard
- Continuing Calibration Blank

10. Procedure

10.1 Equipment Set-up

10.1.1 Sample Preparation

Preliminary treatment of most matrices is necessary because of the complexity and variability of sample matrices. Groundwater samples which have been prefiltered and acidified will not need acid digestion. Samples which are not digested must be matrix matched with the standards.

NOTE: Sample digestates intended for Silver analysis must be analyzed as soon as possible.

10.1.2 Instrument Set-Up

Set up the instrument with proper operating parameters established as detailed below. The instrument must be allowed to become thermally stable before beginning (usually requiring at least 30 minutes of operation prior to calibration).

Startup Procedures

For iCAP Duo 6500

- Turn on power to the chiller
- Click on ThermoSpec Icon; enter analyst initials in login screen
- Click on Plasma icon to start instrument
- Allow to warm up for 30 minutes
- Enter analytical workgroup number (obtained from LIMS) globally under the Instrument menu by selecting Tools, then Options, then Analyst.
- Click on the Sequence tab and enter the sequence by selecting New Autosampler Table, Add Sequence, Add # of spaces.
- Enter the sample locations and IDs
- Press Run Auto-Session button (►) in menu bar.

10.1.2.1 Specific wavelengths are listed in Table 1. Other wavelengths may be substituted if they can provide the needed sensitivity and are corrected for spectral interference. The instrument and operating conditions utilized for determination must be capable of providing data of acceptable quality to the program and data user.

Operating conditions for axial plasma will vary from 1100 – 1500 watts forward power, 15-19 Liters/min argon coolant flow, 0.5 – 0.7 L/min argon nebulizer flow, 140 – 200 rpm pump rate and a default 1 minute preflush time and 10 second measurement time is recommended for all simultaneous instruments.

10.1.2.2 The plasma operating conditions need to be optimized prior to use of the instrument. This routine is not required on a daily basis, but only when first setting up a new instrument or following a change in operating conditions. The following procedure is recommended or follow manufacturer's recommendations. The purpose of plasma optimization is to provide a maximum signal to background ratio for some of the least sensitive elements in the analytical array. The use of a mass flow controller to regulate the nebulizer gas flow or source optimization software greatly facilitates the procedure.

10.1.2.2.1 The Thermo ICP's typically use a Meinhard Nebulizer. The nebulizer flow for each instrument is 1.0 +/- 0.2 mL/min.

10.1.2.2.2 The 6500 Duo instruments automatically perform a wavelength check at start up without user interaction.

10.1.2.2.3 The instrument operating condition finally selected as being optimum must provide the lowest reliable instrument detection limits and method detection limits.

10.1.2.2.4 If either the instrument operating conditions, such as incident power or nebulizer gas flow rate are changed, or a new torch injector tube with a different orifice internal diameter is installed, the plasma and argon pressures must be reoptimized.

10.1.2.2.5 After completing the initial optimization of operating conditions, but before analyzing samples, the laboratory must establish and initially verify an interelement spectral interference correction routine to be used during sample analysis. A general description concerning spectral interference and the analytical requirements for background correction in particular are discussed in the section on interferences. Criteria for determining an interelement spectral interference is an apparent positive or negative concentration for the analyte that falls within ± ½ LLOQ. The upper control limit is the analyte instrument detection limit. Once established, the entire routine is periodically verified every six months. In between that time, IEC's are done on a need be basis per analyte. Only a portion of the correction routine must be verified more frequently or on a daily basis. Initial and periodic verification of the routine must be kept on file. Special cases where continual verification is required are described elsewhere.

10.1.2.3 Sensitivity, instrumental detection limit, precision, linear dynamic range, and interference effects must be established for each individual analyte line on each particular instrument. All measurements must be within the instrument linear range where the correction equations are valid.

10.1.2.3.1 Method detection limits must be established for all wavelengths utilized for each type of matrix commonly analyzed. The matrix used for the MDL calculation must contain analytes of known concentrations within 3-5 times the anticipated detection limit.

10.1.2.3.2 Determination of limits using reagent water MDLs represent a best case situation and do not represent possible matrix effects of real world samples.

10.1.2.3.3 If additional confirmation is desired, reanalyze the seven replicate aliquots on two more non-consecutive days and again calculate the method detection limit values for each day. An average of the three values for each analyte may provide for a more appropriate estimate.

10.1.2.3.4 The upper limit of the linear dynamic range must be established for each wavelength utilized by determining the signal responses with 10% of the true value of each element from a concentration standard at the upper limit of the range run on the same calibration as required by the sample responses above the calibration range. The range which may be used for the analysis of samples must be no more than 90% of the resulting data. Determined analyte concentrations that are above the upper range limit must be diluted and reanalyzed. The analyst must also be aware that if an inter-element correction from an analyte above the linear range exists, a second analyte where the inter-element correction has been applied may be inaccurately reported.

NOTE: Many of the alkali and alkaline earth metals have non-linear response curves due to ionization and self-absorption effects. These curves may be used if the instrument allows; however the effective range must be checked and the second order curve fit must have a correlation coefficient of 0.995 or better. Third order fits are not acceptable. These curves are much more sensitive to changes in operating conditions than the linear lines and must be checked whenever there have been moderate equipment changes.

10.1.2.4 The analyst must (1) verify that the instrument configuration and operating conditions satisfy the analytical requirements and (2) maintain quality control data confirming instrument performance and analytical results.

10.2 Initial Calibration

Calibrate the instrument according to the instrument manufacturer's recommended procedures, using the typical mixed calibration standard solutions described in Section 8.7. Flush the system with the calibration blank (Section 8.8.1) between each standard or as the manufacturer recommends. (Use the average intensity of multiple exposures for both standardization and sample analysis to reduce random error.) The calibration curve consists of a calibration blank, RL standard and a high level standard. Calibration curve verification is accomplished through the analysis of the ICV, ICB and SIC standards.

10.3 Equipment Operation and Sample Processing

10.3.1 For all analytes and determinations, the laboratory must analyze an ICV (Section 8.9), and a calibration blank (ICB, Section 8.8.1), immediately following daily calibration.

A calibration blank (CCB, Section 8.8.1) and a calibration verification standard (CCV, Section 8.9) must be analyzed after every tenth sample and at the end of the sample run. Analysis of the calibration verification (CCV) must verify that the instrument is within 10% of the calibration with the relative standard deviation < 5% from replicate (minimum of three) integrations.

If the calibration cannot be verified within the specified limits, the sample analysis must be discontinued, the cause determined and the instrument recalibrated. All samples following the last acceptable ICV/ICB, or CCV/CCB must be reanalyzed. The analysis

data for the calibration blank, check standard, and ICV or CCV must be kept on file with the sample analysis data.

10.3.2 Rinse the system with the rinse blank solution (Section 8.8.3) before the analysis of each sample. The suggested default rinse time is one minute. Each ICP instrument may establish a reduction in this rinse time through a suitable demonstration.

10.3.3 Dilute and reanalyze samples that exceed the linear range or use a calibrated alternate, less sensitive line for which quality control data is already established.

10.3.4 If less than acceptable accuracy and precision data are generated a series of tests are performed prior to reporting concentration data for analyte elements. At a minimum, these tests should be performed with each batch of samples prepared/analyzed with corresponding unacceptable data quality results. These tests, as outlined in Sections 10.3.5 and 10.3.6, will ensure that neither positive nor negative interferences are operating on any of the analyte elements to distort the accuracy of the reported values.

10.3.5 **Post Digestion Spike Addition:** If the sample concentrations are insufficient to perform a dilution test a post digestion spike added to a portion of a prepared sample, or its dilution for the elements failing the matrix spike recoveries must be run, recovery limits equal to 75% to 125% of the known spike value. If the spike is not recovered within the specified limits If the post-digestion recovery fails to meet the acceptance criteria, the sample results must be reported as estimated values

10.3.6 **Dilution Test:** If the analyte concentration is sufficiently high (minimally, a factor of 25 above the lower limit of quantitation after dilution), an analysis of a 1:5 dilution must agree within ± 20% of the original determination. Elements that fail the dilution test are reported as estimated values.

10.3.7 **CAUTION:** If spectral overlap is suspected, use of computerized compensation, an alternate wavelength, or comparison with an alternate method is recommended.

10.4 Continuing Calibration

10.4.1 Check calibration with an ICV following the initial calibration (Section 8.9). Verify calibration with the Continuing Calibration Verification (CCV) Standard (Section 8.9) at the end of the initial calibration sequence (ICV, ICB), after every ten samples, and at the end of an analytical run. Use a calibration blank (Section 8.8.1) immediately following daily calibration, after every 10 samples and at the end of the analytical run.

10.4.1.1 The results of the ICV are to agree within 10% of the expected value, and CCVs are to agree within 10% of the expected value; if not, terminate the analysis, correct the problem, and recalibrate the instrument. Each may be rerun once to confirm or cure the initial failure.

10.4.1.2 The results of the calibration blank should be below ½ of LLOQ or RL (whichever is lower). If not, repeat the analysis and if the failure is repeated terminate the analysis, correct the problem, recalibrate, and reanalyze the previous 10 samples. If the blank is less than 1/10 the concentration of the action level of interest, and no sample is within ten percent of the action limit, analyses need not be rerun and recalibration need not be performed before continuation of the run.

10.4.2 Verify the inter-element and background correction factors at the beginning of each analytical run. Do this by analyzing the SIC (Section 8.10). Results must be less than +/- LLOQ for all non-spiked elements.

10.4.3 When low-level sensitivity is required, a check standard at the requested limit of quantitation is analyzed to confirm the reported detection limit (RDL). This is performed on a project-by-project basis.

10.5 Preventive Maintenance

Whenever instrument maintenance is performed, it is noted in the instrument's Maintenance Logbook.

10.5.1 Daily

Inspect the nebulizer pump tubing from the Autosampler to the Nebulizer. Replace if necessary.

10.5.2 Monthly or as needed

Remove the torch, "shot glass", nebulizer and spray chamber. Clean each with 10% Nitric Acid and rinse with tap water. Coat the inside of the spray chamber and shot glass with concentrated Sulfuric Acid and soak for one hour, then rinse well with DI water. Soak the torch and nebulizer in aqua regia overnight, then rinse with DI water.

10.5.3 Every 6 months

Preventive Maintenance is performed by the Vendor or in-house personnel as follows:

- check the cooling system
- flush/refill the chiller with distilled water and antibacterial conditioner
- clean the instrument to regain intensity
- clean/replace air filters.

11. Data Evaluation, Calculations and Reporting

11.1 If dilutions were performed, the appropriate factors must be applied to sample values. All results must be reported with up to three significant figures.

11.2 Soil samples

Soil samples are calculated as follows:

$$\mathbf{A} = \frac{\text{Sample weight (grams)}}{\text{Final Volume (mL)}}$$

$$\mathbf{B}\ (\text{concentration in mg/Kg}) = \frac{\text{Concentration of analyte (mg/L)}}{\mathbf{A}}$$

11.2.1 Dry weight correction

The LIMS calculates the dry weight correction, however it is calculated as follows:

$$\text{Final concentration in mg/Kg dry weight} = \frac{B}{\%\ \text{Solids}}$$

11.3 Liquid samples

Liquid samples are calculated as follows:

$$\text{Dilution Factor} = \frac{\text{Final Volume (mL)}}{\text{Sample Volume (mL)}}$$

Final concentration in mg/L = Concentration of analyte (mg/L) x Dilution Factor

11.4 Calculations for Hardness

The method for determining hardness is to compute it from the results of separate determinations of Calcium and Magnesium on aqueous samples.

11.4.1 Total Hardness

Total Hardness, mg equivalent $CaCO_3$/L = [2.497 (Ca, mg/L)] + [4.118 (Mg, mg/L)]

11.4.2 Calcium Hardness

Calcium Hardness, mg equivalent $CaCO_3$/L = [2.497 (Ca, mg/L)]

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

Also refer to Section 9 for Quality Control and acceptance criteria.

If the SIC is outside of the recovery window, then the standard is reanalyzed. If the standard failure continues, the IECs for the element/elements in question are reviewed and recalculated if necessary.

Immediate corrective action for a failing CCV/CCB includes reanalyzing the failing standard. If the standard passes the second time then the analysis may be continued. The raw data is noted. If the standard fails again, the problem must be found and corrected and the instrument is recalibrated. The ICV/ICB standard is reanalyzed and all previous data that had failed back to the previous passing CCV/CCB is reanalyzed.

The reanalysis procedure outline above is also conducted for a failing LCS or Method Blank; they may be rerun alone on the new or any subsequent passing bracket. The LCS or Method Blank do not qualify a bracket of samples but the batch run itself.

If the Matrix Spike does not meet acceptance criteria, a dilution test is performed. If the levels of the native sample is inadequate (see section 10.3.6) The RPD must be within 20% of the true value of the native sample. If the dilution test fails or the concentrations in the native sample are inadequate, the post spike is analyzed and evaluated (section 10.3.5). If these criteria are met, then the Matrix Spike data is reported, with the post spike narrated on the final report. If the post spike fails the data is reported as estimated.

If sample Duplicates are outside of the acceptance criteria, the analyst examines the sample for homogeneity. If the sample is not homogenous, this is narrated on the final report. Clean, homogenous samples are reanalyzed and if still outside of the acceptance limits, redigested and reanalyzed.

Sample nonconformance regarding a Matrix Spike recovery or a duplicate %RSD is narrated on the final report along with the corrective action(s) taken.

The mixed element SIC solution is analyzed at least once per day, immediately after the initial calibration. The concentration measured for any target analytes must be less than +/- the LLOQ. If this criterion is not met then sample analysis may not proceed until the problem is corrected, instrument is recalibrated, verified with the ICV/ICB and the SIC is then re-analyzed. Alternatively, the LLOQ may be raised to twice the concentration observed in the SIC solution if approved by the Department Manger or QA Department and the level is below the regulatory action limit or project specific requirements. The only exceptions are those elements that have been demonstrated to be contaminants in the SIC solutions These may be present up to the concentration documented plus the LLOQ. If failure continues notify the Department Supervisor or Manager.

Silver is only slightly soluble in the presence of chloride unless there is a sufficient chloride concentration to form the soluble chloride complex. Therefore, low recoveries of silver may occur in samples, matrix spikes and even laboratory control samples.

Silver is flagged in our data software during analysis if the concentration of silver is >100ug/L. Liquid samples that exceed 100ug/L will be redigested at dilution. Soil and solid samples that exceed 500ug/L (approximately 20mg/kg) will be re-digested at a reduced weight of 0.625g to allow more silver to become soluble during digestion.

13. Method Performance

13.1 Method Detection Limit Study (MDL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the MDL, LOD, and/or LOQ as outlined in Alpha SOP/08-05 unless supersede within this SOP. These studies performed by the laboratory are maintained on file for review.

13.2 Demonstration of Capability Studies

Refer to Alpha SOP/08-12 for further information regarding IDC/DOC Generation.

13.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

14. Pollution Prevention and Waste Management

Refer to Alpha's Chemical Hygiene Plan and Waste Management and Disposal SOP for further pollution prevention and waste management information.

Method 1633 Analysis of Per- and Polyfluoroalkyl Substances (PFAS) in Aqueous, Solid, Biosolids, Oil and Tissue Samples by LC-MS/MS

References: Method 1633 - Analysis of Per- and Polyfluoroalkyl Substances (PFAS) in Aqueous, Solid, Biosolids, Oil and Tissue Samples by LC-MS/MS (2nd Draft -June 2022)

DOD QSM (US Department of Defense Quality Systems Manual for Environmental Laboratories, version 5.4, 20221)

1. Scope and Application

Matrices: Drinking water, Non-potable Water, Tissues, Oils, Biosolids and Solid Matrices

Definitions: Refer to Alpha Analytical Quality Manual.

1.1 Method 1633 is for use in the Clean Water Act (CWA) for the determination of the per- and polyfluoroalkyl substances (PFAS) in Table 1 in aqueous, solid (soil, biosolids, sediment) and tissue samples by liquid chromatography/mass spectrometry (LC-MS/MS).

1.2 The method calibrates and quantifies PFAS analytes using isotopically labeled standards. Where linear and branched isomers are present in the sample and either qualitative or quantitative standards containing branched and linear isomers are commercially available, the PFAS analyte is reported as a single analyte consisting of the sum of the linear and branched isomer concentrations

1.3 This is a liquid chromatography/tandem mass spectrometry (LC/MS/MS) method for the determination of selected perfluorinated alkyl substances (PFAS) in Non-Drinking Water, tissue soil and biosolid Matrices. Accuracy and precision data have been generated for the compounds listed in Table 1.

1.4 The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one or more of the following laboratory personnel before performing the modification: Area Supervisor, Department Supervisor, Laboratory Director, or Quality Assurance Officer.

1.5 This method is restricted to use by or under the supervision of analysts experienced in the operation of the LC/MS/MS and in the interpretation of LC/MS/MS data. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

2. Summary of Method

2.1 Environmental samples are prepared and extracted using method-specific procedures. Sample extracts are subjected to cleanup procedures designed to remove interferences. Analyses of the sample extracts are conducted by LC-MS/MS in the multiple reaction monitoring (MRM) mode. Sample concentrations are determined by isotope dilution or extracted internal standard quantification using isotopically labeled compounds added to the samples before extraction.

2.2 Aqueous samples are spiked with isotopically labeled standards, extracted using solid-phase extraction (SPE) cartridges and undergo cleanup using carbon before analysis.

2.3 Solid and Oil samples are spiked with isotopically labeled standards, extracted into basic methanol, and cleaned up by carbon and SPE cartridges before analysis

2.4 Tissue samples are spiked with isotopically labeled standards, extracted in potassium hydroxide and acetonitrile followed by basic methanol, and cleaned up by carbon and SPE cartridges before analysis.

2.5 A sample extract is injected into an LC equipped with a C18 column that is interfaced to an MS/MS). The analytes are separated and identified by comparing the acquired mass spectra and retention times to reference spectra and retention times for calibration standards acquired under identical LC/MS/MS conditions. The concentration of each analyte is determined by using the isotope dilution technique. Extracted Internal Standards (EIS) analytes are used to monitor the extraction efficiency of the method analytes.

2.6 Method Modifications from Reference

N/A

3. Reporting Limits

The reporting limit for PFAS's are listed in Table 8.

4. Interferences

4.1 PFAS standards, extracts and samples should not come in contact with any glass containers or pipettes as these analytes can potentially adsorb to glass surfaces. PFAS analyte and EIS standards commercially purchased in glass ampoules are acceptable; however, all subsequent transfers or dilutions performed by the analyst must be prepared and stored in polypropylene containers.

4.2 Method interferences may be caused by contaminants in solvents, reagents (including reagent water), sample bottles and caps, and other sample processing hardware that lead to discrete artifacts and/or elevated baselines in the chromatograms. The method analytes in this method can also be found in many common laboratory supplies and equipment, such as PTFE (polytetrafluoroethylene) products, LC solvent lines, methanol, aluminum foil, SPE sample transfer lines, etc. All items such as these must be routinely demonstrated to be free from interferences (less than 1/2 the RL for each method analyte) under the conditions of the analysis by analyzing laboratory reagent blanks as described in Section 9.1. Subtracting blank values from sample results is not permitted.

4.3 Matrix interferences may be caused by contaminants that are co-extracted from the sample. The extent of matrix interferences will vary considerably from source to source, depending upon the nature of the water. Humic and/or fulvic material can be co-extracted during SPE and high levels can cause enhancement and/or suppression in the electrospray ionization source or low recoveries on the SPE sorbent. Total organic carbon (TOC) is a good indicator of humic content of the sample.

4.4 SPE cartridges can be a source of interferences. The analysis of field and laboratory reagent blanks can provide important information regarding the presence or absence of such interferences. Brands and lots of SPE devices should be tested to ensure that contamination does not preclude analyte identification and quantitation.

5. Health and Safety

5.1 The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material safety data sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

5.2 All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

5.3 PFOA has been described as “likely to be carcinogenic to humans.” Pure standard materials and stock standard solutions of these method analytes should be handled with suitable protection to skin and eyes, and care should be taken not to breathe the vapors or ingest the materials.

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection for Aqueous Samples

6.1.1 Samples must be collected in two (2) 500-mL or 250-mL high density polyethylene (HDPE) container with an unlined plastic screw cap. All sample containers must have linerless HDPE or polypropylene caps.

6.1.2 The sample handler must wash their hands before sampling and wear nitrile gloves while filling and sealing the sample bottles. PFAS contamination during sampling can occur from a number of common sources, such as food packaging and certain foods and beverages. Proper hand washing and wearing nitrile gloves will aid in minimizing this type of accidental contamination of the samples.

6.1.3 Open the tap and allow the system to flush until the water temperature has stabilized (approximately 3 to 5 min). Collect samples from the flowing system.

6.1.4 Fill sample bottles. Samples do not need to be collected headspace free.

6.1.5 After collecting the sample and cap the bottle. Keep the sample sealed from time of collection until extraction.

6.1.6 Maintain all aqueous samples protected from light at 0 - 6 ºC from the time of collection until shipped to the laboratory. Samples must be shipped as soon as practical with sufficient ice to maintain the sample temperature below 6 ºC during transport and be received by the laboratory within 48 hours of collection. The laboratory must confirm that the sample temperature is 0 - 6 ºC upon receipt. Once received by the laboratory, the samples must be stored at ≤ -20 ºC until sample preparation.

6.2 Sample Collection for Solid and Oil samples.

6.2.1 Grab samples are collected in polypropylene containers. Sample containers and contact surfaces containing PTFE shall be avoided. Samples should fill no more than ¾ full.

6.2.2 Maintain solid samples protected from light (in HDPE containers) at 0 - 6 ºC from the time of collection until receipt at the laboratory. The laboratory must confirm that the sample temperature is 0 - 6 ºC upon receipt. Once received by the laboratory, the samples must be stored at ≤ -20 ºC until sample preparation.

6.3 Sample Collection for fish and other tissue samples

6.3.1 If the time of collection to the time of receipt at the laboratory is expected to exceed 24 hours, the tissue samples must be frozen upon collection and shipped to the laboratory on dry ice.

6.3.2 Once received by the laboratory, the samples must be maintained protected from light at ≤ -20 ºC until prepared. Store unused samples in HDPE containers or wrapped in aluminum foil at ≤ -20 ºC.

6.3.3 The nature of the tissues of interest may vary by project. Field sampling plans and protocols should explicitly state the samples to be collected and if any processing will be conducted in the field (e.g., filleting of whole fish or removal of organs). All field procedures must involve materials and equipment that have been shown to be free of PFAS.

6.4 Sample Preservation

Not applicable.

6.5 Sample Shipping

Samples must be chilled during shipment and must not exceed 0 – 6 °C during the first 48 hours after collection. Sample temperature must be confirmed to be at or below 0 – 6 °C when the samples are received at the laboratory. Samples stored in the lab must be held at or below 6 °C until extraction but should not be frozen.

NOTE: Samples that are significantly above 0 – 6 ° C, at the time of collection, may need to be iced or refrigerated for a period of time, in order to chill them prior to shipping. This will allow them to be shipped with sufficient ice to meet the above requirements.

6.6 Sample Handling

6.6.1 Aqueous samples (including leachates) should be analyzed as soon as possible; however, samples may be held in the laboratory for up to 90 days from collection, when stored at ≤ -20 ºC and protected from the light. When stored at 0 - 6 ºC and protected from the light, aqueous samples may be held for up to 28 days, with the caveat that issues were observed with certain perfluorooctane sulfonamide ethanols and perfluorooctane sulfonamidoacetic acids after 7 days. These issues are more likely to elevate the observed concentrations of other PFAS compounds via the transformation of these precursors if they are present in the sample.

6.6.2 Solid samples (soils and sediments), Oil and tissue samples may be held for up to 90 days, if stored by the laboratory in the dark at either 0 - 6 ºC or ≤ -20 ºC, with the caveat that samples may need to be extracted as soon as possible if NFDHA is an important analyte.

6.6.3 Biosolids samples may be held for up to 90 days, if stored by the laboratory in the dark at 0 - 6 ºC or at -20 ºC. Because microbiological activity in biosolids samples at 0 - 6 ºC may lead to production of gases which may cause the sample to be expelled from the container when it is opened, as well as producing noxious odors, EPA recommends that samples be frozen if they need to be stored for more than a few days before extraction. Store sample extracts in the dark at less than 0 - 4 ºC until analyzed. If stored in the dark at less than 0 - 4 ºC, sample extracts may be stored for up to 90 days, with the caveat that issues were observed for some ether sulfonates after 28 days. These issues may elevate the observed concentrations of the ether sulfonates in the extract over time. Samples may need to be extracted as soon as possible if NFDHA is an important analyte.

7. Equipment and Supplies

7.1 SAMPLE CONTAINERS – 500-mL or 250-mL high density polyethylene (HDPE) bottles fitted with unlined screw caps. Sample bottles must be discarded after use.

7.2 SAMPLE JARS – 8-ounce wide mouth high density polyethylene (HDPE) bottles fitted with unlined screw caps. Sample bottles must be discarded after use.

7.3 POLYPROPYLENE BOTTLES – 4-mL narrow-mouth polypropylene bottles.

7.4 CENTRIFUGE TUBES – 50-mL conical polypropylene tubes with polypropylene screw caps for storing standard solutions and for collection of the extracts.

7.5 AUTOSAMPLER VIALS – Polypropylene 0.7-mL autosampler vials with polypropylene caps.

7.5.1 NOTE: Polypropylene vials and caps are necessary to prevent contamination of the sample from PTFE coated septa. However, polypropylene caps do not reseal, so evaporation occurs after injection. Thus, multiple injections from the same vial are not possible.

7.6 POLYPROPYLENE GRADUATED CYLINDERS – Suggested sizes include 25, 50, 100 and 1000-mL cylinders.

7.7 Auto Pipets – Suggested sizes include 5, 10, 25, 50, 100, 250, 500, 1000, 5000 and 10,000-µls.

7.8 PLASTIC PIPETS – Polypropylene or polyethylene disposable pipets.

7.9 Silanized glass wool (Sigma-Aldrich, Cat # 20411 or equivalent) – store in a clean glass jar and rinsed with methanol (2 times) prior to use.

7.10 Disposable syringe filter, 25-mm, 0.2-µm Nylon membrane, PALL/Acrodisc or equivalent

7.11 Variable volume pipettes with disposable HDPE or polypropylene tips (10 µL to 5 mL) used for preparation of calibration standards and spiked samples.

7.12 ANALYTICAL BALANCE – Capable of weighing to the nearest 0.0001 g.

7.13 ANALYTICAL BALANCE – Capable of weighing to the nearest 0.1 g.

7.14 SOLID PHASE EXTRACTION (SPE) APPARATUS FOR USING CARTRIDGES

7.14.1 SPE CARTRIDGES – (Phenomenex WAX 150 or 250mg or equivalent). The SPE sorbent must have a pKa above 8 so that it remains positively charged during the extraction.

7.14.1.1 Note: SPE cartridges with different bed volume (e.g., 500 mg) may be used; however, the laboratory must demonstrate that the bed volume does not negatively affect analyte absorption and elution, by performing the initial demonstration of capability analyses described in Section 13.

7.14.2 VACUUM EXTRACTION MANIFOLD – A manual vacuum manifold with large volume sampler for cartridge extractions, or an automatic/robotic sample preparation system designed for use with SPE cartridges, may be used if all QC requirements discussed in Section 9 are met. Extraction and/or elution steps may not be changed or omitted to accommodate the use of an automated system. Care must be taken with automated SPE systems to ensure the PTFE commonly used in these systems does not contribute to unacceptable analyte concentrations in the MB.

7.14.3 SAMPLE DELIVERY SYSTEM – Use of a polypropylene transfer tube system, which transfers the sample directly from the sample container to the SPE cartridge, is recommended, but not mandatory. Standard extraction manifolds come equipped with PTFE transfer tube systems. These can be replaced with 1/8" O.D. x 1/16" I.D. polypropylene or polyethylene tubing cut to an appropriate length to ensure no sample contamination from the sample transfer lines. Other types of non-PTFE tubing may be used provided it meets the MB and LCS QC requirements.

7.15 EXTRACT CONCENTRATION SYSTEM – Extracts are concentrated by evaporation with nitrogen using a water bath set no higher than 55 °C.

7.16 LABORATORY OR ASPIRATOR VACUUM SYSTEM – Sufficient capacity to maintain a vacuum of approximately 10 to 15 inches of mercury for extraction cartridges.

7.17 LIQUID CHROMATOGRAPHY (LC)/TANDEM MASS SPECTROMETER (MS/MS) WITH DATA SYSTEM

7.17.1 LC SYSTEM – Instrument capable of reproducibly injecting up to 10-µL aliquots and performing binary linear gradients at a constant flow rate near the flow rate used for development of this method (0.4 mL/min). The LC must be capable of pumping the water/methanol mobile phase without the use of a degasser which pulls vacuum on the mobile phase bottle (other types of degassers are acceptable). Degassers which pull vacuum on the mobile phase bottle will volatilize the ammonium acetate mobile phase causing the analyte peaks to shift to earlier retention times over the course of the analysis batch. The usage of a column heater is optional.

7.17.2 LC/TANDEM MASS SPECTROMETER – The LC/MS/MS must be capable of negative ion electrospray ionization (ESI) near the suggested LC flow rate of 0.4 mL/min. The system must be capable of performing MS/MS to produce unique product ions for the method analytes within specified retention time segments. A minimum of 10 scans across the chromatographic peak is required to ensure adequate precision.

7.17.3 DATA SYSTEM – An interfaced data system is required to acquire, store, reduce, and output mass spectral data. The computer software should have the

capability of processing stored LC/MS/MS data by recognizing an LC peak within any given retention time window. The software must allow integration of the ion abundance of any specific ion within specified time or scan number limits. The software must be able to calculate relative response factors, construct linear regressions or quadratic calibration curves, and calculate analyte concentrations.

7.17.4 INSTRUMENT COLUMNS

7.17.4.1 ANALYTICAL: C18 column, 1.7 µm, 50 x 2.1 mm (Waters Acquity UPLC® BEH or equivalent)

7.17.4.2 OPTIONAL GUARD COLUMN: (Phenomenex Kinetex® Evo C18 or equivalent)

8. Reagents and Standards

8.1 GASES, REAGENTS, AND SOLVENTS – Reagent grade or better chemicals must be used.

8.1.1 REAGENT WATER – Purified water which does not contain any measurable quantities of any method analytes or interfering compounds greater than 1/2 the RL for each method analyte of interest. Prior to daily use, at least 3 L of reagent water should be flushed from the purification system to rinse out any build-up of analytes in the system's tubing.

8.1.2 METHANOL (CH_3OH, CAS#: 67-56-1) – High purity, demonstrated to be free of analytes and interferences.

8.1.3 AMMONIUM ACETATE ($NH_4C_2H_3O_2$, CAS#: 631-61-8) – High purity, demonstrated to be free of analytes and interferences. Store at 2-8° and replace 2 years after opening date.

8.1.4 ACETIC ACID (H_3CCOOH, CAS#: 64-19-7) - High purity, demonstrated to be free of analytes and interferences and stored at room temperature.

8.1.4.1 Acetic Acid (0.1%) – Dissolve acetic acid (1 mL) in reagent water (1 L), store at room temperature, replace after 3 months.

8.1.5 1M AMMONIUM ACETATE/REAGENT WATER – High purity, demonstrated to be free of analytes and interferences.

8.1.6 2mM AMMONIUM ACETATE/METHANOL:WATER (5:95) – To prepare, mix 2 ml of 1M AMMONIUM ACETATE,1 ml ACETIC ACID and 50 ml METHANOL into I Liter of REAGENT WATER.

8.1.7 ACETONITRILE – UPLC grade or equivalent, store at room temperature

8.1.8 TOLUENE – HPLC grade or equivalent.

8.1.9 ACETONE – pesticide grade or equivalent

8.1.10 AMMONIUM HYDROXIDE (NH_3, CAS#: 1336-21-6) – High purity, demonstrated to be free of analytes and interferences, and stored at room temperature.

8.1.11 AQUEOUS AMMONIUM HYDROXIDE (3%) – Add ammonium hydroxide (10 mL, 30%) to reagent water (90 mL), store at room temperature, replace after 3 months.

8.1.12 METHANOLIC AMMONIUM HYDROXIDE (0.3%) - add ammonium hydroxide (1 mL, 30%) to methanol (99 mL), store at room temperature, replace after 1 month

8.1.13 METHANOLIC AMMONIUM HYDROXIDE (1%) - add ammonium hydroxide (3.3 mL, 30%) to methanol (97 mL), store at room temperature, replace after 1 month

8.1.14 METHANOLIC AMMONIUM HYDROXIDE (2%) - add ammonium hydroxide (6.6 mL, 30%) to methanol (93.4 mL), store at room temperature, replace after 1 month

8.1.15 METHANOLIC POTASSIUM HYDROXIDE (0.05 M) – add 3.3 g of potassium hydroxide to 1 L of methanol, store at room temperature, replace after 3 months

8.1.16 METHANOL WITH 4% WATER, 1% AMMONIUM HYDROXIDE AND 0.625% ACETIC ACID - add ammonium hydroxide (3.3 mL, 30%), reagent water (1.7 mL) and acetic acid (0.625 mL) to methanol (92 mL), store at room temperature, replace after 1 month. This solution is used to prepare the instrument blank and calibration standards (Section 8.3.2).

8.1.17 FORMIC ACID – (greater than 96% purity or equivalent). Store at room temperature and replace after 2 years.

8.1.18 FORMIC ACID (aqueous, 0.1 M) - dissolve formic acid (4.6 g) in reagent water (1 L), store at room temperature, replace after 2 years.

8.1.19 FORMIC ACID (aqueous, 0.3 M) - dissolve formic acid (13.8 g) in reagent water (1 L), store at room temperature, replace after 2 years.

8.1.20 FORMIC ACID (aqueous, 5% v/v) - mix 5 mL formic acid with 95 mL reagent water, store at room temperature, replace after 2 years.

8.1.21 FORMIC ACID (methanolic 1:1, 0.1 M formic acid/methanol) - mix equal volumes of methanol and 0.1 M formic acid, store at room temperature, replace after 2 years.

8.1.22 FORMIC ACID (aqueous, 50% v/v) - mix 50 mL formic acid with 50 mL reagent water, store at room temperature, replace after 2 years.

8.1.23 POTASSIUM HYDROXIDE – certified ACS or equivalent, store at room temperature, replace after 2 years.

8.1.24 CARBON - – EnviCarb® 1-M-USP or equivalent, verified by lot number before use, stored at room temperature. Loose carbon allows for better adsorption of interferent organics. Note: The single-laboratory validation laboratory achieved better performance with loose carbon than carbon cartridges. Loose carbon will be used for the multi-laboratory validation to set statistically based method criteria.

8.1.25 NITROGEN – Used for the following purposes: Nitrogen aids in aerosol generation of the ESI liquid spray and is used as collision gas in some MS/MS instruments. The nitrogen used should meet or exceed instrument manufacturer's specifications. In addition, Nitrogen is used to concentrate sample extracts (Ultra High Purity or equivalent).

8.1.26 ARGON – Used as collision gas in some MS/MS instruments. Argon should meet or exceed instrument manufacturer's specifications. Nitrogen gas may be used as the collision gas provided sufficient sensitivity (product ion formation) is achieved.

8.2 REFERENCE MATRICES - Matrices in which PFAS and interfering compounds are not detected by this method. These matrices are to be used to prepare the batch QC samples, LOQ/MDL, and IDOC samples.

8.2.1 Reagent water - purified water, Type I

8.2.2 Solid reference matrix Ottawa Sand or equivalent

8.2.3 Tissue Reference matrix – Cod loin or other animal tissue demonstrated to be PFAS free.

8.3 STANDARD SOLUTIONS – When a compound purity is assayed to be 96% or greater, the weight can be used without correction to calculate the concentration of the stock standard. PFAS analyte and IS standards commercially purchased in glass ampoules are acceptable; however, all subsequent transfers or dilutions performed by the analyst must be prepared and stored in polypropylene containers and are stored at ≤4 °C. Standards for sample fortification generally should be prepared in the smallest volume that can be accurately measured to minimize the addition of excess organic solvent to aqueous samples.

8.3.1 Stock standards and diluted stock standards are stored at ≤4 °C. Prepare a spiking solution, containing the method analytes listed in Table 1, in methanol from prime stocks. The solution is used to prepare the calibration standards and to spike the known reference QC samples that are analyzed with every batch. Quantitative standards containing a mixture of branched and linear isomers must be used for method analytes if they are commercially available. Currently, these include PFOS, PFHxS, NEtFOSAA, and NMeFOSAA.

8.3.2 Calibration standard solutions – A series of calibration solutions containing the target analytes and the Labeled extracted internal standards (EIS) and non-extracted internal standards (NIS) is used to establish the initial calibration of the analytical instrument. Table 4 represents the concentrations of the native, EIS and NIS analytes of the calibration curve. Calibration standard solutions are made using the solution described in section 8.1.16.

8.3.3 ISOTOPE DILUTION EXTRACTED INTERNAL STANDARD (EIS) – Isotopically labelled analogs of the target analytes to be used for the quantification of target analytes. EIS stock standard solutions are purchased in glass ampoules and are stored in accordance with the manufacturer's recommendations. The EIS stock solution to be used for the fortification of samples and QC in accordance with the isotope dilution procedure. Table 2 represents the EIS concentrations and nominal sample amounts added to each field sample and QC element.

8.3.4 ISOTOPE DILUTION NON-EXTRACTED INTERNAL STANDARDS (NIS) – Isotopically labelled analogs to be added post extraction for the measurement of EIS extraction efficiency and is added to the final volume of all extractions. Table 3 represents the EIS concentrations and nominal sample amounts added to each field sample and QC element.

9. Quality Control

9.1 Method Blank

9.1.1 A Method Blank (MB) is required with each extraction batch to confirm that potential background contaminants are not interfering with the identification or quantitation of method analytes. An aliquot of reagent water that is treated exactly as a sample including exposure to all glassware, equipment, solvents, reagents and standards. Prep and analyze a MB for every 20 samples. If the MB produces a peak within the retention time window of any analyte that would prevent the determination of that analyte, determine the source of contamination, and eliminate the interference before processing samples. Background contamination must be reduced to an acceptable level before proceeding. Background from method analytes or other contaminants that interfere with the measurement of method analytes must be below the RL. If the method analytes are detected in the MB at concentrations equal to or greater than this level, then all data for the problem analyte(s) must be considered invalid for all samples in the extraction batch.

9.2 Laboratory Control Sample (LCS)

9.2.1 Low Level LCS or OPR (Ongoing Precision Recovery) sample is required with each extraction batch. A LLCS or OPR samples is a method blank spiked with known quantities of analytes. The fortified concentration of the LCS is spiked at 2X the LOQ. Default limits of 70-130% of the true value may be used for analytes until sufficient replicates have been analyzed to generate proper control limits. Calculate the percent recovery (%*R*) for each analyte using the equation:

9.2.2 An LCS or OPR (Ongoing Precision Recovery) sample is required with each extraction batch. A LCS or OPR samples is a method blank spiked with known quantities of analytes. The fortified concentration of the LCS is spiked at the midpoint of the calibration curve. Default limits of 70-130% of the true value may be used for analytes until sufficient replicates have been analyzed to generate proper control limits. Calculate the percent recovery (%*R*) for each analyte using the equation:

$$\%R = \frac{A \times 100}{B}$$

Where:

A = measured concentration in the fortified sample
B =fortification concentration.

9.1.1 Where applicable, in the absence of additional sample volume required to perform matrix specific QC, LCSD's are to be extracted and analyzed. The concentration and analyte

recovery criteria for the LCSD must be the same as the batch LCS The RSD's must fall within ≤30% of the true value for medium and high-level replicates, and ≤50% for low level replicates. Calculate the relative percent difference (RPD) for duplicate MSs (MS and MSD) using the equation:

$$RPD = \frac{|LCS - LCSD|}{(LCS + LCSD) / 2} \times 100$$

9.1.2 If the LCS and or LCSD results do not meet these criteria for method analytes, then all data for the problem analyte(s) must be considered invalid for all samples in the extraction batch.

9.3 Non-extracted Internal Standard Area (NIS)

Each time an initial calibration is performed, use the data from all the initial calibration standards used to meet the linearity test in Section 10.3.3.3 to calculate the mean area response for each of the NIS compounds, using the equation below.

$$\text{Mean Area}_{NISi} = \sum \text{AREA}_{NISi} / n$$

where:

AreaNISi = Area counts for the ith NIS, where i ranges from 1 to 7, for the seven NIS compounds listed in Table 1
n = The number of ICAL standards (the default value is n = 6). If a different number of standards is used for the ICAL, for example, to increase the calibration range or by dropping a point at either end of the range to meet the linearity criterion, change 6 to match the actual number of standards used)

Record the mean areas for each NIS for use in evaluating results for sample analyses. There is no acceptance criterion associated with the mean NIS area data.

9.4 Extracted Internal Standards (EIS)

9.4.1 The EIS standard is fortified into all samples, CCVs, MBs, LCSs, MSs, MSDs, FD, and FRB prior to extraction. It is also added to the CAL standards. The EIS is a means of assessing method performance from extraction to final chromatographic measurement. Calculate the recovery (%R) for the EIS using the following equation:

$$\%R = (A / B) \times 100$$

Where:

A = calculated EIS concentration for the QC or Field Sample
B = fortified concentration of the EIS.

9.4.2 Default limits of 50-150% may be used for analytes until sufficient replicates have been analyzed to generate proper control limits. A low or high percent recovery for a sample, blank, or CCV does not require discarding the analytical data but it may indicate a potential problem with future analytical data. When EIS recovery from a sample, blank, or CCV are outside control limits, check 1) calculations to locate

possible errors, 2) standard solutions for degradation, 3) contamination, and 4) instrument performance. For CCVs and QC elements spiked with all target analytes, if the recovery of the corresponding target analytes meet the acceptance criteria for the EIS in question, the data can be used but all potential biases in the recovery of the EIS must be documented in the sample report. If the associated target analytes do not meet the acceptance criteria, the data must be reanalyzed.

9.5 Matrix Spike (MS/MSD)

9.5.1 Analysis of an MS is prepared one per preparation batch (if required).

9.5.2 Aliquots of field samples that have been fortified with a known concentration of target compounds, prior to sample preparation and extraction, and analyzed to measure the effect of matrix interferences. The use of MS/MSD samples is generally not required in isotope dilution methods because the labeled compounds added to every sample provide more performance data than spiking a single sample in each preparation batch. Aliquots of field samples

9.5.3 Analyte recoveries may exhibit matrix bias. For samples fortified at or above their native concentration, recoveries should range between 50-150%. If the accuracy of any analyte falls outside the designated range, and the laboratory performance for that analyte is shown to be in control in the LCS, the recovery is judged to be matrix biased. The result for that analyte in the unfortified sample is labeled suspect/matrix to inform the data user that the results are suspect due to matrix effects.

9.6 Laboratory Duplicate

9.6.1 FIELD DUPLICATE OR LABORATORY FORTIFIED SAMPLE MATRIX DUPLICATE (FD or MSD) – Within each extraction batch (not to exceed 20 Field Samples), a minimum of one FD or MSD must be analyzed. Duplicates check the precision associated with sample collection, preservation, storage, and laboratory procedures. If method analytes are not routinely observed in Field Samples, an MSD should be analyzed rather than an FD.

9.6.2 Calculate the relative percent difference (*RPD*) for duplicate measurements (*FD1* and *FD2*) using the equation:

$$RPD = \frac{|FD1 - FD2|}{(FD1 + FD2) / 2} \times 100$$

9.6.3 RPDs for FDs should be ≤30%. Greater variability may be observed when FDs have analyte concentrations that are within a factor of 2 of the RL. At these concentrations, FDs should have RPDs that are ≤50%. If the RPD of any analyte falls outside the designated range, and the laboratory performance for that analyte is shown to be in control in the CCV, the recovery is judged to be matrix biased. The result for that analyte in the unfortified sample is labeled suspect/matrix to inform the data user that the results are suspect due to matrix effects.

9.6.4 If an MSD is analyzed instead of a FD, calculate the relative percent difference (RPD) for duplicate MSs (MS and MSD) using the equation:

$$RPD = \frac{|MS - MSD|}{(MS + MSD) / 2} \times 100$$

9.6.5 RPDs for duplicate MSs should be ≤30% for samples fortified at or above their native concentration. Greater variability may be observed when MSs are fortified at analyte concentrations that are within a factor of 2 of the RL. MSs fortified at these concentrations should have RPDs that are ≤50% for samples fortified at or above their native concentration. If the RPD of any analyte falls outside the designated range, and the laboratory performance for that analyte is shown to be in control in the LCSD where applicable, the result is judged to be matrix biased. If no LCSD is present, the associated MS and MSD are to be re-analyzed to determine if any analytical has occurred. If the resulting RPDs are still outside control limits, the result for that analyte in the unfortified sample is labeled suspect/matrix to inform the data user that the results are suspect due to matrix effects.

9.7 Bile Salt Interference Check

9.7.1 The laboratory must analyze a TDCA standard after the initial calibration, prior to the analysis of tissue samples, to check for interferences caused by bile salts. If an interference is present, the chromatographic conditions must be modified to eliminate the interference from TDCA (e.g., changing the retention time of TDCA such that it falls outside the

9.8 Initial Calibration Verification (ICV)

9.8.1 After each ICAL, analyze a QCS sample from a source different from the source of the CAL standards. If a second vendor is not available, then a different lot of the standard should be used. The QCS should be prepared and analyzed just like a CCV. Acceptance criteria for the QCS are identical to the CCVs; the calculated amount for each analyte must be ± 30% of the expected value. If measured analyte concentrations are not of acceptable accuracy, check the entire analytical procedure to locate and correct the problem.

9.9 Instrument Sensitivity Check (ISC)

9.9.1 At the start of each 12-hour shift, analyze a standard at the LOQ. The signal-to-noise ratio of the ISC standard must be greater than or equal to 3:1. If the requirements cannot be met, the problem must be corrected before analyses can proceed.

9.10 Continuing Calibration Verification (CCV)

9.10.1 CCV Standards must be analyzed at the beginning of each analysis batch, after every 10 Field Samples, and at the end of the analysis batch.

9.10.2 The recovery of native and isotopically labeled compounds for the CVs must be within 70 - 130%

9.11 Method-specific Quality Control Samples

9.11.1 Instrument Blank – During the analysis of a batch of samples, a solvent blank is analyzed after samples containing high level of target compounds (e.g., calibration, CV) to monitor carryover from the previous injection. The injection blank consists of the solution in Section 8.1.16 fortified with the EIS and NIS for quantitation purposes.

9.12 Example Method Sequence

- INSTRUMENT BLANK
- INSTRUMENT SENSITIVITY CHECK
- CALIBRATION VERIFICATION STANDARD
- QUALITATIVE IDENTIFICATION STANDARDS
- TDCA STANDARD (only if analyzing tissues)
- INSTRUMENT BLANK
- METHOD BLANK
- LOW-LEVEL LCS/OPR
- OPR/LCS
- SAMPLE (10 or fewer)
- CALIBRATION VERIFICATION STANDARD
- INSTRUMENT BLANK
- SAMPLE (10 or fewer)
- CALIBRATION VERIFICATION STANDARD
- INSTRUMENT BLANK

10. Procedure

10.1 Equipment Set-up

10.1.1 This procedure may be performed manually or in an automated mode using a robotic or automatic sample preparation device. If an automated system is used to prepare samples, follow the manufacturer's operating instructions, but all extraction and elution steps must be the same as in the manual procedure. Extraction and/or elution steps may not be changed or omitted to accommodate the use of an automated system. If an automated system is used, the MBs should be rotated among the ports to ensure that all the valves and tubing meet the MB requirements.

10.1.2 Some of the PFAS's adsorb to surfaces, including polypropylene. Therefore, the aqueous sample bottles must be rinsed with the elution solvent whether extractions are performed manually or by automation. The bottle rinse is passed through the cartridge to elute the method analytes and is then collected.

10.1.3 The SPE cartridges and sample bottles described in this section are designed as single use items and should be discarded after use. They may not be refurbished for reuse in subsequent analyses.

10.1.4 All SPE apparatus, including manifolds, tubing and sample ports must be thoroughly rinsed following each use with 1% methanolic ammonium hydroxide, followed by Methanol and then DI water. Additionally, sample manifold ports and transfer tubing should be inspected regularly for signs of wear and/or

discoloration. When such observations are made, the associated components should be replaced.

10.1.5 Prior to the start of any extraction, sample site information must be evaluated for any potentially high level PFAS concentrations or sample matrix irregularities that may impact the extraction process. If such samples are identified, aqueous samples may be pre-screened via direct aqueous injection prior to analysis to estimate the potential PFAS concentrations present.

10.1.6 To perform a direct aqueous injection (DAI) screen, the sample should be inverted several times to try and evenly disperse any organic matter present. A 1 ml aliquot (or less depending on the matrix) is to be taken from the parent sample, volume adjusted to 1 ml with reagent water if less than 1ml, fortified with EIS and NIS spiking solutions to match the concentrations of an extracted sample (typically 5 µl per 1 ml DAI), and then analyzed under the same analytical conditions as field samples.

10.2 Sample Preparation of Aqueous Samples

10.2.1 Samples are preserved, collected, and stored as presented in Section 6.

10.2.2 Determine sample volume. Weigh all samples to the nearest 1g. If visible sediment is present, centrifuge and decant into a new HDPE bottle and record the weight of the new container.

NOTE: Some of the PFAS's adsorb to surfaces, thus the sample volume may not be transferred to a graduated cylinder for volume measurement.

10.2.3 The MB, LCS and FRB may be prepared by measuring reagent water with a polypropylene graduated cylinder or filling an HDPE sample bottle near the top.

10.2.4 Check that the pH is 6.5 ± 0.5. If necessary, adjust pH with 50% formic acid or ammonium hydroxide and 3% aqueous ammonium hydroxide. The extract is now ready for solid-phase extraction (SPE) and cleanup.

10.2.5 Add 20 µL of the EIS to each sample and QC, cap and invert to mix.

10.2.6 If the sample is an LCS, LCSD, MS, or MSD, add the necessary amount of analyte PDS. Cap and invert each sample to mix.

10.3 Sample Prep and Extraction Protocol for Solids.

10.3.1 Homogenize and weigh 5 grams of sample (measured to the nearest hundredth of a gram) into a 50 ml polypropylene centrifuge tube. For laboratory control blanks and spikes, 5 grams of clean sand is used.

10.3.1.1 For Biosolids and other complex matrices, a small aliquot may be required due to co-extracted matrix interferences.

10.3.1.2 For batch QC samples using 5 g of reference solid, add 2.5 g of reagent water. The addition of reagent water to the sand provides a matrix closer in composition to real-world samples.

10.3.2 Add 20 µL of the EIS to each sample and QC.

10.3.3 If the sample is an LCS, LCSD, MS, or MSD, add the necessary amount of analyte PDS. Cap and invert each sample to mix.

10.3.4 Vortex the samples to evenly disperse the spiking solutions and allow to equilibrate for 30 minutes.

10.3.5 To all samples, add 10 ml of 0.3% methanolic ammonium hydroxide, cap, vortex for 25 seconds.

10.3.6 Following mixing, shake each sample for 30 minutes on a shaker table.

10.3.7 Centrifuge each sample at 2800RPM for 10 minutes.

10.3.8 Remove the supernatant and transfer to a clean 50 ml polypropylene centrifuge tube.

10.3.9 Repeat steps 10.3.4 to 10.3.7, with 15 ml of 0.3% methanolic ammonium hydroxide, combining the supernatants.

10.3.10 Add 5ml of 0.3% methanolic ammonium hydroxide to the sample, vortex for 25 seconds and centrifuge each sample at 2800RPM for 10 minutes.

10.3.11 Remove the supernatant and transfer to the same 50 ml polypropylene centrifuge tube containing eluates from the previous cycles.

10.3.12 Add 10 mg of carbon to the combined extract, mix by occasional hand shaking for no more than five minutes and then centrifuge at 2800 rpm for 10 minutes. Immediately decant the extract into a 50 ml polypropylene centrifuge tube.

10.3.13 Dilute to approximately 35 mL with reagent water. Samples containing more than 50% water may yield extracts that are greater than 35 mL in volume; therefore, do not add water to these. Determine the water content in the sample as follows (percent moisture is determined from the % solids):

Water Content in Sample = (Sample Weight * Percent moisture) / 100

10.3.14 Concentrate each extract at approximately 55 ºC with a gentle N2 flow to a final volume that is based on the water content of the sample (see table below). Allow extracts to concentrate for 10 minutes, then mix (by vortex if the volume is < 20. Continue concentrating and mixing every 5 minutes until the extract has been reduced to the required volume as specified in the table below. If the extract volume appears to stop dropping, the concentration must be stopped and the volume at which it was stopped recorded.

Water Content in Sample	Concentrated Final Volume
< 5 grams	15 ml
5-8 grams	15-20 ml
8-9 grams	20-22.5 ml
9-10 grams	22.5-25 ml

10.3.15 Add 40 - 50 mL of reagent water to the extract and vortex. Check that the pH is 6.5 ±0.5 and adjust as necessary with 50% formic acid or 30% ammonium hydroxide, or with 5% formic acid and 3% aqueous ammonium hydroxide. The extracts are ready for SPE and cleanup.

10.4 Sample Prep and Extraction Protocol for Oils.

10.4.1 Weigh 1-2 grams of sample (measured to the nearest hundredth of a gram) into a 50 ml polypropylene centrifuge tube. For laboratory control blanks and spikes, 1 grams of mineral oil is used.

10.4.1.1 For batch QC samples use 1 g of reference oil.

10.4.2 Add 20 µL of the EIS to each sample and QC.

10.4.3 If the sample is an LCS, LCSD, MS, or MSD, add the necessary amount of analyte PDS. Cap and invert each sample to mix.

10.4.4 Vortex the samples to evenly disperse the spiking solutions and allow to equilibrate for 30 minutes.

10.4.5 To all samples, add 10 ml of 0.3% methanolic ammonium hydroxide, cap, vortex for 25 seconds.

10.4.6 Following mixing, shake each sample for 30 minutes on a shaker table.

10.4.7 Centrifuge each sample at 2800RPM for 10 minutes.

10.4.8 Remove the supernatant and transfer to a clean 50 ml polypropylene centrifuge tube.

10.4.9 Repeat steps 10.3.4 to 10.3.7, with 15 ml of 0.3% methanolic ammonium hydroxide, combining the supernatants.

10.4.10 Add 5ml of 0.3% methanolic ammonium hydroxide to the sample, vortex for 25 seconds and centrifuge each sample at 2800RPM for 10 minutes.

10.4.11 Remove the supernatant and transfer to the same 50 ml polypropylene centrifuge tube containing eluates from the previous cycles.

10.4.12 Add 10 mg of carbon to the combined extract, mix by occasional hand shaking for no more than five minutes and then centrifuge at 2800 rpm for 10 minutes. Immediately decant the extract into a 50 ml polypropylene centrifuge tube.

10.5 Sample Prep and Extraction Protocol for Tissues.

10.5.1 Homogenize and weigh 2 grams of sample (measured to the nearest hundredth of a gram) into a 50 ml polypropylene centrifuge tube. For laboratory control blanks and spikes, 2 grams of clean tissue is used.

10.5.2 Add 20 µL of the EIS PDS to each sample and QC.

10.5.3 If the sample is an LCS, LCSD, MS, or MSD, add the necessary amount of analyte PDS. Cap and invert each sample to mix.

10.5.4 Add 10 mL of 0.05M KOH in methanol to each sample. Vortex to disperse the tissue then place tubes on a mixing table to extract for at 16 hours. Centrifuge at 2800 rpm for 10 minutes and collect the supernatant in a 50-mL polypropylene centrifuge tube.

10.5.5 Add 10 mL of acetonitrile to remaining tissue in the 50-mL centrifuge tube, vortex to mix and disperse the tissue. Sonicate for 30 minutes. Centrifuge at 2800 rpm for 10 minutes and collect the supernatant, adding it to the 50-mL centrifuge tube containing the initial extract.

10.5.6 Add 5 mL of 0.05M KOH in methanol to the remaining sample in each centrifuge tube. Vortex to disperse the tissue and hand mix briefly. Centrifuge at 2800 rpm

for 10 minutes and collect the supernatant, adding it to the 50-mL centrifuge tube containing the first two extracts.

10.5.7 Add 10 mg of carbon to the combined extract, mix by occasional hand shaking over a period of no more than five minutes and then centrifuge at 2800 rpm for 10 minutes. Immediately decant the extract into a 50-mL centrifuge tube.

10.5.8 Add 1 mL of reagent water to each tube and concentrate each extract at approximately 55 ºC with a gentle N2 flow to a final volume of 2.5 ml.

10.5.9 Add reagent water to each evaporation/concentrator tube to dilute the extracts to 50 mL. Check that the pH = 6.5 ± 0.5 and adjust as needed with 50% formic acid, or ammonium hydroxide or with 5% formic acid and 3% aqueous ammonium hydroxide. The extracts are ready for SPE and cleanup.

10.6 SPE Extract: All matrices

10.6.1 Pack clean silanized glass wool to half the height of the WAX SPE cartridge barrel.

10.6.2 Pre-condition the cartridges by washing them with 3 X 5 mL of 1% methanolic ammonium hydroxide, discarding the wash volumes.

10.6.3 Rinse the cartridge with 5 mL of 0.3M formic acid, allowing the cartridge to drain using gravity only, discarding the rinse volume. Do not allow the cartridge to go dry

10.6.4 Adjust the vacuum so that the approximate flow rate is ~5 mL/min and load the sample across the cartridge. Do not allow the cartridge to go dry before all the sample has passed through.

10.6.5 Once all the sample has passed across the cartridge, rinse the walls of the reservoir with 2 X 5 mL reagent water, loading the rinse across the cartridge.

10.6.6 Rinse the walls of the reservoir with 5 mL of 1:1 0.1M formic acid/methanol and pass the rinse through the cartridge using vacuum. Dry the cartridge by pulling air through for 15 seconds.

10.6.7 Rinse the inside of the sample bottle with 5 mL of 1% methanolic ammonium hydroxide. Use vacuum to pull the elution solvent through the cartridge and into the collection tubes. When the cartridge bed and glass wool are submerged, stop the cartridge flow by closing the valve, keeping the sorbent bed and wool submerged.

10.6.8 Let the wetted sorbent bed and wool soak for 1 minute.

10.6.9 Open the cartridge valve and collect the eluate into a 15 ml polypropylene collection tube.

10.6.10 Add 25 µL of concentrated acetic acid to each sample eluted in the collection tubes and vortex to mix.

10.6.11 Add 10 mg of carbon to each sample and batch QC extract, using a 10-mg scoop. Handshake occasionally for no more than 5 minutes. It is important to minimize the time the sample extract is in contact with the carbon. Immediately vortex (30 seconds) and centrifuge at 2800 rpm for 10 minutes.

10.6.12 Add NIS solution to a clean collection tube. Place a syringe filter (25-mm filter, 0.2-µm nylon membrane) on a 5-mL polypropylene syringe. Take the plunger out and carefully decant the sample supernatant into the syringe barrel. Replace the

plunger and filter the entire extract into the new collection tube containing the NIS.

10.6.13 Vortex to mix and transfer a portion of the extract into a .7-mL polypropylene LC vial for LC-MS/MS analysis. Cap the collection tube containing the remaining extract and store at 4 °C

10.7 Sample Volume Determination

10.7.1 If using weight to determine volume, weigh the empty bottle to the nearest 1 g and determine the sample weight by subtraction of the empty bottle weight from the original sample weight. Assume a sample density of 1.0 g/mL. In either case, the sample volume will be used in the final calculations of the analyte concentration.

10.8 Initial Calibration - Demonstration and documentation of acceptable initial calibration is required before any samples are analyzed. After the initial calibration is successful, a CCV is required at the beginning and end of each period in which analyses are performed, and after every tenth Field Sample.

10.8.1 ESI-MS/MS TUNE

10.8.1.1 Calibrate the mass scale of the MS with the calibration compounds and procedures prescribed by the manufacturer.

10.8.1.2 Optimize the [M-H]- or [M-CO_2]- for each method analyte by infusing approximately 0.5-1.0 µg/mL of each analyte (prepared in the initial mobile phase conditions) directly into the MS at the chosen LC mobile phase flow rate (0.4 mL/min). This tune can be done on a mix of the method analytes. The MS parameters (voltages, temperatures, gas flows, etc.) are varied until optimal analyte responses are determined. The method analytes may have different optima requiring some compromise between the optima.

The Mass spec conditions found in Table 7 show the Sciex Triple Quad 5500+ operation conditions used in this method.

10.8.1.3 Optimize the product ion for each analyte by infusing approximately 0.5-1.0 µg/mL of each analyte (prepared in the initial mobile phase conditions) directly into the MS at the chosen LC mobile phase flow rate (approximately 0.4 mL/min). This tune can be done on a mix of the method analytes. The MS/MS parameters (collision gas pressure, collision energy, etc.) are varied until optimal analyte responses are determined. Typically, the carboxylic acids have very similar MS/MS conditions, and the sulfonic acids have similar MS/MS conditions.

The conditions found on table 5 are representative of expected tune optimizations for each analyte. If conditions other the ones close to the values provided in table 5 are achieved, the process should be re-performed and/or instrument maintenance performed to resolve the problem.

10.8.2 Establish LC operating parameters that optimize resolution and peak shape. Modifying the standard or extract composition to more aqueous content to prevent poor shape is not permitted.

Table 6 represents the operation conditions of a Sciex Exion LC system when running this method.

10.8.3 Inject 2µl of a mid-level CAL standard under LC/MS conditions to obtain the retention times of each method analyte. Divide the chromatogram into retention time windows each of which contains one or more chromatographic peaks. During MS/MS analysis, fragment a small number of selected precursor ions ([M-H]-) for the analytes in each window and choose the most abundant product ion. For maximum sensitivity, small mass windows of ±0.5 daltons around the product ion mass were used for quantitation.

10.8.4 Inject a mid-level CAL standard under optimized LC/MS/MS conditions to ensure that each method analyte is observed in its MS/MS window and that there are at least 10 scans across the peak for optimum precision.

NOTE: PFHxS, PFOS, NMeFOSAA, and NEtFOSAA have multiple chromatographic peaks using the LC conditions in Table 7 due to chromatographic resolution of the linear and branched isomers of these compounds. Most PFAS's are produced by two different processes. One process gives rise to linear PFAS's only while the other process produces both linear and branched isomers. Thus, both branched and linear PFAS's can potentially be found in the environment. For the aforementioned compounds that give rise to more than one peak, all the chromatographic peaks observed in the standard must be integrated and the areas totaled. Chromatographic peaks in a sample must be integrated in the same way as the CAL standard.

10.8.5 Prepare a set of CAL standards as outlined in table 5. The lowest concentration CAL standard must be at or below the LOQ.

10.8.6 The LC/MS/MS system is calibrated using the isotope dilution technique. Target analytes are quantitated against their isotopically labeled analog (Extracted Internal Standard) where commercially available. If a labeled analog is not commercially available, the extracted internal standard with the closest retention time and /or closest chemical similarity is to be used. Use the LC/MS/MS data system software to generate a linear regression or quadratic calibration curve for each of the analytes. This curve must always be forced through zero and may be concentration weighted, if necessary. Forcing zero allows for a better estimate of the background levels of method analytes. A minimum of 6 calibration points are required for a linear or quadratic calibration model.

10.8.7 **CALIBRATION ACCEPTANCE CRITERIA** – A linear fit is acceptable if the calculated RSD or RSE for each target analyte is ≤20%. If linear or Quadratic regressions are used, coefficient of determination (r^2) values must be greater than 0.99. When quantitated using the initial calibration curve, each calibration point at or above the LOQ for each analyte must calculate to be within 70-130% of its true value. The calculate value of each EIS analyte must be within 50-150% of its true value. If these criteria cannot be met, corrective action is taken to reanalyze the CAL standards, restrict the range of calibration.

10.8.8 **Bile salts interference check -** The laboratory must analyze a TDCA standard after the initial calibration, prior to the analysis of tissue samples, to check for interferences caused by bile salts. If an interference is present, the chromatographic conditions must be modified to eliminate the interference from TDCA (e.g., changing the retention time of TDCA such that it falls outside the

retention window for PFOS by at least one minute), and the initial calibration repeated.

10.9 CONTINUING CALIBRATION CHECK (CCV) – Minimum daily calibration verification is as follows. Verify the initial calibration at the beginning and end of each group of analyses, and after every tenth sample during analyses. In this context, a "sample" is considered to be a Field Sample. MBs, CCVs, LCSs, MSs, FDs FRBs and MSDs are not counted as samples. The beginning CCV of each analysis batch must be at or below the RL in order to verify instrument sensitivity prior to any analyses. If standards have been prepared such that all low CAL points are not in the same CAL solution, it may be necessary to analyze two CAL standards to meet this requirement. Alternatively, the analyte concentrations in the analyte PDS may be customized to meet these criteria. Subsequent CCVs should alternate between a medium and Low concentration CAL standard.

10.9.1 Inject an aliquot of the appropriate concentration CAL standard and analyze with the same conditions used during the initial calibration.

10.9.2 Calculate the concentration of each analyte and EIS in the CCV. The calculated amount for each native and EIS analyte for medium level CCVs must be within ± 30% of the true. If these conditions do not exist, then all data for the problem analyte must be considered invalid, and remedial action should be taken which may require recalibration. Any Field or QC Samples that have been analyzed since the last acceptable calibration verification should be reanalyzed after adequate calibration has been restored, with the following exception. If the CCV fails because the calculated concentration is greater than 130% for a particular method analyte, and Field Sample extracts show no detection for that method analyte, non-detects may be reported without re-analysis.

10.9.3 REMEDIAL ACTION – Failure to meet CCV QC performance criteria may require remedial action. Major maintenance, such as cleaning the electrospray probe, atmospheric pressure ionization source, cleaning the mass analyzer, replacing the LC column, etc., requires recalibration and verification of sensitivity by analyzing a CCV at or below the LOQ.

10.10 EXTRACT ANALYSIS

10.10.1 The same operating conditions used for the initial calibration and summarized in Tables 6 and 7 are to be used.

10.10.2 Prior to analysis of sample extracts, the Instrument mass calibration verification must be performed using standards whose mass range brackets the masses of interest and performed in the negative ion mode. The mass calibration is verified if the calculated mass is within ± .2 daltons of the specified mass.

10.10.3 Establish an appropriate retention time window for each analyte. This should be based on measurements of actual retention time variation for each method analyte in CAL standard solutions analyzed on the LC over the course of time. A value of plus or minus three times the standard deviation of the retention time obtained for each method analyte while establishing the initial calibration can be used to calculate a suggested window size. However, the experience of the analyst should weigh heavily on the determination of the appropriate retention window size.

10.10.4 Calibrate the system by either the analysis of a calibration curve or by confirming the initial calibration is still valid by analyzing a CCV.

10.10.5 Begin analyzing Field Samples, including QC samples, at their appropriate frequency by injecting the same size aliquots under the same conditions used to analyze the CAL standards.

10.10.6 For concentrations at or above the method LOQ, the total (branched and linear isomer) quantification ion response to the total (branched and linear isomer) confirmation ion response ratio must fall within ± 50% of the ratio observed in the midpoint initial calibration standard.

10.10.7 At the conclusion of data acquisition, use the same software that was used in the calibration procedure to identify peaks of interest in predetermined retention time windows. Use the data system software to examine the ion abundances of the peaks in the chromatogram. Identify an analyte by comparison of its retention time with that of the corresponding method analyte peak in a reference standard.

10.10.7.1 Method analyte, EIS analyte, and NIS analyte RTs must fall within 0.4 minutes of the predicted retention times from the midpoint standard of the ICAL or initial daily CV, whichever was used to establish the RT window position for the analytical batch. All branched isomer peaks identified in either the calibration standard or the qualitative (technical grade) standard must fall within in the retention time window for that analyte.

10.10.7.2 For all method analytes with exact corresponding isotopically labeled analogs, method analytes must elute within 0.1 minutes of the associated EIS.

10.10.8 The analyst must not extrapolate beyond the established calibration range. If an analyte peak area exceeds the range of the initial calibration curve, the sample should be re-extracted with a reduced sample volume in order to bring the out of range target analytes into the calibration range. If a smaller sample size would not be representative of the entire sample, the following options are recommended. Re-extract an additional aliquot of sufficient size to ensure that it is representative of the entire sample. Spike it with a higher concentration of internal standard. Prior to LC/MS analysis, dilute the sample so that it has a concentration of internal standard equivalent to that present in the calibration standard. Then, analyze the diluted extract.3

10.10.9 In instances where re-extraction is not an option, dilute a subsample of the sample extract with 0.1% acetic acid by a factor no greater than 10x adjust the amount of the NIS in the diluted extract, and analyze the diluted extract. If the responses for each EIS in the diluted extract meet the S/N and retention time, and the EIS recoveries from the analysis of the diluted extract are greater than 5%, then the compounds associated with those EISs may be quantified using isotope dilution. Use the EIS recoveries from the original analysis to select the dilution factor, with the objective of keeping the EIS recoveries in the dilution above that 5% lower limit. If the adjusted EIS recoveries are below 5%, the dilution is assumed invalid. If the adjusted EIS recoveries are greater than 5%, adjust the compound concentrations, detection limits, and minimum levels to account for the dilution.

11. Data Evaluation, Calculations and Reporting

11.1 Complete chromatographic resolution is not necessary for accurate and precise measurements of analyte concentrations using MS/MS. In validating this method, concentrations were calculated by measuring the product ions listed in Table 9.

11.2 Calculate analyte concentrations using the multipoint calibration established in Section 10.9. Do not use daily calibration verification data to quantitate analytes in samples. Adjust final analyte concentrations to reflect the actual sample volume determined in Section 10.8

C_{ex} = (Area of target analyte * Concentration of Labeled analog) / (area of labeled analog * CF)

C_s = (C_{ex} / sample volume in ml) * 1000

C_{ex} = The concentration of the analyte in the extract
CF = calibration factor from calibration.

11.3 Prior to reporting the data, the chromatogram should be reviewed for any incorrect peak identification or poor integration.

11.4 PFHxS, PFOS, PFOA, NMeFOSAA, and NEtFOSAA have multiple chromatographic peaks using the LC conditions in Table 7 due to the linear and branch isomers of these compounds (Sect. 10.10.4.). The areas of all the linear and branched isomer peaks observed in the CAL standards for each of these analytes must be summed and the concentrations reported as a total for each of these analytes.

11.5 Calculations must utilize all available digits of precision, but final reported concentrations should be rounded to an appropriate number of significant figures (one digit of uncertainty), typically two, and not more than three significant figures.

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

12.1 Section 9.0 outlines sample batch QC acceptance criteria. If non-compliant organic compound results are to be reported, the Organic Section Head and/or the Laboratory Director, and the Operations Manager must approve the reporting of these results. The laboratory Project Manager shall be notified and may choose to relay the non-compliance to the client, for approval, or other corrective action, such as re-sampling and re-analysis. The analyst, Data Reviewer, or Department Supervisor performing the secondary review initiates the project narrative, and the narrative must clearly document the non-compliance and provide a reason for acceptance of these results.

12.2 All results for the organic compounds of interest are reportable without qualification if extraction and analytical holding times are met, preservation requirements (including cooler temperatures) are met, all QC criteria are met, and matrix interference is not suspected during extraction or analysis of the samples. If any of the below QC parameters are not met, all associated samples must be evaluated for re-extraction and/or re-analysis.

13. Method Performance

13.1 Detection Limit Study (DL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

13.1.1 The laboratory follows the procedure to determine the DL, LOD, and/or LOQ as outlined in Alpha SOP ID 1732. These studies performed by the laboratory are maintained on file for review.

13.2 Demonstration of Capability Studies

13.2.1 Refer to Alpha SOP ID 1739 for further information regarding IDC/DOC Generation.

13.2.2 The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

14. Pollution Prevention and Waste Management

14.1 Refer to Alpha's Chemical Hygiene Plan and Hazardous Waste Management and Disposal SOP for further pollution prevention and waste management information.

14.2 This method utilizes SPE to extract analytes from water. It requires the use of very small volumes of organic solvent and very small quantities of pure analytes, thereby minimizing the potential hazards to both the analyst and the environment as compared to the use of large volumes of organic solvents in conventional liquid-liquid extractions.

14.3 The analytical procedures described in this method generate relatively small amounts of waste since only small amounts of reagents and solvents are used. The matrices of concern are finished drinking water or source water. However, laboratory waste management practices must be conducted consistent with all applicable rules and regulations, and that laboratories protect the air, water, and land by minimizing and controlling all releases from fume hoods and bench operations. Also, compliance is required with any sewage discharge permits and regulations, particularly the hazardous waste identification rules and land disposal restrictions.

17. TOP Assay SOP Addendum

The following modifications are applied to this SOP;

Section 7: Water Bath – Capable of monitoring recording to .1 C maintaining 85 C.

Section 8.1

1. Sodium Hydroxide (NaOH, CAS#: 1310-73-2) – High purity, demonstrated to be free of analytes and interferences.

2. Potassium Persulfate ($K_2S_2O_8$, CAS#: 7727-21-1) - High purity, demonstrated to be free of analytes and interferences.

3. Hydrochloric Acid (HCl, CAS#: 7647-01-0) - High purity, demonstrated to be free of analytes and interferences.

Table 1

Isotope Labeled Standard	Conc. Top Surr Stock (ng/mL)	Vol. of Top Surr Stock (µl)	Final Vol. of Top Surr PDS (mL)	Final Conc. of Top Surr PDS (ng/mL)
$^{13}C_2$-PFOA	50,000	40	4.0	500
$^{13}C_2D_4$-4:2FTS	50,000	80	4.0	1000

Section 10

1. Pretreatment of Samples - For Aqueous samples, prior to Section 10.1, add to each 125 ml sample with Potassium Persulfate until 60 mM (about 2 grams). Add Sodium Hydroxide until the sample is 125 mM (about .625 grams). Sample should have a pH >12.

2. Fortify each sample with 20 µl of TOP pre-assay surrogate containing 1 negative control surrogates and 1 positive control surrogates from table 1.

3. Place sample in a water bath at 85 C for 6 hours.

4. Remove sample from water bath and adjust pH 6-8 with Hydrochloric Acid.

5. Following pre-treatment, follow the aqueous extraction protocol from section 10 of SOP 45852 unaltered.

Section 11 - An additional calculation is added for the final reporting of the TOP assay results.

TOP Assay = Result of Post TOP assay extraction – Result of analysis from Pre-Top Assay extraction.

Nitrate, Nitrite and Nitrate_Nitrite Nitrogen

Methods 4500NO_3-F, 4500NO_2-B: Standard Methods for the Examination of Water and Wastewater. APHA-AWWA-WEF. Standard Methods Online.

Method 10-107-04-1, Lachat Instruments, 6645 West Mill Road, Milwaukee, WI 53218, 1992

1. Scope and Application

Matrices: This method is limited to optically clear water samples with a total concentration of nitrite and nitrate below 8mg N/L.

Definitions: Refer to Alpha Analytical Quality Manual.

In waters and wastewaters, the forms of nitrogen of greatest interest are, in order of decreasing oxidation state, nitrate, nitrite, ammonia, and organic nitrogen. All these forms of nitrogen, as well as nitrogen gas (N_2), are biochemically interconvertible and are components of the nitrogen cycle. They are of interest for many reasons.

Organic nitrogen is defined functionally as organically bound nitrogen in the trinegative oxidation state. It does not include all organic nitrogen compounds. Analytically, organic nitrogen and ammonia can be determined together and have been referred to as “kjeldahl nitrogen,” a term that reflects the technique used in their determination. Organic nitrogen includes such natural materials as proteins and peptides, nucleic acids and urea. Numerous concentrations vary from a few hundred micrograms per liter in some lakes to more than 20mg/L in raw sewage.

Total oxidized nitrogen is the sum of nitrate and nitrite nitrogen. Nitrate generally occurs in trace quantities in surface water but many attain high levels in some groundwater. In excessive amounts, it contributes to the illness known as methemoglobinemia in infants. A limit of 10mg nitrate as nitrogen/L has been imposed on drinking water to prevent this disorder. Nitrate is found only in small amounts in fresh domestic wastewater but in the effluent of nitrifying biological treatment plants, nitrate may be found in concentrations of up to 30mg nitrate as nitrogen/L. It is an essential nutrient for many photosynthetic autotrophs and has been identified as a growth-limiting nutrient.

Nitrite is an intermediate oxidation state of nitrogen, both in the oxidation of ammonia to nitrate and in the reduction of nitrate. Such oxidation and reduction may occur in wastewater treatment plants, water distribution systems, and natural waters. Nitrite can enter a water supply system through its use as a corrosion inhibitor in industrial process water. Nitrite is the actual etiologic agent of methemoglobinemia. Nitrous acid, which is formed from nitrite in acidic solution, can react with secondary amines (RR’NH) to form nitrosamines (RR’N-NO), many of which are known to be carcinogens. The toxicologic significance of nitrosation reactions in vivo and in the natural environment is the subject of much current concern and research.

Within this SOP, organic nitrogen is referred to as organic N, nitrate nitrogen as NO_3^--N, and nitrite nitrogen as NO_2^--N.

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one or more of the following laboratory personnel before performing the modification: Area Supervisor, Department Supervisor, Laboratory Director, or Quality Assurance Officer.

This method is restricted to use by or under the supervision of analysts experienced in the operation of the Lachat Analyzer and in the interpretation of Lachat data. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

2. Summary of Method

Nitrate is quantitatively reduced to nitrite by passage of the sample through a copperized cadmium column. The nitrite (reduced nitrate plus original nitrite) is then determined by diazotizing with sulfanilamide followed by coupling with N-(1-naphthyl)ethylenediamine dihydrochloride. The resulting water-soluble dye has a magenta color, which is read at 520nm. Nitrite alone can be determined by removing the cadmium column. The nitrate is calculated as the difference between the reduced and non-reduced sample

2.1 Method Modifications from Reference

Soils can be analyzed using 1:10 ratio soil to water extraction, following filtration.

3. Reporting Limits

This method has an analytical range of 0.1 to 8.0mg N/L in the form of nitrate, and 0.05 to 8.0mg N/L in the form of nitrite.

The Reporting Limit is 0.1mg/L for Nitrate and 0.05 mg/L for Nitrite. Reporting limit is 1.0 mg/kg for soils

4. Interferences

4.1 Suspended matter in the column will restrict sample flow.

4.2 For turbid samples, filter through 0.45µm membrane filter prior to analysis.

4.3 Low results would be obtained for samples that contain high concentrations of iron, copper or other metals. In this method, EDTA is added to the buffer to reduce this interference.

4.4 Samples that contain large concentrations of oil and grease will coat the surface of the cadmium. In this case, only the water phase of the sample is used for analysis and a narrative is submitted with the data. Dilutions are performed as necessary.

4.5 Residual chlorine can interfere by oxidizing the Cd column, reducing its efficiency. Prior to analysis, check wastewater and drinking water samples for residual chlorine and record results in the Laboratory Notebook. If residual chlorine is present, and the samples are preserved with H_2SO_4, the sample may be analyzed for NO_3/NO_2 determination. However, NO_2 must be performed by a manual method. If it is not possible to analyze NO_2 by a manual method, the result is reported as NA and a narrative is submitted.

4.6 Sample color interferes if it is absorbed at about 540nm.

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material safety data sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

Samples are collected in glass or plastic bottles; 250mL minimum volume. Soils can be collected in plastic or glass containers.

6.2 Sample Preservation

Refrigerate samples at 4 ± 2 °C.

For Nitrate/Nitrite analysis, the samples are preserved with 1:1 H_2SO_4.

6.3 Sample Shipping

No specific requirement.

6.4 Sample Handling

Begin NO_3^- and/or NO_2^- determinations promptly after sampling. If storage is necessary, store for up to 48 hours at 4 ± 2 °C.

NOTE: If the 48-hour hold time cannot be met, the sample is to be handled as follows, only in an emergency situation. These instructions are not to be used on a regular basis.

Prior to the expiration of the 48-hour hold time, the following three steps are executed:

1. A manually colored Nitrite test is performed by Method 354.2. Results are recorded in the Laboratory Notebook.
2. A 50mL aliquot of the sample is preserved to a pH of <2 with concentrated H_2SO_4. Preservation is recorded in the Laboratory Notebook.

Prior to analysis, within 14 days of preservation, the preserved sample is neutralized using 6N NaOH. The sample is analyzed using only the Lachat Instrument.

CAUTION! Samples must NOT be preserved with mercuric chloride or thiosulfate because this will degrade the cadmium column

7. Equipment and Supplies

7.1 Lachat 8000 Automated Ion Analyzer or Lachat QuickChem 8500 Automated Ion Analyzer

7.2 Nitrate+Nitrite Lachat Board

7.3 Nitrite Lachat Board

7.4 Pre-packed Cadmium Columns: Available from Lachat.

7.5 Ottawa sand.

7.6 Disposable Culture Tubes 13x100 ml

7.7 Disposable pipettes.

8. Reagents and Standards

8.1 Stock Nitrate Standard, 1000mg N/L as NO_3^-: Purchased commercially prepared with certificate of analysis. Expires upon manufacturer's expiration date. There must be different manufacturers for calibration stock and ICV/LCS stock.

8.1.1 Stock Nitrate Standard, 200.0mg N/L as NO_3^-: Pipet 50mL of 1000ppm standard (Section 8.1) into 250mL volumetric flask and bring to volume with DI.

Alternately, in a 1L volumetric flask, dissolve 1.444g potassium nitrate (KNO_3) in about 600mL DI. Add 2mL chloroform. Dilute to the mark with DI and invert to mix. Refrigerate at 4±2°C. This solution is stable for six months.

8.2 Stock Nitrite Standard, 1000mg N/L as NO_2^-: Purchased commercially prepared with certificate of analysis. Expires upon manufacturer's expiration date. There must be different manufacturers for calibration stock and ICV/LCS stock.

8.2.1 Stock Nitrite Standard, 200.0mg N/L as NO_2^-: Pipet 50mL of 1000ppm standard (Section 8.2) into 250mL volumetric flask and bring to volume with DI.

Alternately, in a 1L volumetric flask, dissolve 0.986g sodium nitrite ($NaNO_2$) or 1.214g potassium nitrite (KNO_2) in approximately 800mL DI. Add 2mL chloroform. Dilute to the mark with DI and invert to mix. Refrigerate at 4±2°C. This solution is stable for six months.

8.3 Intermediate Nitrate Working Standard, 20 mg N/L as Nitrate: To a 250mL volumetric flask, add 25.0mL of the 200mg N/L NO_3^- stock standard. Dilute to the mark with DI and invert to mix. These solutions are stable for two weeks. Refrigerate at 4±2°C.

8.4 Intermediate Nitrite Working Standard, 20 mg N/L as Nitrite: To a 250mL volumetric flask, add 25.0mL of the 200mg N/L NO_2^- stock standard. Dilute to the mark with DI and invert to mix. These solutions are stable for two weeks. Refrigerate at 4±2°C.

8.5 Set of Six Calibration NO_3^- Standards, 8.0, 4.0, 1.00, 0.40, 0.20 and 0.1mg N/L as Nitrate: These standards are stable for 2 weeks. Refrigerate at 4±2°C.

To four 200mL volumetric flasks, add respectively: 8.0, 4.0, 1.0 and 0.4mL of the 200mg N/L NO_3^- stock standard. Bring to volume with DI water.

To two 200mL volumetric flasks, add respectively: 2.0 and 1.0mL of the 20mg N/L NO_3^- intermediate standard. Bring to volume with DI water.

Alternatively, an autodiluter can be used to make the standards during calibration, in which case only 8.0ppm and 1.0 ppm need to be manually prepared. If an autodiluter is used then it must be checked in an analytical tray by autodiluting 8.0mg N/L as Nitrite. The recovery for NO2 must be within 10% of the true value.

8.6 Set of Six Calibration NO_2^- Standards, 8.0, 4.0, 1.00, 0.40, 0.10 and 0.05mg N/L as Nitrite: These standards are stable for 2 weeks. Refrigerate at 4±2°C.

To three 200mL volumetric flasks, add respectively: 8.0, 4.0 and 1.0 of the 200mg N/L NO_2^- stock standard. Bring to volume with DI water.

To three 200mL volumetric flasks, add respectively:4.0, 1.0mL and 0.5mL of the 20mg N/L NO_2^- intermediate standard. Bring to volume with DI water.

Alternatively, an autodiluter can be used to make the standards during calibration, in which case only 8.0ppm and 1.0 ppm need to be manually prepared.

8.7 Ammonium Chloride Buffer, pH 8.5: In a 2L volumetric flask, dissolve 170g ammonium chloride (NH_4Cl) and 2.0g disodium ethylenediamine tetraacetic acid dihydrate ($Na_2EDTA•2H_2O$) in about 800mL water. Dilute to the mark with DI water and invert to mix. Adjust the pH to 8.5 with concentrated ammonium hydroxide or concentrated HCl. This solution is prepared monthly and stored at room temperature.

8.8 Sulfanilamide Color Reagent: To a 2L volumetric flask add about 1200mL water. Then add 200mL of 85% phosphoric acid (H_3PO_4), 80.0g sulfanilamide, and 2.0g N^-(1-naphthyl)ethylenediamine dihydrochloride (NED). Shake to wet, and stir to dissolve for 30 minutes. Dilute to the mark with DI water and invert to mix. Store in a dark bottle. This solution is stable for one month. Store at room temperature.

8.9 200ppm Nitrate Stock Standard, (for ICV/LCS): Pipet 50mL of 1000ppm standard (Section 8.1) into 250mL volumetric flask and bring to volume with DI. Store refrigerated at 4±2°C. Expires six months from preparation or upon manufacturer's expiration date.

8.10 200ppm Nitrite Stock Standard: Pipet 50mL of 1000ppm standard (Section 8.2) into 250mL volumetric flask and bring to volume with DI. Store refrigerated at 4±2°C. Expires six months from preparation or upon manufacturer's expiration date.

8.11 Initial Calibration Verification Standard (ICV)/Laboratory Control Sample (LCS): Store refrigerated at 4±2°C. Expiration is 2 weeks from date of preparation.

8.11.1 Nitrate LCS, 5.0ppm: Pipet 5.0mL of 200ppm stock (Section 8.9) into a 200mL volumetric flask and bring to volume with DI.

8.11.2 Nitrate ICV, 0.5ppm: Pipet 10.0mL of 5.0ppm standard (Section 8.11.1) into a 100mL volumetric flask and bring to volume with DI.

8.11.3 Nitrite LCS, 5.0ppm: Pipet 5.0mL of 200ppm stock (Section 8.9) into a 200mL volumetric flask and bring to volume with DI.

8.11.4 Nitrite ICV, 0.5ppm: Pipet 10.0mL of 5.0ppm standard (Section 8.11.3) into a 100mL volumetric flask and bring to volume with DI.

8.12 DPD Free Chlorine Reagent Powder Pillows: HACH brand, for 25mL sample. Store at room temperature. Expires upon manufacturer's expiration date.

8.13 1N Hydrochloric acid (HCL): To a 1L volumetric flask add about 600mL DI. Then add 83mL of concentrated hydrochloric acid (HCL) Stir to dissolve. Dilute to the mark with DI water and invert to mix. This solution is stable for six month. Store at room temperature.

8.14 1N Sodium Hydroxide (NaOH): To a 1L volumetric flask add about 600mL DI. Then add 40 g of sodium Hydroxide. Stir to dissolve. Dilute to the mark with DI water and invert to mix. This solution is stable for six month. Store at room temperature

8.15 6N Sulfuric Acid (H2SO4): To a 1L volumetric flask add about 600mL DI. Then add 140 ml of concentrated Sulfuric Acid (H2SO4). Stir to dissolve. Dilute to the mark with DI water and invert to mix. This solution is stable for six month. Store at room temperature

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

9.1 Blank

One Method Blank is analyzed per batch of 20 samples or less The Method Blank consists of DI.

For soils: 5g of Ottawa sand extracted with 50 ml of DI. Results must be < 0.1mg/L. If this criterion is not met, the blank is re-analyzed. If there is still failure, the problem must be found and corrected prior to any sample analysis

9.2 Laboratory Control Sample (LCS)

The 5ppm ICV is reported as the LCS for the batch. See Section 9.3.

For soil LCS: 5g of Ottawa sand extracted with 0.25 ml of 1000 mg/l nitrate (8.1) (or 1000 mg/l Nitrite standard (8.2)) and 50 ml DI. The nitrate standard is used for spikes for Nitrate-N as well as Nitrate/Nitrite-N. LCS recoveries must be recovered within ± 10% of the true value. If these criteria are not met, LCS's must be re-analyzed. If failure continues, the batch has to be re-extracted and re-analyzed.

9.3 Initial Calibration Verification (ICV)

Two ICVs are analyzed at the beginning of the analytical sequence. One is at a concentration of 0.5ppm, and the other is at a concentration of 5.0ppm.

Both must be recovered within ± 10% of the true value. If these criteria are not met, the ICVs must be re-analyzed. If failure continues, the ICVs are to be re-made and/or a new calibration curve is to be generated.

The 5ppm ICV is reported as the LCS for the batch.

9.4 Continuing Calibration Verification (CCV)

At the beginning of the first tray, after every ten samples and at the end of every analytical sequence, a CCV and a CCB pair must be analyzed to verify both calibration curves.

1.0ppm Nitrate CCV (Section 8.5)

1.0ppm Nitrite ICV (Section 8.6)

Calibration Blank (DI)

The results of the CCVs must be within ±10% of the true value, otherwise re-calibration is required.

The results of the CCBs must be less than our standard limit of detection, otherwise the analysis is stopped and the problem corrected.

9.5 Matrix Spike

One Matrix Spike is analyzed per batch of 20 samples or less. Separate spikes are performed for Nitrate and Nitrite. In a 25mL volumetric flask, 0.5mL of 200ppm stock calibration standard (Section 8.1 or 8.2) is added to the sample. The final concentration of the matrix spike is

4.0ppm. The nitrate standard is used for spikes for Nitrate-N as well as Nitrate/Nitrite-N. The nitrite standard is used for spikes for Nitrite-N.

For soils: weigh 5.0 g of sample, add 2.0 ml of 200 mg/l Nitrate or Nitrite standard and 48 ml of DI. The final concentration of the matrix spike is 80.0 mg/kg. The nitrate standard is used for spikes for Nitrate-N as well as Nitrate/Nitrite-N. The nitrite standard is used for spikes for Nitrite-N.

% Recovery for the Matrix Spike must be within in-house control limits. If acceptance criteria are not met, the Matrix Spike is reanalyzed. If failure continues, a narrative is included with the data for inclusion on the Client report.

Note: For samples, analyzed by method **353.2** (NO2-353 and NO3-353) maximum batch size is 10 samples; every 10 samples required separate matrix spike (MS) to be analyzed. % Recovery for the Matrix Spike must be within +/- 10% of true value. If acceptance criteria are not met, the Matrix Spike is reanalyzed. If failure continues, a narrative is included with the data for inclusion on the Client report.

9.6 Laboratory Duplicate

One Duplicate sample is analyzed per batch of 20 samples or less. A separate aliquot of the sample is analyzed for this purpose.

% RPD for the Duplicate must be within in-house control limits. If acceptance criteria are not met, the Duplicate is reanalyzed. If failure continues, a narrative is included with the data for inclusion on the Client report

9.7 Method-specific Quality Control Samples

None.

9.8 Method Sequence

- Calibration
- ICV/LCS – both levels
- Sample analysis
- CCV – every ten samples and at the end of the analytical sequence

10. Procedure

10.1 Equipment Set-up

10.1.1 Preparation

10.1.1.1 Place the Nitrate+Nitrite board (containing the cadmium column) in Channel 1. Place the Nitrite board in Channel 2. Make sure the valve to the cadmium column is closed prior to starting to pump the reagents.

10.1.1.2 Commence pumping of reagents.

10.1.1.3 Once the lines are full of reagent and free of gas bubbles, open the valve to allow reagent to flow through the cadmium column.

NOTE: Be sure to switch the valve back before rinsing the manifold with DI water at the completion of the run.

NOTE: DO NOT LET AIR ENTER THE CADMIUM COLUMN.

10.1.2 Column Efficiency Procedure

10.1.2.1 Visually inspect the column. Check for air bubbles in the column or lines, gaps in the column or any change in the cadmium surface characteristics, (cadmium granules should be dark gray). If air bubbles are present in column, connect the column into the manifold, turn the pump on maximum and tap firmly with a screwdriver handle, being careful not to break the column, working up the column until all air is removed. If air cannot be removed, the column should be repacked. Cadmium columns should be stored filled with buffer. If air enters the column, efficiency will decrease. Check the flow efficiency by disconnecting the cadmium column from the manifold and reconnecting to a green pump tube. Pump buffer through the packed column and collect in a graduated cylinder. The flow rate with the column connected should be greater than 4.0 mL/minute.

10.1.2.2 **Column Efficiency – Slope Ratio Method:** Calibrate with the mid-range NO_3 – N standards. Calibrate with a matching concentration range of NO_2–N standards. The column efficiency is determined by the equation:

$$E = \frac{S_{NO3\text{-}N}}{S_{NO2\text{-}N}} \times 100$$

where:

$S_{NO3\text{-}N}$ = slope of NO_3 calibration
$S_{NO2\text{-}N}$ = slope of NO_2 calibration
E = % efficiency

10.1.2.3 **Column Efficiency – Concentration Ratio Method:** Calibrate with the mid-range NO_2-N and NO_3-N standards. Run a known concentration NO_2-N standard. Run a matching concentration NO_3-N standard. The column efficiency is determined by the following equation:

$$E = \frac{C_{NO3\text{-}N}}{C_{NO2\text{-}N}} \times 100$$

where:

$C_{NO3\text{-}N}$ = concentration of NO_3 standard
$C_{NO2\text{-}N}$ = concentration of NO_2 standard
E = % efficiency

10.1.2.4 **Column Efficiency Result:** If the efficiency is <75%, the column is repacked. All results are recorded and maintained on file in the QC department.

10.1.3 Residual Chlorine Screening

Check all wastewater and drinking water samples for residual chlorine prior to analysis.

10.1.3.1 Add 1 DPD Free Chlorine powder pillow (Section 8.12) to 25mL of sample in a centrifuge tube. An immediate color change to pink indicates residual chlorine is present. If residual chlorine is present, add a small amount of ascorbic acid to a sample aliquot (record this in logbook) and check for residual chlorine presence again. If residual chlorine remains, notify the Department Manager and/or the Laboratory Director. Results will be reported as Not Applicable (N/A).

If residual chlorine is not present, continue with sample analysis.

10.2 Initial Calibration

Calibrate the Lachat ion analyzer according to manufacturer's instructions.

10.2.1 Calibration

Two boards are used to calibrate the Lachat instrument. Each curve has seven calibration points. The correlation coefficient of each curve must be $\geq$0.995, otherwise recalibration is necessary. Prepare standard curves by plotting the peak areas of standards processed through the manifold against NO_3+NO_2 as N and NO_2 as N concentrations in standards.

10.2.1.1 Channel 1 is used to generate a calibration curve for Nitrate/Nitrite ranging from 0 to 8.0ppm.

10.2.1.2 Channel 2 is used to generate a calibration curve for Nitrite ranging from 0 to 8.0ppm.

Note: Instrument is calibrated daily, fixed calibration range is used; linearity is verified daily; three standards are used for linear calibration verification (low ICV (0.5 mg/l), High ICV (5.0 mg/l) and CCV (1.0 mg/l)). All standards must be within 10% of true value

10.2.2 Initial Calibration Verification (ICV)

10.2.2.1 Prior to sample analysis, the following ICVs must be analyzed to verify both calibration curves.

10.2.2.1.1 Nitrate ICV, 0.5ppm (Section 8.12.2)

10.2.2.1.2 Nitrate ICV, 5.0ppm (Section 8.12.1)

10.2.2.1.3 Nitrite ICV, 0.5ppm (Section 8.12.4)

10.2.2.1.4 Nitrite ICV, 5.0ppm (Section 8.12.3)

10.2.2.2 The results must be within $\pm$10% of the true value, otherwise re-calibration is required.

10.3 Equipment Operation and Sample Processing

Follow the manufacturer's directions for the operation of the Lachat 8000.

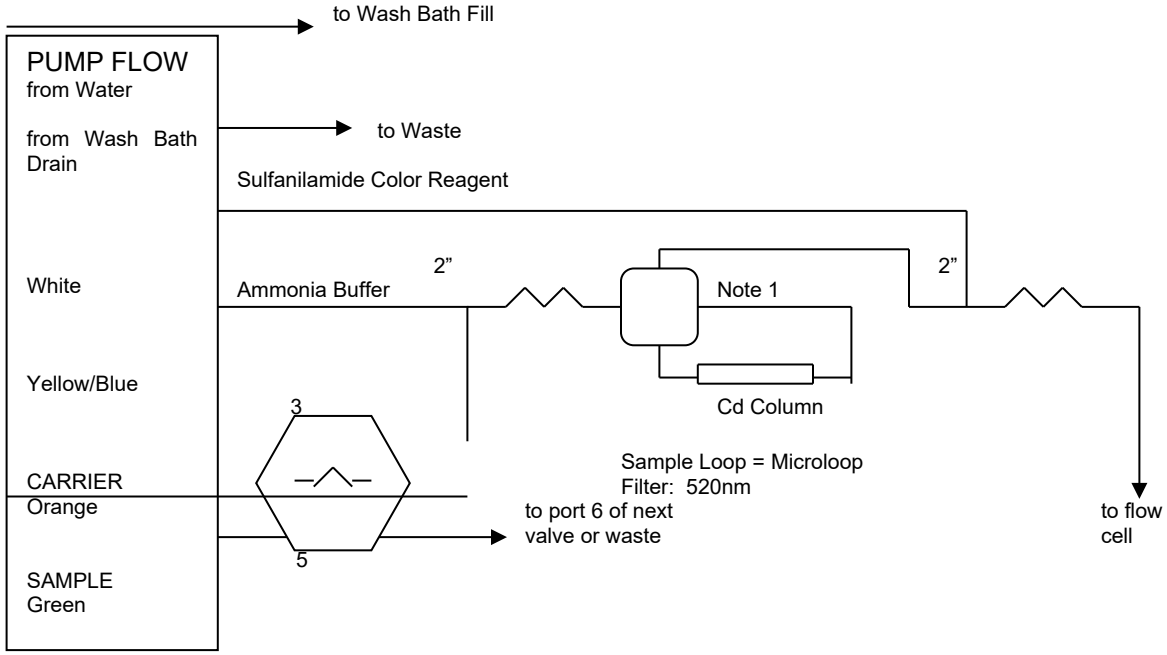
All samples have to be inspected prior to analysis. Samples that are turbid or have sediment have to be filtered prior to analysis.

Check pH of the samples. If pH is less then 5 or greater then 9, then adjust pH using 1N Hydrochloric Acid (HCl) (8.13), 6N Sulfuric Acid (H2SO4) (8.15) or 1N Sodium Hydroxide (NaOH) (8.14). Record pH adjustment in the log book.

For soils: extract soils samples prior to analysis: take 5g of sample, add 50 ml of DI, extract for 30 min, then filter thorough 0.45 nm filter. Record all weights for calculations.

Note: if samples are filtered, then Method blank also have to be filtered

The Manifold Diagram follows:



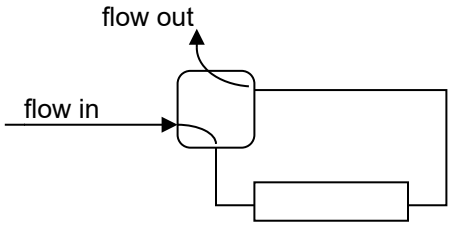
CARRIER is water.

2" is 135cm of tubing on a 2-inch coil support.
APPARATUS: Standard valve, flow cell, and detector head modules are used.

All manifold tubing is 0.8mm (0.032") i.d. This is 5.2µL/cm.

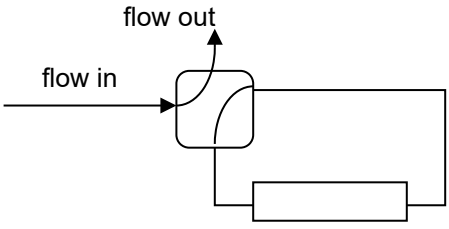
NOTE 1: This is a two-state switching valve used to place the cadmium column in line with the manifold.

State 1: Nitrate + Nitrite



Cd Column

State 2: Nitrite Only



Cd Column

10.4 Continuing Calibration

See Section 9.4

10.5 Preventive Maintenance

Tubing is changed monthly or as needed.

At the end of each analytical sequence, the valve to the column is closed. DI is rinsed through the Lachat for five minutes followed by five minutes of air.

All maintenance is documented in the Instrument Maintenance Logbook.

11. Data Evaluation, Calculations and Reporting

11.1 Nitrate/Nitrite: When the software is set up according to the manufacturer's recommendations, the concentration of nitrate plus nitrite in mg NO_3/NO_2-N/L is reported directly when the Cd column is included in the sample train in Channel 1.

11.2 Nitrite: When the software is set up according to the manufacturer's recommendations, the concentration nitrite in mg NO_2-N/L is reported directly when the Cd is not included in the sample train in Channel 2.

11.3 Nitrate: The concentration of nitrate is determined by the subtraction of the nitrite concentration, (Section 11.2 above), from the nitrate-nitrite concentration, (Section 11.1 above).

11.3.1 If the sample was preserved initially as described in Section 6.3, subtract the Nitrite value generated manually from the Nitrate/Nitrite value generated by the Lachat Instrument. This value is reported as the Nitrate result.

When the sample is preserved initially as described in Section 6.3, the value generated by the Lachat instrument for Nitrite is invalid and therefore disregarded.

11.4 If any sample exceeds a concentration of 8.0 mg/L, the sample must be diluted and re-analyzed. All sample concentrations must fall within the calibration curve.

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

Holding time exceedance and improper preservation are noted on the nonconformance report form.

Perform routine preventative maintenance following manufacturer's specification. Record all maintenance in the instrument logbook.

Review of standards, blanks and standard response for acceptable performance occurs for each batch of samples. Record any trends or unusual performance on a nonconformance action form.

If the CV or LCS recovery of any parameter falls outside the designated acceptance range, the laboratory performance for that parameter is judged to be out of control, and the problem must be immediately identified and corrected. The analytical result for that parameter in the unspiked samples is suspect and is only reported for regulatory compliance purposes with the appropriate nonconformance action form. Immediate corrective action includes reanalyzing all affected samples by using any retained sample before the expiration of the holding time.

13. Method Performance

13.1 Detection Limit Study (DL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the DL, LOD, and/or LOQ as outlined in Alpha SOP ID 1732. These studies performed by the laboratory are maintained on file for review.

The quarterly method reporting limit (MRL) verification requirement is satisfied by the quarterly LOQ analysis, as per SOP/1732

13.2 Demonstration of Capability Studies

Refer to Alpha SOP ID 1739 for further information regarding IDC/DOC Generation.

13.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

14. Pollution Prevention and Waste Management

Refer to Alpha's Chemical Hygiene Plan and Hazardous Waste Management and Disposal SOP for further pollution prevention and waste management information.

15. Referenced Documents

Manual Colorimetric Method

References: **SM 4500NO2-B**, Standard Methods for the Examination of Water and Wastewater, Online (2011).

1. Scope and Application

Matrices: This method is limited to optically clear water samples with a total concentration of nitrite below 1mg N/L. Turbid samples are filtered prior to analysis.

Definitions: See Alpha Laboratories Quality Manual Appendix A

In waters and wastewaters, the forms of nitrogen of greatest interest are, in order of decreasing oxidation state, nitrate, nitrite, ammonia, and organic nitrogen. All these forms of nitrogen, as well as nitrogen gas (N_2), are biochemically interconvertible and are components of the nitrogen cycle. They are of interest for many reasons.

Organic nitrogen is defined functionally as organically bound nitrogen in the trinegative oxidation state. It does not include all organic nitrogen compounds. Analytically, organic nitrogen and ammonia can be determined together and have been referred to as “kjeldahl nitrogen,” a term that reflects the technique used in their determination. Organic nitrogen includes such natural materials as proteins and peptides, nucleic acids and urea. Numerous concentrations vary from a few hundred micrograms per liter in some lakes to more than 20mg/L in raw sewage.

Total oxidized nitrogen is the sum of nitrate and nitrite nitrogen.

Nitrite is an intermediate oxidation state of nitrogen, both in the oxidation of ammonia to nitrate and in the reduction of nitrate. Such oxidation and reduction may occur in wastewater treatment plants, water distribution systems, and natural waters. Nitrite can enter a water supply system through its use as a corrosion inhibitor in industrial process water. Nitrite is the actual etiologic agent of methemoglobinemia. Nitrous acid, which is formed from nitrite in acidic solution, can react with secondary amines (RR’NH) to form nitrosamines (RR’N-NO), many of which are known to be carcinogens. The toxicologic significance of nitrosation reactions in vivo and in the natural environment is the subject of much current concern and research.

Within this SOP nitrite nitrogen is referred to as NO_2^--N.

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one of the following laboratory personnel before performing the modification: Area Supervisor, Laboratory Director, or Quality Assurance Officer.

This method is restricted to use by or under the supervision of analysts experienced in the operation of the Spectrometer. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

2. Summary of Method

The nitrite is determined by diazotizing with sulfanilamide followed by coupling with N-(1-naphthyl)ethylenediamine dihydrochloride. The resulting water-soluble dye has a magenta color, which is read at 540nm.

2.1 Method Modifications from Reference

1. Spectrophotometer reading done at 540 nm, not at 543 nm.

2. Two coloring reagents- sulfanilamide and NED used, instead of one combined coloring reagent.

3. Detection Limits

The laboratory follows the procedure found in 40CFR Part 136 to determine the MDL on an annual basis. The method detection limits determined by the laboratory are on file for review.

This method has an analytical range of 0.02 to 0.3mg N/L in the form of nitrite. The Reported Detection Limit is 0.02 mg N/L.

4. Interferences

4.1 For turbid samples, filter through 0.45µm membrane filter prior to analysis.

4.2 Sample color interferes if it is absorbed at about 540nm.

5. Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material data handling sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

6. Sample Collection, Preservation, and Handling

6.1 Sample Collection

Samples are collected in glass or plastic bottles.

6.2 Sample Preservation

Refrigerate samples at 4 ± 2 °C.

6.3 Sample Handling

Samples are stored under refrigeration at 4 ±2 °C. Analysis must be performed within 48 hours of collection.

7. Equipment and Supplies

7.1 Spectrophotometer: With infrared phototube for use at 540nm, providing a light path of 1.0cm.

7.2 Centrifuge Tubes: 50mL volume. (Must be new and disposable.)

7.3 Acrodisk Membrane Filters, 0.45µm

7.4 Acrodisk Glass Fiber Filters

7.5 Pipets: various volumes.

7.6 Syringe: 10mL and 20mL

8. Standards and Reagents

8.1 Stock Nitrite Standard, 1000mg N/L as NO_2: Purchased commercially prepared. Store in refrigerator at 4 ± 2°C. Expires upon manufacturer's specified date.

8.1.1 Intermediate Nitrite Working Standard, 5mg N/L as Nitrite: To a 200mL volumetric flask, add 1.0mL of the 1000mg N/L NO_2^- stock standard. Dilute to the mark with DI and invert to mix. This solutions are stable for two weeks. Store in the refrigerator at 4 ± 2°C.

8.2 Calibration Standards: Refer to the Table below for preparation instructions. Prepare fresh on each day of use.

Volume of 5.0 mg/L Working Standard (Section 8.3)	Final Volume (mL)	Calibration Standard Final Concentration (mgN/L)
1.0 mL	250	0.02
1.0 mL	100	0.05
2.0 mL	100	0.10
6.0 mL	100	0.30

8.3 ICV-LCS-CCV Stock Standard, 1000mg N/L: A second source standard than what is used in Section 8.1. Store in refrigerator at 4 ± 2°C. Expires upon manufacturer's specified date.

8.3.1 ICV-LCS-CCV Intermediate Standard, 8mg N/L: Add 0.8mL of 1000 mgN/L stock standard (Section 8.3) to 100mL volumetric flask and dilute to volume with DI water. Store refrigerated at 4 ±2 °C. Expires 2 weeks from date of preparation.

8.3.2 ICV-LCS-CCV Intermediate Standard, 5mg N/L: Add 0.5mL of 1000 mgN/L stock standard (Section 8.3) to 100mL volumetric flask and dilute to volume with DI water. Store refrigerated at 4 ±2 °C. Expires 2 weeks from date of preparation

8.3.2.1 ICV-LCS-CCV Working Standard, 0.16mg N/L: Add 1mL of 8 mg/L intermediate standard (Section 8.3.1) to 50mL volumetric flask and dilute to volume with DI water. Prepare fresh on each day of use.

8.3.2.2 ICV-LCS-CCV Working Standard, 0.05mg N/L: Add 0.5mL of 5 mg/L intermediate standard (Section 8.3.2) to 50mL volumetric flask and dilute to volume with DI water. Prepare fresh on each day of use.

8.3.2.3 ICV-LCS-CCV Working Standard, 0.2mg N/L: Add 2.0mL of 5 mg/L intermediate standard (Section 8.3.2) to 50mL volumetric flask and dilute to volume with DI water. Prepare fresh on each day of use.

8.4 NED coloring reagent: Dissolve 1.0g N¯(1-naphthyl)ethylenediamine dihydrochloride (NED) in 1L volumetric flask with DI. Store in a dark place at room temperature for up to 3 months.

8.5 Sulfanilamide Color Reagent: In a 500mL volumetric flask, dissolve 5g of sulfanilamide and 50 mL of 85% Phosphoric Acid. Bring to 500mL volume with DI water. Expires one month from date of preparation. Store in a dark bottle in the refrigerator for up to 1 month..

8.6 1N Hydrochloric acid (HCL): To a 1L volumetric flask add about 600mL DI. Then add 83mL of concentrated hydrochloric acid (HCL) Stir to dissolve. Dilute to the mark with DI water and invert to mix. This solution is stable for six month. Store at room temperature.

8.7 5N Sodium Hydroxide (NaOH): To a 1L volumetric flask add about 600mL DI. Then add 200 g of sodium Hydroxide. Stir to dissolve. Dilute to the mark with DI water and invert to mix. This solution is stable for six month. Store at room temperature.

8.8 6N Sulfuric acid (H2SO4): To a 1L volumetric flask add about 600mL DI. Then add 140mL of concentrated sulfuric acid (H2SO4) Stir to dissolve. Dilute to the mark with DI water and invert to mix. This solution is stable for six month. Store at room temperature.

8.9 **Phosphoric Acid 85%.** Store at room temperature. Expires upon manufacturer's specified date

9. Procedure

9.1 Set Up

Samples to be analyzed for Nitrite are filtered through a 0.45µm membrane filter prior to analysis if turbid or have color. Typically 50-100 mL is filtered. A glass fiber filter may be used to prefilter hard-to-filter samples. Clear samples don't need to be filtered.

9.2 Initial Calibration

Prepare individual calibration curve from a series of four standards (Section 8.2) and blank as per Section 9.4. Plot absorbance vs. nitrite concentration to give a linear curve. The correlation coefficient must be 0.995 or greater for the curve to be considered valid. The calibration curve is verified by a second source standard prior to performing any sample analysis. Recovery of the second source standard must be 90-110% of the true value.

All calibration points are back calculated and should be within 10% from true concentration, except 1 lowest point of calibration curve. %recoveries for low range will be wider, but shouldn't exceed 100% and correlation coefficient will not be worse then 0.995

An Initial Calibration Curve is generated daily.

9.3 Standardization (Continuing Calibration Verification)

The calibration curve is verified by a second source standard after every 20 samples or less. Refer to Section 10.3.

9.4 Equipment Operation

9.4.1 Spectrometer preparation

9.4.1.1 The spectrometer is set to zero absorbance using only DI in 1 cm cell at a wavelength of 540nm.

9.4.2 Sample Analysis

9.4.2.1 Pour 50mL, or a portioned dilution, of each clear sample, Duplicate sample, Method Blank, LCS/ICV and Matrix Spike sample into a corresponding new (never used) centrifuge tube.

9.4.2.2 Check pH of the samples. If pH is less then 5 or greater then 9, then adjust pH using 1N Hydrochloric Acid (HCl) (8.6), 5N Sodium Hydroxide (8.7) or 6N Sulfuric Acid (8.8). Record pH adjustment on excel.

9.4.2.3 Add 2.0mL of NED coloring (Section 8.4) reagent to each 50mL sample and QC sample aliquot and mix thoroughly.

9.4.2.4 Add 2.0mL of Sulfanilamide (Section 8.5) reagent to each 50mL sample and QC sample aliquot and mix thoroughly.

9.4.2.5 After at least 10 minutes but no more than 30 minutes, measure the absorbance of each sample on the spectrophotometer at 540nm with a 1.0cm cell. Record results in the laboratory notebook. ELN can be used for data reporting.

9.4.2.6 If the sample concentration is greater than the highest calibration standard concentration, dilute the original sample with DI water and recolor and reanalyze as outlined above (Section 9.4.2.1 – 9.4.2.5).

9.5 Preventative Maintenance

The Spectrophotometers are calibrated on a semi-annual basis by an instrument service company. Certificates are kept on file.

9.6 Calculations

mg N/L, as NO_2 = mg N (as NO_2 from calibration curve) x dilution factor

10. Quality Control and Data Assessment

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method. When results of sample spikes indicate atypical method performance, a calibration verification standard is used to confirm the measurements were performed in an in-control mode of operation.

10.1 Demonstration of Capability

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method. Each time a method modification is made, the analyst is required to repeat the procedure.

When the parameter tested fails at least one of the acceptance criteria, the analyst must locate and correct the source of the problem and repeat the test.

Repeated failure confirms a general problem with the measurement system or analytical technique of the analyst. If the failure repeats, locate and correct the source of the problem and repeat the test.

10.2 Blanks

10.2.1 Method Blank: One method blank, which consists of 50mL DI water, must be analyzed per batch of 20 samples or less. If samples were filtered, then blank has to be filtered through a 0.45 micron filter. The method blank result must be less than the Reporting Limit. If the method blank is higher than the RL, a fresh aliquot of 50mL DI is used. If the method blank is higher than the RL again, the problem must be identified and corrected before any samples are analyzed.

10.2.2 Continuing Calibration Blank: A continuing calibration blank (CCB) consists of 50mL DI water colored and treated as per Section 9.4. A CCB must be analyzed immediately following the ICV/LCS and immediately prior to the CCV. The CCB result must be less than the Reporting Limit. If the CCB is greater than the RL, all samples analyzed since the last passing CCB must be recolored and reanalyzed.

10.3 Calibration Verification and Laboratory Control Samples (ICV-LCS-CCV)

Analyze one LCS/ICV per batch of 20 samples or less. The calibration curve must be verified by a second source standard prior to performing any sample analysis. The ICV/LCS must be recovered at 90 – 110% of the true value.

If the ICV/LCS fails, re-analyze. If failure remains, stop analysis, find and correct the problem. Re-calibrate and recolor a fresh sample aliquot and reanalyze.

Analyze a CCV after every ten samples or less. The CCV must be recovered at 90 – 110% of the true value.

If the CCV fails, re-analyze. If failure remains, stop analysis, find and correct the problem. Re-calibrate and recolor a fresh sample aliquot and reanalyze.

10.4 Matrix Spike

Analyze one matrix spike per batch of 20 samples or less. The Matrix Spike final concentration is 0.1mg N/L when prepared as follows: Add 1.0mL of the 5 mg N/L Intermediate Standard (Section 8.1.1) to 49mL of sample.

If the MS recovery is outside of acceptance limits, which are based on in-house control limits (Section 10.6), the sample and its spike are reanalyzed. If the MS failure continues, a narrative is submitted with the data for inclusion on the Client report.

10.5 Duplicates

Analyze one sample in duplicate, per batch of 20 samples or less. The RPD acceptance criteria is based on in-house control limits (Section 10.6). If the RPD is outside of acceptance limits, the sample and its duplicate are reanalyzed. If the RPD failure continues, a narrative is submitted with the data for inclusion on the Client report.

10.6 Control Limits

The laboratory maintains performance records to document the quality of data that is generated. Method accuracy for samples is assessed and records maintained.

Control limits for the method parameters are generated. The control limits are calculated based on in-house performance data. The limits are compared to the control limits found in the reference method.

10.7 Analytical Sequence

- Sample filtration, if necessary including blank.
- Calibration Curve generation
- LCS/ICV
- Method Blank
- Samples 1-10
- Sample Duplicate
- Matrix Spike
- CCB
- CCV
- Samples 11-20
- CCB
- CCV

11. Method Performance

The method detection limit (MDL) is defined as the minimum concentration of a substance that can be measured and reported with 99% confidence that the value is above zero. The MDL concentrations were obtained using reagent water. The MDL actually achieved will vary depending on instrument sensitivity and matrix effects.

Verification of the minimum reporting limit (MRL): The minimum reporting level (MRL) is set to a concentration at or above the lowest standard used in the analysis.
Verify quantitation at the MRL initially and at least quarterly by analyzing a QC sample (subjected to all sample-preparation steps) spiked at a level 1 to 2 times the MRL. A successful verification meets the method's or laboratory's accuracy requirements at the MRL.

Method performance data is on file in the laboratory. Comparison of method performance data for the laboratory to the reference method criteria occurs when laboratory in-house acceptance limits are generated. In-house generated data must be within the specifications of the reference method or the analysis is not continued until corrective action is completed.

12. Corrective Actions

Holding time exceedences or improper preservation are noted on the nonconformance report form.

Perform routine preventative maintenance following manufacturer's specification. Record all maintenance in the instrument logbook.

Review of standards, blanks and standard response for acceptable performance occurs for each batch of samples. Record any trends or unusual performance on a nonconformance action form.

If the CCV or LCS recovery of any parameter falls outside the designated acceptance range, the laboratory performance for that parameter is judged to be out of control, and the problem must be immediately identified and corrected. The analytical result for that parameter in the unspiked samples is suspect and is only reported for regulatory compliance purposes with the appropriate nonconformance action form. Immediate corrective action includes reanalyzing all affected samples by using any retained sample before the expiration of the holding time.

13. Pollution Prevention

See Chemical Hygiene Plan for pollution prevention operations.

14. Waste Management

See Chemical Hygiene Plan for waste handling and disposal.

Nitrogen Ammonia

Reference: **SM4500 NH_3-BH,** Standard Methods for the Examination of Water and Wastewater. APHA-AWWA-WEF. Standard Methods Online.

Method 350.1, Methods for the Chemical Analysis of Water and Wastes, EPA 600/ 4-82-055, Revision 2.0, August 1993.

Method 10-107-06-1-A, Methods for Automated Ion Analyzers, May 20, 1998.

1. Scope and Application

Matrices: Ammonia nitrogen can be determined in potable, surface, and saline waters as well as domestic and industrial wastewaters and in soils.

Definitions: Refer to Alpha Analytical Quality Manual.

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one of the following laboratory personnel before performing the modification: Area Supervisor, Laboratory Services Manager, Laboratory Director, or Quality Assurance Officer

This method is restricted to use by or under the supervision of analysts experienced in the operation of the Tecator and/or Lachat Instrument and in the interpretation of Lachat data. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

In waters and wastewaters the forms of nitrogen of greatest interest are, in order of decreasing oxidation state: nitrate, nitrite, ammonia, and organic nitrogen. All these forms of nitrogen, as well as nitrogen gas (N_2), are biochemically interconvertible and are components of the nitrogen cycle. They are of interest for many reasons. Organic nitrogen is defined functionally as organically bound nitrogen in the trinegative oxidation state. It does not include all organic nitrogen compounds. Analytically, organic nitrogen and ammonia can be determined together and have been referred to as “kjeldahl nitrogen,” a term that reflects the technique used in their determination. Organic nitrogen includes such natural materials as proteins and peptides, nucleic acids and urea, and numerous synthetic organic materials. Typical organic nitrogen concentrations vary from a few hundred micrograms per liter in some lakes to more than 20mg/L in raw sewage.

Ammonia is present naturally in surface and wastewaters. Its concentration generally is low in groundwaters because it adsorbs to soil particles and clays and is not leached readily from soils. It is produced largely by deamination of organic nitrogen containing compounds and by hydrolysis of urea. At some water treatment plants ammonia is added to react with chlorine to form a combined chlorine residual.

In the chlorination of wastewater effluents containing ammonia, virtually no free residual chlorine is obtained until the ammonia has been oxidized. Rather, the chlorine reacts with ammonia to form mono- and dichloramines. Ammonia concentrations encountered in water vary from less than 10µg ammonia nitrogen/L in some natural surface and groundwaters to more than 30mg/L in some wastewaters.

In this discussion, organic nitrogen is referred to as organic N, nitrate nitrogen as NO_3-N, nitrite nitrogen as NO_2-N, and ammonia nitrogen as NH_3-N.

2. Summary of Method

The sample is buffered at pH 9.5 with a borate buffer to decrease hydrolysis of cyanates and organic nitrogen compounds. It is distilled into a solution of boric acid. The ammonia in the distillate is determined colorimetrically by the phenate method.

The phenate method is base on the Berthelot reaction. Ammonia reacts with alkaline phenol, then with sodium hypochlorite to form indophenol blue. Sodium nitroprusside (nitroferricyanide) is added to enhance sensitivity. The absorbance of the reaction product is measured at 630nm, and is directly proportional to the original ammonia concentration

2.1 Method Modifications from Reference

Method was modified to include soil sample distillation. Samples are buffered at pH 9.5. pH is checked using pH paper 7.5-14 (not pH meter).

3. Reporting Limits

The RL is determined to be 0.075mg/L based on a 100mL sample size for waters and 7.5 mg/kg based on 1g of soil material used for distillation.

4. Interferences

4.1 Most of the following interferences refer to the direct analysis of a water sample. The distillation steps remove most of these interferences. Residual chlorine must be removed prior to distillation by pretreatment of the sample with sodium thiosulfate.

4.2 Samples with a high concentration of NH_3 may carry-over into the next sample and therefore yield false high results in that next sample. If a sample with a low concentration follows a sample with a high concentration, re-analyze the low sample to ensure results are accurate.

4.3 Glycine, urea, glutamic acid, cyanates, and acetamide hydrolyze very slowly in solution on standing but, of these, only urea and cyanates will hydrolyze on distillation at pH of 9.5. Hydrolysis amounts to about 7% at this pH for urea and about 5% for cyanates. Some of the organic compounds that may interfere, such as formaldehyde, may be eliminated by boiling off at a low pH before nesslerization.

4.4 Color and turbidity of the sample distillate may interfere with analysis. These interferences are removed by manual filtration of the distillate prior to Lachat analysis, or by dilution of the sample prior to distillation.

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material safety data sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

Phenol used in this method is hazardous and general laboratory safety practices must be observed.

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

The most reliable results are obtained on fresh samples. Use plastic or glass containers.

6.2 Sample Preservation

If prompt analysis is impossible, preserve samples with approximately 0.8mL concentrated H_2SO_4/L sample. The pH of the acid-preserved samples should be <2. (Some wastewaters may require more concentrated H_2SO_4 to achieve this pH.) Store samples at 4ºC.

Soils samples are received without preservation and stored at 4ºC

6.3 Sample Shipping

No specific requirements.

6.4 Sample Handling

Samples (both waters and soils) are analyzed within 28 days after collection.

7. Equipment and Supplies

7.1 Distillation apparatus: Tecator Instruments Automatic Distillation Unit. Follow the instrument manufacturer's instructions for proper operation.

7.2 pH Strips: Range 7.5 to 14 units.

7.3 250mL Disposable Polypropylene cups with covers.

7.4 Automated Ion Analyzer: Lachat Instruments.

7.5 Helium gas, He: 140kPa (20 lb/in^2).

7.6 Volumetric flasks, various volumes.

7.7 Pipets, various volumes.

7.8 Analytical Balance

7.9 Centrifuge Tubes: 50mL volume.

7.10 Potassium Iodide Starch Paper: Fisher brand 14-860

8. Reagents and Standards

8.1 Borate buffer solution: Add 88mL 0.1N NaOH solution to 500mL of approximately 0.025M sodium tetraborate ($Na_2B_4O_7$) solution (9.5g $Na_2B_4O_7 \cdot 10\ H_2O$/L) and dilute to 1L with DI water. Store at room temperature. Expires one month from date of preparation.

8.2 Sodium thiosulfate (dechlorinating reagent): Dissolve 0.35g $Na_2S_2O_3 \cdot 5H_2O$ in DI water and dilute to 100mL. Prepare fresh daily as needed.

8.3 Neutralization agents: Prepare with DI water:

8.3.1 Sodium hydroxide, NaOH, 6N: In a 1L volumetric flask, carefully mix 240g of NaOH (Section 8.11) pellets with 500mL DI water. Dissolve and bring to volume with DI water. Store at room temperature. Expires one month from date of preparation.

8.3.2 Sulfuric acid, H_2SO_4, 10%: To a 1L volumetric flask, add 500mL DI water. Carefully add 100mL of concentrated Sulfuric Acid (Section 8.12). Bring to volume with DI water. Store at room temperature. Expires one month from date of preparation.

8.4 Sodium Phenolate: CAUTION! Wear gloves. Phenol causes severe burns and is rapidly absorbed into the body through the skin. In a 1L volumetric flask, dissolve 88mL of 88% liquified phenol or 83g crystalline phenol (C_6H_5OH) in approximately 600mL DI water. While stirring, slowly add 32g sodium hydroxide (NaOH). Cool, dilute to the mark, and invert three times. Do **not** degas this reagent. Store at room temperature. Expires one month from date of preparation.

8.5 Sodium Hypochlorite (approximate 2.6%): In a 500mL volumetric flask, dilute 250mL Regular Chlorine bleach [5.25% sodium hypochlorite (NaOCl)] to the mark with DI water. Invert three times to mix. Store at room temperature. Expires one month from date of preparation.

8.6 Sodium Nitroprusside (coloring agent): In a 1L volumetric flask, dissolve 3.50g sodium nitroprusside (Sodium Nitroferricyanide [$Na_2Fe(CN)_5NO_2 \cdot H_2O$]) dilute to the mark with DI water. Degas with helium to prevent bubble formation. Use He at 140kPa (20 lb/in^2) through a helium degassing tube. Bubble He vigorously through the solution for one minute. Store refrigerated at 4 ± 2 °C. Expires one month from date of preparation.

8.7 Boric 1.5% Boric Acid Solution: To a 1000mL volumetric flask add 15g Boric Acid. Dilute to the mark with DI water. Store at room temperature. Expires one month from date of preparation.

8.8 0.2% Boric Acid Solution (Carrier Solution): To a 2L volumetric flask, dissolve 4g Boric Acid (H_3BO_3) in DI water. Degas by bubbling vigorously with Helium for one minute. Store at room temperature. Expires one month from date of preparation.

8.9 Stock Standard, 1000ppm as NH_3 (for calibration and spike solutions): Commercially prepared. Certificate of analysis is required. Store refrigerated at 4 ± 2 °C. Expires upon manufacturer's specified date.

8.9.1 Intermediate Calibration Stock Standard, 100ppm as NH_3: To a 100mL volumetric flask, add 10.0mL of Stock Standard (Section 8.9) and dilute to the mark with 0.2% Boric Acid solution (Section 8.8). Invert three times. Store refrigerated at 4 ± 2 °C. Expires one month from date of preparation.

8.9.1.1 Nine Working Calibration Standards: The following standards are prepared in volumetric flasks fresh each day of use:

8.9.1.1.1 20.0ppm: 40mL of 100ppm standard (Section 8.9.1) to 200mL with 0.2% Boric Acid solution (Section 8.8).

8.9.1.1.2 10.0ppm: 20mL of 100ppm standard (Section 8.9.1) to 200mL with 0.2% Boric Acid solution (Section 8.8). Prepare fresh each day of use.

8.9.1.1.3 **8.00ppm:** 8mL of 100ppm standard (Section 8.9.1) to 100mL with 0.2% Boric Acid solution (Section 8.8).

8.9.1.1.4 **4.00ppm:** 8mL of 100ppm standard (Section 8.9.1) to 200mL with 0.2% Boric Acid solution (Section 8.8).

8.9.1.1.5 **2.00ppm:** 2mL of 100ppm standard (Section 8.9.1) to 100mL with 0.2% Boric Acid solution (Section 8.8).

8.9.1.1.6 **1.00ppm:** 1mL of 100ppm standard (Section 8.9.1) to 100mL with 0.2% Boric Acid solution (Section 8.8).

8.9.1.1.7 **0.400ppm:** 4mL of 20ppm standard (Section 8.9.1.1.1) to 200mL with 0.2% Boric Acid solution (Section 8.8).

8.9.1.1.8 **0.200ppm:** 1mL of 20ppm standard (Section 8.9.1.1.1) to 100mL with 0.2% Boric Acid solution (Section 8.8). Alternately, this standard may be prepared utilizing autodilution of the 20ppm standard on the autosampler.

8.9.1.1.9 **0.100ppm:** 1mL of 20ppm standard (Section 8.9.1.1.1) to 200mL with 0.2% Boric Acid solution (Section 8.8). Alternately, this standard may be prepared utilizing autodilution of the 20ppm standard on the autosampler.

8.9.1.1.10 **0.050ppm:** 20mL of 0.100ppm standard (Section 8.9.1.1.8) to 40mL with 0.2% Boric Acid solution (Section 8.8). Alternately, this standard may be prepared utilizing autodilution of the 20ppm standard on the autosampler.

8.9.1.2 Continuing Calibration Standards:

8.9.1.2.1 **0.400ppm Low CCV:** 4mL of 20ppm standard (Section 8.9.1.1.1) to 200mL with 0.2% Boric Acid solution (Section 8.8).

8.9.1.2.2 **4.00ppm Hi CCV:** 8mL of 100ppm standard (Section 8.9.1) to 200mL with 0.2% Boric Acid solution (Section 8.8).

8.9.2 Spiking solution, 200ppm as NH_3: To a 100mL volumetric flask add 20mL of 1000ppm Stock Standard (Section 8.9) and dilute to the mark with DI water.

8.10 Stock Standard Solution, 1000ppm as NH_3 (for ICV and LCS): Commercially prepared. Certificate of analysis is required. This must be from a different source than that used for Stock Standard (Section 8.9). Store refrigerated at 4 ± 2 °C. Expires upon manufacturer's specified date.

8.10.1 Initial Calibration Verification Standards (ICV):

8.10.1.1 Hi ICV, 10ppm: To a 100mL volumetric flask add 1mL of 1000ppm standard (Section 8.10). Dilute to the mark with 0.2% Boric Acid Solution (Section 8.8). Expires one month from date of preparation.

8.10.1.2 Hi ICV, 8.0ppm: To a 100mL volumetric flask add 0.8mL of 1000ppm standard (Section 8.10). Dilute to the mark with 0.2% Boric Acid Solution (Section 8.8). Expires one month from date of preparation

8.10.1.3 Low ICV, 1.0ppm: To a 100mL volumetric flask add 10mL of 10ppm ICV (Section 8.10.1.1). Dilute to the mark with 0.2% Boric Acid Solution (Section 8.8). Expires one month from date of preparation.

8.10.2 LCS solution, 200ppm as NH_3: To a 100mL volumetric flask add 20mL of 1000ppm Stock Standard (Section 8.10) and dilute to the mark with DI water. Store refrigerated at 4 ± 2 °C. Expires one month from date of preparation.

8.11 NaOH Pellets: ACS Grade. Store well sealed at room temperature. This salt does not have an expiration date.

8.12 Sulfuric Acid (Concentrated): Store at room temperature. Expires upon manufacturer's specified date. Use extreme caution when handling.

8.13 Ottawa sand: store at room temperature. Expires upon manufacturer's specified date.

8.14 Thymol Blue Sodium Salt 0.04% water solution: used as indicator during pH adjustment prior distillation. Store at room temperature. Expires upon manufacturer's specified date.

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

9.1 Blank

9.1.1 The Distillation Blank is 100 mL DI for waters or 1g of Ottawa sand for soils. Distill one per batch of 20 samples or less. Results for the Distillation Blank must be less than the Reporting Limit. If results for the Distillation Blank are greater than the reporting limit, and all sample results for the batch are greater than 10x the Blank result, sample results may be reported with a narrative to be included on the final report. Otherwise, all samples must be redistilled and reanalyzed.

9.1.2 The Initial Calibration Blank (ICB) and Continuing Calibration Blank (CCB) for the Lachat analysis are not distilled and are 0.2% Boric Acid Solution (Section 8.8).

The ICB is run after the initial calibration verification standards (ICV) and CCB is run after the continuing calibration standards (CCV).

If results for the ICB are greater than the reporting limit, the ICB is reinjected. If failure continues the instrument must be recalibrated. Samples are not to be analyzed until an acceptable ICB is obtained.

If results for the CCB are greater than the reporting limit, the CCB is reinjected. If failure continues the instrument must be recalibrated. All samples that were analyzed since the last passing CCB have to be reanalyzed.

9.2 Laboratory Control Sample (LCS)

9.2.1 Distillation: Distill a Low and a Hi LCS with each batch of 20 samples or less. Recovery of the LCSs must be within +/- 10% of true value for method 350.1 for waters, and within in-house Control Limits for method 4500 and soils. If recovery is outside of this range, the standard is reanalyzed once. If recovery still fails criteria, the entire sample batch must be redistilled and reanalyzed.

9.2.1.1 Low 2ppm LCS: Add 1mL of 200ppm LCS solution (Section 8.10.2) to

100mL DI for waters or for 1.0g of Ottawa sand for soils. This is used for the Low 0 – 2ppm curve

9.2.1.2 **Hi 20ppm LCS:** Add 10mL of 200ppm LCS solution (Section 8.10.2) to 100mL DI for waters or to 1.0g of Ottawa sand for soils. This is used for the Hi 2-20ppm cuve.

9.3 Initial Calibration Verification (ICV)

9.3.1 **Lachat Analysis:** The ICVs are not distilled. Analyze the following Hi and Low ICVs after calibration of the Lachat instrument. Recoveries must be within 10% of the true value. If results are outside of this range, the ICV may be reinjected once. If failure continues, recalibration of the instrument is necessary. Samples are not to be analyzed until acceptable ICV results are obtained.

9.3.1.1 **Low ICV, 1.0ppm** (Section 8.10.1.2)

9.3.1.2 **Hi ICV, 10ppm (**Section 8.10.1.1). **HI ICV** will be **8.0** ppm (Section 8.10.1.2) in case of one board calibration.

9.4 Continuing Calibration Verification (CCV)

9.4.1 **Lachat Analysis:** The CCVs are not distilled. Analyze the following Low and Hi CCVs after every ten samples and at the completion of analysis. Recoveries must be within 10% of the true value.

If recoveries fall outside of this range, the CCV is reanalyzed. If recovery is acceptable, the analysis may continue. If recovery is again unacceptable, the cause for the failure is determined and corrected, and the instrument is recalibrated. All samples that were analyzed since the last CCV that was within range are reanalyzed.

9.4.1.1 **0.4ppm Low CCV** (Section 8.9.1.2.1)

9.4.1.2 **4.0ppm Hi CCV** (Section 8.9.1.2.2)

9.5 Matrix Spike

One matrix spike is prepped and analyzed per batch of **20 samples** or less for **method 4500**. Matrix spike has to be analyzed **for every 10 samples** or **less for method 350.1**. Prior to distillation, use 2mL of 200ppm Intermediate Stock Standard (Section 8.9.2) per 100mL of sample for waters or 1.0g of sample for soils. Recovery of the Matrix Spike must be within +/- 10% of true value for waters and within in-house Control Limits for soils. If the recovery is outside of acceptance criteria, and the LCS is within acceptance criteria, matrix interference may be assumed. The associated data is reported with a narrative to be included on the final report.

9.6 Laboratory Duplicate

Distill one duplicate sample per batch of 20 samples or less. The %RPD for the duplicate sample must be within in-house Control Limits. If results are outside of the acceptance criteria, a narrative to be included on the final report.

9.7 Method-specific Quality Control Samples

None.

10. Procedure

10.1 Equipment Set-up

10.1.1 Prior to analysis, organize samples in order from low to high odor.

10.1.2 Clean 250mL Tecator tubes by rinsing twice with approximately 0.5mL of 6N NaOH solution and 100mL RO water. Rinse twice again with DI water.

10.2 Initial Calibration

Calibrate the Lachat ion analyzer according to manufacturer's instructions.

10.2.1 Calibration

Two boards are used to calibrate the Lachat instrument. Each curve has 7 calibration points. The correlation coefficient of each curve must be $\geq$ 0.995, otherwise re-calibration is necessary. Prepare standard curves by plotting the peak areas of standards processed through the manifold against NH_3-N concentrations in standards.

10.2.1.1 Channel 1 is used to generate a calibration curve on the low range from 0.00 – 2ppm.

10.2.1.2 Channel 2 is used to generate a calibration curve on the high range from 0 – 20ppm.

Alternative method: One board can be used to calibrate the Lachat instrument. 10 point calibration curve will be used with calibration standards 10.0, 8.0, 4.0, 2.0, 1.0,04, 0.2, 0.1, 0.05 mg/l each and blank. The correlation coefficient must

be ≥ 0.995, otherwise re-calibration is necessary. Prepare standard curves by plotting the peak areas of standards processed through the manifold against NH_3-N concentrations in standards.

Calibration coefficient will be calculated using Lachat software. All calibration points are back calculated by Lachat software and should be within 10% from true concentration, except 2 lowest points of calibration curve. %recoveries for low range will be wider, but shouldn't exceed 100% and correlation coefficient will not be worse than 0.995.

10.2.2 Initial Calibration Verification (ICV)

Prior to sample analysis, an ICV is analyzed at 1.0ppm to verify the low calibration curve on Channel 1. Another ICV is analyzed at 10ppm to verify the high calibration curve on Channel 2. Both ICVs must yield results ± 10% of their true value, otherwise re-calibration is necessary.

Note: if instrument is calibrated using one board calibration, then both ICV's (Low and High), will be evaluated and high ICV will be 8.0 mg/l ICV standard (Section 8.10.1.2).

10.2.3 Initial Calibration Blank (ICB)

Following the ICV is the analysis of an ICB. The ICB consists of an aliquot of 0.2% Boric Acid (Section 8.8). Results must be less than the Reporting Limit.

10.3 Equipment Operation and Sample Processing

10.3.1 Sample Preparation

10.3.1.1 Sample Aliquots

10.3.1.1.1 Aqueous Samples

Add 100mL dechlorinated sample or a portion diluted to 100mL with DI water, to pre-washed Tecator tubes that are numbered to correspond with the samples.

10.3.1.1.2 Soil Samples

One gram of a well-homogenized sample is weighed out into a centrifuge tube (record weight in notebook). The sample is then transferred into a Tecator tube with 100 mL of DI.

10.3.1.1.3 QC Samples

In a similar manner, prepare the QC samples to be distilled with the batch (refer to Sections 9.1.1, 9.2, 9.4 and 9.6).

10.3.1.2 Add approximately 1.0mL of $Na_2S_2O_3$ to each tube in order to remove chlorine, followed by 5.0mL of Borate Buffer solution.

10.3.1.2.1 Aqueous Samples

Add small amounts of 6N NaOH until the pH is adjusted to 9.5. 2-3 drops of indicator (sec 8.14) can be used for pH adjustment. Color of solution will change from pink to blue at pH 9.5. Use pH paper to confirm pH reading. Check each sample with Potassium Iodide Starch paper (7.10) for chlorine presence. If starch paper showing presence of chlorine, add extra 1.0mL of $Na_2S_2O_3$ and check again.

10.3.1.2.2 Soil Samples

No pH adjustment is needed.

10.3.2 Distillation

10.3.2.1 **Equipment preparation:** To clean any prior contamination, first rinse the Tecator distillation unit by running a series of 3 rinse tubes. The first rinse containing 90mL DI and 10mL 6N NaOH. The second and third rinses are with100mL DI and 0.5mL 6N NaOH.

10.3.2.2 **Distillation:** Begin by distilling rinse tubes, Blank, Low and Hi LCS, and then Samples and QC Samples using the Tecator Instruments Automatic Distillation Unit according to the manufacturer's instructions.

Distillate is collected from the Tecator unit in 250mL disposable polypropylene cups that contain 20mL of 1.5% Boric acid (Section 8.7). Distillation is complete after collection of approximately 140mL. Fill each cup to 150mL with DI water. Cover and store at 1-4º C if Lachat analysis is to be delayed

10.3.3 Ammonia analysis of distillate: Follow the manufacturer's instructions for the proper operation of the Lachat ion analyzer. The following are specific notes for this analysis.

Sample throughput:	90 samples/hr; 40sec/sample
Pump speed:	35
Cycle period:	40 s
Inject to start of peak period:	25 s
Inject to end of peak period:	63 ± s

10.3.4 System Notes:

10.3.4.1 Allow 15 minutes for heating unit to warm up to 60ºC.

10.3.4.2 System IV GAIN: 175 X 1

10.3.4.3 If standards are not distilled, samples should be multiplied by 1.5 to correct for the increase in volume after the distillation.

10.3.4.4 If baseline drifts, peaks are too wide, or other problems with precision arise, clean the manifold by the following procedure:

10.3.4.4.1 Place all reagent lines in deionized water and pump to clear reagents (2-5 minutes).

10.3.4.4.2 Place reagent lines and carrier in 1M hydrochloric acid (1 volume concentrated HCl added to 11 volumes of deionized water) and pump for several minutes.

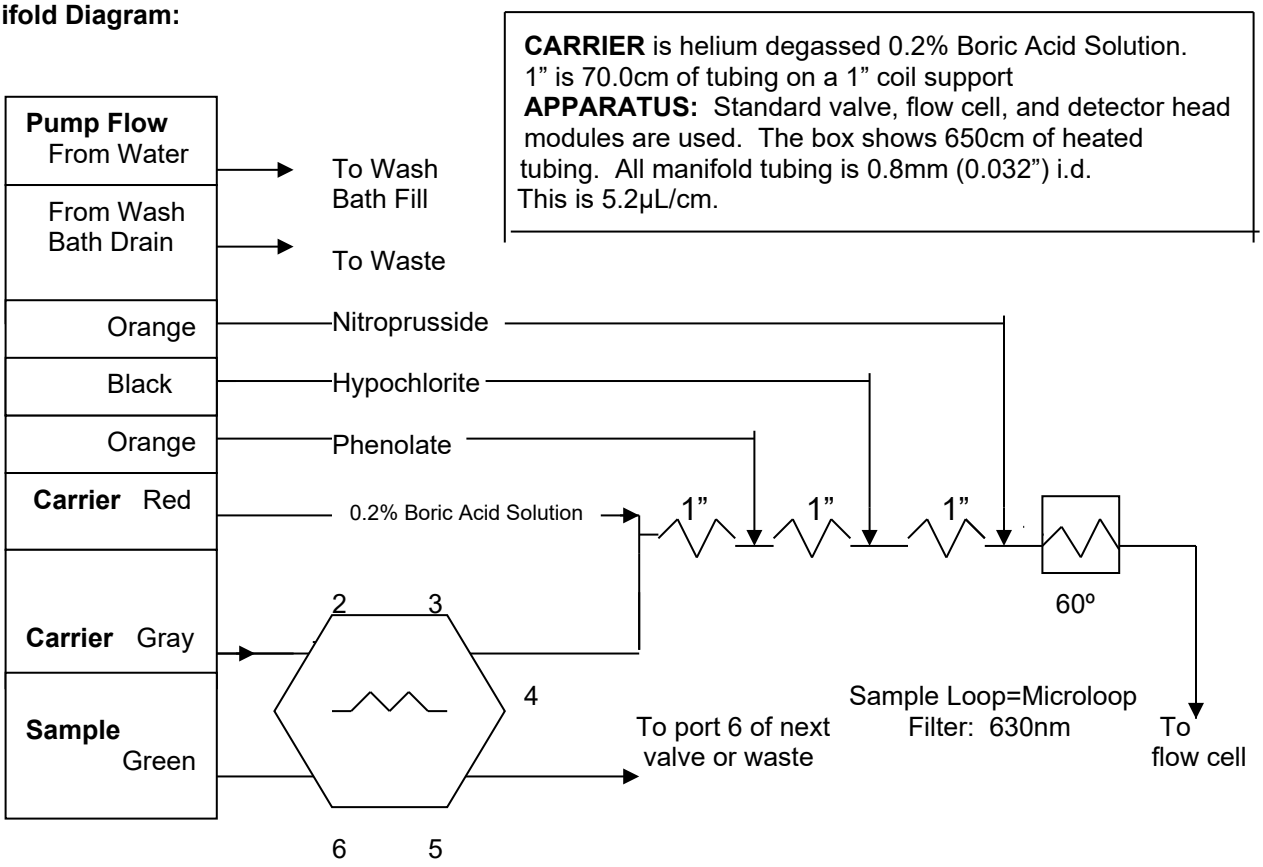
10.3.4.4.3 Place all lines in deionized water and pump until the HCl is thoroughly washed out.

10.3.4.4.4 Resume pumping reagents.

10.3.4.4.5 If sample distillate is colored or turbid, discard the sample distillate and re-distill the original sample at a higher dilution (Sections 10.3.1 and 10.3.2).

If there is not sufficient original sample volume for re-distillation, the colored/turbid distillate may be filtered through a 0.45µm filter and diluted on the Lachat instrument.

Manifold Diagram:



10.4 Continuing Calibration

Analyze the following after every 10 samples and at the completion of analysis:

0.400ppm Low CCV, (Section 8.9.1.2.1)

4.0ppm Hi CCV, (Section 8.9.1.2.2)

Blank, 0.2% Boric Acid Solution. (Section 8.8)

10.5 Preventive Maintenance

10.5.1 All lines are flushed at the end of each run.

10.5.2 All equipment is kept clean.

11. Data Evaluation, Calculations and Reporting

Compute sample NH_3-N concentration by comparing sample peak areas with standard curve, as determined by the Lachat instrument software.

11.1 If the sample has a concentration of less than 2ppm, calculate results by using the low curve generated on Channel 1.

11.2 If the sample concentration is greater than 2ppm but less than 20ppm, calculate results by using the high curve generated on Channel 2.

11.3 If the concentration is greater than 20ppm, dilute the sample and reanalyze.

NOTE: For soil samples Lachat reading is multiplied by extraction volume (150ml) and divided by sample weight (the exact weight is used as recorded in the laboratory notebook). Calculations are done using Lachat software.

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

Holding time exceedance, improper preservation and observed sample headspace are noted on the nonconformance report form.

Perform routine preventative maintenance following manufacturer's specification. Record all maintenance in the instrument logbook.

Review of standards, blanks and standard response for acceptable performance occurs for each batch of samples. Record any trends or unusual performance on a nonconformance action form.

If ICV/CCV and/or ICB/CCB fail acceptance criteria, check sections 9.1.2, 9.3.1 and 9.4.1 for correction actions.

If the Method Blank result exceeds the Reporting Limit (RL) for the analyte, the Blank is reanalyzed. If reanalysis will confirm positive Method blank result, data has to be evaluated and all associated samples have be re-distilled and reanalyzed.

If lab doesn't have samples for reanalysis, then samples with results below RL or more then 10x of reporting limit may be reported with narrative; samples with results between ND and 10x of reporting limit have to be B qualified and reported with narrative

If the LCS recovery falls outside the designated acceptance range, the laboratory performance is judged to be out of control, and the problem must be immediately identified and corrected. Immediate corrective action includes reanalyzing all affected samples by using any retained sample before the expiration of the holding time.

If the Matrix Spike acceptance criteria is not met, the spiked sample is reanalyzed (if possible). If failure continues and if all other QC performance criteria are met, the data is reported and a narrative is included with the final report.

If the RPD for the Duplicate measurements falls outside the Laboratory defined control limits, the sample is reanalyzed (if possible). If failure continues, and if all other QC performance criteria are met, the data is reported and a narrative is included with the final report.

13. Method Performance

13.1 Detection Limit Study (DL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the DL, LOD, and/or LOQ as outlined in Alpha SOP ID 1732. These studies performed by the laboratory are maintained on file for review.
The quarterly method reporting limit (MRL) verification requirement is satisfied by the quarterly LOQ analysis, as per SOP/1732.

Note: Method **350.1** required MDL studies to be performed and evaluated every 6 month.

13.2 Demonstration of Capability Studies

Refer to Alpha SOP ID 1739 for further information regarding IDC/DOC Generation.

13.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

14. Pollution Prevention and Waste Management

NOTE: Lachat Phenol waste is hazardous and must be disposed of in "Hazmat" Lachat waste drums

Refer to Alpha's Chemical Hygiene Plan and Hazardous Waste Management and Disposal SOP for further pollution prevention and waste management information.

Method 10-107-06-2-D, Methods for Automated Ion Analyzers, May 20, 1998.

1. Scope and Application

Matrices: Total Kjeldahl nitrogen can be determined in potable, surface, and saline waters as well as domestic and industrial wastewaters.

Definitions: See Alpha Laboratories Quality Manual Appendix A

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one of the following laboratory personnel before performing the modification: Area Supervisor, Laboratory Director, or Quality Assurance Officer.

This method is restricted to use by or under the supervision of analysts experienced in the operation of the Tecator and/or Lachat Instrument and in the interpretation of Lachat data. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

This method covers the determination of total kjeldahl nitrogen in drinking, surface and saline waters, and domestic and industrial wastes. The procedure converts nitrogen components of biological origin such as amino acids, proteins and peptides to ammonia, but may not convert the nitrogenous compounds of some industrial wastes such as amines, nitro compounds, hydrazones, oximes, semicarbazones and some refractory tertiary amines.

In waters and wastewaters the forms of nitrogen of greatest interest are, in order of decreasing oxidation state, nitrate, nitrite, ammonia, and organic nitrogen. All these forms of nitrogen, as well as nitrogen gas (N_2), are biochemically interconvertible and are components of the nitrogen cycle. They are of interest for many reasons.

Organic nitrogen is defined functionally as organically bound nitrogen in the trinegative oxidation state. It does not include all organic nitrogen compounds. Analytically, organic nitrogen and ammonia can be determined together and have been referred to as “Kjeldahl nitrogen”, a term that reflects the technique used in their determination. Organic nitrogen includes such natural materials as proteins and peptides, nucleic acids and urea, and numerous synthetic organic materials. Typical organic nitrogen concentrations vary from a few hundred micrograms per liter in some lakes to more than 20mg/L in raw sewage.

Ammonia is present naturally in surface and wastewaters. Its concentration generally is low in groundwaters because it adsorbs to soil particles and clays and is not leached readily from soils. It is produced largely by deamination of organic nitrogen containing compounds and by hydrolysis of

urea. At some water treatment plants ammonia is added to react with chlorine to form a combined chlorine residual.

In the chlorination of wastewater effluents containing ammonia, virtually no free residual chlorine is obtained until the ammonia has been oxidized. Rather, the chlorine reacts with ammonia to form mono- and dichloramines. Ammonia concentrations encountered in water vary from less than 10µg ammonia nitrogen/L in some natural surface and groundwaters to more than 30 mg/L in some wastewaters.

In this discussion, organic nitrogen is referred to as organic N, nitrate nitrogen as NO_3–N, nitrite nitrogen as NO_2 - - N, and ammonia nitrogen as NH_3–N.

Total Kjeldahl nitrogen is defined as the sum of free-ammonia and organic nitrogen compounds which are converted to ammonium sulfate $(NH_4)_2SO_4$, under the conditions of digestion described below.

Organic Kjeldahl nitrogen is defined as the difference obtained by subtracting the free-ammonia value from the total Kjeldahl nitrogen value. This may be determined directly by removal of ammonia before digestion.

2. Summary of Method

The organic nitrogen is converted to ammonia via heating in the presence of concentrated sulfuric acid, K_2SO_4, $HgSO_4$, and evaporated until SO_3 fumes are obtained and the solution becomes colorless or pale yellow. The residue is cooled, diluted, and treated and made alkaline with a hydroxide-thiosulfate solution. The digestate is distilled at high pH into a solution of boric acid. The ammonia in the distillate is determined colorimetrically by the phenate method.

The phenate method is based on the Berthelot reaction. Ammonia reacts with alkaline phenol, then with sodium hypochlorite to form indophenol blue. Sodium nitroprusside (nitroferricyanide) is added to enhance sensitivity. The absorbance of the reaction product is measured at 630nm, and is directly proportional to the ammonia concentration in the digestate.

2.1 Method Modifications from Reference

This method has been modified for soil digestion, Section 9.4.1.

3. Detection Limits

The RDL is determined to be 0.3 mg/L for liquid samples and 150 mg/Kg for soil or solid samples.

4. Interferences

4.1 Instrumental

Samples with a high concentration of TKN may carry-over into the next sample and therefore yield false high results in that next sample. If a sample with a low concentration follows a sample with a high concentration, re-analyze the low sample to ensure results are accurate.

4.2 Parameters

High nitrate concentrations (10X or more than the TKN level) result in low TKN values. The reaction between nitrate and ammonia can be prevented by the use of an anion exchange resin (chloride form) to remove the nitrate prior to the TKN analysis.

5. Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material data handling sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

NOTE: Both Phenol and Mercury used in this method are hazardous and general laboratory safety practices must be observed. Due to the Mercury used in this procedure, digestion must be done under a hood.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

6. Sample Collection, Preservation, and Handling

6.1 Sample Collection

The most reliable results are obtained on fresh samples. Use plastic or glass containers.

6.2 Sample Preservation

Samples may be preserved by addition of 2mL of concentrated H_2SO_4 per liter if sample cannot be analyzed immediately. Refrigerate at 4ºC.

6.3 Sample Handling

Even when properly preserved, conversion of organic nitrogen to ammonia may occur. Therefore samples should be analyzed as soon as possible.

7. Equipment and Supplies

7.1 Digestion apparatus: Kjeldahl Digestion System 20, Model 1015 Digester. Follow the instrument manufacturer's instructions.

7.2 Distillation apparatus: Tecator Instruments Automatic Distillation Unit: Follow the instrument manufacturer's instructions for proper operation.

7.3 Automated Ion Analyzer: Lachat Instruments

7.4 Disposable polypropylene cups: 250mL with covers.

7.5 Glass Tuttlecaps: For digestion.

7.6 Glass Pipets: Various volumes.

7.7 Auto-pipettor with tips: For 10mL capability.

7.8 Analytical balances: capable to weigh 0.1000g aliquots.

7.9 Dilu Vials

7.10 Boiling chips

8. Standards and Reagents

8.1 Sodium Phenolate: **CAUTION!** Wear gloves. Phenol causes severe burns and is rapidly absorbed into the body through the skin. In a 1L volumetric flask, dissolve 88mL of 88% liquified phenol or 83g crystalline phenol (C_6H_5OH) in approximately 600mL DI water. While stirring, slowly add 32g sodium hydroxide (NaOH). Cool, dilute to the mark, and invert three times. Do **not** degas this reagent. Expires one month from date of preparation.

8.2 Sodium Hypochlorite (approximate 2.6%): In a 500mL volumetric flask, dilute 250mL Regular Chlorine bleach [5.25% sodium hypochlorite (NaOCl)] to the mark with DI water. Invert three times to mix. Expires one month from date of preparation.

8.3 Sodium Nitroprusside (coloring agent): In a 1L volumetric flask, dissolve 3.50g sodium nitroprusside (Sodium Nitroferricyanide $[Na_2Fe(CN)_5NO_2 \cdot H_2O]$) dilute to the mark with DI water. Degas with helium to prevent bubble formation. Use He at 140kPa (20 lb/in^2) through a helium degassing tube. Bubble He vigorously through the solution for one minute. Expires one month from date of preparation.

8.4 Boric 1.5% Boric Acid Solution: To a 1000mL volumetric flask add 15g Boric Acid. Dilute to the mark with DI water. Expires one month from date of preparation.

8.5 Mercuric Sulfate Solution: Dissolve 8g red mercuric oxide (HgO) in 50mL of l:4 sulfuric acid (10.0mL concentrated H_2SO_4 : 40mL distilled water) and dilute to 100mL with distilled water. Expires one month from date of preparation.

8.6 Digestion Solution (Sulfuric Acid-Mercuric Sulfate-Potassium Sulfate): Dissolve 267g K_2SO_4 in 1300mL distilled water and 400mL concentrated H_2SO_4. Add 50mL mercuric sulfate (Section 8.5) solution and dilute to 2L with distilled water. Expires one month from date of preparation.

8.7 Sodium Hydroxide-Sodium Thiosulfate Solution: Dissolve 500g NaOH and 25g $Na_2S_2O_3 \cdot 5H_2O$ in distilled water and dilute to 1L. Expires one month from date of preparation.

8.8 0.2% Boric Acid Solution (Carrier Solution): To a 2L volumetric flask, dissolve 4g Boric Acid (H_3BO_3) in DI water. Degas by bubbling vigorously with Helium for one minute. Expires one month from date of preparation.

8.9 Stock Standard, 1000ppm as NH_3 (for calibration solutions): Commercially prepared. Certificate of analysis is required.

8.9.1 Intermediate Calibration Stock Standard, 100ppm as NH_3: To a 100mL volumetric flask, add 10.0mL of Stock Standard (Section 8.9) and dilute to the mark with 0.2% Boric Acid solution (Section 8.8). Invert three times. Expires one month from date of preparation.

8.9.1.1 Nine Working Calibration Standards: Prepare the following standards in volumetric flasks:

8.9.1.1.1 20.0ppm: 40mL of 100ppm standard (Section 8.9.1) to 200mL with 0.2% Boric Acid solution (Section 8.8). Prepare fresh each day of use.

8.9.1.1.2 10.0ppm: 20mL of 100ppm standard (Section 8.9.1) to 200mL with 0.2% Boric Acid solution (Section 8.8). Prepare fresh each day of use.

8.9.1.1.3 8.00ppm: 8mL of 100ppm standard (Section 8.9.1) to 100mL with 0.2% Boric Acid solution (Section 8.8). Prepare fresh each day of use.

8.9.1.1.4 4.00ppm: 8mL of 100ppm standard (Section 8.9.1) to 200mL with 0.2% Boric Acid solution (Section 8.8). Prepare fresh each day of use.

8.9.1.1.5 2.00ppm: 2mL of 100ppm standard (Section 8.9.1) to 100mL with 0.2% Boric Acid solution (Section 8.8). Prepare fresh each day of use.

8.9.1.1.6 1.00ppm: 1mL of 100ppm standard (Section 8.9.1) to 100mL with 0.2% Boric Acid solution (Section 8.8). Prepare fresh each day of use.

8.9.1.1.7 0.400ppm: 4mL of 20ppm standard (Section 8.9.1.1.1) to 200mL with 0.2% Boric Acid solution (Section 8.8). Prepare fresh each day of use.

8.9.1.1.8 0.200ppm: 1mL of 20ppm standard (Section 8.9.1.1.1) to 100mL with 0.2% Boric Acid solution (Section 8.8). Alternately, this standard may be prepared utilizing autodilution of the 20ppm standard on the autosampler. Prepare fresh each day of use.

8.9.1.1.9 0.100ppm: 1mL of 20ppm standard (Section 8.9.1.1.1) to 200mL with 0.2% Boric Acid solution (Section 8.8). Alternately, this standard may be prepared utilizing autodilution of the 20ppm standard on the autosampler. Prepare fresh each day of use.

8.9.1.1.10 0.050ppm: 20mL of 0.100ppm standard (Section 8.9.1.1.9) to 40mL with 0.2% Boric Acid solution (Section 8.8). Alternately, this standard may be prepared utilizing autodilution of the 20ppm standard on the autosampler. Prepare fresh each day of use.

8.9.1.2 Continuing Calibration Standards:

8.9.1.2.1 0.400ppm Low CCV: 4mL of 20ppm standard (Section 8.9.1.1.1) to 200mL with 0.2% Boric Acid solution (Section 8.8).

8.9.1.2.2 4.00ppm Hi CCV: 8mL of 100ppm standard (Section 8.9.1) to 200mL with 0.2% Boric Acid solution (Section 8.8).

8.10 Stock Standard, 1000ppm as TKN (for spike): Commercially prepared. Certificate of analysis is required

8.10.1 Intermediate spike Stock Standard, 200ppm as TKN: To a 100mL volumetric flask, add 20.0mL of Stock Standard (Section 8.10) and dilute to the mark with 0.2% Boric Acid solution (Section 8.8). Invert three times. Expires one month from date of preparation.

8.11 Stock Standard Solution, 1000ppm as NH_3 (for ICV only): Commercially prepared. Certificate of analysis is required. This must be from a different source than that used for Stock Standard (Section 8.9).

8.11.1 Initial Calibration Verification Standards (ICV):

8.11.1.1 Hi ICV, 10ppm: To a 100mL volumetric flask add 1mL of 1000ppm standard (Section 8.11). Dilute to the mark with 0.2% Boric Acid Solution (Section 8.8). Expires one month from date of preparation.

8.11.1.2 Hi ICV, 8.0ppm: To a 100mL volumetric flask add 0.8mL of 1000ppm standard (Section 8.11). Dilute to the mark with 0.2% Boric Acid Solution (Section 8.8). Expires one month from date of preparation.

8.11.1.3 Low ICV, 1.0ppm: To a 100mL volumetric flask add 10mL of 10ppm ICV (Section 8.11.1.1). Dilute to the mark with 0.2% Boric Acid Solution (Section 8.8). Expires one month from date of preparation.

8.12 Stock Standard Solution, 1000ppm as TKN (for LCS): Commercially prepared. Certificate of analysis is required. This must be from a different independent source than that used for Stock Standard (Section 8.10).

8.12.1 LCS solution, 200ppm as TKN: To a 100mL volumetric flask add 20mL of 1000ppm Stock Standard (Section 8.12) and dilute to the mark with DI water. Expires one month from date of preparation.

8.13 6N Sodium Hydroxide Solution : Dissolve 240g NaOH in distilled water and dilute to 1L. Expires six month from date of preparation.

9. Procedure

9.1 SET-UP

9.1.1 Clean 250mL Tecator tubes by rinsing twice with approximately 0.5mL of 6N NaOH solution and 100mL RO water. Rinse twice again with DI water.

9.1.2 Rinse glass tuttlecaps under the hood in a 1000mL beaker with approximately 500mL DI and 1.0 mL of 6N NaOH. Allow to sit in this solution until use.

9.2 Initial Calibration

Calibrate the Lachat ion analyzer according to manufacturer's instructions.

9.2.1 Calibration

Two boards are used to calibrate the Lachat instrument. Each curve has 7 calibration points. The correlation coefficient of each curve must be $\geq$ 0.995, otherwise re-calibration is necessary. Prepare standard curves by plotting the peak areas of standards processed through the manifold against NH_3-N concentrations in standards.

9.2.1.1 Channel 1 is used to generate a calibration curve on the low range from 0.00 – 2ppm.

9.2.1.2 Channel 2 is used to generate a calibration curve on the high range from 0 – 20ppm.

Alternative method: One board can be used to calibrate the Lachat instrument. Ten point calibration curve will be used with calibration standards 10.0, 8.0, 4.0, 2.0, 1.0, 0.4, 0.2, 0.1, 0.05 mg/l each and blank. The correlation coefficient must be $\geq$ 0.995, otherwise re-calibration is necessary. Prepare standard curves by plotting the peak areas of standards processed through the manifold against NH_3-N concentrations in standards

Calibration coefficient will be calculated using Lachat software. All calibration points are back calculated by Lachat software and should be within 10% from true concentration, except 2 lowest points of calibration curve. % recoveries for the low range will be wider, but shouldn't exceed 100% and correlation coefficient will not be worse than 0.995. The standards for the calibration curve are recalculated manually to prove the software calculations are within +/- 10% of the true concentrations.

9.2.2 Initial Calibration Verification (ICV)
Prior to sample analysis, an ICV is analyzed at 1.0ppm (Section 8.10.1.2) to verify the low calibration curve on Channel 1. Another ICV is analyzed at 10ppm (Section 8.10.1.1) to verify the high calibration curve on Channel 2. Both ICVs must yield results ± 10% of their true value, otherwise re-calibration is necessary.

Note: if instrument is calibrated using one board calibration, then both ICV's (Low and High), will be evaluated and high ICV will be 8.0 mg/l ICV standard (Section 8.11.1.2)

9.2.3 Initial Calibration Blank (ICB)
Following the ICV is the analysis of an ICB. The ICB consists of an aliquot of 0.2% Boric Acid (Section 8.8). Results must be less than < 0.05mg/L.

9.3 Standardization (Continuing Calibration Verification)

Analyze the following after every 10 samples and at the completion of analysis:

0.400ppm Low CCV, (Section 8.9.1.2.1)

4.0ppm Hi CCV, (Section 8.9.1.2.2)

Blank, 0.2% Boric Acid Solution. (Section 8.8)

9.4 Equipment Operation and Sample Analysis

9.4.1 Aqueous Sample Digestion: Add 50mL of homogenized sample or a portion diluted to 50mL with DI water, to pre-washed Tecator tubes that are numbered to correspond with the samples.

Soil/Solid Sample Digestion: Weigh 0.1g of homogenized soil/solid sample into dilu vial and record the weight in the laboratory notebook. Transfer to a pre-washed, pre-numbered Tecator tube and add 50mL of DI water.

In a similar manner, for each matrix, prepare the QC samples to be digested with the batch (refer to Sections 10.2.1, 10.3.1, 10.7 and 10.8)

Then add approximately 1g of black boiling chips to each tube. Move to hood before adding 10mL of Digestion Solution (Section 8.6) to each tube with a calibrated pipettor.

Rinse glass tuttlecaps with DI and place one onto the top of each Tecator tube. Place Tecator tube rack onto Tecator digestion block and heat to 380°C. Cook for approximately 2 hours to SO_3 fumes. The remaining mixture will be clear or pale yellow in color. Remove tube from digestion block and allow to cool to ~80 °C before adding DI to the 90mL mark on the tube.

9.4.2 Distillation: To minimize contamination, leave distillation apparatus assembled after steaming out and until just before starting sample distillation. Make the digestate alkaline by careful addition of 20mL of sodium hydroxide-thiosulfate solution (Section 8.7) without mixing. Do not mix until the digestion tube has been connected to the distillation apparatus. Connect the Tecator tube to the Tecator distillation unit's stopper as defined in the manual. Distill for 3 minutes 40 seconds as defined in the manual and collect distillate in 20mL boric acid solution (Section 8.4). Distill at maximum rate with the tip of the delivery tube below the surface of boric acid receiving solution. Collect at least 90mL distillate. Dilute to 150mL with DI water. Refrigerate at 0-4ºC if Lachat analysis is delayed.

9.4.3 Ammonia analysis of distillate: Follow the manufacturer's instructions for the proper operation of the ion analyzer. The following are specific notes for this analysis.

Sample throughput:	90 samples/hr; 40 sec/sample
Pump speed:	35
Cycle period:	40 s
Inject to start of peak period:	25 s
Inject to end of peak period:	63 s

9.4.4 System Notes:

9.4.4.1 Allow 15 minutes for heating unit to warm up to 60ºC.

9.4.4.2 System IV GAIN: 175 x 1.

9.4.4.3 If standards are not distilled, samples should be multiplied by procedure dilution (final volume 150mL) divided by initial volume.

9.4.4.4 If baseline drifts, peaks are too wide, or other problems with precision arise, clean the manifold by the following procedure:

9.4.4.4.1 Place all reagent lines in deionized water and pump to clear reagents (2-5 minutes).

9.4.4.4.2 Place reagent lines and carrier in 1M hydrochloric acid (1 volume concentrated HCl added to 11 volumes of deionized water) and pump for several minutes.

9.4.4.4.3 Place all lines in deionized water and pump until the HCl is thoroughly washed out.

9.4.4.4.4 Resume pumping reagents.

9.4.4.5 If samples are colored or are suspected to show a background absorbance, this interference should be subtracted. This can be done by diluting or by the following procedure:

9.4.4.5.1 Calibrate the system in the normal manner.

9.4.4.5.2 Disable the check standard or DQM features and analyze the samples.

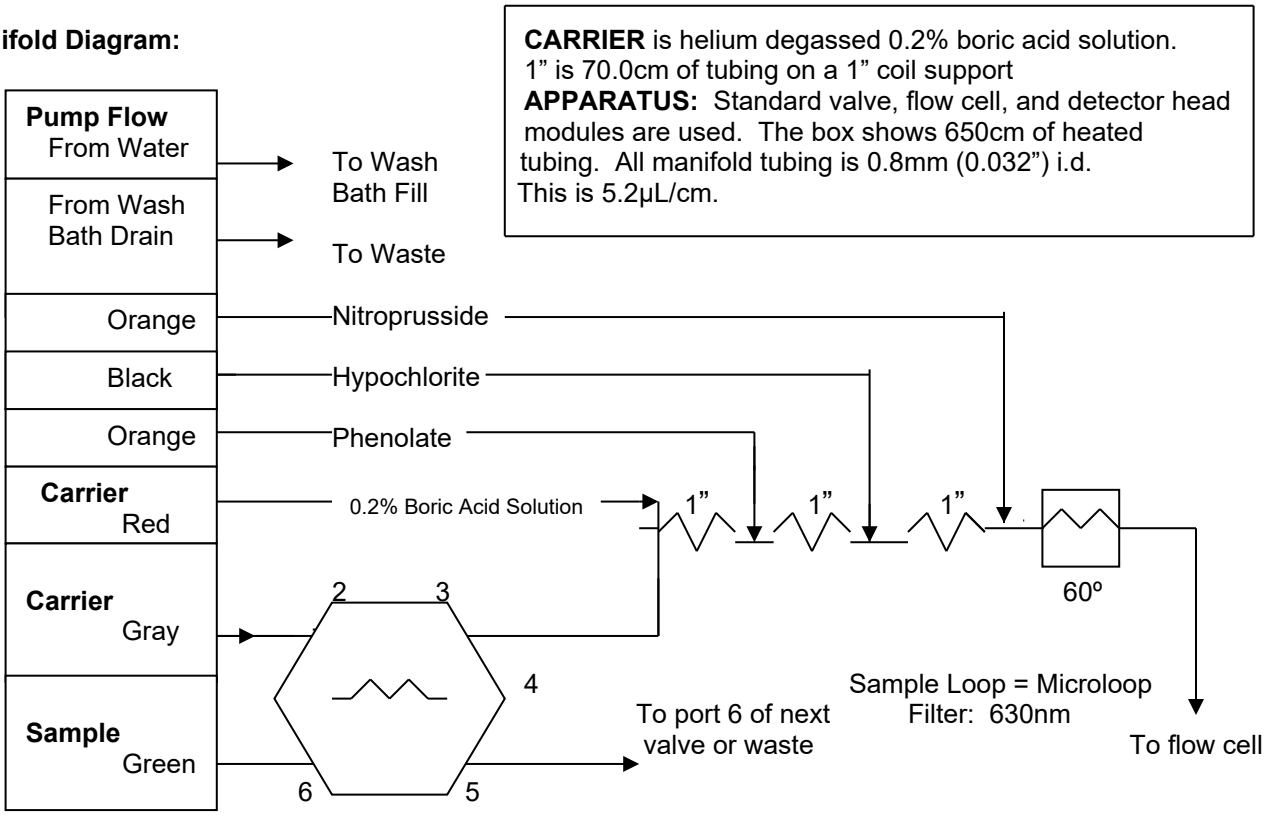
9.4.4.5.3 Place reagent and carrier lines in DI water and allow the baseline to stabilize.

9.4.4.5.4 Inject samples again without recalibrating.

9.4.4.5.5 Subtract the "background" concentration from the original concentration to give the corrected concentration.

Original Concentration – Background Concentration = Corrected Concentration.

Manifold Diagram:



9.5 Preventative Maintenance

9.5.1 All lines are flushed at the end of each run.

9.5.2 All equipment is kept clean.

9.6 Calculations

Prepare standard curves by plotting peak areas of standards processed through the manifold against NH_3 -N concentrations in standards. Compute sample NH_3 -N concentration by comparing sample peak areas with standard curve, as determined by the Lachat instrument software.

9.6.1 If the sample has a concentration of less than 2ppm, calculate results by using the low curve generated on Channel 1.

9.6.2 If the sample concentration is greater than 2ppm, calculate results by using the high curve generated on Channel 2.

Alternative method: use only one Channel and calculate all results from one channel.

To compute final results for aqueous samples, multiply the direct reading by the dilution factor based on the initial preparation volume.

TKN mg/L = mg/L direct reading x dilution factor

To compute results for soil/solid samples, multiply the direct reading by the extraction final volume (150mL) and then divide by the weight of the sample used for extraction (Section 9.4.1), and multiply by a dilution factor as necessary.

$$\text{TKN mg/Kg} = \left[\frac{(\text{mg/L direct reading}) \times \text{extraction final volume (150mL)}}{\text{Sample weight (g)}} \right] \times \text{dilution factor}$$

10. Quality Control and Data Assessment

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method. When results of sample spikes indicate atypical method performance, a calibration verification standard is used to confirm the measurements were performed in an in-control mode of operation.

10.1 Demonstration of Capability

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method. Each time a method modification is made, the analyst is required to repeat the procedure.

When one or more of the parameters tested fail at least one of the acceptance criteria, the analyst must locate and correct the source of the problem and repeat the test for failed parameters of the method.

Repeated failure confirms a general problem with the measurement system or analytical technique of the analyst. If the failure repeats, locate and correct the source of the problem and repeat the test for all parameters listed in the method.

10.2 Blank

10.2.1 The Distillation Blank is 50mL of DI. Distill one per batch of 20 samples or less. Subtract any blank greater than 0.3mg/L from all samples and QC.

10.2.2 The Analytical Blank (ICB) for the Lachat analysis is not distilled and is 0.2% Boric Acid Solution (Section 8.8).

The ICB is run after the initial calibration verification standards (ICV) and another is run after the continuing calibration standards (CCV).

10.3 Laboratory Control Samples (LCS)

10.3.1 Distillation: Distill a Low and a Hi LCS with each batch of 20 samples or less. The results from the Hi LCS are reported for the batch. The Low LCS is used to verify the low curve, but is not reported.

10.3.1.1 Low 4.0ppm LCS: Add 1mL of 200ppm LCS solution (Section 8.10.2) to 50 mL DI. This is used for the Low 0 - 6 ppm curve.

10.3.1.2 Hi 40ppm LCS: Add 10mL of 200ppm LCS solution (Section 8.10.2) to 50 mL DI. This is used for the Hi 0 - 60 ppm curve.

10.4 Initial Calibration Verification Standards

10.4.1 Lachat Analysis: The ICVs are not distilled. Analyze the following after calibration of the Lachat instrument. Recoveries must be within 10% of the true value, otherwise recalibration of the instrument is necessary.

10.4.1.1 Low ICV, 1.0ppm (Section 8.10.1.2)

10.4.1.2 Hi ICV, 10ppm (Section 8.10.1.1); **HI ICV** will be 8.0 ppm (Section 8.10.1.2) in case of one board calibration.

10.5 Continuing Calibration Verification Standards

10.5.1 Lachat Analysis: The CCVs are not distilled. Analyze the following after every ten samples and at the completion of analysis. Recoveries must be within 10% of the true value.

If recoveries fall outside of this range, the cause for the failure is determined and corrected, and the instrument is recalibrated. All samples that were analyzed since the last CCV that was within range are reanalyzed.

10.5.1.1 0.4ppm Low CCV (Section 8.9.1.2.1)

10.5.1.2 4.0ppm Hi CCV (Section 8.9.1.2.2)

10.6 Interference Check Standards

None.

10.7 Matrix Spike

One per batch of 20 samples or less. Prior to distillation, add 2mL of 200ppm Spiking Solution (Section 8.10.1) per 50mL of sample.

10.8 Duplicates

Distill one duplicate sample per batch of 20 samples or less.

10.9 Control Limits

The laboratory maintains performance records to document the quality of data that is generated. Method accuracy for samples is assessed and records maintained.

Control limits for the method parameters are generated by the QC staff. The control limits are calculated based on in-house performance data. The limits are compared to the control limits found in the reference method.

10.10 Analytical Sequences

10.10.1 Distillation Sequence:

Low 1.0ppm ICV
Hi 10ppm ICV or 8.0 ppm ICV
IC Blank
Samples
DQM : Run after every 10 samples and at completion of analysis
Rinse reagent lines with 1M HCl for 5 to 10 minutes
DI water rinse for 5 to 10 minutes
Air rinse 5 to 10 minutes.
Shut-Down.

11. Method Performance

11.1 Method Detection Limit Study (MDL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the MDL, LOD, and/or LOQ as outlined in Alpha SOP/1732 These studies performed by the laboratory are maintained on file for review.

The quarterly method reporting limit (MRL) verification requirement is satisfied by the quarterly LOQ analysis, as per SOP/1732.

11.2 Demonstration of Capability Studies

Refer to Alpha SOP/1734, 1739 for further information regarding IDC/DOC Generation.

11.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

11.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

12. Corrective Actions

Holding time exceedence, improper preservation and observed sample headspace are noted on the nonconformance report form.

Perform routine preventative maintenance following manufacturer's specification. Record all maintenance in the instrument logbook.

Review of standards, blanks and standard response for acceptable performance occurs for each batch of samples. Record any trends or unusual performance on a nonconformance action form.

If the ICV/CCV or LCS recovery of any parameter falls outside the designated acceptance range, the laboratory performance for that parameter is judged to be out of control, and the problem must be immediately identified and corrected. The analytical result for that parameter in the unspiked samples is suspect and is only reported for regulatory compliance purposes with the appropriate nonconformance action form. Immediate corrective action includes reanalyzing all affected samples by using any retained sample before the expiration of the holding time.

13. Pollution Prevention

See Chemical Hygiene Plan for pollution prevention operations.

14. Waste Management

See Chemical Hygiene Plan SOP/1728 for waste handling and disposal.

NOTE: TKN Lachat waste contains Mercury and must be deposited into TKN/Lachat waste stream in the Waste Room.

Oil and Grease

Total Petroleum Hydrocarbons by

n-Hexane Extraction and Gravimetric Method

References: EPA 9071B: N-Hexane Extractable Material (HEM; Oil and Grease) and Silica Gel Treated N-Hexane Extractable Material (SGTHEM; Non-polar Material) by Extraction and Gravimetry. April 1998.

EPA1664 A: N-Hexane Extractable Material (HEM; Oil and Grease) and Silica Gel Treated N-Hexane Extractable Material (SGTHEM; Non-polar Material) by Extraction and Gravimetry. EPA-821-R-98-002. February 1999.

1. Scope and Application

Matrices: This method, as outlined, is limited to soils, sludges, sediment, and solid samples.

Definitions: See Alpha Analytical Quality Manual Appendix A

This method is for the determination of n-hexane extractable material (HEM) in soil, sediment, sludges, and other solid material amenable to chemical drying and solvent extraction with n-hexane. Extractable materials that may be determined are relatively non-volatile hydrocarbons, vegetable oils, animal fats, waxes, soaps, greases and related materials. Method 9071 employs n-hexane as the extraction solvent with Soxhlet extraction.

This method is not applicable to measurement of materials that volatilize at temperatures below approximately 85ºC. Petroleum fuels from gasoline through #2 fuel oil may be partially lost in the solvent removal operation.

Some crude oils and heavy fuel oils contain a significant percentage of materials that are not soluble in n-hexane. Accordingly, recoveries of these materials may be low.

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one of the following laboratory personnel before performing the modification: Area Supervisor, Laboratory Director, or Quality Assurance Officer.

2. Summary of Method

A representative portion is mixed with anhydrous sodium sulfate to dry the sample.

The sample, after drying, is extracted with n-hexane using a Soxhlet apparatus. The n-hexane extract is then distilled from the extract and the HEM is desiccated and weighed.

A separate portion is evaluated for percent solids to make a dry-weight HEM concentration.

The amount of oil and grease is calculated gravimetrically.

For TPH-1664 determination, an amount of silica gel proportionate to the oil and grease result is added to the solution containing the redissolved oil and grease. The solution is then stirred and filtered through sodium sulfate. The solution is then dried and the amount of TPH is calculated gravimetrically.

2.1 Method Modifications from Reference

The laboratory does not use magnesium sulfate monohydrate to dry acidified samples. Samples are used as they are received. In place of evaporating the extract in a waterbath, the use of a Speedvap 9000 has been substituted. MDL Studies utilizing the Speedvap 9000 show no quantitative difference with the boil-down in a waterbath. Using Speedvap technology, the laboratory proved that samples have constant weight during one drying cycle; laboratory doesn't repeat drying, cooling, desiccating and weighing process multiple times

3. Reporting Limits

The reporting limit is 200 mg/Kg when analyzing a 10 g sample.

4. Interferences

4.1 Instrumental

Improperly prepared glassware may result in interferences.

Sodium sulfate may cause interferences, if it is powder form instead of granular.

4.2 Parameters

Samples containing particulates or detergents may cause interferences. Smaller sample volumes may need to be collected in these cases.

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material data handling sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

The Hexane used in this method is hazardous, as well as flammable. This chemical should be used under a laboratory hood and stored in a flammables cabinet.

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

A minimum 100 g of sample should be collected using a metal spatula, spoon or equivalent device. Samples should be collected into a pre-cleaned wide-mouth glass container fitted with a TFE-lined screw cap.

6.2 Sample Preservation

Not applicable.

6.3 Sample Shipping

No special shipping requirements.

6.4 Sample Handling

A holding time has not been established, but it is recommended to analyze as soon as possible.

7. Equipment and Supplies

7.1 Soxhlet extraction apparatus

7.2 Heating mantle- explosion proof, with temperature control

7.3 Boiling flask- 125mL or appropriate size

7.4 Chiller

7.5 Speedvap Evaporator: With spark-proof pump.

7.6 Aluminum Weighing Dishes: Disposable.

7.7 Paper extraction thimble for Soxhlet apparatus.

7.8 Fume Hood

7.9 Desiccator

7.10 Analytical Balance: Capable or weighing to 0.1mg.

7.11 Glass wool

7.12 Porcelain mortar and pestle

7.13 Pipets: 5mL and 10 mL

7.14 Erlenmeyer flasks: 125mL, 250mL

7.15 Glass fiber filter paper – Whatman No. 40 or equivalent

7.16 Boiling chips – Silicon carbide or fluoropolymer

7.17 Glass funnel

7.18 pH Paper: Range 1 – 12 pH units

7.19 Magnetic Stirring Bar

7.20 Filter Paper

7.21 Stirring Plate

8. Reagents and Standards

8.1 Hexadecane / Stearic Acid Stock 4mg/mL and 8 mg/mL (LCS Standard and Spiking Solution): Commercially prepared and purchased. (Available from Environmental Express and Horizon.) Maintain capped and stored in the dark at room temperature. Expires upon manufacturer's specified date

NOTE: The LCS Standard must be from a different source than that used for the Spiking Solution.

8.2 Acetone: ACS residue less than 1mg/L. Store in flammables cabinet. Expires upon manufacturer's specified date.

8.3 Hydrochloric Acid: HCl, 1:1. Store in flammables cabinet. Expires upon manufacturer's specified date.

8.4 n-Hexane: 85% purity, 99.0% minimum saturated C_6 isomers, residue less than 1mg/L. Boiling point, 69°C. Store in flammables cabinet. Expires upon manufacturer's specified date.

8.5 Sodium Sulfate: Na_2SO_4, anhydrous granular crystals. Store in flammables cabinet. Expires upon manufacturer's specified date.

8.6 Magnesium sulfate monohydrate: Prepare $MgSO_4 \cdot H_20$ by spreading a thin layer in a dish and drying in an oven at 150°C overnight. Store in a tightly sealed glass container until used.

8.7 Silica Gel: JT Baker 60-200 mesh, chromatography grade. Activated by baking at 140 °C for a minimum of 14 hours in a shallow tray. Stored in closed glass containers, in a desiccator. All references to silica gel in this method refer to this prepared reagent.

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

9.1 Blank(s)

Analyze one Blank per batch of 20 samples or less. The method blank must be <40 mg/Kg. If the method blank does not meet this criterion, the entire batch is suspect and must be re-extracted.

9.2 Laboratory Control Sample (LCS)

Analyze one LCS per batch of 20 samples or less. The percent recovery must be within the acceptance range of 79-114% for oil and grease, and 64 – 132% for TPH, per the reference method. If this criterion is not met the LCS is reanalyzed. If failure continues a narrative is submitted with the data for inclusion on the Client report.

9.3 Initial Calibration Verification (ICV)

Not applicable.

9.4 Continuing Calibration Verification (CCV)

Not applicable.

9.5 Matrix Spike

Analyze one matrix spike sample per batch of 20 samples or less. A matrix spike concentration must be approximately 1-5 times greater than the concentration of the sample being spiked. The percent recovery must be within the acceptance range of 79% to 114% for oil and grease, and 64 – 132% for TPH, per the reference method. If the percent recovery is outside of these limits, a narrative is submitted with the data for inclusion on the Client report.

9.6 Laboratory Duplicate

Analyze one sample in duplicate per batch of 20 samples or less. The relative difference must be equal or less than 18% for oil and grease, and equal or less than 34% for TPH. If the %RPD is outside of this criterion, a narrative is submitted with the data for inclusion on the Client report.

9.7 Method-specific Quality Control Samples

Not applicable.

9.8 Method Sequence

1. Weigh out the sample and air dry overnight.
2. Blend with sodium sulfate and add to extraction thimble.
3. Extract in Soxhlet apparatus for 4 hours.
4. Filter the extract into a beaker and rinse flask with solvent.
5. Pour the sample into a weighed aluminum dish.
6. Evaporate the sample using the Speedvap 9000.
7. Place the aluminum dishes in a desiccator for 10 minutes.
8. Re-weigh the aluminum dishes.
9. Calculate sample results.
10. TPH-1664
    - Clean-up the sample and QC sample extracts with silica gel.
    - Repeat steps 4 – 8.

10. Procedure

10.1 Equipment Set-up

10.1.1 Clean all glassware.

10.1.2 Turn on the Soxhlet apparatus. Then turn on the chiller.

10.1.3 Check fittings to ensure tightness.

10.1.4 Add boiling chips to boiling flasks containing 90 mL of n-hexane.

10.2 Initial Calibration

Not applicable.

10.3 Equipment Operation and Sample Processing

10.3.1 Weigh out 10g of sample and dry overnight.

10.3.2 Mix with 10g of sodium sulfate to remove any remaining liquid.

10.3.3 Transfer homogenized mixture into an extraction thimble and than into the Soxhlet.

10.3.4 Preparation of QC Samples:

10.3.4.1 **Blank:** Add 10g of sodium sulfate to a clean extraction thimble.

10.3.4.2 **LCS:** Add 10g of sodium sulfate to a clean extraction thimble. Slowly add 5mL of LCS Stock Standard (Section 8.1), by touching the pipet tip to the side of the Soxhlet. Release the contents of the pipet very slowly. (For best recoveries use a warmed LCS Solution.)

10.3.4.3 **Matrix Spike:** To a second aliquot of a chosen sample, slowly add 10mL of the Spiking Solution (Section 8.1) directly onto the sample. Use the same procedure described above in Section 10.3.4.2.

10.3.5 Connect the Soxhlet to the cold fingers and boiling flasks with the sample.

10.3.6 Heat the samples until a cycle rate of 20 cycles/hr is obtained and extract for 4 hours

10.3.7 At the end of the 4 hour extraction period, filter the hexane phase through a filter funnel lined with filter paper that contains sodium sulfate, and into an Erlenmeyer flask. Rinse the boiling flask and sodium sulfate with n-hexane and add to the flask. Rinse the filter funnel with hexane.

NOTE: Sometimes a slightly cloudy white layer will appear between the hexane layer and the colored water layer. Do not transfer this layer to the weighing dish.

10.3.8 Pre-weigh an empty aluminum weighing dish to the nearest 0.0001g. Record weight in the Laboratory Notebook. Transfer the filtered hexane sample into the weighed aluminum dish.

10.3.9 Turn Speedvap 9000. (Switch is on back of instrument.) Turn dial all the way to the right. Push <Release Cover> button and put weighing dishes containing the extracted oil and grease in hexane in the Speedvap.

10.3.10 Allow the evaporator to continue to run until the dish reaches dryness. This takes about 8-10 minutes. **Do Not Over-dry. Do this in a fume hood.**

10.3.11 Turn off Speedvap using button on back. Place the dishes in a desiccator for about 10 minutes.

10.3.12 Re-weigh the aluminum dishes and record weight in the Laboratory Notebook.

Note 1: Record lot numbers for SPE disks, reagents and solvents used for extraction in Laboratory Notebook.

Note 2: On each day of use, the laboratory balances are verified to be accurate at weights that bracket the weight of use. The balance verification performed both before and after a sample batch must pass within the acceptance criteria outlined in the Balance Calibration Verification SOP (SOP ID 1730). If the balance verification is outside of acceptance criteria, the problem must be corrected and the sample extracts re-weighed.

10.3.13 Clean-up Procedure for TPH-1664 Analysis

Using Hexane, rinse the oil and grease from the aluminum dish into a 250mL Erlenmeyer flask. Add a stir bar and silica gel. The amount of silica gel is dependent upon the concentration of oil and grease determined in the sample. For every 100ppm of oil and grease, add 3 grams of silica gel. Place the flask on the stirplate and stir for 5 minutes. Repeat Sections 10.3.7 – 10.3.12.

NOTE: All QC samples in the batch must be treated in the same manner as samples. Therefore, if TPH-1664 is to be determined, the Blank, LCS, matrix spike and duplicate must also go through the TPH-1664 clean-up procedure along with the samples.

10.4 Continuing Calibration

Not applicable.

10.5 Preventive Maintenance

Preventative maintenance is conducted per the manufacturer's instructions. All maintenance is recorded in the Instrument Maintenance Logbook. Rinsing of the lines with a 50/50 Acetone and Hexane mixture is done daily to keep the lines clean.

11. Data Evaluation, Calculations and Reporting

$$\text{mgHEM / Kg} = \frac{\text{Final weight of dish – tared weight}}{\text{weight}} \times 1000$$

Where: weight = dry weight of sample in grams

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

Holding time exceedence and improper preservation are noted on the nonconformance report form.

Perform routine preventative maintenance following manufacturer's specification. Record all maintenance in the instrument logbook.

Review of standards, blanks and standard response for acceptable performance occurs for each batch of samples. Record any trends or unusual performance on a nonconformance action form.

If the LCS recovery falls outside the designated acceptance range, the laboratory performance is judged to be out of control, and the problem must be immediately identified and corrected. Immediate corrective action includes reanalyzing all affected samples by using any retained sample before the expiration of the holding time.

13. Method Performance

13.1 Method Detection Limit Study (MDL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the MDL, LOD, and/or LOQ as outlined in Alpha SOP/1732. These studies performed by the laboratory are maintained on file for review.

13.2 Demonstration of Capability Studies

Refer to Alpha SOP/1739 for further information regarding IDC/DOC Generation.

13.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

14. Pollution Prevention and Waste Management

Refer to Alpha's Chemical Hygiene Plan and Waste Management and Disposal SOP for further pollution prevention and waste management information.

15. Referenced Documents

Organochlorine Pesticides
By Capillary Column Gas Chromatography

Reference Method No.: **Method 8081B**

References: SW-846, Test Methods for Evaluating Solid Waste: Physical/Chemical Methods, EPA SW-846, Update IV, 2007.

Mass DEP CAM QC Requirements and Performance Standards for the Analysis of Chlorinated Pesticides by Gas Chromatography (GC), Revision 2, April 12, 2024.

SW-846 Pesticides by 8081, State of Connecticut Department of Environmental Protection Reasonable Confidence Protocol (RCP), Version 3.0, May 2024

1. Scope and Application

Method 8081B is used to determine the concentrations of various organochlorine pesticides in extracts from solid and liquid matrices. This SOP details the analysis for these compounds using fused-silica, open-tubular, capillary columns with electron capture detectors (ECD).

Matrices: Extracts from solid and liquid matrices.

Definitions: See Pace Analytical Quality Manual

Regulatory Parameter List: The compounds listed below are determined by this method:

Parameter	CAS
Aldrin	309-00-2
Alpha-BHC	319-84-6
Beta-BHC	319-85-7
Gamma-BHC (Lindane)	58-89-9
Delta-BHC	319-86-8
Alpha-chlordane	5103-71-9
Gamma-chlordane	5103-74-2
4,4'-DDD	72-54-8
4,4'-DDE	72-55-9
4,4'-DDT	50-29-3
Dieldrin	60-57-1
Endosulfan I	959-98-8
Endosulfan II	33213-65-9
Endosulfan Sulfate	1031-07-8
Endrin	72-20-8
Endrin Aldehyde	7421-93-4
Endrin Ketone	53494-70-5
Heptachlor	76-44-8
Heptachlor Epoxide	1024-57-3
Methoxychlor	72-43-5
Toxaphene	8001-35-2
Chlordane	57-74-9
Alachlor [+]	15972-60-8
Hexachlorobenzene [++]	118-74-1

[+] CT-RCP only compound [++] MCP/CT only compound

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one of the following laboratory personnel before performing the modification: Area Supervisor, Laboratory Services Manager, Laboratory Director, or Quality Assurance Officer

This method is restricted to use by or under the supervision of analysts experienced in the operation of the gas chromatograph (GC) and in the interpretation of gas chromatograms. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability (see section 13), analyzing a proficiency test sample and completing the record of training.

After initial demonstration, ongoing demonstration is based on acceptable laboratory performance of at least a quarterly laboratory control sample or acceptable performance from an annual proficiency test sample. A major modification to this procedure requires demonstration of performance. The identification of major method modification requiring performance demonstration is directed by the QA Officer and/or Laboratory Director on a case-by-case basis.

2. Summary of Method

A measured volume or weight of sample (for liquids: 100mL, for solids: 15g) is extracted using the appropriate matrix-specific sample extraction technique.

Liquid samples are extracted at neutral pH with methylene chloride using Method 3510C (separatory funnel), or other appropriate technique.

Solid samples are extracted with methylene chloride: acetone (1:1) using Method 3540C (Soxhlet), Method 3546 (microwave extraction), or other appropriate technique.

Wipe samples are extracted with methylene chloride: acetone (1:1) using Method 3540C (Soxhlet) or other appropriate technique.

Oil samples are diluted with hexane following the procedure outlined in the extraction SOP.

After cleanup, the extract is analyzed by injecting a 1µL sample into a gas chromatograph equipped with narrow- or wide-bore fused silica capillary columns and electron capture (GC/ECD) detectors.

2.1 Method Modifications from Reference

None.

3. Reporting Limits

Table 1 lists our routine reporting limits.

4. Interferences

4.1 Only high purity gases are used in the GC system to eliminate this source of possible contamination. Both the hydrogen (carrier gas – 99.999%) and argon-methane (detector make-up gas) are certified by the gas supplier.

4.2 Preventive instrument maintenance is performed routinely, and whenever highly contaminated extracts are analyzed that could result in chromatographic interferences or result in degradation of system performance. Section 9.5 details the maintenance steps.

4.3 Glassware must be scrupulously cleaned. This procedure is detailed in the extraction SOPs. Store dry glassware in a clean environment.

4.4 All solvents used are pesticide grade or equivalent, and reagents are purchased as certified contaminant free. All of these materials are routinely determined to be free of interferences by analysis of extraction blanks with every extraction batch performed.

4.5 Certain compounds (i.e. phthalates) can be extracted from the sample matrix and be detected by the ECD that could possibly result in false positive results or complicate the data interpretation. The use of the cleanup procedures detailed in the extraction SOPs minimize these possible interferences. Analyst experience is also crucial in making compound determinations.

4.6 Interferences co-extracted from the samples will vary considerably from waste to waste. While general cleanup techniques are referenced or provided as part of the method, unique samples may require additional cleanup approaches to achieve desired degrees of discrimination and quantitation.

4.7 Interferences by phthalate esters introduced during sample preparation can pose a major problem in pesticide determinations.

4.7.1 Common flexible plastics contain varying amounts of phthalate esters which are easily extracted or leached from such materials during laboratory operations.

4.7.2 Cross-contamination of clean glassware routinely occurs when plastics are handled during extraction steps, especially when solvent-wetted surfaces are handled.

4.7.3 Interferences from phthalate esters are minimized by avoiding contact with any plastic materials and checking all solvents and reagents for phthalate contamination.

4.8 The presence of elemental sulfur will result in broad peaks that interfere with the detection of early-eluting organochlorine pesticides. Sulfur contamination is often seen in sediment and some soil samples.

4.9 Other halogenated pesticides or industrial chemicals may interfere with the analysis of pesticides. Coeluting chlorophenols are eliminated by using Method 3620B (Florisil).

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material data handling sheets is available to all personnel involved in the chemical analysis. The following analytes covered by this method have been tentatively classified as known or suspected human or mammalian carcinogens: 4,4'-DDT, 4,4'-

DDD, and BHCs. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

5.1 Lab coats, safety glasses, and gloves must be worn when handling samples, extracts, standards or solvents.

5.2 All solvent and extract transfers must be handled in the vented bench area in the GC laboratory.

5.3 All stock standards, working standards, and vialed sample extracts must be placed into the waste bucket in the lab, for future disposal by the Hazardous Waste Manager. The container must be labeled properly with hazard warning labels indicating the container contents.

5.4 Bottles containing flammable solvents must be stored in the flammables cabinet.

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

Aqueous samples are collected in either two 500 ml amber glass jars or two 1L amber glass jars with teflon-lined lids. Solid samples are collected in one 250 mL wide-mouth glass jar with a teflon-lined lid. All containers are purchased pre-cleaned and certified from commercial vendors.

6.2 Sample Preservation

Both aqueous and solid samples are then preserved by packing in coolers with ice or ice packs, to maintain a temperature of 4 ± 2^{o} C. Upon receipt at the laboratory, the samples are transferred into sample storage refrigerators to maintain at a temperature of 4 ± 2^{o} C.

6.3 Sample Shipping

No special shipping requirements.

6.4 Sample Handling

Aqueous samples must be extracted within 7 days of sample collection, solid samples within 14 days of collection. Once extracted, the samples must be analyzed within 40 days of the extraction date.

7. Equipment and Supplies

7.1 Gas Chromatograph, Hewlett Packard 6890 (or equivalent): An analytical system completes with gas chromatograph configured for split-splitless injection and all required accessories including syringes, analytical columns, gases, electron capture detectors (ECD), and data system.

7.1.1 Data System: A computer system is interfaced to the GC for collection of data. Data acquisition is performed using Agilent Technologies GC ChemStation (Rev. A.10.02 [1757]).

7.2 GC Columns: Pace utilizes dual-column analyses. The dual-column approach involves either a single injection that is split between two columns that are mounted in a single gas chromatograph, or dual injections of the split extract on a single GC equipped with two

columns. Typical column pairs used are listed below. Other columns may be used as long as method performance criteria can be met.

7.2.1 Column pair 1

30m x 0.32mm ID fused silica capillary column (RTX-clpesticide), 0.32µm film thickness.

30m x 0.32mm ID fused silica capillary column (RTX-clpesticideII) 0.25µm film thickness.

7.2.2 Column pair 2

30m x 0.32mm ID fused silica capillary column (STX-clpesticide), 0.32µm film thickness.

30m x 0.32mm ID fused silica capillary column (STX-clpesticideII) 0.25µm film thickness.

7.3 Guard Column: Cat. #10027 from Restek or equivalent: 5m, 0.32mm

7.4 Gooseneck splitless injection liner: Cat. #23303 from Restek or equivalent

7.5 Universal "Y" Press-tight tee split: Cat. #20406 from Restek or equivalent **/ Siltek MXT Connector:**

7.6 Class "A" Volumetric Flasks: 10mL, 25mL, 50mL, 100mL, 200mL, and 2000mL, for the preparation of standards.

7.7 Microsyringes/Wiretrol syringes: 10 µL – 1000 µL

7.8 Disposable Borosilicate Pipets

7.9 Vials: 2 mL clear glass, crimp-top and screw-cap.

8. Reagents and Standards

Reagent grade or pesticide grade chemicals are used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. Other grades may be used, provided it is first ascertained that the reagent is of sufficient high purity to permit its use without lessening the accuracy of the determination.

NOTE: Store the standard solutions (stock, composite, calibration, internal, and surrogate) at 4 ± 2°C in Teflon(R)-sealed containers in the dark. When a lot of standards is prepared, aliquots of that lot are stored in individual small vials. All stock standard solutions must be replaced after one year or sooner if routine QC tests indicate a problem. All other standard solutions must be replaced after six months or sooner if routine QC indicates a problem.

8.1 n-Hexane: Pesticide quality or equivalent.

8.2 Acetone: Pesticide quality or equivalent.

8.3 Methylene chloride: Pesticide quality or equivalent.

8.4 Organic-free Reagent Water: All references to water in this method refer to organic-free reagent water from Alpha's RO water treatment system.

8.5 Stock Standard Solutions: All stock standard solutions are purchased from commercial vendors as ampulated certified solutions. When an ampulated stock solution is opened, it is transferred to a labeled amber screw-cap vial. The expiration date of the stock solution is either the vendor specified expiration date, or 6 months from the date the ampule was opened, whichever is sooner. Typical stock standard concentrations are listed in Table 2.

8.6 Calibration Standards: Calibration standards are prepared volumetrically by diluting the appropriate stock standard(s) with hexane. Calibration standards expire 6 months from the date of preparation, or on the earliest expiration date of any of the stock solutions used to prepare the calibration standard. Calibrations are typically performed at 11 concentration levels for individual pesticides, Chlordane and Toxaphene; concentrations for all levels are listed in Table 2. Below are suggested procedures for preparation of individual pesticides (Sec. 8.6.1), Chlordane (Sec. 8.6.2), and Toxaphene (Sec. 8.6.3) initial calibration standards.

8.6.1 Preparation of individual pesticides initial calibration standards;

(syringes needed: *100µL [A], 500µL [B], 1000µL [C]*)
(solvent: *Hexane)*
(glassware: *9x10mL, 2x25mL, 1x50mL, 2x100mL, volumetric flasks*)

ICAL (Initial Calibration) STOCK #1: *2000µg/L; 25mL*
50µL[A] of AccuStandard M-8081-SC (Pesticides mix; 1000µg/mL)
250µL[B] of AccuStandard CLP-032-R (TCMX, Deca; 200µg/mL)
500µL[B] of AccuStandard P-102S (Alachlor; 100µg/mL)
500µL[B] of AccuStandard APP-9-112 (Hexachlorobenzene; 100µg/mL)

ICAL STOCK #2 (=LEVEL 10)**:** *200µg/L; 25mL.*
2500µL[B] of STOCK #1
…..

LEVEL 1, 0.5 µg/L:	25µL[A] of ICAL STOCK #2, 10mL
LEVEL 2, 1.0 µg/L:	50µL[A] of ICAL STOCK #2, 10mL
LEVEL 3, 2.0 µg/L:	100µL[A] of ICAL STOCK #2, 10mL
LEVEL 4, 3.0 µg/L:	150µL[B] of ICAL STOCK #2, 10mL
LEVEL 5, 4.0 µg/L:	200µL[B] of ICAL STOCK #2, 10mL
LEVEL 6, 5.0 µg/L:	250µL[B] of ICAL STOCK #2, 10mL
LEVEL 7, 10 µg/L:	500µL[B] of ICAL STOCK #2, 10mL
LEVEL 8, 50 µg/L:	2500µL[C] of ICAL STOCK #2, 10mL
LEVEL 9, 100 µg/L:	5000µL[C] of ICAL STOCK #2, 10mL
LEVEL 10, 200 µg/L:	2500µL[C] of ICAL STOCK #1, 25mL
LEVEL 11, 400 µg/L:	2000µL[C] of ICAL STOCK #1, 10mL

ICV (Initial Calibration Verification) STOCK #1: *2000µg/L; 100mL*
1000µL[C] of Restek 579104 (Custom Pesticides Mix; 200µg/mL)

ICV STOCK #2: *1000µg/L; 50mL*
250µL[B] of Agilent ISM-320-1 (TCMX, Deca; 200µg/mL)
…..

ICV, 50 µg/L:	2500µL[C] of ICV STOCK #1 with 5000µL[C] of ICV STOCK #2, 100mL

8.6.2 Preparation of Chlordane initial calibration standards:

(syringes needed: *100µL [A], 500µL [B], 1000µL [C]*)
(solvent: *Hexane)*
(glassware: *11x10mL, 1x25mL, 1x50mL, volumetric flasks*)

ICAL STOCK #1: *50µg/mL (Chlordane);10mL*
100µL[A] of Agilent EPA-1086-1 (Chlordane Standard; 5000µg/mL)

ICAL STOCK #2 (=LEVEL 9)**:** *2000µg/L; 25mL.*
1000µL[C] of STOCK #1

LEVEL 1, 2µg/L:	10µL[A] of ICAL STOCK #2, 10mL
LEVEL 2, 5µg/L:	25µL[A] of ICAL STOCK #2, 10mL
LEVEL 3, 10µg/L:	50µL[A] of ICAL STOCK #2, 10mL
LEVEL 4, 20µg/L:	100µL[A] of ICAL STOCK #2, 10mL
LEVEL 5, 100µg/L:	500µL[B] of ICAL STOCK #2, 10mL
LEVEL 6, 250µg/L:	1250µL[B] of ICAL STOCK #2, 10mL
LEVEL 7, 500µg/L:	2500µL[C] of ICAL STOCK #2, 10mL
LEVEL 8, 1000µg/L:	5000µL[C] of ICAL STOCK #2, 10mL
LEVEL 9, 2000µg/L:	1000µL[C] of ICAL STOCK #1, 25mL
LEVEL 10, 5000µg/L:	1000µL[C] of ICAL STOCK #1, 10mL

ICV STOCK: *50µg/mL; 10mL*
500µL[B] of Restek 32021 (Chlordane Standard; 1000µg/mL)
…..
ICV, 1000µg/L: 1000µL[C] of ICV STOCK, 50mL

8.6.3 Preparation of Toxaphene initial calibration standards;

(syringes needed: *100µL [A], 500µL [B], 1000µL [C]*)
(solvent: *Hexane)*
(glassware: *11x10mL, 1x50mL, volumetric flasks*)

ICAL STOCK #1: *100µg/mL (Toxaphene);10mL*
1000µL[C] of Absolute Standards 20021 (Toxaphene; 1000µg/mL)

ICAL STOCK #2 (=LEVEL 8)**:** *2000µg/L; 10mL.*
200µL[A] of STOCK #1

LEVEL 1, 5 µg/L:	25µL[A] of ICAL STOCK #2, 10mL
LEVEL 2, 10 µg/L:	50µL[A] of ICAL STOCK #2, 10mL
LEVEL 3, 20 µg/L:	100µL[A] of ICAL STOCK #2, 10mL
LEVEL 4, 100 µg/L:	500µL[B] of ICAL STOCK #2, 10mL
LEVEL 5, 200 µg/L:	1000µL[C] of ICAL STOCK #2, 10mL
LEVEL 6, 500 µg/L:	50µL[A] of ICAL STOCK #1, 10mL
LEVEL 7, 1000 µg/L:	100µL[A] of ICAL STOCK #1, 10mL
LEVEL 8, 2000 µg/L:	200µL[B] of ICAL STOCK #1, 10mL
LEVEL 9, 5000 µg/L:	500µL[B] of ICAL STOCK #1, 10mL
LEVEL 10, 10000 µg/L:	1000µL[C] of ICAL STOCK #1, 10mL

ICV: *2000µg/L; 50mL*
1000µL[C] of Agilent PP-271-1 (Toxaphene Standard; 100µg/mL)

8.7 Internal Standard Solution: 1-Bromo-2-nitrobenzene is used as the internal standard and is added to all single-component calibration standards and sample extracts to achieve a concentration of 0.25 µg/mL. Standard solution expires 6 months after the date of preparation. Below are suggested procedures for preparation of PCB Internal Standard which is diluted to prepare Pesticides Internal Standard.

8.7.1 Preparation of Internal Standard solution:

(syringe needed: *1000µL [A]*)
(solvent: *Hexane)*
(glassware: *2x200mL, volumetric flasks*)

PCB INTERNAL STANDARD: *25µg/mL; 200mL*
1000µL[A] of Agilent PPS-351-1 (1-Bromo-2-nitrobenzene Standard; 5000µg/mL)

PESTICIDES INTERNAL STANDARD: *2.5µg/mL; 200mL*
20mL[A] of PCB INTERNAL STANDARD

8.8 PEM/DEG Solution: is prepared volumetrically by diluting stock standard in Hexane. Solution expires 6 months from the date of preparation, or on the earliest expiration date of any of the stock solution used to prepare the standard.

- 5mL of Pesticides Deg. Check Solution, Ultra. #ISM-450-1 into 100mL of Hexane

8.9 Surrogate Standards: Tetrachloro-m-xylene and decachlorobiphenyl are used as surrogates. They are added to the calibration standards at the concentrations listed in Table 2, and are spiked into all samples and QC samples prior to extraction. The spiking solution is prepared in acetone at the concentrations listed in Table 2. Standard expires 6 months after the date of preparation. Below are suggested procedures for preparation of surrogate standard.

8.9.1 Preparation of surrogate standard:

(syringe needed: *1000µL [A]*)
(solvent: *Acetone)*
(glassware: *1x2000mL, volumetric flasks*)

- **EXTRACTION SURROGATES:** *2000µg/L; 2000mL*
  20mL[A] of AccuStandard CLP-032-R (Deca. & TCMX; 0.2mg/mL)
- **ICV Surrogate Stock:** is prepared by diluting of 250µL of Pesticides Surrogate Standard (Ultra, Cat. #CS-1947) to 50mL of Hexane to achieve concentration of TCMX and DCB at 1.0µg/mL.

8.10 LCS/MS Spiking Solutions: The LCS/MS spiking solutions are prepared volumetrically by diluting the appropriate stock standards in acetone. The spiking solution concentrations are listed in Table 2. Spiking solution expires 6 months after the date of

preparation. Below are suggested procedures for preparation of individual pesticides, Chlordane, and Toxaphene spiking solutions.

8.10.1 Preparation of spiking solutions:

(syringes needed: *250μL [A], 1000μL [B]*)
(solvent: *Acetone)*
(glassware: *1x25mL, 1x50mL, 1x200mL, volumetric flasks*)

INDIVIDUAL PESTICIDES SPIKE: *2000μg/L; 200mL*
2000μL[B] of Restek 579104 (Custom Pesticides Mix; 200μg/mL)

CHLORDANE SPIKE: *25μg/mL; 50mL*
250μL[A] of Agilent EPA-1086-1 (Chlordane Standard; 5000μg/mL)

TOXAPHENE SPIKE: *25μg/mL; 25mL*
625μL[A] of Absolute Standards 20021 (Toxaphene; 1000μg/mL)

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

9.1 Blank(s)

Extraction blanks are performed with each extraction batch of 20 or less samples, according to the extraction SOPs. The extraction blank must not contain any of the reportable analytes above the reporting limit. If any reportable analytes are detected in the blank, the entire extraction batch is suspect and re-extraction of all associated samples is required. Actions associated with blank failures are listed in Table 5.

9.2 Laboratory Control Sample (LCS)

A Laboratory Control Sample (LCS) is extracted with each analytical batch. The LCS consists of an aliquot of a clean (control) matrix similar to the sample matrix and of the same weight or volume. The LCS is spiked with single component pesticide analytes. The concentration of the spiking solution is listed in Table 2. The recovery acceptance criteria are listed in Table 3. If any recovery criteria are not met, the extract should be reanalyzed. If the criteria are still not met, the entire batch should be re-extracted. If this is not possible, due to insufficient sample or holding time exceedance, the analyst must write up the failure on a narrative sheet for inclusion in the client report. Actions associated with LCS/LCSD failures are listed in Table 5.

9.2.1 LCS Duplicate (LCSD)

A Laboratory Control Sample Duplicate is extracted with each analytical batch. The LCSD consists of an aliquot of a clean (control) matrix similar to the sample matrix and of the same weight or volume. The LCSD is spiked with the single component pesticide analytes. The concentration of the spiking solution is listed in Table 2. The recovery acceptance criteria are listed in Table 3. If Recovery limits are outside acceptance criteria, the non-conformance is narrated.

9.2.2 Connecticut RCP/MCP/NJ LCS Requirements

For CT- Reasonable Confidence Protocol (RCP) 8081B samples, Massachusetts Contingency Plan (MCP) samples, and samples with a state of origin of New Jersey, the LCS recovery criteria is 40 – 140%. MCP allows for up to 10% of reported spike compounds to fail in the LCS/LCSD and still report.

9.3 Initial Calibration Verification (ICV)

Refer to Section 10.2.

9.4 Continuing Calibration Verification (CCV)

Refer to Section 10.4

9.5 Matrix Spike

A matrix spike (MS)/matrix spike duplicate (MSD) is extracted and analyzed upon Client request for each batch of 20 or less samples. MS and MSDs are field samples spiked with a known quantity of the target analyte(s). They are prepared by taking additional sample aliquots of the same weight or volume and adding the appropriate amounts of surrogate and spiking solutions. The spike compounds and levels are listed in Table 2. The recovery acceptance criteria are 30-150%. If the recovery criteria are not met, but are met in the LCS, the failure may be attributed to sample matrix effects. Actions associated with MS/MSD failures are listed in Table 5.

9.6 Laboratory Duplicate (DUP)

A duplicate sample is extracted and analyzed upon Client request for each batch of 20 or less samples. Duplicates are laboratory selected replicate samples, prepared by taking an additional sample aliquot of the same weight or volume of a sample. The % RPD criteria are listed in Table 3. If the %RPD is not met, the failure may be attributed to sample matrix effects. Actions associated with duplicate failures are listed in Table 5.

For samples with a state of origin of New Jersey, a MS and MSD/DUP must be extracted for every twenty samples within a 24hr period.

9.7 Surrogates:

All extracted samples and associated QC are spiked with surrogates at the levels listed in Table 2. The laboratory must evaluate surrogate recovery data from individual samples and QC samples versus the surrogate control limits listed in Table 3. If the surrogate limits are not met, the extract should be reanalyzed to determine if the failure was due to an instrument problem. If the criteria are still not met, the affected samples should be re-extracted to confirm that the failure was due to sample matrix. If matrix effect is confirmed, this must be noted on a narrative sheet for inclusion in the client report.

9.8 Method Sequence

<u>Typical Initial Calibration</u> (each level to identify the standard lot number)

1. Instrument Blank (may be omitted to conserve tray space)
2. Degradation check standard
3. Std Level 1

4. Std Level 2
5. Std Level 3
6. Std Level 4
7. Std Level 5
8. Std Level 6
9. Std Level 7
10. Std Level 8
11. Std Level 9
12. Std Level 10
13. Std Level 11 (Individual Pesticides only)
14. Initial Calibration Verification Standard (ICV)
15. Repeat std Levels 1 –10 for other mixes until curve is complete.

    [**NOTE:** If multiple calibration mixtures are analyzed, it is acceptable to analyze appropriate ICVs after all calibration standards have been injected.]

Typical Daily sequence (each standard must be identified with lot number)

1. Degradation Check Standard
2. Pesticide Continuing Calibration Standard
3. Chlordane Continuing Calibration Standard
4. Toxaphene Continuing Calibration Standard
5. Extraction Blank
6. Laboratory Control Sample
7. Laboratory Control Sample Duplicate
8. Matrix Spike (Upon Client Request)
9. Duplicate/Matrix Spike Duplicate (Upon Client Request)
10. Samples (up to **20 field samples may be analyzed**)
11. Cal check
12. Repeat 1 – 10 (as needed)

10. Procedure

10.1 Equipment Set-up

10.1.1 Sample Extraction

Water samples are extracted at a neutral pH with methylene chloride using a separatory funnel (Method 3510C). See extraction SOP for details.

Solid samples are extracted with methylene chloride: acetone (1:1) using Soxhlet extraction (Method 3540C) or microwave extraction (Method 3546). See extraction SOP for details.

10.1.2 Extract Cleanup

Cleanup procedures may not be necessary for a relatively clean sample matrix, but most extracts from environmental and waste samples will require additional preparation before analysis. The specific cleanup procedure used will depend on the nature of the sample to be analyzed and the data quality objectives for the measurements. See extraction SOPs for details.

10.1.3 GC Conditions:

The dual-column / dual-detector approach involves the use of the columns listed in section 7.2. The columns are connected to an injection tee or dual injection GC, and separate electron capture detectors. Typical GC conditions for the HP 6890 instruments are listed below but may be altered as long as method performance criteria are met.

Temperature 1:	120 °C
Time 1:	0 minute
Ramp 1:	45 °C/minute
Temperature 2	200 °C
Time 2:	0 minutes
Ramp 2:	15 ° C/minute
Temperature 3:	230 °C
Time 3:	0 minutes
Injector temperature:	250 °C
Ramp 3:	30 °C/minute
Final Temperature:	330 °C
Final Time:	2.0 minutes

Injector mode:	Pulsed Split
	4:1 split
Injector Flow:	20 mL/min split flow
Detector temperature:	350 °C
Carrier gas:	Hydrogen
Carrier flow:	28 mL/min
Carrier mode:	Constant flow
Makeup gas:	Nitrogen
Total detector flow:	60 mL/min
Injection volume:	1 µL

10.1.4 DDT and Endrin Breakdown

The breakdown of DDT and Endrin must be measured before samples are analyzed and at the beginning of each 12-hour shift. Injector maintenance must be completed if the breakdown is greater than 15% for either compound (See Section 10.5.1). Both analytical columns must pass DDT/Endrin breakdown criteria prior to sample analysis.

10.2 Initial Calibration

10.2.1 Prepare calibration standards using the procedures in Section 8.6 and the concentrations listed in Table 2. The calibration standards are aliquoted into autosampler vials and capped prior to loading onto the autosampler tray.

10.2.2 Single point calibration might be employed for analysis of the multi-component analytes (Chlordane, Toxaphene). A single calibration standard near the mid-point of the expected

calibration range of each multi-component analyte is included with the initial calibration of the single component analytes for pattern recognition, so that the analyst is familiar with the patterns and retention times on each column. The calibration standard may be at a lower concentration than the mid-point of the expected range, if appropriate for the project.

10.2.3 Establish the GC operating conditions by loading the appropriate GC method. Typical instrument conditions are listed in section 10.1.3. The same operating conditions are used for calibrations and sample analyses. Create the analytical sequence using the Agilent Chemstation data acquisition software.

10.2.3.1 Record the calibration standard, unique lab identifier code (lot), the analytical sequence list.

10.2.4 A 1µL injection volume of each calibration standard is used. Other injection volumes may be employed, provided that the analyst can demonstrate adequate sensitivity for the compounds of interest. The same injection volume must be used for all standards and samples.

10.2.5 Because of the low concentration of pesticide standards injected on a GC/ECD, column adsorption may be a problem when the GC has not been used for a day or more or after system maintenance. The GC column may be primed (or deactivated) by injecting a pesticide standard mixture approximately 20 times more concentrated than the mid-concentration standard. Inject this standard mixture prior to beginning the initial calibration or calibration verification.

Alternately, the system may be primed by baking at the final analytical temperature for approximately 30 minutes.

Several analytes may be observed in the injection just following system priming. Always run an instrument blank after system priming.

10.2.6 Calibration Factors

10.2.6.1 Internal Standard Procedure

Internal standard calibration techniques are employed in this method. In each standard, calculate the response factor (RF) for each analyte, the average RF, and the relative standard deviation (RSD) of the RFs, using the Enviroquant data processing software. The calculations are performed automatically, using the formulae listed in Pace's Quality Manual.

10.2.7 Initial Calibration Criteria

- If the **RSD for an analyte is < 20%,** then the response of the instrument for this compound is considered linear over the range and the mean calibration factor can be used to quantitate sample results.

- If the **RSD for any analyte is > 20%,** then linearity through the origin cannot be assumed. The mean response factor cannot be used for quantitation. An

alternative calculation may be done using **linear regression or quadratic regression** as long as the correlation coefficient is >0.990. If both quantitation methods fail criteria for any compound in the initial calibration, then the system must be reevaluated, and a new calibration curve must be analyzed. If quadratic regression is used for calibration, this must be noted in the laboratory narrative (MCP/RCP-CT only).

- **Percent Relative Error (%RE):** For linear and quadratic fit compounds, the %RE must be calculated for the standard at or near the midpoint and at the lowest level of the initial calibration. The %RE between the calculated and expected concentration of an analyte must be ≤ 30%, otherwise recalibration is necessary.

- **Chlordane/Toxaphene peaks requirements**:

Analyte	Number of Peaks
Chlordane	3-5
Toxaphene	4-6

- **The minimum number of calibration standards based on the type of calibration curve is listed below**:

Type of Calibration Curve	Minimum Number of Calibration Standards
Linear Fit/Avg Response	5
Quadratic Fit	6

- **Removal and replacement of the calibration standards:**

    - The Analyst may remove individual analyte from the lowest (cannot remove RL level) and or the highest calibration levels of the curve. Removal of the individual analyte of interior levels is not permitted.

    - The Analyst may remove an entire single standard calibration level from the interior of the calibration curve when the instrument response demonstrates that the standard was not properly introduced to the instrument, or an incorrect standard was analyzed. The Analyst who chooses to remove a calibration standard from the interior of the calibration shall remove that particular standard calibration level for all analytes.

    - The Analyst may replace a calibration standard provided that:

        - the replacement standard will be analyzed within **twenty-four (24) hours** of the original calibration standard analysis for that particular calibration level;

- all analytes of the replacement calibration standard must be replaced if a standard within the interior of the calibration is replaced;

- the laboratory limits the replacement of calibration standards to one calibration standard concentration.

10.2.8 Retention Time Windows

10.2.8.1 The retention time windows used for the identification of target analytes are calculated using the procedure recommended in Method 8000 and were found to be ± 0.015 minutes.

10.2.8.2 The windows listed above are used as guidance; however, the experience of the analyst weighs heavily in the interpretation of the chromatograms. For example, it has been observed that certain oil matrices can cause the retention times to shift more dramatically. Additionally, if any positive results are questionable and at sufficiently high concentration, GC/MS analysis is used for confirmation.

10.2.9 Initial Calibration Verification

An **Initial Calibration Verification** standard must be run immediately after each initial calibration, near the midpoint of the curve. This standard must be prepared using a second source that is different than the source used for the initial calibration. The **%D** for each analyte to be quantitated must not exceed a **± 20%** difference when compared to the initial calibration curve.

If recovery is outside the 80-120% criteria, the following steps should be taken:

- Analyze the replacement standard. The cause of the failure of the first calibration verification result should be documented.
- If the reanalysis still didn't achieve the criteria, the source of the problem must be investigated, and the instrument must be recalibrated.

10.3 Equipment Operation and Sample Processing

10.3.1 The same GC operating conditions used for the initial calibration must be employed for sample analyses, including sample injection volume (Section 10.1.3).

10.3.2 Tentative identification of an analyte occurs when a peak from a sample extract falls within the retention time window for the compound. Each tentative identification is confirmed using a second GC column of dissimilar stationary phase. Confirmation is positive when the %RPD is $\leq$ 40% from the results of the two columns. In particularly difficult matrices, confirmation by GC/MS may be advisable (see Section 10.3.11).

10.3.3 The concentration reported for an identified target analyte in an extract is calculated using the Enviroquant data processing software. The Enviroquant methods have been configured to utilize the quantitation formulas found in Quality Manual. Proper quantitation requires the appropriate selection of a baseline from which the peak area or height can be determined. See the Manual Integration SOP for integration guidelines.

10.3.3.1 If the responses exceed the calibration range of the system, dilute the extract and reanalyze.

10.3.4 Each sample analysis must begin with an acceptable initial calibration, breakdown standard (PEM) calibration verification standard(s) (each **12-hour analytical shift**), or calibration standards interspersed within the samples.

The **Internal Standard area of the samples must be within 50%-200% of the starting CCV.** When a calibration verification standard fails to meet the QC criteria, all samples that were injected after the last standard that last met the QC criteria must be re-injected.

10.3.5 Sample injections may continue as long as the calibration verification standards and standards interspersed with the samples meet instrument QC requirements. The sequence ends when the set of samples has been injected or when qualitative and/or quantitative QC criteria are exceeded.

10.3.6 Use the calibration standards analyzed during the sequence to evaluate retention time stability. The retention time windows are established using the absolute retention time of each analyte in the mid-concentration standard during the initial calibration as the mid-point of the window. The widths of the windows are defined in Section 10.2.7.

10.3.7 Each subsequent injection of a standard during the 12-hour analytical shift (i.e., those standards injected every 20 field samples, or more frequently) must be checked against the retention time windows. If any of these subsequent standards fall outside their absolute retention time windows, the GC system is out of control. Determine the cause of the problem and correct it. If the problem cannot be corrected, a new initial calibration must be performed.

10.3.8 Identification of mixtures (i.e. Chlordane and Toxaphene) is based on the characteristic 'fingerprint' retention time and shape of the indicator peak(s); and quantitation is based on the area under the characteristic peaks as compared to the area under the corresponding calibration peaks(s) of the same retention time and shape generated using internal calibration procedures.

10.3.9 If compound identification or quantitation is precluded due to interference (e.g., broad, rounded peaks or ill-defined baselines are present) cleanup of the extract may be needed. If instrument problems are suspected, rerun the extract on another instrument to determine if the problem results from analytical hardware or the sample matrix. Refer to the extraction SOPs for the procedures to be followed in sample cleanup.

10.3.10 For secondary column analysis, a second dissimilar column is utilized to confirm positive pesticide results. The laboratory must report the **higher of the two results** unless obvious interference is present on one of the columns. All required QA/QC parameters (e.g. calibrations, LCSs, etc.) must be met on the second column as well.

10.3.10.1 The **Relative Percent Difference (RPD)** should be 40 or lower. If the RPD exceeds 40, this will be denoted with a P flag. If the RPD exceedance is due to interference, the lower of the dual column values can be reported with I and P flags.

10.3.11 GC/MS Confirmation

GC/MS confirmation may be used in conjunction with either single-column or dual-column analysis if the concentration is sufficient for detection by GC/MS.

10.3.11.1 Full-scan GC/MS will normally require a concentration of approximately 10ng/µL in the final extract for each single-component compound.

10.3.11.2 The GC/MS must be calibrated for the specific target pesticides when it is used for quantitative analysis.

10.3.11.3 GC/MS may not be used for confirmation when concentrations are below the sensitivity of the instrument.

10.3.11.4 GC/MS confirmation should be accomplished by analyzing the same extract that is used for GC/ECD analysis.

10.3.11.5 The base/neutral/acid extract and the associated blank may be used for GC/MS confirmation if the surrogates and internal standards do not interfere and if it is demonstrated that the analyte is stable during acid/base partitioning. However, if the compounds are not detected in the base/neutral/acid extract, then GC/MS analysis of the pesticide extract should be performed.

10.3.11.6 A QC reference sample containing the compound should also be analyzed by GC/MS. The concentration of the QC reference sample must demonstrate that those pesticides identified by GC/ECD can be confirmed by GC/MS.

10.4 Continuing Calibration Verification

10.4.1 Verify calibration each 12-hour shift by injecting calibration verification standards (CCV) prior to conducting any sample analyses. A calibration standard must be injected at intervals of not less than once every twenty field samples.

10.4.1.1 The calibration factor (for external standard compounds) and response factor (for internal standard compounds) for each analyte to be quantitated must not exceed a **± 20%** difference when compared to the initial calibration curve. The Enviroquant data processing software automatically calculates the %D for all analytes according to the formulae in Quality Manual. **The Internal Standard area of the CCV must be within 50%-150%** of the Initial Calibration Internal Standard area.

10.4.1.2 If this criterion is exceeded, inspect the gas chromatographic system to determine the cause and perform whatever maintenance is necessary before verifying calibration and proceeding with sample analysis.

10.4.1.3 If routine maintenance does not return the instrument performance to meet the QC requirements (Section 10) based on the last initial calibration, then a new initial calibration must be performed. Due to the large number of analytes present, allowances may be made for a CF or RF that drifts out high, as long as there are no positive hits for that particular analyte in any of the associated samples. Any QC failures must be written up by the analyst on narrative sheets for inclusion with the sample data.

10.4.2 Compare the retention time of each analyte in the calibration standard with the absolute retention time windows described in section 10.2.7. The center of the absolute retention time window for each analyte is its retention time in the mid-concentration standard analyzed during the initial calibration. Each analyte in each standard must fall within its respective retention time window. If not, the gas chromatographic system must either be adjusted so that a second analysis of the standard does result in all analytes falling

within their retention time windows, or a new initial calibration must be performed and new retention time windows established.

10.5 Internal Standard

The use of internal standard calibration does not require that all sample results be bracketed with CCV standard. However, when internal standard calibration is used, the retention times of internal standards and the area response of internal standards should be checked for each analysis.

10.5.1 **IS in CCAL** – The measured area of the internal standard must be no more than ± 50% different from the average area calculated during initial calibration (-50 to 150%).

10.5.2 **IS in samples** - The measured area of the internal standard must be no more than -50% to +100% different from the area calculated from opening CCV (-50 to 200%)

Retention time shifts of more than 30 seconds from the retention time of the most recent calibration standard are cause for concern and must be investigated.

10.6 Preventive Maintenance

Routine preventive maintenance should be performed to maintain GC system performance. This includes periodic replacement of injector septa, replacement of injector liner(s), and replacement of injector seals.

10.6.1 Other Maintenance

Additional maintenance may be required if system performance degrades.

10.6.1.1.1 GC injector ports are of critical concern, especially in the analysis of DDT and Endrin.

10.6.1.1.1.1 Injectors that are contaminated or chemically active can cause the degradation (“breakdown”) of the analytes. Endrin and DDT breakdown to Endrin aldehyde, Endrin ketone, DDD, or DDE.

Check for degradation problems by injecting a standard containing only 4,4’-DDT and Endrin. The presence of 4,4’-DDE, 4,4’-DDD, Endrin ketone or Endrin indicates breakdown. If degradation of either DDT or Endrin exceeds 15%, take corrective action before proceeding with calibration.

When such a breakdown is observed, replacement of the injector liner and seal may solve the problem. If not, clip approximately 3 – 6 inches from the injector end of the GC column. If the degradation does not improve, it may be necessary to replace the column(s).

Calculate percent breakdown as follows:

$$\%\ breakdown\ of\ DDT = \frac{sum\ of\ degradation\ peak\ areas\ (DDE + DDD)}{sum\ of\ all\ peak\ areas\ (DDT + DDE + DDD)} * 100$$

$$\%\ breakdown\ of\ Endrin = \frac{sum\ of\ degradation\ peak\ areas\ (Aldehyde + Ketone)}{sum\ of\ all\ peak\ areas\ (Endrin + Aldehyde + Ketone)} * 100$$

10.6.1.1.2 ECD detectors may also become contaminated, requiring bake out at elevated temperatures, or repair by the manufacturer.

11. Data Evaluation, Calculations and Reporting

11.1 Quantitation of Single Component Pesticides

The single component pesticide compounds are calculated as described in Section 10.3.3 and reported in µg/L or µg/Kg units. After performing technical data review, validating that all QC criteria have been met and confirming all positive hits, the data report is sent electronically to the LIMS computer for generation of the client report. There are two levels of review of the data in the LIMS system prior to release of data. These reviews should be done by two separate individuals.

11.1.1 Quantitation of Multiple-Component Analytes

Quantitation is based on use of 3-5 of the major peaks present for chlordane and 4-6 of the major peaks present for Toxaphene. Each of these peaks is individually calibrated with a 10-point calibration based on average response factors. The %RSD must meet the criteria of ≤20%. The 3 to 5 or 4 – 6 major peaks are calculated as described in Section 10.3.3. After individual calculation meets criteria, the average of the major 3-5 or 4 – 6 peaks is used to determine the final concentration.

11.1.1.1 Toxaphene

Toxaphene is quantitated by the internal standard method, using the 4 – 6 largest peaks found in the standard and averaging the resulting concentrations.

11.1.1.2 Chlordane

Chlordane is a mixture of at least 11 major components and 30 or more minor components. Trans- and cis-Chlordane (alpha and gamma, respectively), are the two major components of Chlordane. However, the exact percentage of each in the chlordane material is not completely defined and is not consistent from batch to batch.

11.1.1.2.1 The GC pattern of a Chlordane residue may differ considerably from that of the chlordane standard. Depending on the sample substrate and its history, residues of Chlordane can consist of almost any combination of constituents from the Chlordane, plant and/or animal metabolites, and products of degradation caused by exposure to environmental factors such as water and sunlight.

11.1.1.2.2 Whenever possible, when Chlordane residue does not resemble Chlordane, the analyst should quantitate the peaks of alpha-Chlordane, gamma-

Chlordane, Heptachlor, and trans-Nonachlor separately against the appropriate reference materials, and report the individual residues.

11.1.1.2.3 When the GC pattern of the residue resembles that of Chlordane, the analyst may quantitate Chlordane residues by comparing the total area of the Chlordane chromatogram using the 3-5 major peaks.

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

Holding time exceedance and/or improper preservation are noted on the nonconformance report form.

All non-conformances, sample preparatory extraction methods and clean-up methods must be addressed in a case narrative and included in the data report.

Perform instrument maintenance as described throughout this SOP as needed when instrument calibration criteria are not met. Record all maintenance in the instrument logbook.

All batch and sample specific QC criteria outlined in Section 10 are evaluated by the analyst prior to approval of the data. When any QC criteria fail, the cause for the failure must be identified and corrected. This may include instrument recalibration followed by sample reanalysis, sample cleanup, or sample re-extraction. If it is determined that the failure is due to sample matrix effects, a project narrative report is written by the analyst for inclusion in the data report. If there is insufficient sample volume to perform the re-analysis for confirmation, this is also noted in the narrative and included in the client report.

13. Method Performance

13.1 Method Detection Limit Study (MDL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the MDL, LOD, and/or LOQ as outlined in Qualtrax ID 1732. These studies performed by the laboratory are maintained on file for review

13.2 Demonstration of Capability Studies

Refer to Qualtrax ID 1739 for further information regarding IDC/DOC Generation.

13.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

14. Pollution Prevention and Waste Management

Refer to Alpha's Chemical Hygiene Plan and Waste Management and Disposal SOP for further pollution prevention and waste management information.

QC FAILURE ACTION PLAN

Blank Failures	Failure Situation	Action(s)
Surrogate Failure	1 of 4 high or low	Report as is
	2 or more high	Report as is
	2 or more low, samples are non-detect with passing surrogates	Report as is
	2 or more low, samples have hits and/or failing surrogates	Revial/rerun Re-extract if still failing
IS Failure	IS not present (less than 10% recovery)	Add IS Rerun
	IS out high or low	Revial/rerun Re-extract if still failing
Contamination	Below RL; sample(s) non-detect, below RL, or concentration 10 times or more above the blank	Report as is
	Below RL, sample(s) concentration above RL	See team leader/manager
	Above RL, sample(s) concentration 10 times or more above the blank	Report as is
	Above RL with non-detect sample(s)	Report as is
	Above RL, sample(s) concentration less than 10 times above the blank and volume available	Revial/rerun Re-extract if contamination still present
	Above RL, sample(s) concentration less than 10 times above the blank and no volume available	Revial/rerun B-flag affected data

LCS/LCSD Failures	Failure Situation	Action(s)
Surrogate Failure	1 or more high or low	Report as is
IS Failure	IS not present (less than 10% recovery)	Add IS Rerun
	IS out high or low	Revial/rerun Re-extract if still failing
Spike Failure	Spike compounds out high and sample(s) are non-detect with passing surrogates	Report as is
	Spike compounds out high and sample(s) have hits	Revial/rerun Re-extract if still high
	Spike compounds out low	Revial/rerun Re-extract if still low
	RPD failure	Report as is

MS/MSD/DUP Failures	Failure Situation	Action(s)
Surrogate Failure	(MS/MSD) 1 or more high or low	Report as is
	(MS/MSD) 2 or more high or low	Report as is
	(DUP) 1 or more high, parent sample non-detect	Report as is
	(DUP) 1 or more low, parent sample matches	Report as is
	(DUP) 1 or more low, parent sample doesn't match	Revial/rerun Re-extract if still failing
IS Failure	IS not present (less than 10% recovery)	Add IS Rerun
	IS out high or low	Revial/rerun Re-extract if still failing
Spike Failure (MS/MSD only)	Compounds out high or low due to sample matrix or hits	Report as is
	Compounds out high or low due to extraction error	Revial/rerun Re-extract if still failing
	RDP failure	Report as is

Oxidation – Reduction Potential (ORP)

References: **ASTM D1498 (Modified),** Annual Book of ASTM Standards, Vol 11.01. September 15, 1993.

1. Scope and Application

Matrices: Water and Soils/Solids

Definitions: Refer to Alpha Analytical Quality Manual.

This practice covers the apparatus and procedure for the electrometric measurement of oxidation-reduction potential (ORP) in water. It does not deal with the manner in which the solutions are prepared, the theoretical interpretation of the oxidation-reduction potential, or the establishment of a standard oxidation-reduction potential for any given system. The practice described has been designed for the routine and process measurement of oxidation-reduction potential.

Oxidation-reduction potential: The electromotive force, Em, developed between a noble metal electrode and a standard reference electrode. This oxidation-reduction potential (ORP) is related to the solution composition by:

$$E_m = E^o + 2.3 \frac{RT}{nF} \log A_{ox}/A_{red}$$

Where:

Em = ORP,
E^o = constant that depends on the choice of reference electrodes.
F = Faraday constant,
R = gas constant,
T = absolute temperature, °C + 273.15,
n = number of electrons involved in process reaction, and
A_{ox} and A_{red} = activities of the reactants in the process.

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one or more of the following laboratory personnel before performing the modification: Area Supervisor, Department Supervisor, Laboratory Director, or Quality Assurance Officer.

This method is restricted to use by or under the supervision of trained analysts. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

2. Summary of Method

This is a practice designed to measure the ORP which is defined as the electromotive force between a noble metal electrode and a reference electrode when immersed in a solution. The practice describes the electronic equipment available to make the measurement and describes how to determine the sensitivity of the electrodes as well as the calibration of equipment to solutions

having a known potential. The ORP electrodes are inert and measure the ratio of the activities of the oxidized to the reduced species in the process reactions.

2.1 Method Modifications from Reference

Modified. One sample is measure in duplicate. Not all samples are read in successive portions until they differ by less than 10 mV.

3. Reporting Limits

Not applicable to this method.

4. Interferences

4.1 The ORP electrodes reliably measured ORP in nearly all aqueous solutions and in general are not subject to solution interference from color, turbidity, colloidal matter, and suspended matter.

4.2 The ORP of an aqueous solution is sensitive to change in temperature of the solution, but temperature correction is rarely done due to its minimal effect and complex reactions. Temperature corrections are usually applied only when it is desired to relate the ORP to the activity of an ion in the solutions.

4.3 The ORP of an aqueous solution is almost always sensitive to pH variations even to reactions that do not appear to involve hydrogen or hydroxyl ions. The ORP generally tends to increase with an increase in hydrogen ions and to decrease with an increase in hydroxyl ions during such reactions.

4.4 Reproducible oxidation-reduction potentials cannot be obtained for chemical systems that are not reversible. Most natural and ground waters do not contain reversible systems, or may contain systems that are shifted by the presence of air. The measurement of end point potential in oxidation-reduction titration is sometimes of this type.

4.5 If the metallic portion of the ORP electrode 1s sponge-like, materials absorbed from solutions may not be washed away, even by repeated rinsings. In such cases, the electrode may exhibit a memory effect, particularly if it is desired to detect a relatively low concentration of a particular species immediately after a measurement has been made in a relatively concentrated solution. A brightly polished metal electrode surface is required for accurate measurements.

4.6 The ORP resulting from interactions among several chemical systems present in mixed solutions may not be assignable to any single chemical.

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by

whatever means available. A reference file of material safety data sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

Samples are collected in plastic or glass containers.

6.2 Sample Preservation

Samples are not preserved.

6.3 Sample Shipping

No special shipping requirements.

6.4 Sample Handling

Liquid samples are analyzed within 24 hours of collection; soil samples are analyzed within 28 days of collection.

The exception is MCP-Hexachrome package soils require ORP soils to have a 24 hour hold time and NJ-Hexachrome package soils need to be analyzed within 24h of HexCr preparation time

7. Equipment and Supplies

7.1 ORP Meter with Oxidation-Reduction Electrode: Orion 555A PH/ORP/Conductivity meter with ORION sure flow combo REDOX/ORP electrode.

7.2 Glass Beakers or plastic cups

7.3 Stir bars

7.4 Stir plate

7.5 Ag/AgCl Reference Electrode Filling Solution

8. Reagents and Standards

8.1 Purity of Reagents: Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended 'hat all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society., Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

8.2 Purity of Water: DI water from Alpha's water system.

8.3 Redox Standard Solution; Ferrous-Ferric Reference Solution: Dissolve 0.745g of potassium chloride (KCL) (EMD), 0.140 g of potassium ferrocyanide (K4(Fe(CN)6)*3H20) and 0.110g of Potassium Ferriccyanide (K3Fe(CN)6) in water and dilute to 100mL. It is necessary to prepare the solution using reagent grade chemicals that have an assay confirming them to be within 1% of the nominal composition. The solution is stored in a closed glass or plastic container. Expiration date is 3 months from the date of preparation.

8.3.1 The ferrous-ferric reference solution is a reasonably stable solution with a measurable oxidation – reduction potential of 230mV.

8.3.2 Zobell Solution: Commercially available Redox standard solution. Same as 8.3 but from a different source. Expires at manufactures date.

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

9.1 Laboratory Control Sample (LCS)

LCS result must be within +/-10% of the true value.

9.2 Initial Calibration Verification (ICV)

ICV result must be within +/-10% of the true value.

9.3 Continuing Calibration Verification (CCV)

CCV result must be within +/-10% of the true value.

9.4 Laboratory Duplicate

% RPD must be within $\leq$ 20%. If %RPD fails, the analyst must check samples for homogeneity and matrix interferences. % RPD failure may be narrated.

9.5 Method Sequence:

- Turn on instrument
- Weigh out soils and spin with DI
- Read ICV
- Read LCS
- Read samples and duplicate
- Read closing CCV

10. Procedure

10.1 Equipment Set-up

10.1.1 Electrode Treatment: Condition and maintain ORP electrodes as recommended by the manufacturer.

10.1.2 ORP Electrode Cleaning: Rinse with DI water.

10.2 Initial Calibration

10.2.1 Before using electronic type meters, turn them on and alloy them *to* warm up thoroughly. Bring them to electrical balance by carefully following the manufacturer's instructions. Set the scale or range to the desired millivolt level expected in the test solution.

10.2.2 Once the instrument is ready. Read the ICV standard, if the standard is within 10% of the true value, proceeds with the analysis.

10.3 Equipment Operation and Sample Processing

10.3.1 Place the sample in a clean glass beaker or sample cup and insert the electrodes. Provide adequate agitation throughout the measurement period. Read the millivolt potential of the solution allowing sufficient time for the system to stabilize.

10.3.2 For Soil samples: Weigh 10g into a cup and add a stir bar. 100mL DI is added and the solution is stirred for 1 hour. After 1 hour, decant out the liquid portion and follow 10.3.1.

10.4 Continuing Calibration

CCV analyzed after every 10 samples and at the end of analytical run.

10.5 Preventive Maintenance

Replace electrode as needed.

.

11. Data Evaluation, Calculations and Reporting

11.1 Report the oxidation-reduction potential in millivolts directly from the meter. The electrode system employed must also be reported.

11.2 If it is desired to report the oxidation-reduction potential referred to the hydrogen electrode, calculate as follows:

$$E_h = E_{obs} + E_{ref}$$

Where:

E_h = oxidation-reduction potential referred to the hydrogen scale, mV,

E_{obs} = observed oxidation-reduction potential of the noble metal-reference electrode employed, mV, and

E_{ref} = oxidation-reduction potential of the reference electrode as related to the hydrogen electrode, mV.

11.3 Report the oxidation-reduction potential to the nearest I mV, interpolating the meter scale as required. When considered appropriate, the temperature at which the measurement was made and the pH at the time of measurement, may also be reported.

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

If the ICV, CCV or LCS fails, remake the solution and reanalyze.

13. Method Performance

13.1 Method Detection Limit Study (MDL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the MDL, LOD, and/or LOQ as outlined in Alpha SOP/ 1732. These studies performed by the laboratory are maintained on file for review.

13.2 Demonstration of Capability Studies

Refer to Alpha SOP/ 1734 and 1739for further information regarding IDC/DOC Generation.

13.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

14. Pollution Prevention and Waste Management

Refer to Alpha's Chemical Hygiene Plan and Waste Management and Disposal SOP for further pollution prevention and waste management information.

15. Referenced Documents

Analysis of Polynuclear Aromatic Hydrocarbons and PCB Congeners by Gas Chromatography/Mass Spectrometry with Selected Ion Monitoring

References: Method EPA 8270E, SW-846,Test Methods for Evaluating Solid Waste: Physical/Chemical Methods, EPA SW-846, Revision VI (Phase II), June 2018.

Compendium of Methods for the Determination of Toxic Organic Compounds in Ambient Air, Second Edition, Compendium Method TO-13A – Determination of Polycyclic Aromatic Hydrocarbons (PAHs) in Ambient Air Using GC/MS-SIM, January 1999.

USEPA, Superfund Analytical Services/Contract Laboratory Program (CLP), Multi-Media, Multi-Concentration Organics Analysis, SOM01.1, Exhibit D - Analytical Methods, "Analytical Method for the Analysis of Semivolatile Organic Compounds," May, 2005.

1. Scope and Application

Matrices: Solid, waste, soil, sediment, tissue, oil, water and Air PUF.

Definitions: Refer to Alpha Analytical Quality Manual.

This standard operating procedure (SOP) is applicable to the quantification of polynuclear aromatic hydrocarbons (PAHs) and PCB Congeners by gas chromatography/mass spectrometry with selected ion monitoring (GC/MS-SIM). Method is modified from USEPA method 8270D for the application of SIM following the SW846 sited CLP SOW reference.

The sample preparation methods described herein are: 3510C (water), 3540 (Air PUF), 3580 (oil) and 3570 (solid/waste, soil, sediment and tissue) from the above reference.

The individual target compounds are found in Table B.

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one or more of the following laboratory personnel before performing the modification: Area Supervisor, Department Supervisor, Laboratory Director, or Quality Assurance Officer.

This method is restricted to use by or under the supervision of analysts experienced in the operation of the GC/MS instrumentation and in the interpretation of GC/MS data. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

2. Summary of Method

Aqueous samples are serially extracted with methylene chloride in a 2 liter separatory funnel at the required pH. Soil, sediment, solid/waste and tissue samples are extracted by micro scale solvent extraction (MSE) 3570 modified. Oil samples are diluted with methylene chloride (1mL sample to 9mL of solvent) following method 3580. Air PUF samples are extracted via soxhlet method 3540 in hexane/ether (90/10). The extracts are concentrated to the required final volume and spiked with internal standards in preparation for analysis. All extraction procedures are documented in the associated sample preparation SOPs. The extracts are analyzed by GC/MS-SIM. The target analytes are resolved on the GC column and detected using a mass selective detector (MSD). Concentrations are determined using mean relative response factors from a multi-level calibration

curve. Response factors for target analytes and surrogate compounds are determined relative to the internal standards.

2.1 Method Modifications from Reference

Section 7.5.5 of EPA SW846 8270C is referred to for the application of SIM, along with EPA SOM01.1, Exhibit D for Semivolatiles. This method has been modified to include a sub list of PCB Congeners that are co-analyzed along with the PAHs. These PCB Congeners are commonly referred to the NOAA 18, or NOAA 22 Congener List. If analyzing for the PCB Congeners in conjunction with the PAHs, the Mass Spectrometer DFTPP tuning criteria for Maximum Sensitivity described in Section 10.1.4.4 must be utilized.

3. Reporting Limits

Reporting limits for individual PAH compounds can range from 10ng/L to 10,000ng/L for water samples, and a range of 8μg/Kg to 8000μg/Kg for soil/sediment, solid/waste and tissue samples. Oil samples can range from 100ug/Kg to 100,000ug/Kg. Air PUF samples can range from 200ng/PUF to 40,000ng/PUF. PCB Congener compounds can range from 1.0ng/L to 500ng/L for water samples and can range from 0.133ug/Kg to 66.7ug/Kg for soil/sediment, solid/waste and tissue samples. Oil samples can range from 5ug/Kg to 5000ug/Kg. Air PUF samples are not analyzed for PCB Congeners following this SOP. Specific reporting limits for each matrix per analyte can be viewed within the LIMS under Applications/Product Catalog.

Project-specific reporting limits may be determined based on the sample size extracted, the extract final volume and the lowest concentration standard included in the initial calibration.

4. Interferences

Phthalate esters can be a major source of contamination if any material containing plasticizers (phthalates) comes in contact with the sample during the extraction process. Use of plastic or any material containing plasticizers (phthalates) should be avoided during extraction or analysis.

When emulsions are formed during the separatory funnel extraction process, centrifuging the extract may be necessary to break down the emulsion before continuing the serial extractions. If water does filter into the collected extract, the extract should be re-filtered through sodium sulfate before the extract is concentrated to its final volume.

Raw GC/MS data from all blanks, samples, and spikes must be evaluated for interferences or carryover. Contamination by carryover can occur whenever high-concentration and low-concentration samples are sequentially analyzed.

The following cleanup methods can be used to help minimize co-extracted matrix/interferences: Method 3610 Alumina Cleanup, Method 3630 Silica Cleanup, Method 3660 Sulfur Removal using Copper and Method 3640 GPC Cleanup.

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material safety data sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

Water samples are collected in pre-cleaned 1-L amber glass bottle with a Teflon lined screw cap. Approximately 1 L of sample is required for the analysis. Soil/Sediment/Solid/Waste/Oil samples are collected in a pre-cleaned 250 mL glass jar with Teflon lined screw cap. Approximately 100g of soil/sediment is required for the analysis although more may be collected to provide a representative sample. Solid/Waste and Oil samples require half this amount, approximately 50g. Tissue samples are typically received from the field wrapped in foil and inside Ziploc baggies. As much tissue sample as possible should be provided. Air PUF samples are collected per the sited TO-13A reference method.

6.2 Sample Preservation

Water, soil/sediment, solid, waste, oil, Air PUF and tissue samples are preserved by cooling to 4°C $\pm$ 2°C and should remain at this temperature until extraction. No chemical preservative is required, and may interfere with the analysis. Sediment and Tissue samples may also be frozen to -20°C $\pm$ 2°C per client specific instructions.

6.3 Sample Shipping

No special sample shipping requirements.

6.4 Sample Handling

Water and Air PUF samples are extracted within seven days of collection. Soil, sediment, solid/waste, oil and tissue samples are extracted within 14 days of collection. Sediment and tissue samples may be frozen to extend holding times per client request. All sample extracts are analyzed within 40 days of sample preparation.

7. Equipment and Supplies

7.1 Gas chromatograph/Mass Spectrometer and Autosampler: Programmable; heating range from 40°C to 350°C; split/splitless-type inlet system; (Agilent 6890 or similar); mass selective detector (Agilent 5973, or similar); automatic injector (Agilent 7683B, or similar)..

7.2 Chromatography Column: Fused silica, capillary column, 0.25 mm ID x 30m length, 0.25µm film thickness (ZB-5, Phenomenex, 5% Phenyl-95% dimethypolysiloxane, Restek RTX5 30m x 0.25mm ID x 0.25um film thickness, or equivalent).

7.3 Data Acquisition System: Computerized system for collecting, storing, and processing detector output (Agilent Enviroquant target software or equivalent

7.4 Gases: BIP Ultra high purity helium (99.9995%), Compressed Nitrogen for N-Evap.

7.5 Hamilton Gas tight Syringes – 10uL to 1.0mL.

7.6 Vials including 2mL, 4mL, 10mL, and 40mL.

8. Reagents and Standards

Use reagent grade chemicals for all reagents. Deionized (DI) water is ASTM Type II laboratory reagent grade water.

8.1 Reagents: All solvent expirations determined as indicated by manufacturer guidelines.

8.1.1 Methylene Chloride: ACS approved, Pesticide grade, see SOP *Reagent, Solvent and Standard Control* (G-008) for additional details regarding solvent purity. Used to extract samples and prepare instrument/analytical standards

8.1.2 Acetone: ACS approved, Pesticide grade, see SOP *Reagent, Solvent and Standard Control* (G-008) for additional details regarding solvent purity. This water soluble solvent is used for surrogate and LCS/MS preparation.

8.1.3 Methanol: ACS approved, Pesticide grade, *Reagent, Solvent and Standard Control SOP* (G-008) for additional details regarding solvent purity.

8.1.4 Hexane: ACS approved, Pesticide grade, see SOP *Reagent, Solvent and Solvent Control* (1816) for additional details regarding solvent purity. This solvent is used in the extraction of Air PUF samples.

8.1.5 Ether: see SOP *Reagent, Solvent and Solvent Control* (1816) for additional details regarding solvent purity. This solvent is used in the extraction of Air PUF samples.

8.2 Analytical Standards

Standards should be stored at -10 or less, away from light when not in use. They should be discarded after 1 year unless the vendor expiration date states otherwise or if degradation is observed. Stock standards are given a 1 year expiration from the preparation date or the expiration of the primary vendor solution, whichever occurs first. Working standards are given a 6 month expiration from the preparation date or the expiration of the primary solution whichever occurs first. All analytical standards are made up in Methylene Chloride. All prep standards are made up in Acetone.

8.3 Primary Standards

8.3.1 PAH Custom Mix – Supelco 21353385 (100ug/mL)

8.3.2 Custom PCB Standard – Accustandard S-7911-2X (NOAA22 Mix 100ug/mL)

8.3.3 3,3',4,4'-Tertachlorobiphenyl – Accustandard C-077S-TP (BZ#77 100ug/mL)

8.3.4 2,3,3',4,6-Pentachlorobiphenyl – Accustandard C-110S-TP (BZ#110 100ug/mL)

8.3.5 3,3',4,4',5-Pentachlorobiphenyl – Accustandard C-126S-TP (BZ#126 100ug/mL)

8.3.6 4,4'-Dibromooctafluorobiphenyl – Ultra PPS-172 (DBOB 5000ug/mL)

8.3.7 2,2',3,3',4,5,5',6-Octachlorobiphenyl – Ultra RPC-075S (BZ#198 100ug/mL)

8.3.8 Custom Deuterated PAH Standard – Restek 563160 (2000ug/mL)

8.3.9 PAH Two Component Mixture – Cambridge Isotope Laboratory ES-5498 (2000ug/mL)

8.3.10 EPA PCB Congener Calibration Check solution – Ultra Scientific RPC-EPA2 (100ug/mL)

8.3.11 **Custom PAH Standard** - Restek 567608 (1000ug/mL)

8.3.12 **MA EPH Aromatic Hydrocarbon Standard** - Restek 31458 (1000ug/mL)

8.3.13 2**,2',3,4,4',5,5'-Heptachlorobiphenyl** – Cambridge Isotope Laboratory EC-1407-3 (BZ#180 13C12 40ug/mL)

8.3.14 **4,4'-Dichlorobiphenyl** – Cambridge Isotope Laboratory EC-1407-3 (BZ#15 13C12 40ug/mL)

8.3.15 **Semi-Volatile GCMS Tuning Standard** – Ultra GCM-150 (1000ug/mL)

8.3.16 **SV Internal Standard Mix** – Restek 31206 (2mg/mL)

8.4 Stock Solutions

8.4.1 **NOAA22 + BZ#198 Stock** – Prepared by Diluting 1.25mL of **Custom PCB Standard** (Accustandard S-7911-2X 100ug/mL), 1.25ml of **2,2',3,3',4,5,5',6-Octachlorobiphenyl** (Ultra RPC-075S BZ#198 100ug/mL), and 25ul of **4,4'-Dibromooctafluorobiphenyl** (Ultra PPS-172 DBOB 5000ug/mL) to 25mL in Hexane. Final concentration 5000ng/mL.

8.4.2 **BZ77/110/126 Stock** – Prepared by diluting 0.5ml of each **3,3',4,4'-Tertachlorobiphenyl** (Accustandard C-077S-TP BZ#77 100ug/mL), **2,3,3',4,6-Pentachlorobiphenyl** (Accustandard C-110S-TP BZ#110 100ug/mL), and **3,3',4,4',5-Pentachlorobiphenyl** (Accustandard C-126S-TP BZ#126 100ug/mL) to 10ml in hexane. Final concentration 5000ng/mL.

8.4.3 **BZ#198 and DBOB Stock** - Prepared by diluting 1.25ml of **2,2',3,3',4,5,5',6-Octachlorobiphenyl** (Ultra RPC-075S BZ#198 100ug/mL), and 25ul of **4,4'-Dibromooctafluorobiphenyl** (Ultra PPS-172 DBOB 5000ug/mL) to 25mL in Hexane. Final concentration 5000ng/mL.

8.4.4 **PCB Congener ICV Stock –** Prepared by diluting 0.020mL of **EPA PCB Congener Calibration Check solution** (Ultra Scientific RPC-EPA2 100ug/mL) to a final volume of 10mL in methylene chloride. Final concentration 200ng/mL.

8.4.5 **PAH ICV Stock –** Prepared by diluting 0.1 mL of **Custom PAH Standard** (Restek 567608 1000ug/mL), and 0.1mL of **MA EPH Aromatic Hydrocarbon Standard** (Restek 31458 1000ug/mL), to a final volume of 10mL in Methylene chloride. Final concentration 10ug/mL.

8.5 Spiking Solutions

8.5.1 **PAH Extraction Surrogate** – Prepared by diluting 1.25mL of **Custom Deuterated PAH Standard** (Restek 563160 2000ug/mL) to 500ml in Methylene Chloride. Final Concentration 5.0ug/ml.

8.5.2 **PAH Field Surrogate** – Prepared by diluting 1.0mL of **PAH Two Component Mixture** (C.I.L. ES-5498 2000ug/ml) to 10ml in Methylene Chloride. Final concentration 200ug/ml. 20ul of this resulting solution is spiked into all PUF samples prior to shipment to the client.

8.5.3 **PAH Laboratory Control Standard** – Prepared by diluting 0.5mL of **Custom PAH Standard** (Restek 567608 1000ug/mL), and 0.5ml of **MA EPH Aromatic Hydrocarbon Standard** (Restek 31458 100ug/mL) to 100mL in Acetone. Final concentration 100ug/mL.

8.5.4 Pest/Cong Surrogate Spike – Prepared by diluting 2.0mL of **BZ#198 and DBOB Stock** to 100ml in Acetone. Final concentration 100ug/mL.

8.5.5 PCB Laboratory Control Standard – Prepared by diluting 0.1mL of **Custom PCB Standard** (NOAA22 Mix, Accustandard S-7911-2X 100ug/mL), and 10mL of **Pesticide LCS Solution** (1000ng/mL) to a final volume of 100mL in Acetone. Final concentration 100ng/mL). Information for the formulation of the Pesticide LCS Solution can be found in SOP (2158_ Determination of Organochlorine Pesticides by Gas Chromatography/Electron Capture Detection. Pesticides are not reported by the method outlined in this SOP but combined extraction is sometimes performed.

8.5.6 PAH SIM Internal Standard - Prepared by diluting 0.125mL of **SV Internal Standard Mix** (Restek 31206 2000ug/ml) to 10ml in Methylene Chloride. Final Concentration 25ug/ml. 20ul of this solution is spiked into every 1ml of sample extract prior to instrument analysis. This solution can also be prepared from a serial dilution of the **8270 Internal Standard Mixture** (250ug/mL). Information for the preparation of the 8270 Internal Standard Mixture can be found in SOP (2155) Semivolatile Organic Compounds by Gas Chromatography/Mass Spectroscopy.

8.5.7 Internal Standard Primary Standard for PCB Congeners – Prepared by diluting 2.5ml of 2**,2',3,4,4',5,5'-Heptachlorobiphenyl** (Cambridge Isotope Laboratory EC-1407-3 BZ#180 13C12 40ug/mL), and **4,4'-Dichlorobiphenyl** (Cambridge Isotope Laboratory EC-1407-3 BZ#15 13C12 40ug/mL) to 10ml in Hexane. Final concentration 10ug/mL. 20ul of this solution is spiked into every 1ml of sample extract prior to instrument analysis.

8.6 Calibration Solutions

8.6.1 PAH/PCB Combo ICAL /Stock Solution – Prepared by following the recipe outlined in the following table, bringing the components to either a final volume of 1mL or 10mL in methylene chloride. The final concentration is 5,000ng/ml for PAHs and 500ng/mL for PCB congeners.

Standard/Solution	Volume Added
PAH Custom Mix (Supelco 21383385 100ug/ml	1.0mL
Custom Deuterated PAH Standard (Restek 563160 2000ug/mL)	50uL
PAH Two Component Mixture (C.I.L. ES-5498 2000ug/ml	50uL
NOAA 22 + Surrogates Stock	1.0mL
BZ77/110/126 Stock	1.0mL

The following calibration levels are prepared by diluting the indicated volume of the above stock solution to 10mL in methylene chloride.

8.6.1.1 Level 1 (10/0.5ng/mL): 0.010mL of Stock diluted to a final volume of 10mL in methylene chloride.

8.6.1.2 Level 2 (20/1.0ng/mL): 0.020mL of Stock diluted to a final volume of 10mL in methylene chloride.

8.6.1.3 Level 3 (100/5ng/mL): 0.100mL of Stock diluted to a final volume of 10mL in methylene chloride.

8.6.1.4 Level 4 (200/10ng/mL): 0.200mL of Stock diluted to a final volume of 10mL in methylene chloride.

8.6.1.5 Level 5 (500/25ng/mL): 0.500mL of Stock diluted to a final volume of 10mL in methylene chloride.

8.6.1.6 Level 6 (1000/50ng/mL): 1.0mL of Stock diluted to a final volume of 10mL in methylene chloride.

8.6.1.7 Level 7 (2000/100ng/mL): 0.200mL of Stock diluted to a final volume of 1.0mL in methylene chloride.

8.6.1.8 Level 8 (5000/250ng/mL): 5.0mL of Stock diluted to a final volume of 10mL in methylene chloride.

8.6.2 Initial Calibration Verification Solutions (ICV)

8.6.2.1 Initial Calibration Verification PAH SIM Working Solution (500ng/ml): Created by diluting 0.5ml of **PAH ICV Stock** solution (10,000ng/ml) to 10ml in methylene chloride

8.6.2.2 PCB Congener ICV Working (25ng/mL): 1.25mL of **PCB Congener ICV Stock** solution (200ng/mL) diluted to a final volume of 10mL in methylene chloride.

8.6.3 DFTPP Tuning Solution – Prepared by diluting 1.25mL of **Semi-Volatiles GCMS Tuning Standard (**Ultra GCM-150 1000ug/mL) diluted to a final volume of 25mL in methylene chloride.

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

9.1 Blank(s)

A method blank (must be extracted with every batch of samples extracted or every 20 samples, whichever is more frequent. Organic compounds of interest must not be detectable in the method blank at a concentration greater than the reporting limit.

Corrective Action: Extraction of the method blank and all associated samples must be performed until the blank is in control. Samples cannot be analyzed until an acceptable method blank analysis is obtained. The results are qualified with a “B” flag for any associated sample concentrations that are less then 10x the blank concentration for the analyte. Exceptions may be made with if the samples associated with the out of control method blank are non-detect for the compound of interest, or if sample concentrations are greater than 10x the blank levels. In such cases when the sample results are accepted, the client is notified in a project narrative associated with the sample results.

9.2 Laboratory Control Sample (LCS)

Laboratory control samples (LCS/LCSD) must be prepared once per every 20 samples or per extraction batch, whichever is more frequent, and spiked with PAH SIM/PCB Congener spike solution, or TO-13 spike solution.

Acceptable Recovery limits are 40% - 140% for all matrices, except for TO-13 Air PUF - see Table D for TO13 LCS recovery criteria. The acceptable relative percent difference (RPD) between the LCS/LCSD is ≤30%. ≤10% of target compounds are allowed out provided recovery is >10%.

PAH and PCB portions need to be evaluated separately

Limits are adapted from MADEP-MCP protocol and/or TO-13A.

Corrective Action: Analysis must be repeated if an analytical error is suspected. If the LCS/LCSD recoveries and/or %RPD are still out of control, re-extract and re-analyze the LCS/LCSD and all associated samples. Samples cannot be reported until an acceptable LCS is obtained.

9.3 Initial Calibration Verification (ICV)

The initial calibration for each compound of interest must be verified prior to sample analysis. This is accomplished by analyzing a second source calibration standard (Section 8.2.10).

Calculate the % D for each analyte. If the % D for each analyte is ≤30% then the calibration is assumed to be valid. If this criterion is not met, the standard is reanalyzed once. If the standard failure continues, corrective action must be taken prior to sample analysis.

A new initial calibration must be performed and acceptable ICV results obtained prior to any sample analysis.

9.4 Continuing Calibration Verification (CCV)

On a daily basis after the DFTPP has passed, a mid-level (500/25ng/mL) continuing calibration verification standard which contains all of the analytes of interest is analyzed.

9.5 Matrix Spike/ Matrix Spike Duplicate (MS/MSD)

Matrix spike / matrix spike duplicate (MS/MSD) samples will be performed upon client and/or work plan request. MS/MSD is not performed for Method TO-13A.

See Section 12 for MS/MSD recovery limits and %RPD limits.

Calculate the %RPD as described in Section 9.6.

Corrective Action: If the % recovery and/or %RPD exceeds the control limits and the LCS is compliant; include a project narrative with the results to client noting that there may be potential matrix effects on the accuracy or precision of the reported results as evidenced by MS/MSD recoveries and/or %RPD outside of QC limits.

9.6 Laboratory Duplicate

Duplicate analyses are performed upon client and/or work plan request. Acceptable relative percent differences (RPD) of duplicates are listed in Section 12. Acceptance criterion is not applicable to sample concentrations less than 5 times the reporting limit.

Calculate the RPD as follows:

$$RPD = \frac{R1 - R2}{\frac{[R1 + R2]}{2}} \times 100$$

where:
R1 = sample Replicate #1
R2 = sample Replicate #2

Corrective Action: If the % RPD exceeds the control limits; include a project narrative with the results to client noting that there may be potential matrix effects on the precision of the reported organic results as evidenced by the matrix duplicate % RPD exceedance.

9.7 Method-specific Quality Control Samples

9.7.1 Surrogate Spikes: Surrogate spikes must be added to QC and field samples to evaluate the extraction method performance.

See Section 12 for surrogate recovery acceptance criteria.

Corrective Action: Up to one surrogate can be out in the PAH portion and in the PCB portion, but not less than 10% recovery, before any corrective action is necessary. Otherwise, analysis must be repeated if an analytical is suspected. If the % recovery still exceeds the control limits the sample must be re-extracted and re-analyzed to confirm the sample matrix. If *obvious* matrix interferences are noted, consultation with the Department Manager, Laboratory Director or QA Officer may be necessary to confirm the need for sample re-extraction. If no re-extraction occurs, the surrogate results and reasons for the no re-extract decision must be discussed in the project narrative to the client.

9.7.2 Standard Reference Materials (SRMs): Standard reference materials (SRMs) are available from the National Institute of Standards and Technology (NIST) and are extracted and analyzed with samples on a project-specific basis. These are not used as controls, but rather to evaluate potential matrix effects in associated samples for the target compounds being evaluated.

See Section 12 for SRM recovery acceptance criteria.

Corrective Action: Analysis must be repeated if an analytical error is suspected. If the % recovery and/or %D still exceeds the control limits, and the LCS and MS/MSD pair are compliant, include a project narrative with the results to client noting that there may be potential matrix effects on the accuracy or precision of the reported results as evidenced by SRM % recoveries and/or %D values outside of QC limits. These cases are normally isolated to the SRM, if all other controls are within limits.

9.7.3 Internal Standards: Internal standards must be added to all sample extracts, QC samples and standards for quantitation purposes.

The internal standards in the samples should remain at constant area counts with respect to the continuing calibration analyzed at the beginning of the run. Sample IS areas must be 50% to 200% of the Internal Standards in the Continuing Calibration.

Additionally, the IS retention times should not differ more than +0.06 RRT from the Continuing Calibration.

Corrective Action: Analysis must be repeated once unless there are obvious samples matrix interferences, e.g. If the sample extract was very colored and viscous, or there are obvious chromatographic interferences. If *obvious* matrix interferences are noted, consultation with the SemiVolatiles Department Manager, Laboratory Director or QA Officer may be necessary to confirm the need for sample re-analysis.

9.8 Method Sequence

- Tune
- CCV
- Method Blank
- LCS
- LCSD
- Samples

10. Procedure

10.1 Equipment Set-up

10.1.1 The **basic GC parameters** are as follows:

Injection Port Temp: 300°C
Oven Equib Time: 0.50 min
Oven Max: 350°C
Oven: On
Cryo: Off
Ambient: 45°C
Cryo Blast: Off
Initial Temp.: 45°C
Initial Time: 3.00 min

Level	Rate (°C /min)	Final Temp. (°C)	Final Time (min)
1	25.00	250	0
2	10.00	310	5.0
3	0.0off		

Final Time: 22.2min

10.1.2 The **basic injection port parameters** are as follows:

"Split" mode
Equilibrium Time: 0.50 minute
Temp: 300°C
Pressure: 8.28 psi (10.5 psi) Total Flow: 69.3mL/min)
Split: 50:1
Split Flow: 65 mL/min

Injection volume: 3uL

Please note that this may differ slightly from one instrument to another.

10.1.3 Column conditions parameters are as follows:

Column flow: 1.3mL/min
Linear Velocity: 42 cm/sec

10.1.4 Tuning:

10.1.4.1 Tune acceptance should be verified at the beginning of every 12 hour analytical shift. Before the analytical standards are analyzed the mass spectrometer must be adjusted to meet the proper ion criteria for DFTPP. This is demonstrated by injecting into the GC/MS system 1uL of a 50ug/mL DFTPP solution.

10.1.4.2 Within the Enviroquant software, "Autofind" is used first to evaluate Tune. Three scans (the peak apex scan and the scans immediately preceding and following the apex) are acquired and averaged. Background subtraction is required, and must be accomplished using a single scan acquired within 20 scans of the elution of DFTPP. The background subtraction should be designed only to eliminate column bleed or instrument background ions. Do not subtract part of the DFTPP peak or any other discrete peak that does not coelute with DFTPP.

10.1.4.3 If the "AutoFind" tune evaluation does not meet the criteria below, manual evaluation of the tune can be performed by attempting either of the options below:

- Blow up the DFTPP peak on the screen and select either one single scan at the apex of the peak, or a scan immediately preceding or following the apex.
- Take the average of the scans across the entire peak.

The following DFTPP mass intensity criteria should be used:

- **for PAH SIM analysis:**

The response of Benzidine and Pentachlorophenol, when monitored on a daily basis, will indicate the efficiency of the chromatographic system. Benzidine and Pentachlorophenol should be present at their normal responses and no peak tailing should be visible. The tailing factor of Benzidine and Pentachlorophenol must not exceed 2. DDT breakdown must be <20%. Although moderate tailing may indicate maintenance on the instrument will be required soon, these additional compounds in the DFTPP standard are included as an aid in instrument performance evaluation

DFTPP KEY MASSES AND ABUNDANCE CRITERIA

Mass	m/z Abundance criteria
68	Less than 2 percent of mass 69.
69	confirmed to be present
70	Less than 2 percent of mass 69.
197	Less than 2 percent of mass 198.
198	Base peak, or >50 percent of Mass 442.
199	5-9 percent of mass 198.
365	Greater than 1 percent of mass 198.
441	Present but less than 24 percent of mass 442.
442	Base Peak, or > 50 percent of mass 198.
443	15-24 percent of mass 442.

- For PAH/PCB combined analysis:

DFTPP KEY MASSES AND ABUNDANCE CRITERIA
(Maximum Sensitivity)

Mass	m/e Abundance criteria
51	N/A
68	N/A
70	N/A
127	30-80 percent of mass 198.
197	Less than 3 percent of mass 198.
198	Greater than 40 percent of mass 442.
199	5-15 percent of mass 198.
275	15-50 percent of mass 198.
365	Greater than 3 percent of mass 198.
441	Present but less than mass 443.
442	Base peak, 100 percent relative abundance.
443	18-30 percent of mass 442.

10.2 Initial Calibration

10.2.1 After the DFTPP passes criteria, a set of multi-level calibration standards listed in Section 8.2.9 are analyzed, from low concentration to high. A minimum of five calibration levels are analyzed. The calibration standards are stored in the standards freezer. When the Initial Calibration is typed into a sequence, the standard ID for each of the levels must be noted in the “comments” of the sequence. (Refer to the Reagent Solvent and Standard Control SOP (SOP 1816) for further information regarding standard labeling convention.

10.2.2 Once the calibration curve is accepted and prior to processing any samples, the analyst must demonstrate through the analysis of a MB or instrument blank that equipment and reagents are free from contaminants and interferences. If a peak is found in the blank that would prevent the identification or bias the measurement of an analyte, the analyst should determine the source of the contaminant peak and eliminate it, if possible. Blanks

are generally considered to be acceptable if target analyte concentrations are less than one half the LLOQ or are less than project specific requirements. Blanks may contain analyte concentrations greater than acceptance limits if the associated samples in the batch are unaffected

10.2.3 Once the standards have been analyzed, they are reduced by the search software of the Enviroquant data system. Once all the components are identified, a linear curve is calculated for the components. The criteria for evaluation are as follows:

The RSD of each target analyte, for each level in the ICAL, must meet the minimum response factor criteria found in Table C. The %RSD for each target analyte must not exceed 20%. If the %RSD for any target exceeds 20%, then the linear calibration model must be employed. A linear fit is acceptable if the correlation coefficient is greater than 0.99. A minimum of 5 levels are required for a linear calibration model and a minimum of 6 levels are required for a quadratic calibration model. When calculating calibration curves using the linear regression model, a minimum quantitation check must be performed on the lowest calibration point. The recalculated concentration of the lowest calibration point should be within 30% of the true value. If this criterion is not met then corrective action must take place and a new initial calibration must be performed prior to sample analysis.

10.3 Equipment Operation and Sample Processing

10.3.1 Sample Extraction and Cleanup

Samples for PAH SIM/ PCB Congeners are generally extracted using one of the following SOPs:

- *Separatory Funnel Extraction* 3510C (SOP 2165)
- *Microscale Solvent Extraction* 3570 (SOP 2172)
- *Soxhlet Extraction for PUF* 3540C (SOP 2174)
- *Waste Dilution and Oil Prep* 3580 (SOP 2265)

Samples for PAH SIM/ PCB Congeners may be cleaned up before transfer to the instrument laboratory using one of the following SOPs:

- *Gel Permeation Column Cleanup* SOP (SOP 2167)
- *Silica Gel Clean-up* SOP (SOP 2170)
- *Sulfur Cleanup* SOP (SOP 2168)

10.3.2 The prep lab staff will transfer the samples to the instrument laboratory. The samples are generally brought to a 1.0mL to 4.0mL final volume; 1.0mL is transferred and any remaining sample is put into archive. One aliquot of each sample is then logged into the Internal Chain of Custody book and placed in the sample extract holding refrigerator located in the instrument laboratory.

10.3.3 All samples and standards are spiked with Internal Standards (IS) before analysis. The IS is intended to be used for both quantification and the establishment of relative retention times.

10.3.4 The analyst may determine to screen any samples for needed dilution. A sample that will need a dilution either for target analytes that are over calibration, or samples may need to

be diluted solely for matrix issues when the chromatogram shows a large UCM (unresolved complex mixture) or other non-target interferences, or when the extract itself is very colored and viscous. All of the samples at 500uL (including the QC samples of a method blank and LCS) are spiked with 10uL internal standard (see section 10.3.2 for specifics regarding the internal standard) for a concentration of 5ug/mL. The samples are shaken briefly after the internal standard is added to ensure mixing.

10.3.5 After the samples have been analyzed, the data files from the instrument are transferred to the server. The samples are quantified versus the proper method. The QCPRN1.MAC macro creates a form with which to easily check internal standard and surrogate criteria. The ISTDRPT.MAC macro may also be utilized to check the internal standard and surrogate criteria. The following should be reviewed initially:

10.3.5.1 Are all the surrogates within QC criteria? See Section 12 and Table A for surrogate recovery ranges.

10.3.5.2 Are all the internal standards within 50-200% and within ±0.06 RRT of the daily CCAL? If not, the samples should be checked for matrix interferences that may be causing these issues. The IS peaks should also be evaluated for peak splitting or incorrect integration by the software. A sample may not need to be reanalyzed if it can be determined (with guidance from a supervisor) that the QC is exceeded due to matrix interference.

10.3.5.3 Are all target analytes within calibration range? If not, the sample must be diluted and re-analyzed. If a dilution is performed after the internal standard has already been added, it will be necessary to add additional IS in order to provide a concentration of 5ug/mL. Conversely, if a sample has been over-diluted, it may need to be analyzed at less of a dilution to detect target analytes that may have been diluted out.

10.3.5.4 Are all analyses within 12 hour tune time? If a sample is analyzed outside tune time, it must be re-analyzed within another tune clock.

10.3.6 The sequence should also be printed out from Chemstation, initialed and dated, placed in the working logbook.

10.3.7 If anything in the initial review of the data indicates that there should be a re-analysis or a re-extract, the reason for re-analysis or re-extract should be noted on the sequence.

10.3.8 If a re-extract is required, the “Request for Reanalysis/Repreparation” book should be filled out and a photocopy of the appropriate page should be given to the Preparation Group leader or the SemiVolatile Organics Department Manager.

10.3.9 A standard sequence (saved as S5073001;”S” for semivolatile;”5” for PAH5; 0730 for July 30, and 01 is the first sequence that day) would appear as follows:

Tune: WG#-1, -4, etc. This is the Analytical working group number generated by the Alpha LIMS that denotes the Tune.

CCV: WG#-2, -3, etc. This is the Analytical working group number generated by the Alpha LIMS that denotes the calibration verification.

10.4 Continuing Calibration

10.4.1 On a daily basis after the DFTPP has passed, a mid-level (500/25ng/mL) continuing calibration standard which contains all of the analytes of interest is analyzed. The criteria for acceptance are :

10.4.1.1 The %D for all targets must be ≤20%. Up to 20% of all targets are allowed to have %D > 20% with high bias as long as all associated samples are non-detect for those analytes. If any of the targets have %D > 20% with low bias, corrective action must take place and all associated samples must be reanalyzed.
PAH and PCB portions need to be evaluated separately.

10.4.1.2 The retention times of the internal standards must be within ±0.05 RRT of the previous daily standard.

10.4.1.2 The area counts of the internal standards within the continuing calibration must be within 50 to 200% of the mid-level in previous ICAL

10.5 Preventive Maintenance

All repair and non-routine maintenance records including outside service visits are maintained in the instrument maintenance logbooks.

Injection Port Maintenance: Maintenance should be done when the daily CCAL starts to demonstrate degradation. The type of samples analyzed will have an effect on how soon maintenance should be performed.

Septum Maintenance: The septum needs to be changed approximately every two-hundred injections. Unscrew the top septum nut, remove the pierced septum, and replace with a new 11mm Thermolite green septum (Restek) or equivalent. Screw the top septum nut back on.

Column Maintenance: Maintenance should be done when the daily CCAL starts to demonstrate degradation. The type of samples analyzed will have an effect on how soon maintenance should be performed. Generally maintenance is performed by trimming 6 cm off the front of the column. The column is then installed into the injection port liner, and the inlet nut is tightened.

11. Data Evaluation, Calculations and Reporting

11.1 Qualitative Analysis

11.1.1 The qualitative identification of compounds determined by this method is based on retention time and on comparison of mass spectrum, after background correction, with characteristic ions in a reference mass spectrum. The reference mass spectrum must be generated by the laboratory using the conditions of this method. The characteristic ions from the reference mass spectrum are defined as three ions of greatest relative intensity, or any ions over 20% relative intensity, if less than three such ions occur in the reference spectrum. Compounds are identified when the following criteria are met.

11.1.2 The intensities of the characteristic ions of a compound must maximize in the same scan or within one scan of each other. A peak selected by the data system, based on the presence of target specific ions at a target specific retention time will be accepted as meeting this criteria.

11.1.3 The relative retention time of the sample component is within ± 0.06 RRT units of the RRT of the standard component.

11.1.4 The relative intensities of the characteristic ions agree within 30% of the relative intensities of these ions in the reference spectrum. (Example: For an ion with an abundance of 50% in the reference spectrum, the corresponding abundance in a sample spectrum can range between 20% and 80%). Outlying abundances maybe included due to the presence of non-target interference. The relative intensities are monitored daily. The relative intensities will be updated when they exceed established values from the reference spectrum.

11.1.5 Structural isomers that produce very similar mass spectra should be identified as individual isomers if they have sufficiently different GC retention times. Sufficient GC resolution is achieved if the height of the valley between two isomer peaks is less than 50% of the sum of the two peak heights. Otherwise, structural isomers are identified as isomeric pairs.

11.1.6 Identification is hampered when sample components are not resolved chromatographically and produce mass spectra containing ions contributed by more than one analyte. When gas chromatographic peaks obviously represent more than one sample component (i.e. a broadened peak with shoulder(s) or a valley between two or more maxima), appropriate selection of analyte spectra and background spectra is important.

11.1.7 Examination of extracted ion current profiles of appropriate ions can aid in the selection of spectra and in qualitative identification of compounds. When analytes coelute, (i.e. only one chromatographic peak is apparent), the identification criteria may be met, but each analyte spectrum may contain extraneous ions contributed by the coeluting compounds.

11.2 Response factors and %RSD to evaluate initial calibration acceptability

Calculate RF by:

$$RF = \frac{area_{cmp}}{area_{is}} \times \frac{conc_{is}}{conc_{cmp}}$$

where:

area cmp = Area of the characteristic ion for the compound being measured.
area is = Area of the characteristic ion for the specific internal standard.
conc is = Concentration of the specific internal standard.
conc cmp = Concentration of the compound being measured.

Calculate %RSD by:

$$\%RSD = \frac{SD}{\bar{x}} \times 100 \qquad SD = \sqrt{\sum_{i=1}^{N} \frac{(x_i - \bar{x})^2}{N-1}}$$

where:

%RSD = percent relative standard deviation
x = average of RF's
SD = standard deviation
xi = analytical results of each level in the final reporting units
N = number of results (levels)

11.3 % Difference to evaluate daily calibration standard

Calculate %D by:

$$\%D = \frac{\overline{RF}_i - RF_c}{\overline{RF}_i} \times 100$$

where:

RFi = initial calibration average RF
RFc = continuing calibration RF

11.4 Results of Water Analysis

Calculation as performed in worksheet:

$$\textit{concentration (ng/L)} = \frac{\textit{(Conc) (Vf) (DF) x 1000}}{\textit{(Vi)}}$$

where:

Conc = Raw result concentration obtained from the quantitation report in ng/mL (ppb)
Vf = Final volume of extract (mL)
Vi = Volume of sample extracted (mL)
DF = Dilution factor, for manually prepared dilutions, not instrumental “dilutions”

11.5 Results of Sediment/Soil, Sludge/Waste Tissue, Oil and Air PUF Analysis

Calculation as performed in Excel worksheet:

$$\textit{concentration (}\mu\textit{g/Kg)} = \frac{\textit{(Conc) (Vf) (DF)}}{\textit{(W) (\%S)}}$$

where:

Conc = Raw result concentration obtained from the quantitation report in ng/mL (ppb)
DF = Dilution factor, for manually prepared dilutions, not instrumental “dilutions”
Vf = Extract final volume (mL)
W = Aliquot of sample (wet), g (for Air PUF, sample amount is 1)
%S = Sample % solid

NOTE: Tissue samples are calculated in the same manner, however %S may, or may not be utilized depending upon the client request to report data as a wet or dry weight. Oil and Air PUF sample calculations do not use %S in the final concentration.

11.6 The calculation for percentage breakdown for DDT is:

$$\%\ \text{Breakdown DDT} = \frac{\text{(Area DDD + Area DDE)}}{\text{(Area DDD + Area DDT + Area DDE)}} \times 100$$

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

All results for the organic compounds of interests are reportable without qualification if extraction and analytical holding times are met, preservation (including cooler temperatures) is met, all QC criteria are met, and matrix interference is not suspected during extraction or analysis of the samples. If any of the below QC parameters are not met, all associated samples must be evaluated for re-extraction and/or re-analysis.

If non-compliant organic compound results are to be reported, the SemiVolatile Organics Department Manager, the Laboratory Director, and/or the QA Officer must approve the reporting of these results. The laboratory Project Manager shall be notified, and may chose to relay the non-compliance to the client, for approval, or other corrective action, such as re-sampling and re-analysis. The analyst or Department Manager performing the secondary review initiates the project narrative, and the narrative must clearly document the non-compliance and provide a reason for acceptance of these results.

QC Parameter	Acceptance Criteria
Initial Calibration Curve	Initial Calibration Curve ≤20%RSD or ≥0.99 linear for all targets. If linear regression is used, recalculation of the lowest calibration standard is required to be within 30% of the true value.
Independent Check Verification	+/- 30% recovery of the true values,
Continuing Calibration Verification	Analyzed every 12hr or at the minimum of every 20 samples, < +20% D for all target analytes. .
Method Blank	No analyte detected at or above the reporting limit, "B" qualify analyte if detected concentration is less than 10X the concentration found in the associated sample(s)
Laboratory Control Sample and LCSD	40-140% for all matrices, except for TO-13 - see Table D; 30% RPD.
Matrix Spike / Matrix Spike Duplicate	40-140 recovery; 30% RPD between the duplicates.
Sample / Sample Duplicate	30% RPD between the duplicates.
Surrogates	PAHSIM 30-130% all matrices; PAH/PCB: PAH 30-150% and PCB 50-125% all matrices; USACOE RIM PAH/PCB: 30-150% all matrices; TO-13: see Table A One Surrogate is allowed out from each PAH or PCB portion
Internal Standards	50% - 200% of the daily CCV area for the Internal Standards
Standard Reference Material	40-140% recovery based on values provided by Vendor
Project specific work plans and DQOs supersede the above limits.	

13. Method Performance

13.1 Method Detection Limit Study (MDL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the MDL, LOD, and/or LOQ as outlined in Alpha SOP/08-05. These studies performed by the laboratory are maintained on file for review.

13.2 Demonstration of Capability Studies

Refer to Alpha SOP/08-12 for further information regarding IDC/DOC Generation.

13.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

14. Pollution Prevention and Waste Management

Refer to Alpha's Chemical Hygiene Plan and Hazardous Waste and Sample Disposal SOP (1797) for further pollution prevention and waste management information.

1. Scope and Application

Matrices: Soil and sediment samples, as received from the field.

Definitions: Refer to Alpha Analytical Quality Manual.

This analytical method covers the quantitative determination of the distribution of particle size in soils and sediments. The distribution of particle sizes larger than 75μm (retained on the No.200 sieve) is determined by sieving. The distribution of particle sizes smaller than 75μm (not retained on the No.200 sieve) is determined by a sedimentation process, using a hydrometer.

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one or more of the following laboratory personnel before performing the modification: Area Supervisor, Department Supervisor, Laboratory Director, or Quality Assurance Officer.

This method is restricted to use by or under the supervision of analysts experienced in the operation of the equipment and in the interpretation of data. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability and completing the record of training.

A major modification to this procedure requires demonstration of performance. The identification of major method modification requiring performance demonstration is directed by the Quality Assurance Officer and/or Laboratory Director on a case-by-case basis.

2. Summary of Method

Particle Size *without* Hydrometer (often referred to as *Wet Sieve* or *Grain Size Analysis*) is determined by drying a homogenized soil sample. The dried homogenate is placed onto a number 200 sieve, washed with tap water, re-dried, and re-homogenized. The dried soil is

mechanically sieved with an array of sieve sizes. The distribution of soil sample remaining in each of the sieves is determined by weight and represents various classes of soil including cobble, gravel, course and fine sand, silt and clay.

Particle Size with Hydrometer is determined by drying a homogenized soil sample and immersing it in a *sodium hexametaphosphate* solution. A hydrometer test is then performed which defines the fraction of sample that is silt and clay. The sample from the hydrometer test is transferred to a number 200 sieve and washed with tap water to remove all particles less than 75 μm. The sample remaining on the number 200 sieve is then re-dried and re-homogenized and is mechanically sieved with an array of sieve sizes that define the medium and fine sands present in the sample.

When receiving limited amount of sample (e.g. 75-100gm), the test can be performed on a wet sample. % solids must be analyzed and the dry weight used for final calculations. Then proceed as in Section 10.3.2.

2.1 Method Modifications from Reference

The hydrometers are left in place between reads to ensure stability and reduce loss of material and testing volume. An internal study demonstrated equivalent data results through real world sample duplicates.

3. Reporting Limits

Not Applicable

4. Interferences

Special consideration should be given to soils from a marine environment or other sources where high soluble salt concentrations may be present. The degree to which the salts present in these soils are diluted or concentrated must be given consideration if meaningful results are to be obtained.

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material safety data sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

A minimum of 200-grams of sample should be collected in an 8 oz. plastic jar.

6.2 Sample Preservation

None.

6.3 Sample Shipping

No special shipping requirements.

6.4 Sample Handling

The samples must be aliquoted and dried in an oven or air dried in a hood. Remaining sample can be stored at room temperature. Hold times are not applicable to particle-size determination.

7. Equipment and Supplies

7.1 Analytical balance: Capable of weighing to the nearest 0.01g

7.2 Aluminum pie tins, plastic 250-mL beakers, *Parafilm*

7.3 Vapor hood, sink with tap water for rinsing/cleaning

7.4 Mechanical stirring apparatus

7.5 Stainless steel spatulas, spoons, and mixing bowls

7.6 Drying ovens: Maintained at 110±5°C , 40°C±5°C

7.7 Hydrometer: 151H, (or 152H for high fines samples) per ASTM specifications E 100

7.8 Sedimentation cylinder: 1000mL glass with large rubber stoppers to fit

7.9 Thermometer: Accurate to 0.5°C (able to read 20°C)

7.10 Timing device: electronic timer

7.11 Constant room-temperature, 22±5°C

7.12 Mechanical sieve shakers: Models RX-29, Type:110V, 60HZ and CI-305A-1, Type: 120V, 60HZ

7.13 Sieves: Square-mesh, woven-wire cloth per ASTM specifications E11: 3in., 2in., 1.5in., 1.0in., 0.75in., 0.375in., #4, #10, #20, #40, #60, #100, #140, #200, Pan

7.14 Bristle brushes: For sieve cleaning

7.15 Mortar and Pestle

8. Reagents and Standards

8.1 Deionized (DI) water or RO water: Lab generated. Note: Tap water cannot be used for the soaking or hydrometer solutions.

8.2 Sodium Hexametaphosphate Solution: Dissolve 240g into approx.1000-mL DI water, dilute to 6-L with DI water. (Solution expires monthly, and must be kept at a pH of 8-9, using sodium carbonate.) Store at room temperature.

8.3 Sodium Carbonate, 0.5M: Thoroughly dissolve 26.49g of Na_2CO_3 in 400-mL DI water, dilute to 500-mL. Store at room temperature; expires in one year stored in a closed vessel.

8.4 Wide-Range pH paper.

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

9.1 Blank(s)

Not applicable.

9.2 Laboratory Control Sample (LCS)

Not applicable.

9.3 Initial Calibration Verification (ICV)

Not applicable.

9.4 Continuing Calibration Verification (CCV)

Not applicable.

9.5 Matrix Spike

Not applicable.

9.6 Laboratory Duplicate

One Duplicate per 20 or one duplicate per batch.

RPD <25%, narrate non-conformances in the final report

9.7 Method-specific Quality Control Samples

Not applicable.

9.8 Method Sequence

Refer to Section 10

10. Procedure

10.1 Equipment Set-up

Not applicable.

10.2 Initial Calibration

Not applicable.

10.3 Equipment Operation and Sample Processing

10.3.1 Sample Preparation – Particle Size with/without Hydrometer

Samples are prepared immediately upon arrival.

10.3.1.1 Homogenize the sample using a stainless steel mixing bowl, spatula, and/or spoon. Transfer a sample aliquot into a properly labeled aluminum pie tin and dry in an oven or set to air-dry in a hood. (It is recommended for visually wet samples that the entire sample is set to dry to ensure adequate mass is available, since dry weight is unknown.) A matrix duplicate, if not already specified by the client, is chosen and set to dry in its own tin. *Note: Samples can be dried overnight in an oven set at 110 ℃, with the exception of claylike samples. Claylike samples are partially dried in an oven or in the hood and broken up as they are drying to help prevent solidifying of samples. Note in the case of limited sample, a smaller aliquot may be taken upon approval of the Project Manager.*

10.3.1.2 Carefully grind dried sample using a mortar and pestle. Do not grind any shells, wood, rocks, or large particles. Remove any matter that does not properly represent the sample.

10.3.1.3 If only a limited amount of sample is available, see Section 2.0 regarding Hydrometer analysis.

10.3.2 Particle Size (without Hydrometer) Analysis

10.3.2.1 Weigh approximately 100g to 500g of the sample, as prepared in Sec.10.3.1.1, and record this weight as the *original sample weight*. A sample consisting of heavy materials, such as large rocks, requires a greater *original sample weight* for proper sample representation.

10.3.2.2 Transfer entire sample aliquot to a No. 200 sieve and wash with tap water until the wash water is clear. (Be very careful not to damage the sieve or to lose any soil by splashing the material out of the sieve. Do not force material through sieve with fingers.) Transfer washed material on the No. 200 sieve to aluminum tin. Dry the residue in an oven at 105°C, overnight, or until completely dry.

10.3.2.3 Remove dried sample residue from oven. Gently grind and weigh the residue. Record this weight as the *post-wash weight*.

10.3.2.4 Refer to Section 7.13 for list of sieves. Add sample residue to the stack of sieves. Place lid on stack of sieves. Shake sieves containing sample for four (4) minutes. *Note: Seven sieves and pan will fit on each mechanical shaker at one time, but up to thirteen sieves may be required. Consult the Section Supervisor for proper guidance.*

10.3.2.5 Remove the stack of sieves from the shaker and record the final weight of the contents of each sieve. A brush is used to remove all sample from sieves and collected onto the weighing container.

10.3.2.6 Optionally, if oily material adheres to the sieves after brush cleaning: Soak in soapy hot water and use the wire (coarse) sieve brush to remove particulate, taking care not to damage the wire mesh. Brush the sieve on both sides, paying attention to fine matter. Once there are no particles left on the sieve mesh, and the sieve rinses clean, it is ready for reuse.

10.3.3 Particle Size with Hydrometer Analysis

10.3.3.1 Weigh approximately 50g of the sample, as prepared in Section 10.3.1.1, into a 1000ml glass cylinder. The suspended sediment capacity of the 152H hydrometer is about 55 g of dry soil and the capacity of the 151H is about 45 g. Record this weight as *original sample weight* or *hydrometer weight.* Add 125-mL of sodium hexametaphosphate solution, seal with a rubber stopper, and let sit for at least 16 hours at room temperature.

10.3.3.1.1 If a limited amount of wet sample is available, refer to Section 2.0.

10.3.3.2 Homogenize the contents of the glass cylinder. Bring up to 1000-mL mark with RO water. Cap with rubber stopper. Note: The water used for volumizing should be at room temperature.

10.3.3.3 At a constant room temperature, mix the contents of the capped cylinder for up to one minute by inverting until all contents are suspended (residue on bottom of cylinder has loosened completely). At this point, immediately begin timing analysis. *Note: Small variations of temperature do not introduce differences that are of practical significance however, loss of water does and must be avoided.*

10.3.3.4 Slowly immerse the 151H hydrometer into the sample 30 seconds prior to the time the initial reading should be taken in order to assure that the hydrometer stabilizes before the reading. Take readings at 2, 5, 15, 30, 60, 240, and 1440 minutes (total elapsed time). Cover the cylinder and hydrometer with an inverted plastic funnel to inhibit evaporation beyond the 30 minute reading.

10.3.3.5 Follow steps 10.3.3.1 through 10.3.3.4 for each sample.

10.4 Continuing Calibration

Not applicable.

10.5 Preventive Maintenance

Not applicable.

11. Data Evaluation, Calculations and Reporting

11.1 Particle size with/without hydrometer is calculated by entering raw data, recorded in the laboratory notebook, into the LIMS. Using the particle percent retained, calculated in LIMS, the analyst calculates the particle percent passing for each sample. This is calculated as follows:

Percent Passing (%) = 100 – Percent Retained (%)

The analyst transfers this data, along with sample identification, into*, GEOSYSTEM.* This program performs all necessary calculations. It determines the particle size distribution ratios and illustrates them graphically.

11.2 To report *Particle Size With/Without Hydrometer*, first go to the LIMS and “batch” all samples in this analytical batch. Then enter the results from the laboratory notebook into *GEOSYSTEM.* Finally, use the results to create a graph in *GEOSYSTEM.*

11.2.1 Enter “*GEOSYSTEM*”

11.2.2 To create a New Project

11.5.2.1 Type name of project as LIMS Workgroup number in bottom left hand box that reads "Name"

11.5.2.2 Click "Open." A box will come up that reads "The Project (name of the project just created) can't be found. Would you like to create it?" Click "Create." This will open a new window

11.5.3 To Set up Project Data

11.5.3.1 Click "Project Data" in left hand column

11.5.3.2 Type full client name, project name, and project number (WG number)

11.5.4 To Set up Samples

11.5.4.1 Click first button on left hand side of the screen (green "+") to create a new source. Each new source is a sample - create one for each sample in the ETR.

11.5.4.2 Type Sample ID on the "Source" line in the right hand screen and Lab ID where it says "Sample No." in the first card.

11.5.4.3 Repeat for each sample.

11.5.5 To Enter Data

11.5.5.1 Click link for USCS in sample card

11.5.5.2 Click link for Grain Size at the top of the screen

11.5.5.3 Click tab for Sieve Test

11.5.5.4 Choose a 'sieve nest' from the drop down list, (*i.e.*, Army Corps Sieve). If your group of sieves does not match any of these, create a new nest.

11.5.5.4.1 Type sieve sizes in Sieve opening size column, using enter to move between columns, and click "save current sieve nest" at the top of the screen - it will ask you to name the nest.

11.5.5.5 For samples with hydrometer, enter sample weight into box for "Dry sample and tare weight." Type 0 in box for "Tare weight." (For samples with sieve only, skip to 15.5.5.14)

11.5.5.6 Type sample weight into "Dry Sample and Tare" column in line 1 and 0 in "Tare" column.

11.5.5.7 Enter "Weight retained" (our Sieve minus sample Weight as read from tared scale) and enter 0 for "Sieve weight" for each sieve. Use enter to move from column to column. Do not enter pan. Click disk icon to save.

11.5.5.8 Click hydrometer test tab. (For samples with sieve only, skip to 15.5.5.14)

11.5.5.9 Hydrometer sample box: Enter sample weight as total dry weight. Specific gravity = 2.65

11.5.5.10 Corrections box: Hydrometer correction @ 20°C = hydrometer correction factor, Meniscus correction = 0

11.5.5.11 Hydrometer box: Select 151H

11.5.5.12 Enter hydrometer data starting with 2 minutes; enter reading as whole numbers (i.e. 14 rather than 1.014). Use the enter key to move through columns; do not need to reenter temperature with every hydrometer reading.

11.5.5.13 Click disk icon to save.

11.5.5.14 Click on reports tab.

11.5.5.15 Select "Similar to the Corps of Engineers report form (GSGEOSYS)" from the drop down box.

11.5.5.16 Click printer icon.

11.5.5.17 Click "Test 1" tab from right side of the screen.

11.5.5.18 Click disk for save to LIMS. Add analyst initials to end of file name with a comma and no space to have the analyst initials appear correctly on the LIMS report.

11.6 Forward all hand recorded raw data from the laboratory notebook, Excel spreadsheets, LIMS batch printouts, and *GEOSYSTEM* graphs for secondary review.

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

Section 9 outlines sample batch QC and acceptance criteria. Corrective action for non-compliant data is discussed in Section 9. If a situation arises (such as loss of sample, or the inability for re-extraction or re-analysis) that requires additional action, the Project Manager and QA Officer will be immediately notified and will contact the client for discussion and/or instruction for any further action. The situation and the agreed upon actions will be discussed in the project narrative that accompanies the data package.

13. Method Performance

13.1 Detection Limit Study (MDL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the DL, LOD, and/or LOQ as outlined in Alpha SOP/1732. These studies performed by the laboratory are maintained on file for review.

These studies are not applicable to this method.

13.2 Demonstration of Capability Studies

Refer to Alpha SOP/1739 for further information regarding IDC/DOC Generation.

13.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

14. Pollution Prevention and Waste Management

Refer to Alpha's Chemical Hygiene Plan and Waste Management and Disposal SOP for further pollution prevention and waste management information.

PCBs

By Capillary Column Gas Chromatography

Reference Methods: Method 8082A SW-846, Test Methods for Evaluating Solid Waste: Physical/Chemical Methods, EPA SW-846, Update IV, 2007.

Quality Control Requirements and Performance Standards for Analysis of Polychlorinated Biphenyls (PCBs) by Gas Chromatography (GC) in Support of Response Action under the Massachusetts Contingency Plan (MCP), Revision No.2, February 15, 2024.

State of Connecticut, Department of Environmental Protection, RRCP, Version 3.0, May 2024.

1. Scope and Application

Method 8082A is used to determine the concentrations of Polychlorinated Biphenyls (PCBs) as Aroclors in extracts from solid, oil and liquid matrices. This SOP details the analysis for PCBs using fused-silica, open-tubular, capillary columns with electron capture detectors (ECD).

Matrices: Extracts from solid, oil and liquid matrices.

Definitions: See Alpha Laboratories Quality Manual Appendix A

Regulatory Parameter List: The standard compounds listed below are determined by this method.

Parameter	CAS#
Aroclor 1016	12674-11-2
Aroclor 1221	11104-28-2
Aroclor 1232	11141-16-5
Aroclor 1242	53469-21-9
Aroclor 1248	12672-29-6
Aroclor 1254	11097-69-1
Aroclor 1260	11096-82-5
* Aroclor 1262	37324-23-5
*Aroclor 1268	11100-14-4

*Note – not certified by NJ for the oil matrix

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one of the following laboratory personnel before performing the modification: Area Supervisor, Laboratory Director, or Quality Assurance Officer.
This method is restricted to use by or under the supervision of analysts experienced in the operation of the gas chromatograph (GC) and in the interpretation of gas chromatograms. Each analyst must demonstrate

the ability to generate acceptable results with this method by performing an initial demonstration of capability (see section 13.2).

2. Summary of Method

A measured volume or weight of sample (100mL for liquids, 1g for oil and up to 15g for solids) is extracted using the appropriate matrix-specific sample extraction technique.

Liquid samples are extracted at neutral pH with methylene chloride using Method 3510C (separatory funnel), or other appropriate technique. See extraction SOP for details.

Solid samples are extracted with methylene chloride: acetone (1:1) using Method 3540C (Soxhlet), or other appropriate technique. Solid samples may also be extracted with hexane: acetone (1:1) using Method 3546 (microwave). See extraction SOP for details.

Wipe samples are extracted with methylene chloride: acetone (1:1) using Method 3540C (Soxhlet) or other appropriate technique. See extraction SOP for details.

Oil samples are diluted with hexane following the procedure outlined in the extraction SOP.

Sulfuric acid cleanup (Method 3665A), Copper cleanup (Method 3660B) and Silica Gel cleanup (Method 3630) are utilized for PCB extracts. See extraction SOP for details.

After cleanup, the extract is analyzed by injecting 1µL into a gas chromatograph equipped with narrow- or wide-bore fused silica capillary columns and electron capture (GC/ECD) detectors.

2.1 Method Modifications from Reference

Not applicable.

3. Reporting Limits

The reporting limits for this method as outlined is as follows:

- **Aqueous samples**: 0.04 ug/L / Aroclor based on a 100mL extraction
- **Soil Samples**:
  - 33.3 ug/kg / Aroclor based on 15g extraction
  - 50.0 ug/kg / Aroclor based on 10g extraction
  - 100.0 ug/kg / Aroclor based on 5g extraction
  - 250.0 ug/kg / Aroclor based on 2g extraction
- **Oil Samples**: 5 mg/kg based on 1g extraction
- **Solid of Difficult Matrices** (i.e Caulking, Concrete, etc. are logged using the Alpha Low Level 8082 products): based on a 15g extraction
  - Aroclors 1016, 1221, 1232, 1242, 1254: 20 ug/kg
  - Aroclors 1248, 1260: 13.3 ug/kg
  - Aroclors 1262, 1268: 6.67 ug/kg

4. Interferences

4.1 Instrumental

4.1.1 Only high purity gases are used in the GC system to eliminate this source of possible contamination. Both the Hydrogen (carrier gas) and Nitrogen (detector make-up gas) are certified by the gas supplier.

4.1.2 Preventive instrument maintenance is performed routinely, and whenever highly contaminated extracts are analyzed that could result in chromatographic interferences or result in degradation of system performance. Section 10.6 describes the maintenance steps.

4.1.3 Glassware must be scrupulously cleaned. This procedure is detailed in the Organic Extraction Cleaning and Handling SOP/1953. Store dry glassware in a clean environment.

4.2 Parameters

4.2.1 All solvents used are pesticide grade or equivalent, and reagents are purchased as certified contaminant free. All these materials are routinely determined to be free of interferences by analysis of extraction blanks with every extraction batch performed.

4.2.2 Certain compounds (i.e. phthalates) can be extracted from the sample matrix and be detected by the ECD that could possibly result in false positive results or complicate the data interpretation. The use of the cleanup procedures detailed in the extraction SOP minimizes these possible interferences. Analyst experience is also crucial in making compound determinations.

4.2.3 Interferences co-extracted from the samples will vary considerably from waste to waste. While a general cleanup technique is referenced or provided as part of the method, unique samples may require additional cleanup approaches to achieve desired degrees of discrimination and quantitation.

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound must be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material data handling sheets is available to all personnel involved in the chemical analysis. PCBs have been tentatively classified as known or suspected human or mammalian carcinogens. Additional references to laboratory safety are available in the Chemical Hygiene Plan.
All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

5.1 Lab coats, safety glasses, and gloves must be worn when handling samples, extracts, standards or solvents.

5.2 All solvent and extract transfers must be handled in the vented bench area in the GC laboratory.

5.3 All stock standards, working standards, and vialed sample extracts must be placed into the waste bucket in the lab, for future disposal by the Hazardous Waste Manager. The container must be labeled properly with hazard warning labels indicating the container contents.

5.4 Bottles containing flammable solvents must be stored in the flammable cabinet.

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

Aqueous samples are collected in two 100mL amber glass jars with Teflon-lined lids. Solid samples are collected in one 250mL wide-mouth glass jar with a Teflon-lined lid. Oil samples are collected in a glass jar with Teflon-lined lids. All containers are purchased pre-cleaned and certified from commercial vendors.

6.2 Sample Preservation

Both aqueous and solid samples are then preserved by packing in coolers with ice or ice packs, to maintain a temperature of 4 ± 2° C. Upon receipt at the laboratory, the samples are transferred into sample storage refrigerators to maintain at a temperature of 4 ± 2° C. Preservation is not required for oil samples.

6.3 Sample Handling

- TCLP/SPLP tumbled extracts, NJ DKQP aqueous samples must be extracted within 7 days of sample collection.
- NJ DKQP soil/solid and oil samples within 14 days of collection (NJ DKQP allows 365 days for solids if frozen).
- All other samples, both aqueous and solids, have a 365-day hold time.
- Once extracted, the samples must be analyzed within 40 days of the extraction date.

7. Equipment and Supplies

7.1 Gas Chromatograph, Agilent 6890, 7890: An analytical system completed with gas chromatograph configured for split-splitless injection and all required accessories including syringes, analytical columns, gases, electron capture detectors (ECD), and data system.

7.2 GC Columns: Alpha utilizes dual-column analyses. The dual-column approach involves a single injection that is split between two columns that are mounted in a single gas chromatograph. Typical column pair used is listed below. Other columns may be used as long as method performance criteria can be met.

Column pair:

RTX-CLP: Cat. #11141 from Restek or equivalent; 30m, 0.32mm, 0.32µm

RTX-CLPII Cat. #11324 from Restek or equivalent; 30m, 0.32mm, 0.25µm

7.3 Guard Column: Cat. #10027 from Restek or equivalent; 5m, 0.32mm

7.4 Class "A" Volumetric Flasks: 10mL and 25mL (and other volumes), for standards preparation

7.5 Microsyringes: 10 µL – 1000 µL

7.6 Gooseneck splitless injecton liner, Cat #20799-214.5 from Restek or equivalent

7.7 Universal "Y" Press-tight tee split: Cat. #20406 from Restek or equivalent / **Siltek MXT Connector:** Cat. #21388 from Restek or equivalent

8. Reagents and Standards

Reagent grade or pesticide grade chemicals are used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. Other grades may be used, provided it is first ascertained that the reagent is of sufficient high purity to permit its use without lessening the accuracy of the determination.
NOTE: Store the standard solutions (stock, composite, calibration, internal, and surrogate) at 4 ± 2° C in Teflon(R)-sealed containers in the dark. When a Lot of standards is prepared, aliquots of that Lot are stored in individual small vials. All stock standard solutions must be replaced after one year or sooner if routine QC tests indicate a problem. All other standard solutions must be replaced after six months or sooner if routine QC indicates a problem.

8.1 n-Hexane: Pesticide quality or equivalent.

8.2 Acetone: Pesticide quality or equivalent.

8.3 Organic-free Reagent Water: All references to water in this method refer to organic-free reagent water from Alpha's RO water treatment system.

8.4 Stock Standard Solutions: All stock standard solutions are purchased from commercial vendors as ampullated certified solutions. When an ampullated stock solution is opened, it is transferred to a labeled amber screw-cap vial. The expiration date of the stock solution is either the vendor specified expiration date, or 1 year from the date the ampule was opened, whichever is sooner.

8.5 Calibration Standards: Calibration standards are prepared volumetrically by diluting the appropriate stock standard(s) with hexane. Calibration standards expire 6 months from the date of preparation, or on the earliest expiration date of any of the stock solutions used to prepare the calibration standard. Calibrations are performed at the 6 concentration levels listed in Table 1. The list of ampullated calibration standards is obtain from **Agilent**:

- Aroclor 1016, Cat. #PP-282, at 100ug/mL
- Aroclor 1260, Cat. #PP-361, at 100ug/mL
- Aroclor 1262, Cat. #PP-371, at 100ug/mL
- Aroclor 1268, Cat. #PP-382, at 100ug/mL
- Aroclor 1221, Cat. #PP-292, at 100ug/mL
- Aroclor 1232, Cat. #PP-302, at 100ug/mL

- Aroclor 1242, Cat. #PP-312, at 100ug/mL
- Aroclor 1248, Cat. #PP-342, at 100ug/mL
- Aroclor 1254, Cat. #PP-351, at 100ug/mL

8.5.1 Preparation of Initial Calibration Standards:

8.5.1.1 SOIL ICAL:

- **1660 L7**: (mix of Aroclors 1016 and 1260) is prepared by diluting
  - 5mL 1016 Standard (Agilent, Cat. #PP-282)
  - 5mL 1260 Standard (Agilent, Cat. #PP-361)
  - 6.4mL of PCB ICAL Surrogate Stock

  to 25ml of Hexane to achieve concentration of
  - 1016 and 1260 at 20ug/mL
  - TCMX at 1.28ug/mL and DCB at 2.56ug/mL.

- **2154 L7:** (mix of Aroclors 1221 and 1254) is prepared by diluting
  - 5mL 1221 Standard (Agilent, Cat. #PP-292)
  - 5mL 1254 Standard (Agilent, Cat. #PP-351)

  to 25ml of Hexane to achieve concentration of
  - 1221 and 1254 at 20ug/mL
- **4268 L7** (mix of Aroclors 1242 and 1268), **3262 L7** (mix of Aroclors 1232 and 1262) and **1248 L7;** all are prepared from their respective Stock Standards according to the formula used for L7 of 2154.
- Levels 1-6 are prepared by serial dilutions and a formula with volumes needed can be found in Table 2.

8.5.1.2 RVT ICAL:

- Prepare 2 Intermediate ICAL Standards by diluting 1016/1260 L7 of Soil ICAL:
  - **Stock#1** (10ug/mL): 500uL of 1660 L7 + 500uL of Hexane
  - **Stock#2** (0.5ug/mL): 25uL of 1660 L7 + 975uL of Hexane
- Use the VYPER programs: **pcb_rvt_L1-L6** and **pcb_rvt_L7-L10** to vial 1660 ICAL according to the formula and to achieve the concentrations provided in Table 3.
- Prepare one-point cal standards for all other Aroclors by diluting respective L7 stock solutions by using the VYPER program:

  12.5uL of L7 + 987.5uL of Hexane
  pcb_rvt_1point_set

8.6 Second Source Standards: (ICV) Initial Calibration Verification standards are prepared volumetrically by diluting the appropriate stock standard(s) with hexane. Initial Calibration Verification standards expire 6 months from the date of preparation, or on the

earliest expiration date of any of the stock solutions used to prepare the standard. The list of ampullated standards is obtain from **Accustandard**:

- Aroclor 1016, Cat. #C-216S-H-10X, at 1000ug/ml
- Aroclor 1260, Cat. #C-260S-H-10X, at 1000ug/ml
- Aroclor 1262, Cat. #C-262S-H-10X, at 1000ug/ml
- Aroclor 1268, Cat. #C-268S-H-10X, at 1000ug/ml
- Aroclor 1221, Cat. #C-221S-H-10X, at 1000ug/ml
- Aroclor 1232, Cat. #C-232S-H-10X, at 1000ug/ml
- Aroclor 1242, Cat. #C-242S-H-10X, at 1000ug/ml
- Aroclor 1248, Cat. #C-248S-H-10X, at 1000ug/ml
- Aroclor 1254, Cat. #C-254S-H-10X, at 1000ug/ml

8.6.1 Preparation of ICV Standards:

- **1660 ICV:** is prepared by diluting
  - 50uL 1016 Standard (AccuStandard, Cat. #C-216S-H-10X)
  - 50uL 1260 Standard (AccuStandard, Cat. #C-260S-H-10X)
  - 320uL of PCB CCAL Surrogate Stock

  to 20ml of Hexane to achieve concentration of
  - 1016 and 1260 at 2.5ug/mL
  - TCMX at 0.16ug/mL and DCB at 0.32ug/mL

- **2154, 4268, 3262 and 1248 ICVs** are prepared from their respective Stock Standards according to the formula used for 1660 ICV.

- Prepare **RVT ICVs** for all Aroclor standard solutions by diluting respective ICV stocks by using VYPER's pcb_rvt_icv program:
  - 100uL of ICV to 900uL of Hexane, achieving a concentration of
  - 1016 and 1260 at 0.25ug/mL
  - TCMX at 0.016ug/mL and DCB at 0.032ug/mL

8.7 Internal Standard Solution: 1-Bromo-2-nitrobenzene (Ultra, Cat. #PPS-351) is used as the internal standard and is added to all single-component calibration standards and sample extracts to achieve a concentration of 0.25µg/mL. For RVT, this solution is diluted 10X more, achieving a concentration of 0.025µg/mL.

8.8 Surrogate Standards: Tetrachloro-m-xylene (TCMX) and Decachlorobiphenyl (DCB) are used as surrogates for Aroclor analysis. They are added to the calibration standards at the concentrations listed in Table 1, Continuing Calibration Standards and are spiked into all samples and QC samples prior to extraction.

- **ICAL Surrogates Stock:** is prepared by diluting 500uL of Pesticides Surrogates Standard Spiking Solution (Ultra, Cat. #ISM-320-1) and 500uL of Decachlorobiphenyl (Accustandard, Cat. #CLP-032-R-01) to 20mL of Hexane to achieve concentration of TCMX at 5ug/mL and DCB at 10ug/mL.

- **CCAL Surrogates Stock:** is prepared by diluting 1mL of TCMX&DCB (Accustandard, Cat. #CLP-032-R) and 1mL of Decachlorobiphenyl (Accustandard, Cat. #CLP-032-R-01) to 20mL of Hexane to achieve concentration of TCMX at 10ug/mL and DCB at 20ug/mL.
- **Extraction Surrogates Stock:** is prepared by diluting 10mL of TCMX&DCB (Accustandard, Cat. #CLP-032-R) to 1000mL of Acetone to achieve concentration of TCMX and DCB at 2ug/mL.
- **RVT Extraction Surrogates Stock**: is prepared by diluting 1.25mL of TCMX&DCB (Accustandard, Cat. #CLP-032-R) to 500mL of Acetone to achieve concentration of TCMX and DCB at 0.5ug/mL.
- **PCB Caulking Surrogates Stock:** is prepared by diluting 10mL of TCMX&DCB (Accustandard, Cat. #CLP-032-R) to 100mL of Acetone to achieve concentration of TCMX and DCB at 20ug/mL.
- **PCB Oil Surrogate Stock:** is prepared by diluting 5mL of TCMX&DCB (Accustandard, Cat. #CLP-032-R) to 500mL of Hexane to achieve concentration of TCMX and DCB at 2.0ug/mL.

8.9 LCS/MS Spiking Solutions:

- **PCB Matrix Spike:** The LCS/MS spiking solution is prepared by diluting 6.25mL of Arochlor 1016/1260 (Restek, Cat. #32039) to 500mL of Acetone to achieve concentration of Arochlor 1016/1260 at 12.5ug/ml. For **RVT**, 1.25mL of the stock solution is diluted to 500mL of Acetone to achieve a concentration of Aroclor 1016/1260 at 2.5 ug/mL.

- **PCB Caulking Matrix Spike:** The LCS/MS spiking solution is prepared by diluting 6.25mL of Arochlor 1016/1260 (Restek, Cat. #32039) to 50mL of Acetone to achieve concentration of Arochlor 1016/1260 at 125ug/mL.

- **PCB Oil Matrix Spike:** The LCS/MS spiking solution is prepared by diluting 2.5mL of Arochlor 1016/1260 (Restek, Cat. #32039) to 200mL of Hexane to achieve concentration of Arochlor 1016/1260 at 12.5ug/mL.

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

9.1 Blank(s)

A Method Blank is an aliquot of a clean reference matrix (reagent water for water samples, Ottawa sand for soil/sediment samples, or PCB free transformer oil for oil samples) that is carried through the entire analytical procedure. Extraction blanks are performed with each extraction batch of 20 or less samples, according to the extraction SOPs. The extraction blank must not contain any of the reportable analytes above the reporting limit. If any reportable analytes are detected in the blank, the entire extraction batch is suspect and re-extraction of all associated samples is required, unless the associated samples are non-detect or concentration of the analyte in the samples is 10 times greater than the concentration of this analyte in the blank. The surrogate recoveries must also be within the acceptance criteria listed in Table 4. If surrogate acceptance criteria are exceeded, the extraction batch must be evaluated to determine if re-extraction or re-analysis is necessary. Actions associated with Method Blank failures are listed in Table 6.

9.2 Laboratory Control Sample (LCS)

A Laboratory Control Sample (LCS)/ Laboratory Control Sample Duplicate (LCSD) pair is extracted with each analytical batch. The LCS/LCSD consist of an aliquot of a clean (control) matrix similar to the sample matrix and of the same weight or volume. For Aroclor analysis, the LCS/LCSD are spiked with a mixture of Aroclor 1016 and 1260 (1660) at the levels listed in Table 5. The recovery acceptance criteria are listed in Table 4. If any recovery criteria are not met, the extract may be re-analyzed. If the criteria are still not met, the **entire batch is re-extracted**, unless the recoveries are high, and the associated samples are non-detect. If this is not possible, due to insufficient sample or holding time exceedances, the analyst must narrate the failure in the LIMS for inclusion in the client report. Actions associated with LCS/LCSD failures are listed in Table 6.

9.3 Initial Calibration Verification (ICV)

Refer to Section 10.2.7.

9.4 Continuing Calibration Verification (CCV)

Refer to Section 10.4.

9.5 Matrix Spike/ Matrix Spike Duplicate (MS/MSD)

Matrix Spike and Matrix Spike Duplicate are field samples spiked with known target analyte(s) at the levels listed in Table 5. Upon client request, an MS/MSD pair is extracted and analyzed with each batch of 20 or less samples. MS samples serve as a measure of extraction accuracy, by allowing the comparison of the found amount(s) of target analyte(s) with the spiked amount(s). An MS/MSD set also allows for the calculation of the extraction precision, by comparing the results of the two samples. The recovery acceptance criteria are listed in Table 4. If the recovery criteria are not met, but are met in the LCS, the failure may be attributed to sample matrix effects. Actions associated with MS/MSD failures are listed in Table 6.

For samples with a state of origin of New Jersey, a MS must be extracted for every twenty samples within a 24hr period.

9.6 Laboratory Duplicate (DUP)

Duplicates are laboratory selected replicate samples, prepared by taking an additional sample aliquot of a sample. Upon client request, a DUP is extracted and analyzed with batch of 20 or

less samples. Duplicates serve as a measure of the extraction precision, by comparing the results of the sample and duplicate. The relative percent difference (RPD) acceptance criteria are listed in Table 4. If the RPD criteria are not met, the failure may be attributed to matrix effect. Actions associated with DUP failures are listed in Table 6.

For samples with a state of origin of New Jersey, a DUP must be extracted for every twenty samples within a 24hr period.

9.7 Surrogates

All extracted samples and associated QC are spiked with surrogates at the levels listed in Table 5. The laboratory must evaluate surrogate recovery data from individual samples and QC samples versus the surrogate control limits listed in Table 4. If the surrogate limits are not met, the extract may be reanalyzed to determine if the failure was due to an instrument problem. If the criteria are still not met, the affected samples must be re-extracted to confirm that the failure was due to sample matrix, unless the surrogate recovery is high, and the associated sample is non-detect. If matrix effect is confirmed, this must be noted on a narrative sheet for inclusion in the client report.

9.8 Method Sequence

Typical Initial calibration (each level and ICV to identified with the standard lot number)

1. Prime
2. Blank
3. Standard Level 1
4. Standard Level 2
5. Standard Level 3
6. Standard Level 4
7. Standard Level 5
8. Standard Level 6
9. Standard Level 7
10. Initial Calibration Verification Standard (ICV)

Repeat steps 3 – 9 as needed for each Aroclor necessary for calibration.

NOTE: If multiple calibration mixtures are analyzed, it is acceptable to analyze appropriate ICVs after all calibration standards have been injected.

Typical Daily Sequence

1. 1660 Continuing Calibration Standard **(identified with the standard lot number)**
2. Extraction Blank

3. Laboratory Control Sample / Laboratory Control Sample Duplicate
4. Matrix Spike / Matrix Spike Duplicate (if requested by Client)
5. Duplicate (if included with batch QC)
6. Samples - **up to 20 field samples**
7. Repeat 1 – 6 as needed.

10. Procedure

10.1 Equipment Set-up

10.1.1 GC Conditions:

The dual-column / dual-detector approach involves the use of the columns listed in section 7.2. The columns are connected to an injection tee or dual injection GC, and separate electron capture detectors. Alpha typical GC conditions are listed below but may be altered as long as method performance criteria are met.

	INSTRUMENT CONDITIONS
Injector temperature	250^{0}C
Injector mode	Split 10:1
Split Flow	60.1 mL/min
Total Flow	78.2 mL/min
Detector temperature	350^{0}C
Carrier gas	Hydrogen
Carrier flow	20mL/min
Carrier mode	Constant flow
Makeup gas	Nitrogen
Total detector flow	60mL/min
Injection Volume	1µL

	OVEN TEMP PROGRAM
Temperature 1	150 ^{0}C
Time 1	0 min
Ramp 1	45^{0}C/minute
Temperature 2	230^{0}C
Time 2	0 min
Ramp 2	30^{0}C/minute
Temperature 3	330^{0}C
Time 3	1 min

10.2 Initial Calibration

10.2.1 Prepare calibration standards using the standards listed in Section 8.5 to achieve the concentrations from Table 1.

For Analysis of Aroclors which use an **Average Response Factor model (AVG)** the minimum requirement is to perform an initial multi-point calibration for a mixture of 1016/1260 and to use a **one-point initial calibration** to determine the calibration factor and pattern recognition for the remaining Aroclors (TNI standard 1.7.1.1.m). The concentrations of the other Aroclors should generally correspond to the mid-point of the linear range of the detector, but lower concentrations may be employed.

10.2.2 Establish the GC operating conditions by loading the appropriate GC method. Typical instrument conditions are listed in section 10.1.1. The same operating conditions are used for calibrations and sample analyses. Create the analytical sequence using the Agilent Chemstation data acquisition software. Record the

calibration standard, unique lot number (PP#) and analyst's initials in the analytical sequence list.

10.2.3 A 1µL injection volume of each calibration standard is typically used. Other injection volumes may be employed, provided that the analyst can demonstrate adequate sensitivity for the compounds of interest. The same injection volume must be used for all standards and samples.

10.2.4 Column adsorption may be a problem when the GC has not been used for a day or more or after system maintenance. The GC column may be primed (or deactivated) by injecting a PCB standard mixture approximately 20 times more concentrated than the mid-concentration standard. Inject this standard mixture prior to beginning the initial calibration or calibration verification.

Alternately, the system may be primed by baking at the final analytical temperature for approximately 30 minutes.

Several analytes may be observed in the injection just following system priming. Always run an instrument blank after system priming.

10.2.5 **Calibration Factor:** Internal Standard Calibration techniques are employed in this method.

10.2.7.1 Internal Standard Procedure. In each standard, calculate the response factor (RF) for each analyte, the average RF, and the relative standard deviation (RSD) of the RFs, using the Enviroquant data processing software. The calculations are performed automatically, using the formula listed in Quality Manual.

Alternatively, standards of the other seven Aroclors are necessary for pattern recognition. When employing the traditional model of a linear calibration through the origin, these standards are also used to determine a single-point calibration factor for each Aroclor, assuming that the Aroclor 1660 mixture has been used to describe the detector response.

The standards for these seven Aroclors should be analyzed before the analysis of any samples with hits above the RL. For example, an Aroclor 1254 standard should be analyzed before a sample with a hit of Aroclor 1254.

10.2.6 Initial Calibration Criteria

- If the **RSD for an analyte is < 20%**, then the response of the instrument for this compound is considered linear over the range and the mean calibration factor can be used to quantitate sample results.
- If the **RSD for any analyte is > 20%**, then linearity through the origin cannot be assumed. The mean response factor cannot be used for quantitation. An alternative calculation may be done using **linear regression** or **quadratic regression** (minimum of six ICAL points are needed and regression must be weighted inversely proportional to concentration) if the correlation coefficient is **>0.990**. If both quantitation methods fail criteria for any compound in the initial calibration, then the system must be reevaluated, and a new calibration curve must be analyzed. If quadratic regression is used for calibration, this must be noted in the laboratory narrative.

- **A minimum of 3 peaks must be chosen** for each Aroclor and preferably 5 peaks (11.4.6.1 8082A).

- **The minimum number of calibration standards** based on the type of calibration curve is listed below:

Type of Calibration Curve	Minimum Number of Calibration Standards
Linear Fit/Avg Response	5
Quadratic Fit	6

- **Removal and replacement of the calibration standards:**
  - The Analyst may remove individual analyte from the lowest (cannot remove RL level) and or the highest calibration levels of the curve. Removal of the individual analyte of interior levels is not permitted.
  - The Analyst may remove an entire single standard calibration level from the interior of the calibration curve when the instrument response demonstrates that the standard was not properly introduced to the instrument, or an incorrect standard was analyzed. The Analyst who chooses to remove a calibration standard from the interior of the calibration shall remove that particular standard calibration level for all analytes.
  - The Analyst may replace a calibration standard provided that:
    - the replacement standard will be analyzed within twenty-four (24) hours of the original calibration standard analysis for that particular calibration level;
    - all analytes of the replacement calibration standard must be replaced if a standard within the interior of the calibration is replaced;
    - the laboratory limits the replacement of calibration standards to one calibration standard concentration.

- **Percent Relative Error (%RE)**: For linear and quadratic fit compounds, the %RE must be calculated for the standard at or near the midpoint and at the lowest level of the initial calibration. The %RE between the calculated and expected concentration of an analyte must be **≤ 30%**, otherwise recalibration is necessary.

10.2.7 Initial Calibration Verification

An initial calibration verification standard must be run immediately after each initial calibration, near the midpoint of the curve. The standard must be prepared using a second source that is different than the source used for the initial calibration. (Standards listed in Section 8.6). The **%D** has to be within **20%** when compared to the mean response factor from the initial calibration.

If recovery is **outside the 80-120% criteria**, the following steps should be taken:

- Analyze the replacement standard. The cause of the failure of the first calibration verification result should be documented.
- If the reanalysis still didn't achieve the criteria, the source of the problem must be investigated, and instrument must be recalibrated.

10.2.8 Retention Time Window

10.2.8.1 The retention time window used for the identification of target analytes is ± 0.07 minutes. These criteria have been adopted from the EPA CLP Statement of Work (OLM04.2). It has been found that these limits work well, being wide enough to eliminate false-negatives while being tight enough to eliminate false-positives. Windows that are calculated using the procedure recommended in Method 8000 tend to be very narrow, creating the risk of false negative results.

10.2.8.2 The windows listed above are used as guidance; however, the experience of the analyst weighs heavily in the interpretation of the chromatograms. For example, it has been observed that certain oil matrices can cause the retention times to shift more dramatically.

10.3 Sample Processing

The determination of PCB Aroclors is accomplished by comparing the sample chromatogram to that of the most similar Aroclor standard. The use of PCB overlays is extremely helpful, either by using hardcopies of chromatograms or by utilizing the Enviroquant software. A choice must be made as to which Aroclor is most similar and whether that standard is truly representative of the PCB in the sample. Both retention time and pattern are important when determining PCBs in a sample.

Samples that contained weathered PCB present special analytical challenges. Weathering could alter the Aroclor pattern to the extent that different peaks have to be selected for quantitation. Samples that contained more than one Aroclor present similar problems. For these samples, the Analyst may have to consider selecting the earlier eluting peaks for the lower boiling Aroclor and selecting the later eluting peaks for the higher boiling Aroclors to minimize overlapping peaks.

Minimum of 3 peaks must be chosen for each Aroclor. In these instances, the Analyst may need request the assistance of someone with more expertise in determining the presence of PCB Aroclor.

If compound identification or quantitation is precluded due to interference (e.g., broad, rounded peaks or ill-defined baselines are present) cleanup of the extract may be needed. If instrument problems are suspected, rerun the extract on another instrument to determine if the problem results from analytical hardware or the sample matrix. Refer to the extraction SOPs for the procedures to be followed in sample cleanup.

- The laboratory must report the ***HIGHER*** of the two results unless obvious interference is present on of the columns.

- The **Relative Percent Difference (RPD)** should be **≤ 40%.** If the RPD exceeds 40, this will be denoted with a P flag. If the RPD exceedance is due to interference, the lower of the dual column values can be reported with I and P flags.

If any peaks are above the calibration, a dilution must be done. The dilution reported is the least dilute level at which the peak area is within the calibration range.

10.4 Continuing Calibration

10.4.1 Verify calibration each **12-hours** shift by injecting calibration verification standards prior to conducting any sample analyses. A calibration standard must also be injected at intervals of not less than **once every twenty filed samples**.

A bracketing CCV is not required with the use of internal standard calibration (Method 8082A 11.6.8)

For Aroclor analysis, the calibration verification standard should be a mixture of Aroclor 1016 and 1260 (1660). The calibration verification process does not require analysis of the other Aroclor standards used for pattern recognition (Method 8082A 11.6.2). However, if the one-point calibration is used for the seven other Aroclor, a calibration standard must be analyzed before the sample for any hits.

10.4.2 The **Response Factor** (for internal standard compounds) for each analyte to be quantitated must not exceed a **± 20% difference** when compared to the initial calibration curve The Enviroquant data processing software automatically calculates the **%D** for all analytes.

10.5 Internal Standard

The use of internal standard calibration does not require that all sample results be bracketed with CCV standard. However, when internal standard calibration is used, the retention times of internal standards and the area response of internal standards should be checked for each analysis (10.4.3).

10.5.1 **IS in CCAL** – The measured area of the internal standard must be no more than ± 50% different from the average area calculated during initial calibration **(-50 to 150%).**

10.5.2 **IS in samples** - The measured area of the internal standard must be no more than -50% to +100% different from the area calculated from opening CCV **(-50 to 200%)**

Retention Time shift >30 seconds from the retention time of the most recent calibration standard are cause for concern and must be investigated.

10.6 Preventive Maintenance

10.6.1 **Preventive Maintenance:** Routine preventive maintenance is performed to maintain GC system performance. This includes periodic replacement of injector septa, replacement of injector liner(s), and replacement of injector seals.

10.6.2 Other Maintenance: ECD detectors may become contaminated, requiring bake out at elevated temperatures, (no greater than 375°C) or repair by the manufacturer.

11. Data Evaluation, Calculations and Reporting

11.1 Quantitation of Aroclors

Per Method 8082A, quantitation is based on the use of a minimum of 3 of the major peaks present in the analyte, although the use of 5 of the major peaks is recommended. Each of these peaks is individually calibrated with a **minimum of five calibration points** based on average response factors. The %RSD must meet the criteria of ≤20% for the ICAL. The five major peaks are calculated as described below. After individual calculation meets criteria, the average of the peaks selected for quantitation is used to determine the final concentration.

11.1.1 Aqueous samples

$$\text{Concentration } (\mu g/L) = \frac{C \times DF \times Vf \times 1000}{Vo}$$

where:
C = Extract concentration (µg/mL), **NOTE**: ng on column = ng/injection volume = ng/uL = ug/mL
DF = Dilution factor
Vf = Final extract volume (mL)
Vo = Sample volume (mL)

11.1.2 Soil/sediment samples

$$\text{Concentration } (\mu g/Kg, \text{ dry weight}) = \frac{C \times DF \times Vf \times 1000}{W\ (gm)} \div \%S$$

where:
C = Extract concentration (µg/mL), **NOTE**: ng on column = ng/injection volume = ng/uL = ug/mL
DF = Dilution factor
Vf = Final extract volume (mL)
W = Weight of the sample extracted (10g for high, 30g for low)
%S = Percent solids, as a decimal value

11.1.3 Reporting Results

11.1.3.1 After performing technical data review, validating that all QC criteria have been met and confirming all positive hits, the data report is sent electronically to the LIMS computer for generation of the client report. There are two levels of review of the data in the LIMS system prior to release of data. These reviews must be done by two separate individuals.

11.1.3.2 Reporting Results for PCBs in Caulking Samples

If in the screen sample Aroclor concentration as calculated above is **≥20000ppm**, the Client is contacted by a Customer Service Representative and these results are sent to the LIMS and reported to the Client.

If the sample concentration as calculated above for any Aroclor is **<20000ppm**, the sample is sent for re-extraction by Method 3540C (Alpha SOP/1954).

11.1.3.3 Summation Rules

"TOTAL" concentrations are calculated for **ALL samples and Quality Control Samples** (i.e. LCS, MS, DUP, BLK).

TOTAL = sum of "reportable" Aroclors

Reportable- all Aroclors reported for associated project.

For dual-column analysis, Total is reported as part of column "A" data, unless all individuals are reported from "B" column. "Total" is calculated based on the associated "Report List". See Work Instruction #14335 for details.

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

Holding time exceedance and/or improper preservation are noted on the nonconformance report form.

Perform instrument maintenance as described throughout this SOP as needed when instrument calibration criteria are not met. Record all maintenance in the instrument logbook.

All batch and sample specific QC criteria outlined in Section 10 are evaluated by the analyst prior to approval of the data. When any QC criteria fail, the cause for the failure must be identified and corrected. This may include instrument recalibration followed by sample reanalysis, sample cleanup, or sample re-extraction. If it is determined that the failure is due to sample matrix effects, a project narrative report is written into the LIMS by the analyst for inclusion in the data report. If there is insufficient sample volume to perform the re-analysis for confirmation, this is also noted in the narrative and included in the client report.

13. Method Performance

13.1 Method Detection Limit Study (MDL) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the MDL, LOD, and/or LOQ as outlined in Pace SOP/1732. These studies performed by the laboratory are maintained on file for review.

13.2 Demonstration of Capability Studies

Refer to Pace SOP/1739 for further information regarding IDC/DOC Generation.

13.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

14. Pollution Prevention and Waste Management

Refer to Pace's Chemical Hygiene Plan and Waste Management and Disposal SOP for further pollution prevention and waste management information.

PFAS by EPA 537 in Drinking Water by LC/MS/MS

EPA Method 537.1, Version 2, March 2020,
Document #: EPA/600/R-20/006

Department of Defense, Quality Systems Manual for
Environmental Laboratories, Version 5.4, 2021

1. Scope and Application

Matrices: Drinking Water

Definitions: Refer to Alpha Analytical Quality Manual.

1.1 This is a liquid chromatography/tandem mass spectrometry (LC/MS/MS) method for the determination of selected perfluorinated alkyl substances (PFASs) in drinking water. Accuracy and precision data have been generated for the compounds listed in Table 1.

1.2 The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one or more of the following laboratory personnel before performing the modification: Area Supervisor, Department Supervisor, Laboratory Director, or Quality Assurance Officer.

1.3 This method is restricted to use by or under the supervision of analysts experienced in the operation of the LC/MS/MS and in the interpretation of LC/MS/MS data. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

Table 1

Parameter	Acronym	CAS
Hexafluoropropylene oxide dimer acid [1]	HFPO-DA	13252-13-6

4,8-dioxa-3H-perfluorononanoic acid [1]	ADONA	919005-14-4

2. Summary of Method

2.1 A 250-mL water sample is fortified with surrogates and passed through a solid phase extraction (SPE) cartridge containing polystyrenedivinylbenzene (SDVB) to extract the method analytes and surrogates. The compounds are eluted from the solid phase with a small amount of methanol. The extract is concentrated to dryness with nitrogen in a heated water bath, and then adjusted to a 1-mL volume with 96:4% (vol/vol) methanol: water after adding the IS(s). A 2 µL injection is made into an LC equipped with a C18 column that is interfaced to an MS/MS. The analytes are separated and identified by comparing the acquired mass spectra and retention times to reference spectra and retention times for calibration standards acquired under identical LC/MS/MS conditions. The concentration of each analyte is determined by using the internal standard technique. Surrogate analytes are added to all Field and QC Samples to monitor the extraction efficiency of the method analytes.

2.2 Method Modifications from Reference

2.2.1 None.

3. Reporting Limits

3.1 The reporting limit for PFAS's is 2 ng/L (4ng/L for HFPO-DA).

4. Interferences

4.1 PFAS standards, extracts and samples should not come in contact with any glass containers or pipettes as these analytes can potentially adsorb to glass surfaces. PFAS analyte, IS and SUR standards commercially purchased in glass ampoules are acceptable; however, all subsequent transfers or dilutions performed by the analyst must be prepared and stored in polypropylene containers.

4.2 Method interferences may be caused by contaminants in solvents, reagents (including reagent water), sample bottles and caps, and other sample processing hardware that lead to discrete artifacts and/or elevated baselines in the chromatograms. The method analytes in this method can also be found in many common laboratory supplies and equipment, such as PTFE (polytetrafluoroethylene) products, LC solvent lines, methanol, aluminum foil, SPE sample transfer lines, etc. All items such as these must be routinely demonstrated to be

free from interferences (less than 1/3 the RL for each method analyte) under the conditions of the analysis by analyzing laboratory reagent blanks as described in Section 9.2. **Subtracting blank values from sample results is not permitted.**

4.3 Matrix interferences may be caused by contaminants that are co-extracted from the sample. The extent of matrix interferences will vary considerably from source to source, depending upon the nature of the water. Humic and/or fulvic material can be co-extracted during SPE and high levels can cause enhancement and/or suppression in the electrospray ionization source or low recoveries on the SPE sorbent. Total organic carbon (TOC) is a good indicator of humic content of the sample. Under the LC conditions used during method development, matrix effects due to total organic carbon (TOC) were not observed.

4.4 Relatively large quantities of the preservative (Sect. 6.2.1) are added to sample bottles. The potential exists for trace-level organic contaminants in these reagents. Interferences from these sources should be monitored by analysis of laboratory reagent blanks (Sect. 9.2.1), particularly when new lots of reagents are acquired.

4.5 SPE cartridges can be a source of interferences. The analysis of field and laboratory reagent blanks can provide important information regarding the presence or absence of such interferences. Brands and lots of SPE devices should be tested to ensure that contamination does not preclude analyte identification and quantitation.

5. Health and Safety

5.1 The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material safety data sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

5.2 All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

5.3 PFOA has been described as “likely to be carcinogenic to humans.” Pure standard materials and stock standard solutions of these method analytes should be handled with suitable protection to skin and eyes, and care should be taken not to breathe the vapors or ingest the materials.

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

6.1.1 Samples must be collected in two (2) 250-mL high density polyethylene (HDPE) container with an unlined plastic screw cap.

6.1.2 The sample handler must wash their hands before sampling and wear nitrile gloves while filling and sealing the sample bottles. PFAS contamination during sampling can occur from a number of common sources, such as food packaging and certain foods and beverages. Proper hand washing and wearing nitrile gloves will aid in minimizing this type of accidental contamination of the samples.

6.1.3 Open the tap and allow the system to flush until the water temperature has stabilized (approximately 3 to 5 min). Collect samples from the flowing system.

6.1.4 Fill sample bottles, taking care not to flush out the sample preservation reagent. Samples do not need to be collected headspace free.

6.1.5 After collecting the sample, cap the bottle and agitate by hand until preservative is dissolved. Keep the sample sealed from time of collection until extraction.

6.1.6 Field Reagent Blank (FRB)

6.1.6.1 A FRB must be submitted with each sample set. At the laboratory, fill an unpreserved 250 mL container with reagent water. For each FRB, an empty sample bottle (containing only the Trizma preservative) must also be shipped. At the sampling site, the sampler must open the shipped FRB and pour the reagent water into the empty shipped sample bottle, seal and label this bottle as the FRB. The FRB is shipped back to the laboratory along with the samples and analyzed to ensure that PFASs were not introduced into the sample during the sample collection/handling.

6.1.6.2 The same batch of preservative must be used for the FRBs as for the field samples.

6.1.6.3 The reagent water used for the FRBs must be initially analyzed for method analytes as a MB and must meet the MB criteria in Section 9.2.1 prior to use. This requirement will ensure samples are not being discarded due to contaminated reagent water rather than contamination during sampling.

6.2 Sample Preservation

6.2.1 The preservation reagent, listed in the table below, is added to each sample bottle as a solid prior to shipment to the field (or prior to sample collection).

Table 2

Compound	Amount	Purpose
Trizma	5.0 g/l	Buffering reagent and removes free chlorine

6.3 Sample Shipping

6.3.1 Samples must be chilled during shipment and must not exceed 10 °C during the first 48 hours after collection. Sample temperature must be confirmed to be at or below 10 °C when the samples are received at the laboratory. Samples stored in the lab must be held at or below 6 °C until extraction but should not be frozen.

NOTE: Samples that are significantly above 10° C, at the time of collection, may need to be iced or refrigerated for a period of time, in order to chill them prior to shipping. This will allow them to be shipped with sufficient ice to meet the above requirements.

6.4 Sample Handling

6.4.1 Holding Times

6.4.1.1 Water samples should be extracted as soon as possible but must be extracted within 14 days. Extracts must be stored at room temperature and analyzed within 28 days after extraction.

7. Equipment and Supplies

7.1 SAMPLE CONTAINERS – 250-mL high density polyethylene (HDPE) bottles fitted with unlined screw caps. Sample bottles must be discarded after use.

7.2 POLYPROPYLENE BOTTLES – 4-mL narrow-mouth polypropylene bottles.

7.3 CENTRIFUGE TUBES – 15-mL conical polypropylene tubes with polypropylene screw caps for storing standard solutions and for collection of the extracts.

7.4 AUTOSAMPLER VIALS – Polypropylene 0.7-mL autosampler vials with polypropylene caps.

7.4.1 NOTE: Polypropylene vials and caps are necessary to prevent contamination of the sample from PTFE coated septa. However, polypropylene caps do not reseal, so evaporation occurs after injection. Thus, multiple injections from the same vial are not possible.

7.5 POLYPROPYLENE GRADUATED CYLINDERS – Suggested sizes include 25, 50, 100 and 1000-mL cylinders.

7.6 MICRO SYRINGES – Suggested sizes include 5, 10, 25, 50, 100, 250, 500 and 1000-µL syringes.

7.7 PLASTIC PIPETS – Polypropylene or polyethylene disposable pipets.

7.8 pH PAPER – Capable of increments of .5

7.9 ANALYTICAL BALANCE – Capable of weighing to the nearest 0.0001 g.

7.10 SOLID PHASE EXTRACTION (SPE) APPARATUS FOR USING CARTRIDGES

7.10.1 SPE CARTRIDGES – 0.5 g, 6-mL SPE cartridges containing styrenedivinylbenzene (SDVB) sorbent phase.

7.10.2 VACUUM EXTRACTION MANIFOLD – A manual vacuum manifold with large volume sampler for cartridge extractions, or an automatic/robotic sample preparation system designed for use with SPE cartridges, may be used if all QC requirements discussed in Section 9 are met. Extraction and/or elution steps may not be changed or omitted to accommodate the use of an automated system. Care must be taken with automated SPE systems to ensure the PTFE commonly used in these systems does not contribute to unacceptable analyte concentrations in the MB (Sect. 9.2.1).

7.10.3 SAMPLE DELIVERY SYSTEM – Use of a polypropylene transfer tube system, which transfers the sample directly from the sample container to the SPE cartridge, is recommended, but not mandatory. Standard extraction manifolds come equipped with PTFE transfer tube systems. These can be replaced with 1/8” O.D. x 1/16” I.D. polypropylene or polyethylene tubing cut to an appropriate length to ensure no sample contamination from the sample transfer lines. Other types of non-PTFE tubing may be used provided it meets the MB (Sect. 9.2.1) and LCS (Sect. 9.3) QC requirements. The PTFE transfer tubes may be used, but an MB must be run on each PFTE transfer tube and the QC requirements in

Section 13.2.2 must be met. In the case of automated SPE, the removal of PTFE lines may not be feasible; therefore, MBs will need to be rotated among the ports and must meet the QC requirements of Sections 13.2.2 and 9.2.1.

7.11 EXTRACT CONCENTRATION SYSTEM – Extracts are concentrated by evaporation with nitrogen using a water bath set no higher than 60-65 °C.

7.12 LABORATORY OR ASPIRATOR VACUUM SYSTEM – Sufficient capacity to maintain a vacuum of approximately 10 to 15 inches of mercury for extraction cartridges.

7.13 LIQUID CHROMATOGRAPHY (LC)/TANDEM MASS SPECTROMETER (MS/MS) WITH DATA SYSTEM

7.13.1 LC SYSTEM – Instrument capable of reproducibly injecting up to 10-µL aliquots and performing binary linear gradients at a constant flow rate near the flow rate used for development of this method (0.3-1 mL/min). The LC must be capable of pumping the water/methanol mobile phase without the use of a degasser which pulls vacuum on the mobile phase bottle (other types of degassers are acceptable). Degassers which pull vacuum on the mobile phase bottle will volatilize the ammonium acetate mobile phase causing the analyte peaks to shift to earlier retention times over the course of the analysis batch. The usage of a column heater is optional.

7.13.2 LC/TANDEM MASS SPECTROMETER – The LC/MS/MS must be capable of negative ion electrospray ionization (ESI) near the suggested LC flow rate of 0.3-1 mL/min. The system must be capable of performing MS/MS to produce unique product ions for the method analytes within specified retention time segments. A minimum of 10 scans across the chromatographic peak is required to ensure adequate precision.

7.13.3 DATA SYSTEM – An interfaced data system is required to acquire, store, reduce, and output mass spectral data. The computer software should have the capability of processing stored LC/MS/MS data by recognizing an LC peak within any given retention time window. The software must allow integration of the ion abundance of any specific ion within specified time or scan number limits. The software must be able to calculate relative response factors, construct linear regressions or quadratic calibration curves, and calculate analyte concentrations.

7.13.4 ANALYTICAL COLUMN – An LC C_{18} column (2.1 x 50 mm) packed with 1.7 µm d_p C_{18} solid phase particles was used. Any column that provides adequate resolution, peak shape, capacity, accuracy, and precision (Sect. 9) may be used.

8. Reagents and Standards

8.1 GASES, REAGENTS, AND SOLVENTS – Reagent grade or better chemicals should be used.

8.1.1 REAGENT WATER – Purified water which does not contain any measurable quantities of any method analytes or interfering compounds greater than 1/3 the RL for each method analyte of interest. Prior to daily use, at least 3 L of reagent water should be flushed from the purification system to rinse out any build-up of analytes in the system's tubing.

8.1.2 METHANOL (CH_3OH, CAS#: 67-56-1) – High purity, demonstrated to be free of analytes and interferences.

8.1.3 AMMONIUM ACETATE ($NH_4C_2H_3O_2$, CAS#: 631-61-8) – High purity, demonstrated to be free of analytes and interferences.

8.1.4 2 mM AMMONIUM ACETATE/REAGENT WATER – To prepare 1 L, add .154 g ammonium acetate to 1 L of reagent water. This solution is prone to volatility losses and should be replaced at least every 48 hours.

8.1.5 TRIZMA PRESET CRYSTALS, pH 7.0 – Reagent grade. A premixed blend of Tris [Tris(hydroxymethyl)aminomethane] and Tris HCL [Tris(hydroxymethyl)aminomethane hydrochloride]. Alternatively, a mix of the two components with a weight ratio of 15.5/1 Tris HCL/Tris may be used. These blends are targeted to produce a pH near 7.0 at 25 °C in reagent water. Trizma functions as a buffer, and removes free chlorine in chlorinated finished waters (Sect. 6.2.1).

8.1.6 NITROGEN – Used for the following purposes: Nitrogen aids in aerosol generation of the ESI liquid spray and is used as collision gas in some MS/MS instruments. The nitrogen used should meet or exceed instrument manufacturer's specifications. In addition, Nitrogen is used to concentrate sample extracts (Ultra High Purity or equivalent).

8.1.7 ARGON – Used as collision gas in MS/MS instruments. Argon should meet or exceed instrument manufacturer's specifications. Nitrogen gas may be used as the collision gas provided sufficient sensitivity (product ion formation) is achieved.

8.2 STANDARD SOLUTIONS – When a compound purity is assayed to be 96% or greater, the weight can be used without correction to calculate the concentration of the stock standard. PFAS analyte, IS and SUR standards commercially purchased in glass ampoules are acceptable; however, all subsequent transfers or dilutions performed by the analyst must be prepared and stored in polypropylene containers. Standards for sample fortification generally should be prepared in the smallest volume that can be accurately measured to minimize the addition of excess organic solvent to aqueous samples.

NOTE: Stock standards (Sect. 8.2.1, 8.2.3 and 8.2.5) are stored at ≤4 °C. Primary dilution standards (Sect. 8.2.2 and 8.2.4) are stored at room temperature to prevent adsorption of the method analytes onto the container surfaces that may occur when refrigerated. Storing the standards at room temperature will also minimize daily imprecision due to the potential of inadequate room temperature stabilization.

8.2.1 IS STOCK STANDARD SOLUTIONS - IS stock standard solutions are stable for at least 6 months when stored at 4 °C. The stock solution is purchased at a concentration range of 1-4 ng/µl.

8.2.2 INTERNAL STANDARD PRIMARY DILUTION (IS PDS) STANDARD (0.5-2 ng/µL) – Prepare the IS PDS at a concentration of 0.5-2 ng/µL. The IS PDS is prepared in 96:4% (vol/vol) methanol:water. The IS PDS is stable for at least two months when stored in polypropylene centrifuge tubes at room temperature.

Table 3

Internal Standard	Conc. of IS Stock (ng/uL)	Vol. of IS Stock (mL)	Final Vol. of IS PDS (mL)	Final Conc. of IS PDS (ng/µL)
^{13}C-PFOA	1	1.0	2.0	0.5

^{13}C-PFOS	3	1.0	2.0	1.5
d_3-NMeFOSAA	4	1.0	2.0	2.0

8.2.3 SUR STOCK STANDARD SOLUTIONS – SUR stock standard solutions are stable for at least 6 months when stored at 4 °C.

8.2.4 SURROGATE PRIMARY DILUTION STANDARD (SUR PDS) (0.5-2 ng/µL) – Prepare the SUR PDS at a concentration of 0.5-2 ng/µL. The SUR PDS is prepared in 96:4% (vol/vol) methanol:water. This solution is used to fortify all QC and Field Samples. The PDS is stable for one year when stored in polypropylene centrifuge tubes at room temperature.

Table 4

Surrogate	Conc. of SUR Stock (ng/µL)	Vol. of SUR Stock (mL)	Final Vol. of SUR PDS (,L)	Final Conc. of SUR PDS (ng/µL)
^{13}C-PFHxA	1.0	1.0	2.0	0.5
^{13}C-PFDA	1.0	1.0	2.0	0.5
d_5-NEtFOSAA	4.0	1.0	2.0	2.0
Tetrafluoro-2-heptafluoropropoxy-13C3-propanoic acid	50	1.0	2.0	0.5

8.2.5 ANALYTE STOCK STANDARD SOLUTION – Analyte stock standards are stable for at least 6 months when stored at -15 °C. When using these stock standards to prepare a PDS, care must be taken to ensure that these standards are at room temperature and adequately vortexed.

Table 5

Analyte	Analyte Stock Solvent	Concentration (ug/mL)
PFHxA	100% methanol	1.0
PFHpA	100% methanol	1.0
PFOA	100% methanol	1.0
PFNA	100% methanol	1.0
PFDA	100% methanol	1.0
PFUnA	100% methanol	1.0
PFDoA	100% methanol	1.0
PFTrDA	100% methanol	1.0
PFTA	100% methanol	1.0
PFBS	100% methanol	1.0
PFHxS	100% methanol	1.0
PFOS	100% methanol	1.0
NEtFOSAA	100% methanol	1.0
NMeFOSAA	100% methanol	1.0
HFPO-DA	100% methanol	50.0
11-chloroeicosafluoro-3-oxaundecane-1-sulfonic acid	100% methanol	50.0
9-chlorohexadecafluoro-3-oxanone-1-sulfonic acid	100% methanol	50.0

Analyte	Analyte Stock Solvent	Concentration (ug/mL)
4,8-dioxa-3H-perfluorononanoic acid	100% methanol	50.0

8.2.6 LOW, MEDIUM AND HIGH LEVEL LCS – The LCS's will be prepared at the following concentrations and rotated per batch; 2 ng/L, 40 ng/L, 160 ng/l. The analyte PDS contains all the method analytes of interest at various concentrations in methanol containing 4% water. The analyte PDS has been shown to be stable for 6 months when stored at room temperature.

8.2.7 CALIBRATION STANDARDS (CAL) –

Current Concentrations (ng/mL): 0.25, 0.5, 5.0, 10.0, 50.0 and 100 (optional)

Prepare the CAL standards over the concentration range of interest from dilutions of the analyte PDS in methanol containing 4% reagent water. The IS and SUR are added to the CAL standards at a constant concentration (10-40 ng/L). The lowest concentration CAL standard must be at or below the RL (2 ng/L), which may depend on system sensitivity. The CAL standards may also be used as CCVs (Sect. 9.9). The CAL standards are stable for at least two weeks when stored at room temperature. Longer storage times are acceptable provided appropriate QC measures are documented demonstrating the CAL standard stability.

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

9.1 REPORTING LIMIT (RL) CONFIRMATION

9.1.1 Fortify, extract, and analyze seven replicate LCSs at 2 ng/l. These LCSs must contain all method preservatives described in Section 6.2.1. Calculate the mean measured concentration (*Mean*) and standard deviation for these replicates. Determine the Half Range for the prediction interval of results (HR_{PIR}) using the equation below

$$HR_{PIR} = 3.963s$$

Where:

s = the standard deviation
3.963 = a constant value for seven replicates.

9.1.2 Confirm that the upper and lower limits for the Prediction Interval of Result ($PIR = Mean \pm HR_{PIR}$) meet the upper and lower recovery limits as shown below

The Upper PIR Limit must be ≤150% recovery.

$$\frac{Mean + HR_{PIR}}{Fortified\ Concentration} \times 100\% \leq 150\%$$

The Lower PIR Limit must be ≥ 50% recovery.

$$\frac{Mean - HR_{PIR}}{Fortified\ Concentration} \times 100\% \geq 50\%$$

9.1.3 The RL is validated if both the Upper and Lower PIR Limits meet the criteria described above. If these criteria are not met, the RL has been set too low and must be determined again at a higher concentration.

9.2 Blank(s)

9.2.1 **METHOD BLANK (MB) -** A Method Blank (MB) is required with each extraction batch to confirm that potential background contaminants are not interfering with the identification or quantitation of method analytes. If more than 20 Field Samples are included in a batch, analyze an MB for every 20 samples. If the MB produces a peak within the retention time window of any analyte that would prevent the determination of that analyte, determine the source of contamination and eliminate the interference before processing samples. Background contamination must be reduced to an acceptable level before proceeding. Background from method analytes or other contaminants that interfere with the measurement of method analytes must be below 1/3 of the RL. Blank contamination is estimated by extrapolation, if the concentration is below the lowest CAL standard. This extrapolation procedure is not allowed for sample results as it may not meet data quality objectives. If the method analytes are detected in the MB at concentrations equal to or greater than 1/3 of the RL, then re-extraction must be performed for all samples in the batch that have those target analytes above the reporting limit.

9.2.2 **FIELD REAGENT BLANK (FRB)** - The purpose of the FRB is to ensure that PFASs measured in the Field Samples were not inadvertently introduced into the sample during sample collection/handling. Analysis of the FRB is required only if a Field Sample contains a method analyte or analytes at or above the RL. The FRB is processed, extracted and analyzed in exactly the same manner as a Field Sample. If the method analyte(s) found in the Field Sample is present in the FRB at a concentration greater than 1/3 the RL, then all samples collected with that FRB are invalid and must be recollected and reanalyzed.

9.3 Laboratory Control Sample (LCS)

9.3.1 An LCS is required with each extraction batch. The fortified concentration of the LCS must be rotated between low, medium, and high concentrations from batch to batch.

9.3.2 The low concentration LCS must be as near as practical to, but no more than two times, the RL. Similarly, the high concentration LCS should be near the high end of the calibration range established during the initial calibration (Sect. 10.6).

9.3.3 Results of the low-level LCS analyses must be 50-150% of the true value. Results of the medium and high-level LCS analyses must be 70-130% of the true value. If the LCS results do not meet these criteria for method analytes, then all data for the problem analyte(s) must be considered invalid for all samples in the extraction batch.

9.3.4 It is the responsibility of the extraction chemist to view the previous extraction batch to determine the next spiking concentration. (Low → Medium → High)

9.4 Internal Standards (IS)

The analyst must monitor the peak areas of the IS(s) in all injections during each analysis day. The IS responses (peak areas) in any chromatographic run must be within 70-140% of the response in the most recent CCV and must not deviate by more than 50% from the average area measured during initial analyte calibration. If the IS areas in a chromatographic run do not meet these criteria, inject a second aliquot of that extract aliquoted into a new capped autosampler vial. Random evaporation losses have been observed with the polypropylene caps causing high IS(s) areas.

9.4.1 If the reinjected aliquot produces an acceptable IS response, report results for that aliquot.

9.4.2 If the reinjected extract fails again, the analyst should check the calibration by reanalyzing the most recently acceptable CAL standard. If the CAL standard fails the criteria of Section 9.9, recalibration is in order per Section 10.6. If the CAL standard is acceptable, extraction of the sample may need to be repeated provided the sample is still within the holding time. Otherwise, report results obtained from the reinjected extract, but annotate as suspect. Alternatively, collect a new sample and re-analyze.

9.5 Surrogate Recovery

The SUR standard is fortified into all samples, CCVs, MBs, LCSs, MSs, MSDs, FD, and FRB prior to extraction. It is also added to the CAL standards. The SUR is a means of assessing method performance from extraction to final chromatographic measurement. Calculate the recovery (%R) for the SUR using the following equation

$$\%R = (A / B) \times 100$$

Where:

A = calculated SUR concentration for the QC or Field Sample
B = fortified concentration of the SUR.

9.5.1.1 SUR recovery must be in the range of 70-130%. When SUR recovery from a sample, blank, or CCV is less than 70% or greater than 130%, check 1) calculations to locate possible errors, 2) standard solutions for degradation, 3) contamination, and 4) instrument performance. Correct the problem and reanalyze the extract.

9.5.1.2 If the extract reanalysis meets the SUR recovery criterion, report only data for the reanalyzed extract.

9.5.1.3 If the extract reanalysis fails the 70-130% recovery criterion, the analyst should check the calibration by injecting the last CAL standard that passed. If the CAL standard fails the criteria of Section 10.7, recalibration is in order per Section 10.6. If the CAL standard is acceptable, extraction of the sample should be repeated provided the sample is still within the holding time. If the re-extracted sample also fails the recovery criterion, report all data for that sample as suspect/SUR recovery to inform the

data user that the results are suspect due to SUR recovery. Alternatively, collect a new sample and re-analyze.

9.6 Matrix Spike (MS)

9.6.1 Analysis of an MS is required in each extraction batch and is used to determine that the sample matrix does not adversely affect method accuracy. Assessment of method precision is accomplished by analysis of a Field Duplicate (FD) (Sect. 9.7); however, infrequent occurrence of method analytes would hinder this assessment. If the occurrence of method analytes in the samples is infrequent, or if historical trends are unavailable, a second MS, or MSD, must be prepared, extracted, and analyzed from a duplicate of the Field Sample. Extraction batches that contain MSDs will not require the extraction of a field sample duplicate.

9.6.2 Within each extraction batch, a minimum of one Field Sample is fortified as an MS for every 20 Field Samples analyzed. The MS is prepared by spiking a sample with an appropriate amount of the Analyte Stock Standard (Sect. 8.2.5). Use historical data and rotate through the low, mid and high concentrations when selecting a fortifying concentration. Calculate the percent recovery (%*R*) for each analyte using the equation

$$\%R = \frac{(A - B)}{C} \times 100$$

Where:

A = measured concentration in the fortified sample
B = measured concentration in the unfortified sample
C = fortification concentration.

9.6.3 Analyte recoveries may exhibit matrix bias. For samples fortified at or above their native concentration, recoveries should range between 70-130%, except for low-level fortification near or at the RL (within a factor of 2-times the RL concentration) where 50-150% recoveries are acceptable. If the accuracy of any analyte falls outside the designated range, and the laboratory performance for that analyte is shown to be in control in the CCVs, the recovery is judged to be matrix biased. The result for that analyte in the unfortified sample is labeled suspect/matrix to inform the data user that the results are suspect due to matrix effects.

9.7 Laboratory Duplicate

9.7.1 FIELD DUPLICATE OR LABORATORY FORTIFIED SAMPLE MATRIX DUPLICATE (FD or MSD) – Within each extraction batch (not to exceed 20 Field Samples), a minimum of one FD or MSD must be analyzed. Duplicates check the precision associated with sample collection, preservation, storage, and laboratory procedures. If method analytes are not routinely observed in Field Samples, an MSD should be analyzed rather than an FD.

9.7.2 Calculate the relative percent difference (*RPD*) for duplicate measurements (*FD1* and *FD2*) using the equation

$$RPD = \frac{|FD1 - FD2|}{(FD1 + FD2) / 2} \times 100$$

9.7.3 RPDs for FDs should be ≤30%. Greater variability may be observed when FDs have analyte concentrations that are within a factor of 2 of the RL. At these concentrations, FDs should have RPDs that are ≤50%. If the RPD of any analyte falls outside the designated range, and the laboratory performance for that analyte is shown to be in control in the CCV, the recovery is judged to be matrix biased. The result for that analyte in the unfortified sample is labeled suspect/matrix to inform the data user that the results are suspect due to matrix effects.

9.7.4 If an MSD is analyzed instead of a FD, calculate the relative percent difference (RPD) for duplicate MSs (MS and MSD) using the equation

$$RPD = \frac{|MS - MSD|}{(MS + MSD) / 2} \times 100$$

9.7.5 RPDs for duplicate MSs should be ≤30% for samples fortified at or above their native concentration. Greater variability may be observed when MSs are fortified at analyte concentrations that are within a factor of 2 of the RL. MSs fortified at these concentrations should have RPDs that are ≤50% for samples fortified at or above their native concentration. If the RPD of any analyte falls outside the designated range, and the laboratory performance for that analyte is shown to be in control in the CCV, the recovery is judged to be matrix biased. The result for that analyte in the unfortified sample is labeled suspect/matrix to inform the data user that the results are suspect due to matrix effects.

9.8 Initial Calibration Verification (ICV)

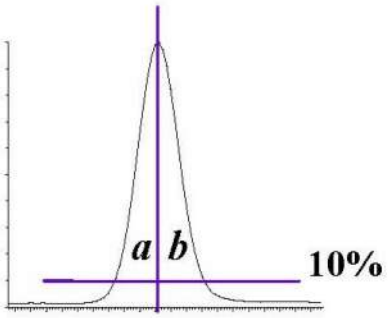
9.8.1 As part of the IDC (Sect. 13.2), each time a new Analyte Stock Standard solution (Sect. 8.2.5) is used, and at least quarterly, analyze a QCS sample from a source different from the source of the CAL standards. If a second vendor is not available, then a different lot of the standard should be used. The QCS should be prepared and analyzed just like a CCV. Acceptance criteria for the QCS are identical to the CCVs; the calculated amount for each analyte must be ± 30% of the expected value. If measured analyte concentrations are not of acceptable accuracy, check the entire analytical procedure to locate and correct the problem.

9.9 Continuing Calibration Verification (CCV)

9.9.1 CCV Standards are analyzed at the beginning of each analysis batch, after every 10 Field Samples, and at the end of the analysis batch. See Section 10.7 for concentration requirements and acceptance criteria.

9.10 Method-specific Quality Control Samples

9.10.1 PEAK ASYMMETRY FACTOR – A peak asymmetry factor must be calculated using the equation below during the IDL and every time a calibration curve is generated. The peak asymmetry factor for the first two eluting peaks in a midlevel CAL standard (if only two analytes are being analyzed, both must be evaluated) must fall in the range of



0.8 to 1.5. Modifying the standard or extract composition to more aqueous content to prevent poor shape is not permitted. See guidance in Section 10.6.4.1 if the calculated peak asymmetry factors do not meet the criteria.

$$A_s = b / a$$

Where:

A_s = peak asymmetry factor
b = width of the back half of the peak measured (at 10% peak height) from the trailing edge of the peak to a line dropped perpendicularly from the peak apex
a = the width of the front half of the peak measured (at 10% peak height) from the leading edge of the peak to a line dropped perpendicularly from the apex.

10. Procedure

10.1 Equipment Set-up

10.1.1 This procedure may be performed manually or in an automated mode using a robotic or automatic sample preparation device. If an automated system is used to prepare samples, follow the manufacturer's operating instructions, but all extraction and elution steps must be the same as in the manual procedure. Extraction and/or elution steps may not be changed or omitted to accommodate the use of an automated system. If an automated system is used, the MBs should be rotated among the ports to ensure that all the valves and tubing meet the MB requirements (Sect. 9.2).

10.1.2 Some of the PFASs adsorb to surfaces, including polypropylene. Therefore, the aqueous sample bottles must be rinsed with the elution solvent (Sect 10.3.4) whether extractions are performed manually or by automation. The bottle rinse is passed through the cartridge to elute the method analytes and is then collected (Sect. 10.3.4).

10.1.3 **NOTE:** The SPE cartridges and sample bottles described in this section are designed as single use items and should be discarded after use. They may not be refurbished for reuse in subsequent analyses.

10.2 Sample Preparation

10.2.1 Samples are preserved, collected and stored as presented in Section 6. All Field and QC Samples, including the MB, LCS and FRB, must contain the dechlorinating agent listed in Section 6.2.1. Determine sample volume. An indirect measurement may be done in one of two ways: by marking the level of the sample on the bottle or by weighing the sample and bottle to the nearest 1 g. After extraction, proceed to Section 10.5 for final volume determination. Some of the PFASs adsorb to surfaces, thus the sample volume may **NOT** be transferred to a graduated cylinder for volume measurement. The MB, LCS and FRB may be prepared by measuring 250 mL of reagent water with a polypropylene graduated cylinder or filling a 250-mL sample bottle to near the top.

Before extraction, verify the pH of the sample is 7 ± 0.5 by taking a drop of sample using a plastic (polypropylene or polyethylene) disposable pipet and transfer to a strip of pH paper with 0.5 unit increments. The sample pH is to be recorded in the laboratory extraction logbook.

The entire sample that is received must be sent through the SPE cartridge. In addition, the bottle must be solvent rinsed and this rinse must be sent through the SPE cartridge as well. The method blank (MB) and laboratory control sample (LCS) must be extracted in exactly the same manner (i.e., must include the bottle solvent rinse). It should be noted that a water rinse alone is not sufficient. This does not apply to samples with high concentrations of PFAS that are prepared using serial dilution and not SPE.

10.2.2 Add 20 µL of the SUR PDS (Sect. 8.2.4) to each sample, cap and invert to mix for a final concentration of 10 ng/L for ^{13}C-PFHxA and ^{13}C-PFDA and 40 ng/L for d_5-NEtFOSAA.

10.2.3 In addition to the SUR(s) and dechlorination agent, if the sample is an LCS, MS, or MSD, add the necessary amount of analyte PDS (Sect. 8.2.5). Cap and invert each sample to mix.

10.3 Cartridge SPE Procedure

10.3.1 CARTRIDGE CLEAN-UP AND CONDITIONING – DO NOT allow cartridge packing material to go dry during any of the conditioning steps. Rinse each cartridge with 15 mL of methanol. Next, rinse each cartridge with 18 mL of reagent water, without allowing the water to drop below the top edge of the packing. If the cartridge goes dry during the conditioning phase, the conditioning must be started over. Add 4-5 mL of reagent water to each cartridge, attach the sample transfer tubes (Sect. 7.2.3), turn on the vacuum, and begin adding sample to the cartridge.

10.3.2 SAMPLE EXTRACTON – Adjust the vacuum so that the approximate flow rate is 10-15 mL/min. Do not allow the cartridge to go dry before all the sample has passed through.

10.3.3 SAMPLE BOTTLE AND CARTRIDGE RINSE – After the entire sample has passed through the cartridge, rinse the sample bottles with two 7.5-mL aliquots of reagent water and draw each aliquot through the sample transfer tubes and the cartridges. Draw air or nitrogen through the cartridge for 5 min at high vacuum (10-15 in. Hg).

NOTE: If empty plastic reservoirs are used in place of the sample transfer tubes to pass the samples through the cartridges, these reservoirs must be treated like the transfer tubes. After the entire sample has passed through the cartridge, the reservoirs must be rinsed to waste with reagent water.

10.3.4 SAMPLE BOTTLE AND CARTRIDGE ELUTION – Turn off and release the vacuum. Lift the extraction manifold top and insert a rack with collection tubes into the extraction tank to collect the extracts as they are eluted from the cartridges. Rinse the sample bottles with 4 mL of methanol and elute the analytes from the cartridges by pulling the 4 mL of methanol through the sample transfer tubes and the cartridges. Use a low vacuum such that the solvent exits the cartridge in a dropwise fashion. Repeat sample bottle rinse and cartridge elution with a second 4-mL aliquot of methanol.

NOTE: If empty plastic reservoirs are used in place of the sample transfer tubes to pass the samples through the cartridges, these reservoirs must be treated like the transfer tubes. After the reservoirs have been rinsed in Section 10.3.3, the elution solvent used to rinse the sample bottles must be swirled down the sides of the reservoirs while eluting the cartridge to ensure that any method analytes on the surface of the reservoirs are transferred to the extract.

10.4 Extract Concentration

10.4.1 Concentrate the extract to dryness under a gentle stream of nitrogen in a heated water bath (60-65 °C) to remove all the water/methanol mix. Add the appropriate amount of 96:4% (vol/vol) methanol:water solution and the IS PDS (Sect. 8.2.2) to the collection vial to bring the volume to 1 mL and vortex. Transfer a small aliquot with a plastic pipet (Sect. 7.6) to a polypropylene autosampler vial.

NOTE: It is recommend that the entire 1-mL aliquot not be transferred to the autosampler vial because the polypropylene autosampler caps do not reseal after injection. Therefore, do not store the extracts in the autosampler vials as evaporation losses can occur occasionally in these autosampler vials. Extracts can be stored in 15-mL centrifuge tubes (Sect. 7.3).

10.5 Sample Volume Determination

10.5.1 If the level of the sample was marked on the sample bottle, use a graduated cylinder to measure the volume of water required to fill the original sample bottle to the mark made prior to extraction. Determine to the nearest 10 mL. If using weight to determine volume, weigh the empty bottle to the nearest 10 g and determine the sample weight by subtraction of the empty bottle weight from the original sample weight (Sect. 10.2.1). Assume a sample density of 1.0 g/mL. In either case, the sample volume will be used in the final calculations of the analyte concentration (Sect. 11.2).

10.6 Initial Calibration - Demonstration and documentation of acceptable initial calibration is required before any samples are analyzed. After the initial calibration is successful, a

CCV is required at the beginning and end of each period in which analyses are performed, and after every tenth Field Sample.

10.6.1 ESI-MS/MS TUNE

10.6.1.1 Calibrate the mass scale of the MS with the calibration compounds and procedures prescribed by the manufacturer.

10.6.1.2 Optimize the [M-H]- for each method analyte by infusing approximately 0.5-1.0 µg/mL of each analyte (prepared in the initial mobile phase conditions) directly into the MS at the chosen LC mobile phase flow rate (approximately 0.6 mL/min). This tune can be done on a mix of the method analytes. The MS parameters (voltages, temperatures, gas flows, etc.) are varied until optimal analyte responses are determined. The method analytes may have different optima requiring some compromise between the optima.

10.6.1.3 Optimize the product ion for each analyte by infusing approximately 0.5-1.0 µg/mL of each analyte (prepared in the initial mobile phase conditions) directly into the MS at the chosen LC mobile phase flow rate (approximately 0.6 mL/min). This tune can be done on a mix of the method analytes. The MS/MS parameters (collision gas pressure, collision energy, etc.) are varied until optimal analyte responses are determined. Typically, the carboxylic acids have very similar MS/MS conditions and the sulfonic acids have similar MS/MS conditions.

10.6.2 Establish LC operating parameters that optimize resolution and peak shape. Modifying the standard or extract composition to more aqueous content to prevent poor shape is not permitted.

10.6.3 Inject a mid-level CAL standard under LC/MS conditions to obtain the retention times of each method analyte. If analyzing for PFTA, ensure that the LC conditions are adequate to prevent co-elution of PFTA and the mobile phase interferants. These interferants have the same precursor and products ions as PFTA, and under faster LC conditions may co-elute with PFTA. Divide the chromatogram into retention time windows each of which contains one or more chromatographic peaks. During MS/MS analysis, fragment a small number of selected precursor ions ([M-H]-) for the analytes in each window and choose the most abundant product ion. For maximum sensitivity, small mass windows of ±0.5 daltons around the product ion mass were used for quantitation. If sufficient sensitivity exists to meet the RL, wider mass ranges may be used to obtain more confirmation ions.

10.6.4 Inject a mid-level CAL standard under optimized LC/MS/MS conditions to ensure that each method analyte is observed in its MS/MS window and that there are at least 10 scans across the peak for optimum precision.

10.6.4.1 If broad, split or fronting peaks are observed for the first two eluting chromatographic peaks (if only two analytes are being analyzed, both must be evaluated), change the initial mobile phase conditions to higher aqueous content until the peak asymmetry ratio for each peak is 0.8 – 1.5. The peak asymmetry factor is calculated as described in Section 9.10.1 on a mid-level CAL standard. The peak asymmetry factor must meet the above criteria for the first two eluting peaks during the IDL and every time a new calibration curve is generated. Modifying the standard or extract composition to more aqueous content to prevent poor shape is not permitted.

10.6.5 Prepare a set of CAL standards as described in Section 8.2.7. The lowest concentration CAL standard must be at or below the RL (2 ng/L), which may depend on system sensitivity. It is recommended that at least four of the CAL standards are at a concentration greater than or equal to the RL.

10.6.6 The LC/MS/MS system is calibrated using the IS technique. Use the LC/MS/MS data system software to generate a linear regression or quadratic calibration curve for each of the analytes. This curve **must always** be forced through zero and may be concentration weighted, if necessary. Forcing zero allows for a better estimate of the background levels of method analytes.

10.6.6.1 The isotopically labeled IS(s) in this method may undergo suppression in the ESI source if the concentration of the co-eluting unlabeled method analyte(s) is too high. The analyte concentration at which suppression may occur can vary depending on the instrument, LC conditions, ESI conditions, IS concentration, etc. To evaluate whether suppression is occurring during calibration, calculate the relative percent difference (*RPD*) for each IS using the equation

$$RPD = \frac{(H - L)}{(H + L) / 2} \times 100$$

10.6.6.2 The RPD calculated above must be <20% for each IS during calibration. If the calculated RPD is >20% for any IS, the analyst must recalibrate at lower analyte concentrations until the IS RPDs are <20%.

10.6.7 CALIBRATION ACCEPTANCE CRITERIA – When quantitated using the initial calibration curve, each calibration point, except the lowest point, for each analyte should calculate to be within 70-130% of its true value. The lowest CAL point should calculate to be within 50-150% of its true value. If these criteria cannot be met, the analyst will have difficulty meeting ongoing QC criteria. It is recommended that corrective action is taken to reanalyze the CAL standards, restrict the range of calibration, or select an alternate method of calibration (forcing the curve through zero is still required).

10.7 CONTINUING CALIBRATION CHECK (CCV) – Minimum daily calibration verification is as follows. Verify the initial calibration at the beginning and end of each group of analyses, and after every tenth sample during analyses. In this context, a “sample” is considered to be a Field Sample. MBs, CCVs, LCSs, MSs, FDs FRBs and MSDs are not counted as samples. The beginning CCV of each analysis batch must be at or below the RL in order to verify instrument sensitivity prior to any analyses. If standards have been prepared such that all low CAL points are not in the same CAL solution, it may be necessary to analyze two CAL standards to meet this requirement. Alternatively, the analyte concentrations in the analyte PDS may be customized to meet this criterion. Subsequent CCVs should alternate between a medium and high concentration CAL standard.

10.7.1 Inject an aliquot of the appropriate concentration CAL standard and analyze with the same conditions used during the initial calibration.

10.7.2 Determine that the absolute areas of the quantitation ions of the IS(s) are within 70-140% of the areas measured in the most recent continuing calibration check, and within 50-150% from the average areas measured during initial calibration. If any of the IS areas has changed by more than these amounts, adjustments must

be made to restore system sensitivity. These adjustments may include cleaning of the MS ion source, or other maintenance as indicated in Section 10.7.4. Major instrument maintenance requires recalibration (Sect 10.6) and verification of sensitivity by analyzing a CCV at or below the RL (Sect 10.7). Control charts are useful aids in documenting system sensitivity changes.

10.7.3 Calculate the concentration of each analyte and SUR in the CCV. The calculated amount for each analyte and SUR for medium and high level CCVs must be within ± 30% of the true value. The calculated amount for the lowest calibration point for each analyte must be within ± 50% and the SUR must be within ± 30% of the true value. If these conditions do not exist, then all data for the problem analyte must be considered invalid, and remedial action should be taken (Sect. 10.7.4) which may require recalibration. Any Field or QC Samples that have been analyzed since the last acceptable calibration verification should be reanalyzed after adequate calibration has been restored, with the following exception. **If the CCV fails because the calculated concentration is greater than 130% (150% for the low-level CCV) for a particular method analyte, and Field Sample extracts show no detection for that method analyte, non-detects may be reported without re-analysis.**

10.7.4 REMEDIAL ACTION – Failure to meet CCV QC performance criteria may require remedial action. Major maintenance, such as cleaning the electrospray probe, atmospheric pressure ionization source, cleaning the mass analyzer, replacing the LC column, etc., requires recalibration (Sect 10.6) and verification of sensitivity by analyzing a CCV at or below the RL (Sect 10.7).

10.8 EXTRACT ANALYSIS

10.8.1 Establish operating conditions equivalent to those summarized in Tables 5-8 of Section 16. Instrument conditions and columns should be optimized prior to the initiation of the IDC.

10.8.2 Establish an appropriate retention time window for each analyte. This should be based on measurements of actual retention time variation for each method analyte in CAL standard solutions analyzed on the LC over the course of time. A value of plus or minus three times the standard deviation of the retention time obtained for each method analyte while establishing the initial calibration and completing the IDC can be used to calculate a suggested window size. However, the experience of the analyst should weigh heavily on the determination of the appropriate retention window size.

10.8.3 Calibrate the system by either the analysis of a calibration curve (Sect. 10.6) or by confirming the initial calibration is still valid by analyzing a CCV as described in Section 10.7. If establishing an initial calibration, complete the IDC as described in Section 13.2.

10.8.4 Begin analyzing Field Samples, including QC samples, at their appropriate frequency by injecting the same size aliquots, under the same conditions used to analyze the CAL standards.

10.8.5 At the conclusion of data acquisition, use the same software that was used in the calibration procedure to identify peaks of interest in predetermined retention time windows. Use the data system software to examine the ion abundances of the peaks in the chromatogram. Identify an analyte by comparison of its retention time with that of the corresponding method analyte peak in a reference standard.

10.8.6 Comparison of the MS/MS mass spectra is not particularly useful given the limited ±0.5 dalton mass range around a single product ion for each method analyte.

10.8.7 The analyst must not extrapolate beyond the established calibration range. If an analyte peak area exceeds the range of the initial calibration curve, the extract may be diluted with 96%:4% vol/vol) methanol:water solution and the appropriate amount of IS added to match the original concentration. Re-inject the diluted extract. Incorporate the dilution factor into the final concentration calculations. Acceptable SUR performance (Sect. 9.5.1.1) should be determined from the undiluted sample extract. The resulting data should be documented as a dilution, with an increased RL.

11. Data Evaluation, Calculations and Reporting

11.1 Complete chromatographic resolution is not necessary for accurate and precise measurements of analyte concentrations using MS/MS. In validating this method, concentrations were calculated by measuring the product ions listed in Table 8. Other ions may be selected at the discretion of the analyst.

11.2 Calculate analyte and SUR concentrations using the multipoint calibration established in Section 10.6. Do not use daily calibration verification data to quantitate analytes in samples. Adjust final analyte concentrations to reflect the actual sample volume determined in Section 10.5.

11.3 Prior to reporting the data, the chromatogram should be reviewed for any incorrect peak identification or poor integration.

11.4 PFHxS, PFOS, NMeFOSAA, and NEtFOSAA have multiple chromatographic peaks using the LC conditions in Table 5 due to the linear and branch isomers of these compounds (Sect. 10.6.4.1). The areas of all the linear and branched isomer peaks observed in the CAL standards for each of these analytes must be summed and the concentrations reported as a total for each of these analytes.

11.5 Calculations must utilize all available digits of precision, but final reported concentrations should be rounded to an appropriate number of significant figures (one digit of uncertainty), typically two, and not more than three significant figures.

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

12.1 Section 9.0 outlines sample batch QC acceptance criteria. If non-compliant organic compound results are to be reported, the Organic Section Head and/or the Laboratory Director, and the Operations Manager must approve the reporting of these results. The laboratory Project Manager shall be notified and may choose to relay the non-compliance to the client, for approval, or other corrective action, such as re-sampling and re-analysis. The analyst, Data Reviewer, or Department Supervisor performing the secondary review initiates the project narrative, and the narrative must clearly document the non-compliance and provide a reason for acceptance of these results.

12.2 All results for the organic compounds of interest are reportable without qualification if extraction and analytical holding times are met, preservation requirements (including cooler temperatures) are met, all QC criteria as defined in Section 9 are met, and matrix interference is not suspected during extraction or analysis of the samples. If any of the below QC parameters are not met, all associated samples must be evaluated for re-extraction and/or re-analysis.

13. Method Performance

13.1 Detection Limit Study (DL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

13.1.1 The laboratory follows the procedure to determine the DL, LOD, and/or LOQ as outlined in Alpha SOP ID 1732. These studies performed by the laboratory are maintained on file for review.

13.2 Demonstration of Capability Studies

13.2.1 The IDC must be successfully performed prior to analyzing any Field Samples. Prior to conducting the IDC, the analyst must first generate an acceptable Initial Calibration following the procedure outlined in Section 10.6.

13.2.2 INITIAL DEMONSTRATION OF LOW SYSTEM BACKGROUND – Any time a new lot of SPE cartridges, solvents, centrifuge tubes, disposable pipets, and autosampler vials are used, it must be demonstrated that an MB is reasonably free of contamination and that the criteria in Section 9.2.1 are met. If an automated extraction system is used, an MB should be extracted on each port to ensure that all the valves and tubing are free from potential PFAS contamination.

13.2.3 INITIAL DEMONSTRATION OF PRECISION (IDP) – Prepare, extract, and analyze four to seven replicate LCSs fortified near the midrange of the initial calibration curve according to the procedure described in Section 10. Sample preservatives as described in Section 6.2.1 must be added to these samples. The relative standard deviation (RSD) of the results of the replicate analyses must be less than 20%.

13.2.4 INITIAL DEMONSTRATION OF ACCURACY (IDA) – Using the same set of replicate data generated for Section 13.2.3, calculate average recovery. The average recovery of the replicate values must be within ± 30% of the true value.

13.2.5 INITIAL DEMONSTRATION OF PEAK ASYMMETRY FACTOR – Peak asymmetry factors must be calculated using the equation in Section 9.10.1 for the first two eluting peaks (if only two analytes are being analyzed, both must be evaluated) in a mid-level CAL standard. The peak asymmetry factors must fall in the range of 0.8 to 1.5. See guidance in Section 10.6.4.1 if the calculated peak asymmetry factors do not meet the criteria.

13.2.6 Refer to Alpha SOP ID 1739 for further information regarding IDC/DOC Generation.

13.2.7 The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

14. Pollution Prevention and Waste Management

14.1 Refer to Alpha's Chemical Hygiene Plan and Hazardous Waste Management and Disposal SOP for further pollution prevention and waste management information.

14.2 This method utilizes SPE to extract analytes from water. It requires the use of very small volumes of organic solvent and very small quantities of pure analytes, thereby minimizing the potential hazards to both the analyst and the environment as compared to the use of large volumes of organic solvents in conventional liquid-liquid extractions.

14.3 The analytical procedures described in this method generate relatively small amounts of waste since only small amounts of reagents and solvents are used. The matrices of concern are finished drinking water or source water. However, laboratory waste management practices must be conducted consistent with all applicable rules and regulations, and that laboratories protect the air, water, and land by minimizing and controlling all releases from fume hoods and bench operations. Also, compliance is required with any sewage discharge permits and regulations, particularly the hazardous waste identification rules and land disposal restrictions.

[a] Segments are time durations in which single scan events occur; segments overlap where R.T. dictate.
[b] Precursor and product ions listed in this table are nominal masses. During MS and MS/MS optimization, the analyst should determine the precursor and product ion masses to one decimal place by locating the apex of the mass spectral peak place. These precursor and product ion masses (with one decimal place) should be used in the MS/MS method for all analyses.
[c] Ions used for quantitation purposes.
[d] Nitrogen used as collision gas at a flow rate of 9 PSI
[e] Analyte has multiple resolved chromatographic peaks due to linear and branched isomers. All peaks summed for quantitation purposes.

pH, Liquid Samples

Reference Methods: **Method 9040C,** SW-846, Test Methods for Evaluating Solid Waste: Physical/Chemical Methods, EPA SW-846, Update IIIB, 2004.

SM 4500H$^+$-B, Standard Methods for the Examination of Water and Wastewater. APHA-AWWA-WEF. Standard Methods Online.

1. Scope and Application

Matrices: This method is used to measure the pH of aqueous wastes and those multiphase wastes where the aqueous phase constitutes at least 20% of the total volume of the waste.

The corrosivity of concentrated acids and bases, or of concentrated acids and bases mixed with inert substances, cannot be measured. The pH measurement requires some water content.

Definitions: See Alpha Laboratories Quality Manual Appendix A

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one or more of the following laboratory personnel before performing the modification: Area Supervisor, Department Supervisor, Laboratory Director, or Quality Assurance Officer.

This method is restricted to use by or under the supervision of analysts experienced in the operation of the pH Meter and in the interpretation of pH data. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

2. Summary of Method

The pH of the sample is determined electrometrically using a temperature compensating combination electrode.

2.1 Method Modifications from Reference

The pH meter that is utilized will compensate for the temperature of the sample. Therefore, the temperature is not reported with the data. However, the sample is analyzed at room temperature.

3. Reporting Limits

None.

4. Interferences

4.1 Errors will occur when the electrode becomes coated. If an electrode becomes coated with an oily material that will not rinse free, the electrode can (1) be cleaned with an ultrasonic bath, or (2) be washed with detergent, rinsed several times with water, placed in 1:10 HCl so that the lower third of the electrode is submerged, and then thoroughly rinsed with water, or (3) be cleaned per the manufacturer's instructions.

4.2 Samples with a very low or very high pH may give incorrect readings on the meter.

For samples with a true pH of >10, the measured pH may be incorrectly low. This error can be minimized by using a low-sodium-error electrode.

Strong acid solutions, with a true pH of <1, may give incorrectly high pH measurements.

4.3 Coatings of oily material or particulate matter can impair electrode response. These coatings can usually be removed by gentle wiping or detergent washing, followed by rinsing with distilled water. An additional treatment with hydrochloric acid (1:10) may be necessary to remove any remaining film.

4.4 Temperature effects on the electrometric determination of pH arise from two sources. The first is caused by the change in electrode output at various temperatures. This interference is controlled with instruments having temperature compensation. The second source of temperature effects is the change of pH due to changes in the sample as the temperature changes. This error is sample-dependent and cannot be controlled. However, prior to analysis the samples are brought to room temperature (20 – 25 °C).

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material data handling sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

Samples are collected in plastic or glass containers. The minimum volume required is 100mL.

6.2 Sample Preservation

None.

6.3 Sample Shipping

No special shipping requirements.

6.4 Sample Handling

Samples are to be analyzed as soon as possible, within 24 hours of collection. Samples are stored at 4 ±2 °C. However, prior to analysis, samples are allowed to come to room temperature.

7. Equipment and Supplies

7.1 pH Meter: Laboratory benchtop model with automatic temperature compensation.

7.1.1 Combination electrode: Incorporates measuring and referenced functions; solid, gel-type filling material. For use with benchtop pH Meter (Section 7.1).

7.2 Titrator: T70 Mettler Toledo, with Inmontion Flex Autosampler and Computer with LabX software package.

7.2.1 Combination electrode: Mettler Toledo, Type DG111-SC, Part #00089596. For use with Titrator (Section 7.2).

7.3 Plastic Cups: Mettler Toledo brand, 100mL volume.

7.4 Magnetic stirrer

7.5 Teflon-coated stirring bar

7.6 Glass Beakers

7.7 Kimwipes

7.8 Plastic cups

8. Reagents and Standards

8.1 pH Buffers: Commercially available pH 4 (or 4.01), pH 7 (two sources), pH 10 (or 10.01). Buffers must have been validated by comparison to NIST standards. Certificate of analysis is kept on file.

9. Quality Control

9.1 Blank(s)

Not applicable.

9.2 Laboratory Control Sample (LCS)

One LCS is analyzed with each batch 20 of samples or less. It is a pH 7 buffer of a different source than the calibration buffer. Results must be within ±0.05.

When the LCS fails the acceptance criteria, the analyst must locate and correct the source of the problem and repeat the calibration. Repeated failure confirms a general problem with the measurement system or analytical technique of the analyst.

9.3 Initial Calibration Verification (ICV)

Refer to LCS Section 9.2.

9.4 Continuing Calibration Verification (CCV)

The calibration is also verified at the end of the sample sequence and after every 10 samples. The results of the continuing calibration verification must be within ± 2% (6.86-7.14). If this criterion is not met, the titrator or meter must be re-calibrated and any samples analyzed since the last acceptable CCV are reanalyzed

9.5 Matrix Spike

Not applicable.

9.6 Laboratory Duplicate

One sample is analyzed in duplicate per batch of 20 samples or less. %RPD for Duplicates must be within in-house acceptance criteria determined from Control Charts. If the result is outside of the criteria, the duplicate result may be narrated.

9.7 Method-specific Quality Control Samples

Not applicable.

9.8 Method Sequence

- Calibration
- Initial Calibration Verification (LCS)
- Sample analysis, 1-10 samples
- Duplicate analysis
- Continuing Calibration Verification (CCV), analyzed every 10 samples and at the end of analytical run.

10. Procedure

10.1 Equipment Set-Up

Thoroughly rinse and gently wipe the electrode prior to measuring the pH of buffers for calibration.

10.2 Initial Calibration

10.2.1 Benchtop Meter

The benchtop pH meter is calibrated on a daily basis using three pH buffers (Section 8.1). Follow manufacturer's instructions for a 3-point calibration of the pH meter. The results of the calibration must be recorded in the pH Calibration Log including correlation coefficient. Slope of the meter must fall within 95% to 105%.

Initial Calibration Verification: Prior to sample analysis, the calibration is initially verified by using a pH 7 buffer from a source other than the source used for calibration. The results of the initial verification must be within ± 0.05. If this criterion is not met, the meter must be re-calibrated.

10.2.2 Titrator

The pH titrator is calibrated on a daily basis using three pH buffers (Section 8.1).

- Pour 20-25mL of pH 4, 7 and 10 buffers (Section 8.1) into separate plastic cups (Section 7.3). Record the Lot numbers of the buffers into the Laboratory Notebook.
- Place the cups onto the Inmontion Flex Autosampler in that order.
- Ensure the Titrator is in "Remote Control" mode.
- Open LabX software package. Select "Open View" on the Titrator. Choose the appropriate method: Method 1 – PH Calibration.
- With a right-click on the mouse, select "Create Task". Type in the series ID (Cal-MM/DD/YYYY), and the sample sequence: PH 4, PH 7, PH 10. Select the "Save" button.
- The Series ID will appear in the "Samples" column. Click on that Series ID and using a right mouse click, select "Run" from the drop down menu.

After the run is complete, check for printout results. . Slope of the meter must fall within 95% to 105%.

Initial Calibration Verification: Prior to sample analysis, the calibration is initially verified by using a pH 7 buffer from a source other than the source used for calibration. The results of the initial calibration verification (LCS) must be within ±2%. If this criterion is not met, the Titrator must be recalibrated before any samples are analyzed.

10.3 Equipment Operation and Sample Processing

10.3.1 Benchtop Meter

Place the sample in a clean glass beaker or plastic cup using a sufficient volume to cover the sensing elements of the electrode and to give adequate clearance for the magnetic stirring bar.

Thoroughly rinse and gently wipe the electrode prior to measuring the pH of samples. Immerse the electrode into the sample beaker and gently stir at a constant rate to provide homogeneity and suspension of solids. Note and record the sample pH when meter has stabilized. Record temperature at which pH is recorded.

10.3.2 Titrator

- Pour 20-25mL of each sample into a separate, labeled plastic cup (Section 7.3).
- Place the cups onto the Inmontion Flex Autosampler.
- Choose the appropriate method: Method 2 – PH Measurement.
- With a right-click on the mouse, select “Create Task”. Type in the series ID (LCS-MM/DD/YYYY), and the sample sequence. Make sure the order of the samples on the autosampler matches the sample sequence. Select the “Save” button.
- The Series ID will appear in the “Samples” column. Click on that Series ID and using a right mouse click, select “Run” from the drop down menu.
- After the run is complete, check for printout results.

10.4 Continuing Calibration

10.4.1 Benchtop Meter

The meter calibration is also verified at the end of the sample sequence and after every 10 samples. The results of the continuing calibration verification must be within ± 2%. If this criterion is not met, the meter must be re-calibrated and any samples analyzed since the last acceptable CCV are reanalyzed.

10.4.2 Titrator

The titrator calibration is also verified at the end of the sample sequence and after every 10 samples. The results of the continuing calibration verification must be within ± 2%. If this criterion is not met, the titrator must be re-calibrated and any samples analyzed since the last acceptable CCV are reanalyzed.

10.5 Preventative Maintenance

The combination electrode on the benchtop meter is rinsed with DI and gently dried with a KimWipe between sample readings. Both electrodes are stored in buffer 7 when not in use.

11. Data Evaluation, Calculations and Reporting

pH is read directly from the pH benchtop meter or Titrator. No calculations are necessary.

For pH readings of less than 1, the reported result is: pH <1.

For pH readings greater than 10, report result in 3 significant figures.

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

Holding time exceedence and improper preservation are noted on the nonconformance report form.

Perform routine preventative maintenance following manufacturer's specification. Record all maintenance in the instrument logbook.

The combination electrode is replaced as necessary.

Review of standards for acceptable performance occurs for each batch of samples. Record any trends or unusual performance on a nonconformance action form.

If the LCS recovery falls outside the designated acceptance range, the laboratory performance for that parameter is judged to be out of control, and the problem must be immediately identified and corrected. Re-calibration of the meter or titrator is necessary prior to sample analysis.

13. Method Performance

13.1 Method Detection Limit Study (MDL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the MDL, LOD, and/or LOQ as outlined in Alpha SOP/1732. These studies performed by the laboratory are maintained on file for review.

Not applicable to this method.

13.2 Demonstration of Capability Studies

Refer to Alpha SOP/1734, 1739 for further information regarding IDC/DOC Generation.

13.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

14. Pollution Prevention and Waste Management

pH, Soil and Waste

References: **Method 9045D, Soil and Waste pH,** Test Methods for Evaluating Solid Waste: Physical/Chemical Methods, EPA SW-846, Revision 4, November 2004.

Method 9040C, Test Methods for Evaluating Solid Waste: Physical/Chemical Methods, EPA SW-846, Revision 3, November 2004.

NJDEP Site Remediation Program, Data of Known Quality Protocol, Version 1, April 2014

1. Scope and Application

Matrices: Soils and wastes, including solids, sludges, or non-aqueous liquids.

Definitions: See Alpha Laboratories Quality Manual Appendix A

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one or more of the following laboratory personnel before performing the modification: Area Supervisor, Department Supervisor, Laboratory Director, or Quality Assurance Officer.

This method is restricted to use by or under the supervision of analysts experienced in the operation of the pH meter and in the interpretation of pH data. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

2. Summary of Method

The sample is mixed with reagent water, and the pH of the resulting aqueous solution is measured.

2.1 Method Modifications from Reference

The pH meter that is utilized will compensate for the temperature of the sample. Therefore, the temperature is not reported with the data. However, the sample is analyzed at room temperature. Only one aliquot is used for measurement.

3. Reporting Limits

None.

4. Interferences

4.1 Errors will occur when the electrode becomes coated. If an electrode becomes coated with an oily material that will not rinse free, the electrode can (1) be cleaned with an ultrasonic bath, or (2) be washed with detergent, rinsed several times with water, placed in 1:10 HCl so that the lower third of the electrode is submerged, and then thoroughly rinsed with water, or (3) be cleaned per the manufacturer's instructions.

4.2 Samples with a very low or very high pH may give incorrect readings on the meter.

For samples with a true pH of >10, the measured pH may be incorrectly low. This error can be minimized by using a low-sodium-error electrode.
Strong acid solutions, with a true pH of <1, may give incorrectly high pH measurements.

4.3 Coatings of oily material or particulate matter can impair electrode response. These coatings can usually be removed by gentle wiping or detergent washing, followed by rinsing with distilled water. An additional treatment with hydrochloric acid (1:10) may be necessary to remove any remaining film.

4.4 Temperature effects on the electrometric determination of pH arise from two sources. The first is caused by the change in electrode output at various temperatures. This interference should be controlled with instruments having temperature compensation. The second source of temperature effects is the change of pH due to changes in the sample as the temperature changes. This error is sample-dependent and cannot be controlled. However, prior to analysis the samples are brought to room temperature (20 – 25 °C).

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material data handling sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

Samples are collected in 4-ounce glass jars.

6.2 Sample Preservation

None.

6.3 Sample Shipping

No special shipping requirements.

6.4 Sample Handling

Samples are to be analyzed as soon as possible after sampling. Samples are stored at 4 ± 2°C. Samples that are to be run in conjunction with NJ-Hex DAK acceptance criteria must be analyzed within 24 hours of Hex sample preparation.

7. Equipment and Supplies

7.1 pH Meter: Laboratory benchtop model with automatic temperature compensation.

7.1.1 Combination electrode: Incorporates measuring and referenced functions; solid, gel-type filling material. For use with benchtop pH Meter (Section 7.1).

7.3 Beakers: 50mL glass or plastic

7.4 Magnetic Stirrer

7.5 Teflon-coated stirring bar

7.6 Analytical Balance: Capable of weighing 0.1g

7.7 Kimwipes

8. Reagents and Standards

8.1 Reagent Water: All references to water in this method refer to reagent water.

8.2 pH Buffers: Commercially available pH 4 (or 4.01), pH 7, pH 10 (or 10.01). In addition, an alternate source of pH 7 Buffer is necessary. All Buffers must have been validated by comparison to NIST standards. Certificate of analysis is required. Buffers are stored at room temperature and expire upon manufacturer's specified date.

9. Quality Control

9.1 Blank(s)

Not applicable.

9.2 Laboratory Control Sample (LCS)

One LCS is analyzed with each batch of 20 samples or less. It is a pH 7 buffer of a different source than the calibration buffer. Results must be within ± 0.05.

9.3 Initial Calibration Verification (ICV)

Refer to LCS Section 9.2.

9.4 Continuing Calibration Verification (CCV)

A CCV of pH 7 is analyzed at the end of the analytical run. Results must be within ± 0.2 units.

9.5 Matrix Spike

Not applicable.

9.6 Laboratory Duplicate

One duplicate sample is analyzed per batch of 20 samples or less

9.7 Method-specific Quality Control Samples

Not applicable.

9.8 Method Sequence

- Calibration
- Calibration Verification (LCS)
- Sample analysis
- Duplicate Analysis
- Calibration Verification (CCV)

10. Procedure

10.1 Equipment Set-up

10.1.1 Sample Preparation

In a 50mL beaker, weigh 20 grams of soil; record the weight. Add 20mL of reagent water, cover and continuously stir the suspension for 30 minutes, using a teflon stir bar on a magnetic stirrer. Let samples stand for 1 hour before measurement.

Additional dilutions are permissible if working with hydroscopic soils, salts or other problematic matrices.

NOTE: If the sample is hygroscopic and absorbs all the reagent water, begin again using 20 grams of sample and 40mL of reagent water.

NOTE: If the supernatant is multiphasic, decant the oily phase and measure the pH of the aqueous base. The electrode may need to be cleaned (Section 4.1) if it becomes coated with an oily material.

10.2 Initial Calibration

The pH meter is calibrated on a daily basis using three pH buffers (Section 8.1). Follow manufacturer's instructions for a 3-point calibration of the pH meter. The results of the calibration must be recorded in the pH Calibration Log.

10.3 Equipment Operation and Sample Processing

10.3.1 Allow the sample suspension to stand for about 30 minutes to allow suspended material to settle out from the suspension.

10.3.2 Immerse the pH electrode just below the suspension and allow pH meter to stabilize. Note and record the sample pH in the Laboratory notebook. Report sampletemperature at the time of measurement.

10.3.3 Rinse the electrode thoroughly between samples, using reagent water.

10.4 Continuing Calibration

Prior to sample analysis, the calibration is initially verified by using a pH 7 buffer from a source other than the source used for calibration. The results must be within ± 0.2. If this criterion is not met, the meter must be re-calibrated before sample analysis can begin.

10.5 Preventative Maintenance

The pH probe is rinsed with DI and gently dried with a KimWipe between sample readings.

11. Data Evaluation, Calculations and Reporting

pH is read directly from the pH meter. No calculations are necessary.

For pH readings of less than 1, the reported result is: pH <1.

For pH readings greater than 10, report result in 3 significant figures.

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

Holding time exceedence and improper preservation are noted on the nonconformance report form.

Perform routine preventative maintenance following manufacturer's specification. Record all maintenance in the maintenance logbook.

The pH electrode is replaced as necessary.

Review of standards for acceptable performance occurs for each batch of samples. Record any trends or unusual performance on a nonconformance action form.

If the LCS or CCV recovery falls outside the designated acceptance range, the laboratory performance for the parameter is judged to be out of control, and the problem must be immediately identified and corrected. Re-calibration of the meter is necessary prior to sample analysis. All samples analyzed since the last acceptable QC standard must be reanalyzed following re-calibration of the meter.

13. Method Performance

13.1 Method Detection Limit Study (MDL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the MDL, LOD, and/or LOQ as outlined in Alpha SOP/1732. These studies performed by the laboratory are maintained on file for review.

13.2 Demonstration of Capability Studies

Refer to Alpha SOP 1739 for further information regarding IDC/DOC Generation.

13.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

14. Pollution Prevention and Waste Management

Refer to Alpha's Chemical Hygiene Plan and Waste Management and Disposal SOP for further pollution prevention and waste management information.

Reference Methods: **EPA 9065**, SW-846, Test Methods for Evaluating Solid Waste: Physical/Chemical Methods, EPA SW-846, Update III, 1986.

EPA 420.1, Methods for the Chemical Analysis of Water and Wastes, EPA 600/ 4-79-020, 1983.

1. Scope and Application

Matrices: This method is applicable to the analysis of ground water, drinking, surface, and saline waters, domestic and industrial wastes, and soils.

Definitions: See Alpha Analytical Quality Manual Appendix A

Phenols, defined as hydroxy derivatives of benzene and its condensed nuclei, may occur in domestic and industrial wastewaters and in drinking water supplies. Chlorination of such waters may produce odoriferous and objectionable-tasting chlorophenols, which may include o-chlorophenol, p-chlorophenol, 2,6-dichlorophenol, and 2,4-dichlorophenol. Phenol removal processes in water treatment include superchlorination, chlorine dioxide or chlorine ammonia treatment, ozonation, and activated carbon adsorption.

This method uses the 4-aminoantipyrine colorimetric method that determines phenol, the ortho- and metasubstituted phenols, and, under proper pH conditions, those parasubstituted phenols in which the substitution is a carboxyl, halogen, methoxyl, or sulfonic acid group.

This method is restricted to use by or under the supervision of analysts experienced in the operation of the distillation units and the spectrophotometer, and in the interpretation of spectrophotometer data. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

2. Summary of Method

The phenols are distilled at a more or less constant rate from the nonvolatile impurities. The rate of volatilization of the phenols is gradual, so that the volume of the distillate must equal that of the sample being distilled. The use of $CuSO_4$ during distillation of an acidic sample permits the formation of cupric sulfide without subsequent decomposition to H_2S. The acidic solution also prevents the precipitation of cupric solution hydroxide, which acts as an oxidizing agent toward phenols.

The steam-distilled phenols react with 4-aminoantipyrine at a pH of 10.0 in the presence of potassium ferricyanide to form a colored antipyrine dye. This dye is kept in an aqueous solution and the absorbance is measured at 510nm

2.1 Method Modifications from Reference

The aqueous sample size has been reduced from 500mL to 250mL. Consequently, the volume of reagents added for distillation has been reduced by half.

Method 420.1 specify 24h holding time; lab is using 28 days holding time per method 9065; all samples are acidified.

3. Reporting Limits

The Reported Detection Limit for this analysis is 0.03mg phenol/L for liquids and 0.75mg/Kg for soils.

4. Interferences

4.1 Instrumental

Distillate turbidity will interfere with Spectrophotometer reading. Refer to Section 10.3.1.3.

4.2 Parameters

4.2.1 Domestic and industrial wastewaters may contain such interferences as phenol-decomposing bacteria, oxidizing and reducing substances, and alkaline pH values. Biological degradation is inhibited by the addition of $CuSO_4$ to the sample. Acidification with H_2SO_4 assures the presence of the copper ion and eliminates any chemical changes resulting from the presence of strong alkaline conditions.

4.2.2 Some of the treatment procedures used for the removal of interferences before analysis may result in an unavoidable loss of certain types of phenols. Consequently, some highly contaminated wastewaters may require specialized screening techniques for elimination of interferences and for quantitative recovery of the phenolic compounds.

4.2.3 Color response of phenolic materials with 4-aminoantipyrine is not the same for all compounds. Because phenolic-type wastes usually contain a variety of phenols, it is not possible to duplicate a mixture of phenols to be used as a standard. For this reason phenol has been selected as a standard and any color produced by the reaction of other phenolic compounds is reported as phenol. This value will represent the minimum concentration of phenolic compounds present in the sample.

4.2.4 Interferences from sulfur compounds are eliminated by acidifying the sample to a pH of < 4 with H_2SO_4 and aerating briefly by stirring.

4.2.5 Oxidizing agents such as chlorine, detected by the liberation of iodine upon acidification in the presence of potassium iodide, are removed immediately after sampling by the addition of an excess of ferrous ammonium sulfate. If chlorine is not removed, the phenolic compounds may be partially oxidized and the results may be low.

4.2.6 Oils and tars contain phenol, and if present in the sample would cause interference. Refer to the original method for guidance in the extraction of oils and tars from the sample.

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material data handling sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

Collect aqueous samples in a 1L Amber Glass bottle and soil samples in an 8-ounce glass jar.

6.2 Sample Preservation

Phenols in concentrations usually encountered in wastewaters are subject to biological and chemical oxidation. If analysis cannot be done within 4 hours after collection, acidify to a pH <4 with H_2SO_4. If H_2S or SO_2 is known to be present, briefly aerate or stir the sample with caution.

Soil samples are not preserved.

6.3 Sample Shipping

No special shipping requirements.

6.4 Sample Handling

Keep the sample refrigerated at 4±2ºC. Analyze the preserved aqueous samples and soil samples within 28 days after collection.

Soil distillates must be analyzed within 24 hours of distillation. Soil distillates are kept refrigerated at 4±2ºC if not immediately analyzed.

7. Equipment and Supplies

7.1 Distillation apparatus: All glass, consisting of 500mL Pyrex distilling flasks with condenser and heating apparatus. Steam cleaned, per Section 10.1.1.

7.2 pH meter, calibrated.

7.3 Spectrophotometer: for use at 510nm.

7.4 Volumetric Pipettes: 1mL, 2mL, 3mL

7.5 Volumetric Flasks: 100mL, 200mL

7.6 Glass Beakers: 250mL or greater

7.7 Chiller.

7.8 Analytical Balance.

7.9 Syringes 10-20 ml

7.10 Acrodisks.

7.11 pH Paper

7.12 Boiling Chips

7.13 Timer

8. Standards and Reagents

8.1 DI Water.

8.2 1000ppm LCS Stock Phenol Solution: Commercially available with a certificate of analysis. Store at room temperature. Expires upon manufacturer's specified date.

8.2.1 200ppm LCS Working Solution: Dilute 20mL of 1000ppm LCS Stock Phenol Solution (Section 8.2) to 100mL with DI. Store at room temperature. Expires 3 months from date of preparation.

8.3 1000ppm Stock Calibration Standard: Commercially available with a certificate of analysis; must be purchased from a different source than the 1000ppm LCS Stock Phenol Solution (Section 8.2). Store at room temperature. Expires upon manufacturer's specified date.

8.3.1 10ppm Working Calibration Standard: Pipet 10mL of the 1000ppm Stock Calibration Standard (Section 8.3) into a 1L volumetric flask and bring to volume with DI. Prepare fresh on each day of use.

8.3.2 200ppm Spiking Solution: Pipet 20mL of the 1000ppm Stock Calibration Standard (Section 8.3) into a 100mL volumetric flask and bring to volume with DI. Store at room temperature. Expires 3 months from date of preparation.

8.4 Copper sulfate solution: Dissolve 100g $CuSO_4 \cdot 5H_2O$ in 1L of DI. Store at room temperature. Expires one year from date of preparation.

8.5 Sulfuric acid, H_2SO_4: Concentrated

8.6 Buffer Solution: Dissolve 16.9g of NH_4Cl in 143mL concentrated NH_4OH and dilute to 250mL with DI water. Typically, 2mL of Buffer adjusts 100mL of distillate to pH 10. Store at room temperature. Expires 3 months from date of preparation.

8.7 Aminoantipyrine solution: Dissolve 2g of 4-aminoantipyrine (4-AAP) in DI and dilute to 100mL. Prepare a fresh solution on each day of use.

8.8 Potassium ferricyanide solution: Dissolve 8.0g K3Fe $(CN)_6$ in DI and dilute to 100mL. Filter if necessary. Store at room temperature. Prepare fresh each week of use.

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

9.1 Blank(s)

One distillation blank per batch of 10 samples or less. A Distillation Blank will determine if any contamination has occurred. (Section 10.1.2.2)

9.2 Laboratory Control Sample (LCS)

Analysis of a LCS/ICV and all samples in the batch takes place after the spectrophotometer is set to zero using an undistilled Blank. One LCS is run per batch of 10 samples or less. (Section 10.1.2.3)

The LCS recovery must be within ± 30% for aqueous samples and ± 35% for solid samples. If LCS recovery is outside acceptance criteria, the entire batch is re-distilled and reanalyzed.

The ICV must be within +/- 10% of the true value before reading any sample on the spectrophotometer. If the ICV recovery is not within the limits, then a new calibration curve is generated.

9.3 Initial Calibration Verification (ICV)

Refer to Section 9.2.

9.4 Continuing Calibration Verification (CCV)

After every 10 or less samples, or for every hour of continuous analysis, verify the calibration curve by coloring and reading the absorbance of an undistilled phenol standard (CCV). The CCV must recover within +/- 10% of the true value. If the CCV recovery is not within the limits, CCV is re-poured and re-analyzed. If the CCV failure continues, then a new calibration curve is generated (Section 10.2.1).

9.5 Matrix Spike

Prep and analyze one matrix spike per batch of 10 samples or less. (Section 10.1.2.4) The spike recovery for aqueous samples must be within ± 30% and within ± 35% for solid samples. If recovery is outside of the acceptance criteria, the matrix spike is re-distilled and reanalyzed to confirm matrix interference. If interference is confirmed, a narrative is submitted to be included on the Client report.

9.6 Laboratory Duplicate

Prep and analyze one duplicate per batch of 10 samples or less. (Section 10.1.2.5) The %RPD for aqueous samples must be within ± 20% and within ± 30% for solid samples. If %RPD is outside of acceptance criteria, the sample and its duplicate are re-distilled and reanalyzed. If failure continues, a narrative is submitted to be included on the Client report.

9.7 Method-specific Quality Control Samples

Not applicable.

9.8 Method Sequence

- Glassware preparation
- Calibration curve generation
- Distillation
- Coloring
  - Blank
  - ICV/LCS
  - Samples and QC Samples
  - CCV
- Reading of absorbances
- Calculations

10. Procedure

10.1 Equipment Set-up

10.1.1 Preparation of Distillation Glassware

Prior to use, steam clean the distillation apparatus using 150mL of DI water plus 1mL concentrated H_2SO_4. Add boiling chips and assemble the stills. Turn on the chiller and heating units. Distill over about 100mL distillate. After stills cool, discard the distillate appropriately, then rinse the flask, the arm, and the column with DI.

10.1.2 Distillation Set-up

10.1.2.1 Samples

10.1.2.1.1 Liquid Samples

Measure 250mL of well-homogenized sample and 50mL of DI into a 500mL distilling flask. Check the pH using pH paper. Adjust the pH to <4 using H_2SO_4 if necessary.

10.1.2.1.2 Solid Samples

Weigh approximately 10g of well-homogenized soil sample using an analytical balance. Record the exact weight in a logbook.

Measure 300mL of DI into a 500mL distilling flask and add the 10g of soil sample. Check the pH using pH paper. Adjust the pH to <4 using H_2SO_4 if necessary.

10.1.2.2 Blank

Measure 300mL of DI into a 500mL distilling flask. Adjust the pH to <4 using H_2SO_4 if necessary.

For a batch of solid samples, also weigh approximately 10g of boiling chips(Section 8.9). Record the exact weight in the logbook and add to the distilling flask.

Prepare one Blank per batch of 10 samples or less.

10.1.2.3 Laboratory Control Sample (LCS) / Initial Calibration Verification (ICV)

Measure 300mL of DI into a 500mL distilling flask and add 1mL of 200ppm LCS Working Solution (Section 8.2.1). Adjust the pH to <4 using H_2SO_4 if necessary. Final concentration is 0.8ppm.

For a batch of solid samples, also weigh approximately 10g of boiling chips (Section 8.9). Record the exact weight in the logbook and add to the distilling flask 300mL of DI and add 1mL of 200ppm LCS Working Solution (Section 8.2.1). Adjust the pH to <4 using H_2SO_4 if necessary. Final concentration is 0.8ppm

Prepare one LCS/ICV per batch of 10 samples or less.

10.1.2.4 Matrix Spike

Measure 250mL of sample and 50mL of DI water into a 500mL distilling flask and add 1mL of 200ppm Spiking Solution (Section 8.3.2). If the pH is not <4, adjust using H_2SO_4. Final concentration is 0.8ppm. Prepare one matrix spike per batch of 10 samples or less.
For a batch of solid samples, also weigh approximately 10g of sample Record the exact weight in the logbook and add to the distilling flask. Measure 300mL of DI and add 1mL of 200ppm Spiking Solution (Section 8.3.2).

10.1.2.5 Sample Duplicate

Prepare one sample in duplicate per batch of 10 samples or less, as per Section 10.1.2.1.

10.2 Initial Calibration

10.2.1 Calibration Curve Generation: A calibration curve is prepared fresh on each day of analysis, with four calibration standards and a blank

10.2.1.1 Preparing the Standards

Using the 10ppm working calibration standard (Section 8.3.1), prepare the following standards in volumetric flasks using DI water:

10ppm Working Calibration Standard (mL)	Final Volume (Volumetric Flask – mL)	Concentration (mg/L)
0.0	100	0.0
0.5	200	0.025

1.0	100	0.10
10.0	100	1.0
25.0	100	2.5

10.2.1.2 Coloring and Reading the Standards

10.2.1.2.1 To 100mL of standard, add 2mL of buffer solution (Section 8.6) and mix. The pH of the standards must be 10. Additional buffer solution may be added if necessary.

10.2.1.2.2 Add 2.0mL aminoantipyrine solution (Section 8.7) and mix.

10.2.1.2.3 Add 2.0mL of potassium ferricyanide solution (Section 8.8) and mix.

10.2.1.2.4 After 15 minutes, zero the spectrophotometer at 510nm with the 0.0ppm standard (Blank) sample in a 2.5 cm cell.

10.2.1.2.5 Read the standard absorbances on the Spectrophotometer at 510nm, in a 2.5cm cell and record in the laboratory notebook.

10.2.1.3 Preparing a Standard Curve

Plot a curve of the absorbance values of the standards versus the corresponding phenol concentrations. Correlation coefficient will be calculated. All calibration points are back calculated on excel and should be within 10% from true concentration, except lowest point of calibration curve. %recoveries for low range will be wider, but shouldn't exceed 50% and correlation coefficient must be > or = 0.995. If calibration curve criteria failed, then new calibration standards have to be re-analyzed and new calibration curve has to be generated and all calibration points have to be recalculated to meet criteria. If second calibration curve fails acceptance criteria, then analysis have to stopped, problem has to be identified; new calibration standards made and analyzed.

10.3 Equipment Operation and Sample Processing

10.3.1 Distillation

10.3.1.1 To each distilling flask add one scoop of boiling chips and 3mL of $CuSO_4$ Solution (Section 8.4). Swirl vigorously.

10.3.1.2 Assemble the stills; turn on the chiller and heating units and collect 250mL of distillate into each glass beaker. Record the distillate volume in the laboratory notebook.

NOTE: At this point the distillate can be covered and refrigerated until the next day for the coloring procedure, if desired.

Check pH of distillate; it should be 10+/- 0.2. If pH is outsed of the range, it should be adjusted using Buffer solution (8.6)

10.3.1.3 Turbid Distillate

Initial distillation should purify the sample adequately. Occasionally, however, the distillate is turbid.

NOTE: *In this case, notify the Department Supervisor before proceeding.*

Refer to the original method for guidance in removing turbidity from the distillate; distillate may be filtered prior to colorimetric procedure to reduce turbidity and avoid false positive reading, using syringe and acrodisk

10.3.2 Coloring Procedure

Pour 100mL of distillate into a clean glass beaker. Add the following in order, and mix following each addition:

- 2mL of Buffer Solution (Section 8.6)
- 2mL of 4-AAP (Section 8.7)
- 2mL of $K_3Fe(CN)_6$ (Section 8.8).

10.3.3 Spectrophotometer Reading

10.3.3.1 Color DI water as in 10.3.2 above. After 15 minutes, use this to zero the Spectrophotometer at 510nm using a 2.5cm cell.

10.3.3.2 Read the colored distilled blank. If the Spectrophotometer reading is less than 0.010 absorbance, re-zero the instrument using the colored distilled blank. If the absorbance of the colored distilled blank is 0.010 or greater, then a contamination has occurred and the batch must be re-distilled.

10.3.3.3 Read the colored sample and QC sample distillates on the Spectrophotometer at 510nm in a 2.5cm cell. Record absorbances in the laboratory notebook.

10.3.3.4 If a sample distillate has an absorbance that is greater than that of the highest standard on the calibration curve (Section 10.2.1), dilute a fresh aliquot of distillate with DI water and re-color (Section 10.3.2) the sample distillate. Read again on the spectrophotometer as outlined above.

10.4 Continuing Calibration

After every 10 or less samples, or for every hour of continuous analysis, verify the calibration curve by coloring and reading the absorbance of an undistilled phenol standard (as in Section 10.2.1.2). Samples analyzed for NJ- use mid-point calibration standard for CCV

10.5 Preventive Maintenance

The Spectrophotometer is calibrated on a semi-annual basis by an instrument service company. These records are kept on file.

11. Data Evaluation, Calculations and Reporting

11.1 Calculate the concentration value of the sample directly from the standard curve. (Section 10.2.1.3).

$$\text{Phenol (mg/L)} = \frac{\text{absorbance} - \text{y-intercept}}{\text{slope}} \times \text{Dilution factor}$$

11.2 For liquid samples, calculate mg/L phenol as follows:

$$\text{mg/L phenol} = \mathbf{A} \times \frac{\mathbf{250}}{\mathbf{B}}$$

where:

A = mg/L phenol, from calibration curve (Section 11.1)
B = mL original sample.

11.3 For solid samples, calculate mg/kg phenol as follows:

$$\text{mg/kg phenol} = \mathbf{A} \times \frac{\mathbf{250}}{\mathbf{B}}$$

where:

A = mg/L phenol, from calibration curve (Section 11.1)
B = g original sample.

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

Holding time exceedence and improper preservation are noted on the nonconformance report form.

Perform routine preventative maintenance following manufacturer's specification. Record all maintenance in the instrument logbook.

Review of standards, blanks and standard response for acceptable performance occurs for each batch of samples. Record any trends or unusual performance on a nonconformance action form.

If the LCS recovery falls outside the designated acceptance range, the laboratory performance is judged to be out of control, and the problem must be immediately identified and corrected. The analytical result for the unspiked samples is suspect and is only reported for regulatory compliance purposes with the appropriate nonconformance action form. Immediate corrective action includes reanalyzing all affected samples by using any retained sample before the expiration of the holding time.

13. Method Performance

13.1 Method Detection Limit Study (MDL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the MDL, LOD, and/or LOQ as outlined in Alpha SOP/1732. These studies performed by the laboratory are maintained on file for review.

13.2 Demonstration of Capability Studies

Refer to Alpha SOP/1739 for further information regarding IDC/DOC Generation.

13.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

14. Pollution Prevention and Waste Management

Refer to Alpha's Chemical Hygiene Plan and Waste Management and Disposal SOP for further pollution prevention and waste management information.

15. Referenced Documents

Polynuclear Aromatic Hydrocarbons (PAHs) by SIM EPA 8270E (M)

Reference: EPA 8270E (Modified). SW-846, Test Methods for Evaluating Solid Waste: Physical/Chemical Methods, EPA SW-846, Update VI (Phase II), June, 2018.

1. Scope and Application

Matrices: This method is used to determine the concentration of Semivolatile organic compounds in extracts prepared from many types of solid waste matrices, soils, groundwater and wastewater samples

Definitions: Refer to Alpha Analytical Quality Manual.

This method is used to quantitate the neutral, acidic, and basic organic compounds listed in Table 6 that are soluble in methylene chloride and capable of being eluted, without derivatization, from a gas chromatographic fused-silica capillary column coated with a slightly polar silicone.

The following compounds may require special treatment when being determined by this method:

- Pentachlorophenol, is subject to erratic chromatographic behavior, especially if the GC system is contaminated with high boiling material.

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one of the following laboratory personnel before performing the modification: Area Supervisor, Laboratory Services Manager, Laboratory Director, or Quality Assurance Officer.

This method is restricted to use by or under the supervision of analysts experienced in the operation of a gas chromatograph/mass spectrometer operating in the selected ion monitoring (SIM) mode. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

2. Summary of Method

The samples are introduced into the GC/MS by injecting 1µL of the sample extract (or 2µL for Large Volume Injection, or LVI, method) into a gas chromatograph (GC) with a narrow-bore fused-silica capillary column. The GC column is temperature-programmed to separate the analytes, which are then detected with a mass spectrometer (MS) connected to the gas chromatograph.
The mass spectrometer is operated in the selected ion monitoring (SIM) mode. In this mode of operation, only the characteristic ions of the compounds listed in Table 5 are detected. It is not possible to identify any other compounds that may be present in the sample.

Analytes eluted from the capillary column are introduced into the mass spectrometer via direct connection. Identification of target analytes is accomplished by comparing the retention times of the characteristic ions with the retention times of these compounds in the daily check standard. Quantitation is accomplished using the internal standard method, using the average response factors from the initial calibration curve

2.1 Method Modifications from Reference

Operating the mass spectrometer in the SIM mode is a modification from method 8270, which requires operating in the scan mode. This SIM method is used when a project requires lower reporting limits than can be achieved running method 8270 or 625.

3. Reporting Limits

The laboratory follows the procedure found in 40CFR Part 136 to determine the MDL. The method detection limits determined by the laboratory are on file for review.

Table 6 lists our routine reporting limits. Whenever MDL studies are performed, the MDL results are compared with our reporting limits to ensure that the calculated MDLs are equal to or below our reporting limits

4. Interferences

4.1 Only high purity helium is used in the GC system to eliminate this source of possible contamination. The helium (carrier gas) is certified by the gas supplier.

4.2 Preventive instrument maintenance is performed routinely. Section 10.5 details the maintenance steps.

4.3 Contaminated solvents or reagents are also possible sources or contamination. All solvents used are pesticide grade or equivalent, and reagents are purchased as certified contaminant free. All of these materials are routinely determined to be free of interferences by analysis of extraction blanks with every extraction batch performed.

4.4 Glassware must be scrupulously cleaned. This procedure is detailed in the Organic Extraction Glassware Cleaning & Handling SOP 1953. Store dry glassware in a clean environment

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material safety data sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

5.1 Lab coats, safety glasses, and gloves should be worn when handling samples, extracts, standards or solvents.

5.2 All solvent and extract transfers should be handled in the vented bench area in the GC/MS laboratory.

5.3 All stock standards, working standards, and vialed sample extracts must be placed into the waste bucket in the lab for future disposal by the Health and Safety Officer. The container must be labeled properly with hazard warning labels indicating the container contents.

5.4 Flammable solvent bottles must be stored in the flammables cabinet.

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

Aqueous samples are collected in two 1L amber glass jars with Teflon-lined lids. Solid samples are collected in 250mL wide-mouth glass jars with Teflon-lined lids. All containers are purchased pre-cleaned and certified from commercial vendors

6.2 Sample Preservation

Both aqueous and solid samples are then preserved by packing in coolers with ice or ice packs, to maintain a temperature of ≤ 4ºC. Upon receipt at the laboratory, the samples are transferred into sample storage refrigerators to maintain at a temperature of ≤ 4ºC

6.3 Sample Shipping

No specific requirements.

6.4 Sample Handling

Aqueous samples must be extracted within 7 days of sample collection, solid samples within 14 days of collection. Once extracted, the samples must be analyzed within 40 days of the extraction date.

7. Equipment and Supplies

7.1 Gas Chromatograph/Mass Spectrometer System:

7.1.1 **Gas Chromatograph, Hewlett Packard 6890 or equivalent:** An analytical system complete with a temperature-programmable gas chromatograph configured for split/splitless-injection and all required accessories, including syringes, analytical columns, and gases. The capillary column is directly coupled to the source.

7.1.2 **Column:** 30m x 0.25mm ID, 0.25 µm film thickness silicone-coated, fused-silica capillary column (RTX-5MS, Restek), or equivalent.

7.1.3 **Mass Spectrometer, Hewlett Packard 5973 or equivalent:** Scanning in SIM mode using 70 volts (nominal) electron energy in the electron impact ionization mode. The mass spectrometer is capable of producing a mass spectrum for Decafluorotriphenylphosphine (DFTPP) which meets the criteria in Table 1 when 1 µL of the GC/MS tuning standard is injected through the GC (50ng of DFTPP).

7.1.4 **Data System:** A computer system is interfaced to the Mass Spectrometer. The system allows the continuous acquisition and storage on machine-readable media of all mass spectra obtained throughout the duration of the chromatographic program. The computer software allows the analyst to search for any GC/MS data file for ions of specific mass and plot such ion abundances versus time or scan number. *HP ChemServer* software is used for data acquisition and *Enviroquant MSD Chemstation version E.02.02* is used for data reduction.

7.2 Syringes: 10, 25, 50, 100, 250, 500, and 1000µL.

7.3 Volumetric Flasks, Class A: Appropriate sizes with ground-glass stoppers.

7.4 Vials: Glass autosampler vials with Polytetrafluoroethylene (PTFE)-lined crimp top caps.

8. Reagents and Standards

8.1 Stock Standard Solutions

All stock standard solutions are purchased from commercial vendors. They can be replaced with different standards as long as they contain all target analytes.

8.1.1 Internal Standard Stock Solution

The stock internal standard solution: (Restek, 2000µg/mL in Methylene Chloride, catalog# 31206).

1,4-dichlorobenzene-d_4
naphthalene-d_8
acenaphthene-d_{10}
phenanthrene-d_{10}
chrysene-d_{12}
perylene-d_{12}

8.1.2 Calibration Stock Solutions

Stock Standard	Number	Concentration
Restek Acid Surrogate Mix	31025	2000µg/mL
Restek B/N Surrogate Mix	31024	1000µg/mL
Ultra Scientific o-Terphenyl Solution	IST-480	2000µg/mL
Restek 8270 MegaMix	31850	500-1000µg/mL

8.2 Intermediate/Working Standard Solutions

8.2.1 Internal Standard SIM Solution

The SIM internal standard solution is prepared by diluting the internal standard stock solution with Methylene Chloride. Bring 1mL of the internal standard stock solution up to 10mL final volume with Methylene Chloride in a volumetric flask, resulting in a final concentration of 200µg/mL.

Standards, blanks, QC and sample extracts are spiked in the ratio of 10µL of working SIM internal standard to 500µL of extract, resulting in a concentration of 4µg/mL.

8.2.2 Surrogate Spiking Solution

The surrogate spiking solution is prepared from vendor supplied solutions, as follows:

To a 1L volumetric flask add 5mL each of:

Stock Standard	Catalog Number	Concentration
Restek Acid Surrogate Mix	31087	10000µg/mL
Restek B/N Surrogate Mix	31086	5000µg/mL

Bring to volume with Acetone. The final concentration is 50µg/mL for the acid surrogates and 25µg/mL for the B/N surrogates.

1mL of this surrogate spiking solution is added to each sample, blank and QC samples prior to extraction. See the extraction SOPs for details.

The **LVI surrogate** is a 10 fold dilution of the surrogate solution prepared above. For example, to make 200mL of LVI surrogate, add 20mL of the 50/25µg/mL surrogate solution to a 200mL volumetric flask and fill to volume with Acetone. The resulting surrogate concentration is 5µg/mL for the acid surrogates and 2.5µg/mL for the B/N surrogates

8.2.3 Calibration Standards

Calibration standards are prepared by diluting the stock standard solutions (Section 8.1.2) with Methylene Chloride. Two sources of standards are prepared, one is used for the initial calibration curve, and the other is used for the initial calibration verification standard. These intermediate solutions are then used to prepare the working initial calibration as listed in the table in Section 8.2.4.

8.2.3.1 Target Compound Calibration Standard

Using a calibrated syringe, combine the following to a 50mL volumetric flask:

2mL of 8270 MegaMix

Bring up to volume with Methylene Chloride. The final target compound concentration is 40µg/mL.

8.2.3.2 Surrogate Compound Calibration Standard

Using a calibrated syringe, add the following to a 10mL volumetric flask.

2mL of Acid Surrogate 31025

4mL of B/N Surrogate 31024

2mL of o-Terphenyl Solution IST-480-1

Bring up to volume with Methylene Chloride. The final target compound concentration is 400 µg/mL

8.2.3.2.1 Additional Surrogate Compound Calibration Standard for LVI

Using a calibrated syringe, add 1mL of the standard prepared in 8.2.3.2 to a 10mL volumetric flask and bring to volume with Methylene Chloride. The final target compound concentration is 40ug/mL

8.2.4 Working Calibration Standards

A minimum of a five point calibration is used for each target compound.

The daily continuing calibration check standard is from the same source, at 5 µg/mL for Sim curve and 1.0 µg/mL for LVI Sim curve.

SIM CURVE	
Level	**Concentration (µg/mL) (Target/Surrogate)**
L1	**0.05/0.5**
L2	**0.1/1.0**
L3	**0.2/2.0**
L4	**0.5/5.0**
L5	**1.0/10**
L6	**2.0/20**
L7	**5.0/40**
L8	**10/60**
L9	**15/0**
L10	**20/0**

SIM CURVE for LVI method	
Level	**Concentration (µg/mL) (Target/Surrogate)**
L1	**0.005**
L2	**0.010**
L3	**0.025**
L4	**0.05**
L5	**0.1**
L6	**0.25**
L7	**1.000**
L8	**5.000**
L9	**10.000**
L10	**20.000**

8.2.5 Calibration Standards 8270E NJSIMTECH and PA Compounds

Calibration standards are prepared by diluting the stock standard solutions (8.1.2) with Methylene Chloride. Two sources of standards are prepared, one is used for the initial calibration curve and the other is used for the initial calibration verification standard. These intermediate solutions are then used to prepare the working initial calibration and working initial calibration verification.

8.2.5.1 Target Compound Calibration Standard

Using a calibrated syringe, combine the following to a 25mL volumetric flask:

5mL of 8270 MegaMix
2.5mL of Acid Surrogate 31025
5mL of B/N Surrogate 31024

Bring up to volume with Methylene Chloride. The final target compound concentration is 200µg/mL

8.2.5.2 Working Calibration Standards

A minimum of a five point calibration is used for each target compound. The daily continuing calibration check standard is from the same source, at 5µg/mL.

NJSIMTECH AND PA SIM CURVE	
Level	**Concentration (µg/mL) (Target/Surrogate)**
L1	**0.02/0.2**
L2	**0.05/.5**
L3	**0.1/1.0**
L4	**0.2/2.0**
L5	**0.5/5.0**
L6	**1.0/20**
L7	**2.0/30**
L8	**5.0/60**
L9	**10.0**
L10	**20.0**

8.2.6 LCS/MS/MSD Spiking Standards

SPIKE 1

Restek:

8270 Mega Mix	500-1000µg/ml	cat#31850
Benzoic Acid Mix	2000µg/ml	cat#31879
Benzaldehyde Std	2000µg/ml	cat#33017
Custom AP9 ICAL Std	2000µg/ml	cat#571813-FL

Spike 1: In a 500mL volumetric flask add 20mL of 8270 Mega Mix; 10mL of each Benzoic Acid Mix, Custom AP9 ICAL Std, and Benzaldehyde Std. Bring up to volume with Acetone. The final concentration is 40µg/mL for all compounds except Acetophenone and 3,3'-Dichlorobenzidine which are at 80µg/mL

8.2.6.1 SIM/625.1SIM LCS/MS/MSD Spiking Solution

PAH Low Spk 1:

Take 25mL of the current lot of LCS/MS/MSD Spike 1 add it to a 100mL volumetric flask. Bring to volume with acetone. Final concentration is 10µg/mL for all SIM reportable compounds. If SIM spiking solution is not available, 250uL of the LCS/MS/MSD SPK 1 may be substituted.

The **LVI PAH Low Spk1** is a 10 fold dilution of the above preparation. For example, to make 100mL of LVI Spk 1, add 10mL of the 10µg/mL PAH Low Spk 1 solution to a 100mL volumetric flask and fill to volume with Acetone. The resulting analyte concentration is 1µg/mL

8.2.7 GC/MS Tuning Standard

The stock standard solution contains Decafluorotriphenylphosphine (DFTPP), 4,4'-DDT, Pentachlorophenol, and Benzidine at 1000 µg/mL (Ultra Scientific, Catalog# GCM-150, or equivalent).

The intermediate standard is prepared by taking 5uL of the stock solution and bringing up to 1mL in Methylene Chloride. The resulting concentration is

5µg/mL. The 4,4'-DDT, Pentachlorophenol, and Benzidine are used to verify injection port inertness and GC column performance

8.3 Secondary Source Standards 8270E SIM Compounds

Stock Standard	Catalog Number	Concentration
Restek – 8270 Mega Mix	31850	500-1000 µg/mL
Restek – Acid Surrogate Mix	31025	2000 µg/mL
Restek – B/N Surrogate Mix	31024	1000 µg/mL
Accustandard – o-Terphenyl	DRH-006-SS	1000 µg/mL

8.3.1 Second Source Std

Targets: add 1mL of 31850 into 25mL of Methylene Chloride. Final concentration is 40 µg/mL

Surrogates: add 2mL of 31024, 1mL of 31025 and 2mL of DRH-006-SS to a 10mL volumetric flask. Bring to volume with Methylene Chloride. Final concentration is 200 µg/mL.

8.3.2 ICV Standard

Add 1250µL of the Targets and 2000µL of Surrogate Std Sol (8.3.1) to 10mL of Methylene Chloride. Final concentration of target/surrogates analytes will be 5/40 µg/mL. This standard is used for Initial Calibration Verification.

For the LVI method ICV, add 1250µL of the Targets and 250µL of Surrogate Std Sol (8.3.1) to 10mL of Methylene Chloride. Final concentration of target and surrogates analytes will be 5 µg/mL

8.4 Secondary Source Standards 8270E NJSIMTECH and PA Compounds

Stock Standard	Catalog Number	Concentration
Restek – 8270 Mega Mix	31850	500-1000 µg/mL
Restek – Acid Surrogate Mix	31025	2000 µg/mL
Restek – B/N Surrogate Mix	31024	1000 µg/mL

8.4.1 Second Source Std

Add 2mL of 31850, 2mL of 31024 and 1mL of 31025 to a 10mL volumetric flask. Bring to volume with Methylene Chloride. Final concentration is 200µg/Ml.

8.4.2 ICV Standard

Add 2.5mL SIMTECH ICV Standard Stock to a 50mL volumetric flask. Bring to volume with Methylene Chloride. Final concentration is 10µg/mL

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

9.1 Blank

Extraction blanks are performed with each extraction batch of 20 or less samples. The extraction blank must not contain any of the reportable analytes above the reporting limit. Corrective actions:

- No corrective action required if concentration of contaminant in sample is >10x concentration in blank or if contaminant not detected in sample

- If the blank have reportable hits and re-extraction could not be performed due to lack of additional sample volume, the sample results are reported and qualified with “B” flag for any associated samples that concentration is less than 10x the blank concentration

For NJ regulatory work the method blank must have all the target analytes less than RL except for Phthalates which must be less than 5x of the RL. Sample results are qualified with “B” flag for analytes observed in the blank greater than RL and the Phthalates observed in the blank greater than 5x RL

The surrogate recoveries must also be within the acceptance criteria listed in Table 2. If surrogate acceptance criteria are exceeded, the extraction batch must be evaluated to determine if re-extraction or re-analysis is necessary

9.2 Laboratory Control Sample (LCS)

A Laboratory Control Sample/ Laboratory Control Sample Duplicate pair (LCS/LCSD) are extracted with each analytical batch and analyzed for each batch of 20 or fewer samples.

The recovery acceptance criteria are listed in Table 5-7. If any recovery criteria are not met, the extract should be reanalyzed. If less than 10% of spike compounds does not meet the criteria this should be noted on a narrative inclusion. If more than 10% of spike compounds is out the entire batch should be re-extracted. If this is not possible, due to insufficient sample or holding time exceedance, the analyst must write up the failure on a narrative sheet for inclusion in the client report. If >10% of analytes are recovered above control limits, this is deemed acceptable as long as the analytes in question are not detected in associated samples

9.3 Initial Calibration Verification (ICV)

See Section 10.2.2

9.4 Continuing Calibration Verification (CCV)

See Section 10.4

9.5 Matrix Spike

A matrix spike/matrix spike duplicate pair is extracted and analyzed for each batch of 20 or fewer samples per client request. The recovery acceptance criteria are listed in Table 5-7. If the recovery criteria are not met, but are met in the LCS, this should be noted on a narrative sheet for inclusion in the client report.

9.6 Laboratory Duplicate

The LCSD is typically used as the laboratory duplicate sample for the batch.

9.7 Method-specific Quality Control Samples

9.7.1 Surrogates

All extracted samples and associated QC are spiked with surrogates as described in Section 8.2.2. The laboratory must evaluate surrogate recovery data from individual samples and QC samples versus the surrogate control limits listed in Table 2.

Corrective action: Up to one surrogate can be out in each fraction (Acid and Base/Neutral) but not less than 10% recovery, before any corrective action is necessary. Otherwise, analysis must be repeated once to see if an analytical error has occurred. If the % recovery still exceeds the control limits the sample must be re-extracted and re-analyzed to confirm sample matrix. If matrix effect is confirmed, this must be noted on a narrative sheet for inclusion in the client report.

Re-extraction is not required if surrogate recoveries are high and target analytes are not detected in the sample

9.8 Method Sequence

In a 12-hour period, the typical analytical sequence is:

- DFTPP
- Continuing Calibration Std
- Method Blank/Instrument Blank
- Samples
- QC (as required)

10. Procedure

10.1 Equipment Set-up

10.1.1 GC/MS Operating Conditions for SIM and 625.1SIM:

Typical GC/MS operating conditions are listed below but may be altered as long as method performance criteria are met.

Mass range:	SIM Mode
Initial temperature:	40°C, hold for 2 minutes
Temperature program 1:	25°C / minute
Final temperature 1:	245°C, no hold.
Temperature program 2:	6°C / minute
Final temperature 2:	288°C, hold for 1 minute
Temperature program 3:	15°C / minute
Final temperature 3:	355°C, no hold
Injector temperature:	300°C
Transfer line temperature:	280°C
Source temperature:	230ºC
Injector:	Split-injection, ratio 5:1
Injection volume:	1µL
Carrier gas:	Helium at 1.1 cm / second, constant flow

GC/MS Operating Conditions for SIM and SIM LVI fast method:

Mass range:	SIM Mode
Initial temperature:	60°C, hold for 0.65 minutes
Temperature program 1:	42.7°C / minute
Final temperature 1:	285°C, no hold.
Temperature program 2:	4.7°C / minute
Final temperature 2:	305°C, no hold
Injector temperature:	270°C
Transfer line temperature:	280°C
Source temperature:	330ºC
Injector:	Split- injection, Ratio 20:1
Injection volume:	2µL, 5µl for LVI
Carrier gas:	Helium at 1.2mL/min, constant flow

10.1.2 GC/MS Tune Check:

At the beginning of every 12 hour sequence, analyze the 5µg/L GC/MS tuning standard (Section 8.2.7).

The resultant mass spectrum for DFTPP must meet the criteria given in Table 1 before standard or sample analysis may begin. The mass spectrum of DFTPP should be acquired in the following manner:

(1) Three scans (the peak apex scan, the scan immediately preceding the apex and the scan immediately following the apex) are acquired and averaged.

(2) Background subtraction is performed using a single scan of no more than 20 scans prior to the elution of DFTPP.

The GC/MS tuning standard is also used to assess GC column performance and injection port inertness. Benzidine and pentachlorophenol should be present at their normal responses and no peak tailing should be visible.

The tailing factor for benzidine and pentachlorophenol should be calculated in every DFTPP run. (See Table 8)

10.2 Initial Calibration

10.2.1 Initial Calibration

10.2.1.1 Prepare calibration standards for the target analytes at the ten concentration levels specified in Section 8.2.4 or in 8.2.5.1.

10.2.1.2 Initial Calibration Minimum RRF Criteria:

It is recommended that a minimum response factor for the most common target analytes, as noted in Table 11, be demonstrated for each individual calibration level as a means to ensure that these compounds are behaving as expected. In addition, meeting the minimum response factor criteria for the lowest calibration standard is critical in establishing and demonstrating the desired sensitivity.

10.2.1.3 Initial Calibration RSD Criteria:

For all analytes, the RSD must be < 20% for the mean response factor to be used for sample quantitation. If the RSD for any target analyte exceeds 20%, the fit must be ≥0.99 quadratic or > 0.995 linear fit for all target analytes. A minimum of 5 levels are required for a linear calibration model and a minimum of 6 levels are required for a quadratic calibration model. When calculating calibration using

the linear regression model, a quantitation check must be performed on the lowest calibration point, or the point that corresponds to that compound's established reporting limit. The recalculated concentration of the low calibration point (especially where the linear regression fits are used) should be within ± 50% of the standard's true concentration, and the recalculated concentration of any calibration standards above the LLOQ should be ± 30%. If this criterion is not meet then the corrective action must take place and a new initial calibration must be performed prior to sample analysis

For RCP, the RSD must be < 30% for the mean response factor to be used for sample quantitation.

Percent Relative Error (%RE): For linear and quadratic fit compounds, the %RE must be calculated for the standard at or near the midpoint and at the lowest level of the initial calibration. The %RE between the calculated and expected concentration of an analyte must be ≤ 30%, otherwise recalibration is necessary.

10.2.1.4 Evaluation of Retention Times:

The relative retention time (RRT) of each target analyte in each calibration standard should agree within 0.05 RRT units.

10.2.2 Initial Calibration Verification (Second Source Verification)

10.2.2.1 The initial calibration (Section 10.2) for each compound of interest must be verified prior to sample analysis. This is accomplished by analyzing second source calibration standards at a concentration near the midpoint concentration for the calibrating range of the GC/MS.

10.2.2.2 Analyze the standards and calculate the % Difference for each analyte according to the formula in Alpha's Quality Manual.

If the % Difference for each analyte is ± 30%, then the calibration is assumed to be valid. If this criterion is not met, then corrective action must be taken prior to the analysis.

10.2.2.3 In cases where compounds fail (greater than 30% difference), they may still be reported as non-detects.

10.2.2.4 Once the calibration curve is accepted and prior to processing any samples, the analyst must demonstrate through the analysis of a MB or instrument blank that equipment and reagents are free from contaminants and interferences. If a peak is found in the blank that would prevent the identification or bias the measurement of an analyte, the analyst should determine the source of the contaminant peak and eliminate it, if possible. Blanks are generally considered to be acceptable if target analyte concentrations are less than one half the LLOQ or are less than project specific requirements. Blanks may contain analyte concentrations greater than acceptance limits if the associated samples in the batch are unaffected.

10.3 Equipment Operation and Sample Processing

10.3.1 Preparation/Analysis of samples

All extracted samples in K-D tubes need to be brought up to 1mL volume with Methylene Chloride. Liquid extracts are adjusted to get as close to 1:1 as possible as long as the

initial volume is ≥ 800mL; 500uL is transferred to autosampler vial, then spiked with 10µL of Internal Standard and capped/crimped.

10.3.2 GC/MS Analysis of Samples

If the response of any quantitation ion exceeds the initial calibration range of the GC/MS system, the sample extract must be diluted and reanalyzed.

10.4 Continuing Calibration

10.4.1 The initial calibration (Section 10.2) for each target compound must be verified once every 12 hours prior to sample analysis. This is accomplished by analyzing a calibration standard at the midpoint level. An acceptable GC/MS tuning standard must be run prior to analyzing the continuing calibration standard.

10.4.2 If the % Difference for each analyte is ≤ 20%, then the calibration is assumed to be valid. If the criterion are not met for more than 20% of the compounds then corrective action must be taken prior to the analysis of samples.

- Note that for NJ and CT methods, % Difference ≤ 30% is acceptable.

Allowances may be made for an RF that drifts out high, as long as there are no positive hits for that particular analyte in any of the associated samples

10.4.3 If this criterion is exceeded, inspect the gas chromatographic system to determine the cause and perform whatever maintenance is necessary before verifying calibration and proceeding with sample analysis.

10.4.4 If routine maintenance does not return the instrument performance to meet the QC requirements based on the last initial calibration, then a new initial calibration must be performed. Due to the large number of analytes present, allowances may be made for a RF that drifts out high, as long as there are no positive hits for that particular analyte in any of the associated samples. Any QC failures must be written up by the analyst on narrative sheets for inclusion with the sample data.

10.4.5 Internal Standard Response

If the area for any of the internal standards in the calibration verification standard changes by a factor of two (50% to 200%) from that in the mid-point standard level of the most recent initial calibration sequence, the mass spectrometer must be inspected for malfunctions and corrections must be made, as appropriate. When corrections are made, reanalysis of samples analyzed while the system was malfunctioning is required.

10.5 Preventive Maintenance

When poor sensitivity is observed, replacement of the injector liner and seal may solve the problem. If not, clip approximately 3 – 6 inches from the injector end of the GC column. If the sensitivity does not improve it may be necessary to replace the split line or the injector weldment assembly. If the problem persists, it may be necessary to replace the GC column.

Periodic cleaning (typically twice per year) of the mass spectrometer ion source is required. More frequent source cleaning may be needed, especially if dirty samples are analyzed.

11. Data Evaluation, Calculations and Reporting

11.1 When a parameter is identified, the quantitation of that parameter should be based on the integrated abundance of the quantitation characteristic m/z given in Table 9.

11.2 Calculate the concentration in the sample using the average response factor (RF) from the initial calibration curve according to the formulae in Alpha's Quality Manual.

11.2.1 Aqueous samples

$$\text{Concentration } (\mu g/L) = \frac{C \times DF \times Vf \times 1000}{Vo}$$

where:

C = Extract concentration (µg/mL)
DF = Dilution factor
Vf = Final extract volume (mL)
Vo = Sample volume (mL)

11.2.2 Soil/sediment samples

$$\text{Concentration } (\mu g/Kg, \text{ dry weight}) = \frac{(C \times DF \times Vf \times 1000)}{W \text{ (gm)}} * \%S$$

where:

C = Extract concentration (µg/mL)
DF = Dilution factor
Vf = Final extract volume (mL)
W = Weight of the sample extracted (10g for high, 30g for low)
%S = Percent solids, as a decimal value

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

See Corrective Actions in Section 9.

13. Method Performance

13.1 Detection Limit Study (DL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the DL, LOD, and/or LOQ as outlined in Alpha SOP ID 1732. These studies performed by the laboratory are maintained on file for review.

13.2 Demonstration of Capability Studies

Refer to Alpha SOP ID 1739 for further information regarding IDC/DOC Generation.

13.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

14. Pollution Prevention and Waste Management

Refer to Alpha's Chemical Hygiene Plan and Hazardous Waste Management and Disposal SOP for further pollution prevention and waste management information.

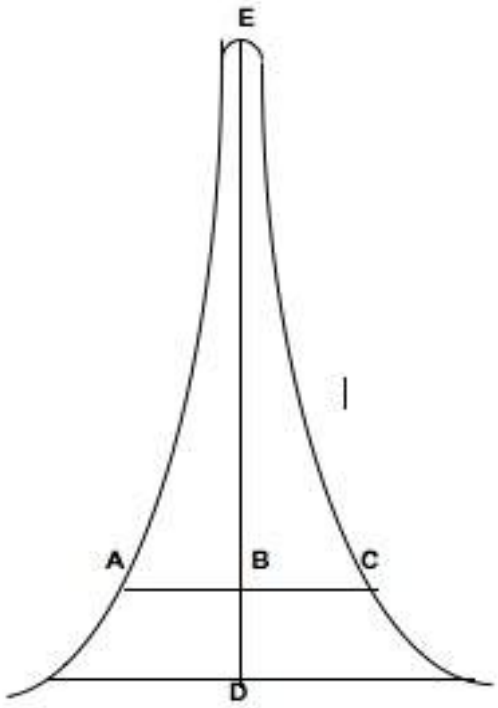
TABLE 8



Tailing Factor = $\frac{BC}{AB}$

$\overline{AB}$

Example calculation:

Peak Height = DE = 100mm
10% Peak Height = BD = 10mm
Peak Width at 10% Peak Height = AC = 23mm

AB = 11mm
BC = 12mm

Therefore: Tailing Factor = $\frac{12}{11}$ = 1.1

Tailing factor for benzidine < 2.0

Tailing factor for pentachlorophenol < 2.0

TABLE 9

CHARACTERISTIC IONS FOR SEMIVOLATILE COMPOUNDS

The ions and intervals are determined by an experienced analyst and are subject to changes.

Reactive Sulfide and Reactive Cyanide

Reference Method: This standard operating procedure (SOP) is a performance-based method. This SOP describes the procedure as developed by Alpha Analytical.

1. Scope and Application

Matrices: This method is applicable to water, wastewater, seawater, soil and solid samples with the condition that the samples combined with acids do not form explosive mixtures.

Definitions: See Alpha Analytical Quality Manual

The regulation in 40CFR 261.23 defines reactive wastes to include wastes that have any of the following properties:

(1) readily undergo violent chemical change;

(2) react violently or form potentially explosive mixtures with water;

(3) generate toxic fumes when mixed with water or, in the case of cyanide- or sulfide-bearing wastes, when exposed to mild acidic or basic conditions;

(4) explode when subjected to a strong initiating force;

(5) explode at normal temperatures and pressures; or

(6) fit within the Department of Transportation's forbidden explosives, Class A explosives, or Class B explosives classifications.

This definition is intended to identify wastes that, because of their extreme instability and tendency to react violently or explode, pose a problem at all stages of the waste management process. The definition is to a large extent a paraphrase of the narrative definition employed by the National Fire Protection Association. The Agency chose to rely almost entirely on a descriptive, prose definition of reactivity because most of the available tests for measuring the variegated class of effects embraced by the reactivity definition suffer from a number of deficiencies.

This procedure releases only the hydrogen sulfide evolved at the test conditions. It is not intended to measure forms of sulfide other than those that are evolvable under the test conditions.

This test measures only the hydrocyanic acid evolved at the test conditions. It is not intended to measure forms of cyanide other than those that are evolvable under the test conditions.

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one of the following laboratory personnel before performing the modification: Area Supervisor, Laboratory Services Manager, Laboratory Director, or Quality Assurance Officer.

This method is restricted to use by or under the supervision of trained analysts. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

2. Summary of Method

An aliquot of acid is added to a fixed volume or weight of sample in a closed system. The generated gas is swept into a scrubber. The analyte is quantitated.

2.1 Method Modifications from Reference

None.

3. Reporting Limits

The reported reactive sulfide detection limit is 1.0 mg/L (aqueous samples) and 10mg/kg (solid samples).

The reported reactive cyanide detection limit is 1.0 mg/L (aqueous samples) and 10mg/kg (solid samples).

4. Interferences

4.1 Reactive Sulfide Interferences

4.1.1 Strong reducing agents interfere in the methylene blue method by preventing formation of the blue color.

4.1.2 Thiosulfate at concentrations about 10mg/L may retard color formation or completely prevent it.

4.1.3 High Concentration of sulfide itself may inhibit blue color development. To avoid the possibility of reporting false negative results, test a 1000x dilution of the scrubber solution to see if blue color develops. (Refer to Section 10.3.1).

4.1.4 Ferrocyanide is a positive interference since it produces a blue color; distillation process will minimize interference.

4.2 Reactive Cyanide Interferences

Reactive Cyanide interferences are undetermined.

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. Therefore, analysts should take every precaution by utilizing latex/nitrile gloves, safety glasses and a lab coat to minimize or eliminate exposure. A reference file of material safety data sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

Samples are collected with minimum aeration in either a glass or plastic bottle or jar. Fill the container completely and cover, ensuring no head space is present.

6.2 Sample Preservation

Samples are stored at 4 ± 2° C.

6.3 Sample Shipping
No special shipping requirements.

6.4 Sample Handling
Aqueous samples are analyzed with 7 days of collection. Soil samples are analyzed within 14 days of collection.

7. Equipment and Supplies

7.1 Spectrophotometer: Genesys 10vis (or equivalent); for use at a wavelength of 664nm and 578nm with cells providing light paths of 1cm.

7.2 Centrifuge Tubes: 50mL capacity

7.3 Pipets: Class A, glass, volumetric, various volumes

7.4 Volumetric Flasks: Class A, various volumes

7.5 Non-rubber Flexible Tubing: For connection from pump supply to apparatus.

7.6 Analytical Balance: Capable of weighing to 0.001g.

7.7 Midi Distillation System: Lab-Crest (or equivalent); 10-position distillation unit equipped with a full set of glassware including 10 each of the following:

7.7.1 Reaction Flask: Flat-bottom flask with sufficient volume (over 100mL) to contain violent reactions; has permanent 50mL indicator.

7.7.2 Absorption Flask: Identical to Reaction Flask (Section 7.7.1).

7.7.3 Reflux Impinger: Fits the reaction flask; has air and reagent intake, full-length impinger, and hose barb.

7.7.4 Cold Finger: Fits the Reflux Impinger; has two hose barbs for water circulation, which is not utilized for this test. It can therefore be substituted with a glass or plastic stopper of the same size.

7.7.5 Absorption Impinger: Full-length impinger with 13mm, medium porosity glass filter, and two hose barbs.

8. Reagents and Standards

8.1 Reagent water: Deionized water (DI) produced by Alpha's water treatment system.

8.2 Sulfide Calibration Stock Standard: Weigh 1.5779 gram of $Na_2S \cdot 9H_2O$ in a 200mL volumetric flask and fill to top with DI water. Mix by swirling gently to prevent oxygen entrapment. Store in the refrigerator in the amber glass bottle. Solution expires one month from the date of preparation. Final concentration is 1097 mg/L

8.3 Sulfide 1 Reagent: Available commercially from HACH Company. Store at 4 ± 2°C. Reagent expires on manufacturer's specified expiration date.

8.4 Sulfide 2 Reagent: Available commercially from HACH Company. Store at 4 ± 2°C. Reagent expires on manufacturer's specified expiration date.

8.5 Sulfide Calibration Standards: These standards are used to generate the calibration curve in Section 9.1.1. Prepare a series of sulfide solutions by diluting the Sulfide Calibration Stock Standard (Section 8.2) with 0.1N NaOH (Section 8.6.2).

Into seven 100mL volumetric flasks, pipet 1mL, 2mL, 5mL, 10mL, 15mL, 30mL and 0mL of the sulfide stock standard (Section 8.2) Bring each flask to volume using 0.1N NaOH solution (Section 8.6.2).

The concentration of the calibration standards is determined by the results of the standardization of the stock sulfide standard, as described in Section 8.2.1. The lowest calibration standard must be 0.1mg/L or less. If necessary, add an additional point to the curve by pipetting 0.5mL of Stock Sulfide Standard (Section 8.2) into an eighth 100mL volumetric flask.

Note: This calibration curve is identical to calibration curve, used for Total Sulfide.

8.6 Sodium Hydroxide, NaOH: In pellet form.

8.6.1 Sodium Hydroxide Solution, NaOH, 1N: Dissolve 40g NaOH (Section 8.11) in 1L of DI water. Store at room temperature. Expires three months from the date of preparation.

8.6.2 Sodium Hydroxide Solution, NaOH, 0.1N: In a 100mL volumetric flask, pipet 10mL of 1N NaOH (Section 8.11.1). Bring to volume with DI water. Store at room temperature. Expires three months from the date of preparation.

8.7 Sulfide LCS Stock Standard: Using a different source than was used for the Calibration Stock Standard. (8.2)

8.8 Sulfide LCS Standard: Pipet 0.5mL of LCS Sulfide Stock Standard (Section 8.7) into a 25mL volumetric flask. Bring to volume with DI water. True value: 22 mg/l.

8.8.1 Sulfide ICV / CCV Standard: Pipet 1.0 mL of LCS Sulfide Standard (Section 8.7) into a 50mL volumetric flask, add 5 ml of 1N NAOH. Bring to volume with DI water. Acceptance criteria +/- 25%; if failed outside of acceptance criteria, data is invalid.

8.9 Cyanide LCS/ICV/CCV Stock Standard, 1000ppm: Commercially available with a certificate of analysis. This must be from a different source than the Calibration Standard Stock. Store at 4 ± 2 °C. Expires on manufacturer's specified expiration date.

8.9.1 Cyanide LCS/ICV/CCV Working Standard, 40ppm: To a 25mL volumetric flask, add 1mL of 1000ppm cyanide LCS Stock Standard (Section 8.9). Bring to volume with DI water. Prepare fresh on each day of use.

8.9.1.1 Cyanide ICV/CCV 0.8ppm Standard: Into a 25mL volumetric flask, pipet 0.5mL of the 40ppm cyanide working calibration standard (Section 8.9.1). Bring to volume using 0.1N NaOH (Section 8.6.2) (5 ml of 1N NaOH can be used and volume brought up to 50 ml with DI. This standard is prepared fresh at the time of use.

8.10 Cyanide 1000ppm Stock Calibration Standard Stock Standard: Commercially purchased with a certificate of analysis. The ICV stock must be a different lot than the calibration standards.

8.10.1 Cyanide 10ppm Working Calibration Standard: Into a 100mL volumetric flask, pipet 1mL of 1000ppm cyanide stock calibration standard (Section 8.10) and bring to volume with 0.1N NaOH (Section 8.6.2). This standard expires after one week. Store in a brown bottle at room temperature, out of direct light.

8.10.1.1 0.0ppm Cyanide Calibration Standard: To a 100mL volumetric flask, add 0.0mL of Cyanide 10ppm Working Calibration Standard (Section 8.10.1). Bring to volume with 0.1N NaOH (Section 8.6.2). This standard is prepared fresh at the time of calibration.

8.10.1.2 0.05ppm Cyanide Calibration Standard: To a 100mL volumetric flask, add 0.5mL of Cyanide 10ppm Working Calibration Standard (Section 8.10.1). Bring to volume with 0.1N NaOH (Section 8.6.2). This standard is prepared fresh at the time of calibration.

8.10.1.3 0.1ppm Cyanide Calibration Standard: To a 100mL volumetric flask, add 1.0mL of Cyanide 10ppm Working Calibration Standard (Section 8.10.1). Bring to volume with 0.1N NaOH (Section 8.6.2). This standard is prepared fresh at the time of calibration.

8.10.1.4 0.2ppm Cyanide Calibration Standard: To a 100mL volumetric flask, add 2.0mL of Cyanide 10ppm Working Calibration Standard (Section 8.10.1). Bring to volume with 0.1N NaOH (Section 8.6.2). This standard is prepared fresh at the time of calibration.

8.10.1.5 0.4ppm Cyanide Calibration Standard: To a 100mL volumetric flask, add 4.0mL of Cyanide 10ppm Working Calibration Standard (Section 8.10.1). Bring to volume with 0.1N NaOH (Section 8.6.2). This standard is prepared fresh at the time of calibration.

8.10.1.6 0.5ppm Cyanide Calibration Standard: To a 100mL volumetric flask, add 5.0mL of Cyanide 10ppm Working Calibration Standard (Section 8.10.1). Bring to volume with 0.1N NaOH (Section 8.6.2). This standard is prepared fresh at the time of calibration.

8.11 Chloramine-T Solution: Dissolve 1.0g of Chloramine-T in 100mL DI water. Prepare fresh on each day of use.

8.12 Sodium dihydrogen phosphate monohydrate, $NaH_2PO_4 \cdot H_2O$

8.12.1 Phosphate Buffer: Dissolve 138g sodium dihydrogen phosphate monohydrate (Section 8.12) in DI water and dilute to 1L. Store at room temperature. Expires one month from the date of preparation.

8.13 Barbituric acid: Store at room temperature. No expiration date.

8.14 Pyridine: Store in Flammables cabinet. Expires on manufacturer's specified expiration date.

8.15 Concentrated Hydrochloric Acid, HCl: Store in Acids cabinet. No expiration date.

8.16 6M Hydrochloric Acid (HCl): Dilute 500mL of concentrated HCl (Section 8.20) into 500mL DI water. Store at room temperature. No expiration date.

8.17 Pyridine-Barbituric Acid Reagent: Place 60g barbituric acid (Section 8.13) in a 1000mL volumetric flask and add just enough DI water to wash sides of flask and wet barbituric acid. Add 300mL pyridine (Section 8.14) and mix. Add 60mL conc HCl (Section 8.15), mix and cool to room temperature. Dilute to volume and mix until barbituric acid is dissolved. The solution is stable for one month if stored in an amber bottle at 4 ± 2 °C. Discard if precipitate develops.

8.18 Concentrated Sulfuric Acid, H_2SO_4: Store in Acids cabinet. Expires on manufacturer's specified expiration date.

8.19 Reactivity Stock Solution: Add 2.8mL of conc H_2SO_4 (Section 8.18) to a 1L volumetric flask and bring to volume with DI. Prepare fresh on each day of use.

8.19.1 Reactivity Working Solution, 0.025M: Add 100mL of reactivity stock solution (Section 8.19) to a 1L volumetric flask and bring to volume DI.

8.20 Ottawa sand

8.21 Boiling chips

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

9.1 Blank(s)

Prepare and analyze one Method Blank per batch of 20 samples or less. Blank results must be less than the RL. If this criterion is not met, a batch narrative is included with the Client Report and/or the sample batch is reanalyzed. Refer to Section 12 for corrective actions.

For soils: weigh 1.0 g of Ottawa sand, for water- use 10 ml if DI and analyze with batch.

9.2 Laboratory Control Sample (LCS)

9.2.1 Reactive Sulfide

Run one LCS using the LCS Working Solution per batch of 20 samples or less. .

For waters: to 10 ml of DI add 2.0 ml of LCS Standard (8.8); final concentration is 4.4 mg/l

For soils: to 1.0 g of Ottawa sand add 2.0 ml of LCS Standard (8.8); final concentration 44 mg/kg

The LCS must be recovered within 60 – 125%, otherwise the entire sample batch is reanalyzed. Refer to Section 12 for corrective actions.

9.2.2 Reactive Cyanide

Run one LCS using the LCS Working Solution per batch of 20 samples or less.

For waters: to 10 ml of DI add 1.0 ml of LCS Standard (8.9.1); final concentration is 4.0 mg/l

For soils: to 1.0 g of Ottawa sand add 1.0 ml of LCS Standard (8.9.1); final concentration 40 mg/kg

The LCS must be recovered within 30 – 125%, otherwise the entire sample batch is reanalyzed. Refer to Section 12 for corrective actions.

9.3 Initial Calibration Verification (ICV)

9.3.1 Reactive Sulfide

The ICV is analyzed at the beginning of each sample batch. The ICV must be recovered within 75 – 125%, otherwise the entire sample batch is reanalyzed. Refer to Section 12 for corrective actions.

9.3.2 Reactive Cyanide

An ICV is analyzed at the beginning of each sample batch. The ICV must be recovered within 75 – 125%, otherwise the entire sample batch is reanalyzed. Refer to Section 12 for corrective actions.

9.4 Continuing Calibration Verification (CCV)

9.4.1 Reactive Sulfide

A CCV is read on the spectrophotometer after every 10 samples and at the end of each sample batch. The CCV must be recovered within 75 – 125%, otherwise the entire sample batch is reanalyzed. Refer to Section 12 for corrective actions.

9.4.2 Reactive Cyanide

A CCV is read on the spectrophotometer after every 10 samples and at the end of each sample batch. The CCV must be recovered within 75 – 125%, otherwise the entire sample batch is reanalyzed. Refer to Section 12 for corrective actions.

9.5 Matrix Spike

Not applicable.

9.6 Laboratory Duplicate

Prepare and analyze one sample in duplicate per batch of 20 samples or less. The %RPD for liquid samples must be $\leq$ 25%. For solid/soil samples, the %RPD must be $\leq$ 40%. If %RPD is not within the specified range, the sample and its duplicate must be narrated and/or reanalyzed. Refer to Section 12 for corrective actions.

9.7 Method-specific Quality Control Samples

Not applicable.

9.8 Method Sequence

- Generate calibration curves.
- Prepare samples and QC samples.
- Analyze samples and QC samples.
- Calculate results.

10. Procedure

10.1 Equipment Set-up

10.1.1 Calibration Curve Generation

Calibration curves are generated yearly or when ICV/CCV are not passing acceptance criteria.

10.1.1.1 Reactive Sulfide

Prepare a calibration curve using the standards in Section 8.5. Analyze the standards as described in Section 10.3.1. Plot the concentration vs. absorbance. Determine the slope and the y-intercept. The correlation coefficient must be $\geq$ 0.995.

10.1.1.2 Reactive Cyanide

Prepare a calibration curve using the standards in Section 8.10. Analyze the standards as described in Section 10.3.2. Plot the concentration vs. absorbance. Determine the slope and the y-intercept. The correlation coefficient must be $\geq$ 0.995.

10.1.2 Sample Preparation

10.1.2.1 Add 10mL of 1N NaOH solution to the absorption flask, and bring to a volume of 50mL with DI.

10.1.2.2 Weigh 1g of solid sample or 10mL of liquid sample into a 50mL centrifuge tube and record the weight/volume in the laboratory notebook. Label the tube and secure the cap. For solid Blank and LCS, use PTFE boiling stones or Ottawa sand. Add the contents of the tube to the reaction vessel. Record the tube number and corresponding sample number in the laboratory notebook. Assemble the Midi Distillation Unit.

10.1.2.2.1 Ensure the pump is plugged in and connected to the Midi unit via a Teflon hose. After adding the sample to the reaction vessel (large tube in the back of the unit), place the absorption flask in the front of the unit ; flask should be filled with NaOH. Place the reflux impinger in the reaction flask and place the cold finger (or stopper) into the impinger. Make sure that all of the glass connections are tight. Place the absorption impinger into the absorption flask and make sure that the glass seal is tight. Connect the absorption impinger to the reaction impinger by connecting the front hose of the absorption impinger to the Midi Distillation unit (where the air comes out) and the rear hose to the reaction impinger. Make sure that all glass connections are tight and that all of the hoses are snug.

10.1.2.3 Turn on the pump and adjust the air flow rate of air so that the gas scrubbers produce small bubbles (approx. 60mL/minute).

10.1.2.4 Add the appropriate LCS to their respective reaction vessels. Then add the reactivity solution (Section 8.19.1) to each reaction vessel so that the final volume is about 50mL.

10.1.2.5 Make sure all of the glassware is connected and all of the tubes are connected. All of the reflux impingers should now be producing air bubbles in the reaction (rear) vessels. For any are not, the glassware is not air tight. Run the pump for 30 minutes, and then shut the pump off. Record in the laboratory notebook the time started and the time ended.

10.1.2.6 Disconect the apparatus and bring the volume of the absorption tube to 100mL in DI with a volumetric flask. The normality of this hydroxide solution will be 0.1N.

10.1.2.7 Pour off 25mL into a 50mL centrifuge tube for Sulfide analysis. Pour off 20mL into a 50mL centrifuge tube for Cyanide analysis.

10.2 Initial Calibration

Refer to Sections 10.1.1 and 9.3.

10.3 Equipment Operation and Sample Processing

10.3.1 Reactive Sulfide Analysis

Take a 25mL aliquot of the calibration standards (Section 8.5) or of the volumized scrubber solution for each sample and color as follows:

Add 1.0mL Sulfide 1 reagent (Section 8.3) and swirl to mix. Add 1mL of Sulfide 2 reagent (Section 8.4). Let the reaction continue for 5 minutes. Excessive time between the addition of the “1” and “2” Sulfide coloring reagents causes low results by loss of H_2S as a gas before it has had time to react. The presence of sulfide will be indicated by the appearance of blue color. Wait 5 minutes and read the absorbance on the spectrophotometer (below).

Absorbance Determination: Set the spectrophotometer to a wavelength of 664nm. Zero the instrument with a portion of the blank sample. Read the absorbances of the samples and QC samples and record this information in the laboratory notebook.

If the absorbance of a sample is greater than the highest standard in the calibration curve, the sample must be diluted with 0.1N NaOH and reanalyzed as in Section 10.3.1 above. Record in the laboratory notebook any dilutions that are prepared.

NOTE: Very high sulfide concentrations interfere with blue color formation. For a sample in which high sulfide is suspected, but no blue color develops, make a 1000x dilution of the scrubber solution with 0.1N Color with Reagent 1 (Section 8.3) and Reagent 2 (Section 8.4). Experiment with various dilutions until the absorbance falls within the calibration curve.

10.3.2 Reactive Cyanide Analysis

Take a 20mL aliquot of the calibration standards (Section 8.10.1) or of the volumized scrubber solution and color as follows:

Add 5mL of phosphate buffer solution (Section 8.12.1), 2mL of chloramine-T solution (Section 8.11), 5mL of pyridine (Section 8.14). Bring final volume to 50mL with DI. The presence of a pink color indicates cyanide.

Absorbance Determination: Set the spectrophotometer to a wavelength of 578nm. Zero the instrument with a portion of the blank sample. Read the absorbances of the samples and QC samples and record this information in the laboratory notebook.

If the absorbance is greater than the highest standard in the calibration curve, the sample must be diluted with 0.1N NaOH and reanalyzed as in Section 10.3.2 above. Record in the laboratory notebook any dilutions that are prepared.

10.4 Continuing Calibration

Refer to Section 9.4.

10.5 Preventive Maintenance

The spectrophotometers are calibrated on a semi-annual basis by an instrument service company. Certificates are kept on file.

11. Data Evaluation, Calculations and Reporting

11.1 Reactive Sulfide

Calculate reactive sulfide concentration using the calibration curve generated in Section 10.1.1.1:

$$\text{Reactive Sulfide (mg/L)} = \frac{\text{Absorbance} - \text{y intercept}}{\text{Slope}} \times \text{Dilution factor}$$

$$\text{Reactive Sulfide (mg/kg)} = \frac{\text{Absorbance} - \text{y intercept}}{\text{Slope}} \times \frac{\text{Dilution factor}}{\text{Weight (g)}}$$

11.2 Reactive Cyanide

Calculate reactive cyanide concentration using the calibration curve generated in Section 10.1.1.2:

$$\text{Reactive CN (mg/L)} = \frac{\text{Absorbance} - \text{y intercept}}{\text{Slope}} \times \text{Dilution factor}$$

$$\text{Reactive CN (mg/kg)} = \frac{\text{Absorbance} - \text{y intercept}}{\text{Slope}} \times \frac{\text{Dilution factor}}{\text{Weight (g)}}$$

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

Holding time exceedence, improper preservation and sample headspace (liquid samples) are noted on the nonconformance report form.

Perform routine preventative maintenance following manufacturer's specification. Record all maintenance in the instrument logbook.

Review of standards, blanks and standard response for acceptable performance occurs for each batch of samples. Record any trends or unusual performance on a nonconformance action form.

If the method blank contains a reportable amount of cyanide of Sulfide, evaluate the method blank as follows. If the samples associated with the method blank are non-detect, or if a sample has an analyte concentration that is greater than 10X the concentration of the contaminated method blank, the data may be reported and the method blank results narrated on the final report. If sample results are positive, but at a concentration less than 10X the concentration of the method blank, then those samples should be re-digested and re-analyzed.

If the LCS fails acceptance criteria, then the entire batch must be re-digested and re-analyzed. If there is insufficient sample volume to re-digest, then the Client Services Department is notified, and the batch results are narrated on the final report as estimated.

If the ICV fails acceptance criteria, a fresh aliquot is poured and re-analyzed. If the standard still fails, prepare a fresh ICV and begin analysis again. If the ICV fails again, and the spectrophotometer is working properly, prepare a new calibration curve.

If the ICB fails acceptance criteria, a fresh aliquot is poured and re-analyzed. If the blank still fails, ensure that the spectrophotometer is “blanked” correctly. If the ICB failure continues, and the spectrophotometer working properly, prepare a new calibration curve.

If the CCV fails acceptance criteria, a fresh aliquot is poured and re-analyzed. If the standard still fails, prepare and analyze a fresh CCV and re-analyze the last 10 samples up to the last passing CCV. If the CCV recovery is greater than 125%, and all associated samples are non-detect, then analysis may be continued. If the CCV recovery is greater than 125%, any associated positive samples are re-prepared and re-analyzed.

If the CCB fails acceptance criteria, a fresh aliquot is poured and re-analyzed. If the CCB still fails, ensure that the spectrophotometer is working properly. Also ensure that the cell is clean and has no smudges, and is indexed correctly. When the problem has been corrected, all samples analyzed since the last passing CCB must be re-analyzed.

If %RPD of duplicates fails acceptance criteria, the non-conformance is narrated and the information is included on the final report.

13. Method Performance

13.1 Method Detection Limit Study (MDL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the MDL, LOD, and/or LOQ as outlined in Alpha SOP/1732. These studies performed by the laboratory are maintained on file for review.

13.2 Demonstration of Capability Studies

Refer to Alpha SOP/1734, 1739 for further information regarding IDC/DOC Generation.

13.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

14. Pollution Prevention and Waste Management

Refer to Alpha's Chemical Hygiene Plan and Waste Management and Disposal SOP for further pollution prevention and waste management information.

15. Referenced Documents

Connecticut Department of Environmental Protection. Recommended Reasonable Confidence Protocols. Version 2.0 July 2006

1. Scope and Application

Matrices: Solid, waste and waste water, soil, sediment, tissue and ground water.

Definitions: Refer to Alpha Analytical Quality Manual.

This method is applicable to the quantification of acidic, neutral and basic organic compounds soluble in methylene chloride. The extraction and cleanup methods that are typically used for this method are listed in Section 10.3.1. Please see the appropriate extraction SOP(s) for further information. The individual target compounds are found in Section 16, Table D, and include polynuclear aromatic hydrocarbons, chlorinated hydrocarbons, pesticides, phthalate esters, nitrosamines, aldehydes, ethers, anilines, pyridines, aromatic nitro compounds and phenols, including nitro phenols.

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one or more of the following laboratory personnel before performing the modification: Area Supervisor, Department Supervisor, Laboratory Director, or Quality Assurance Officer.

This method is restricted to use by or under the supervision of analysts experienced in the operation of the GC/MS and in the interpretation of GC/MS data. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

2. Summary of Method

Aqueous samples are extracted with methylene chloride in a 2 Liter Separatory Funnel (Method 3510) at the required pH. Soil samples are generally extracted by Microscale Solvent Extraction (Method 3570), however other extraction methods can be applied. The extract is concentrated to its final volume in preparation for analysis, or may now undergo cleanups.

Analytes are introduced into the GC/MS by injecting a known volume of the calibration standards, quality control samples, and sample extracts into the GC equipped with a narrow-bore capillary column. The GC column is temperature programmed to separate the analytes, which are then detected with a mass spectrometer (MS). Identification of target analytes is accomplished by comparing their mass spectra with the electron impact spectra of the calibration standards. Concentrations are determined using mean relative response factors from a multi-level calibration curve. Response factors for target analytes and surrogate compounds are determined relative to the internal standards.

2.1 Method Modifications from Reference

None.

3. Reporting Limits

Analytes determined are measured in the range of 0.5 to 25ug/L for water samples, and 33.3 to 1667ug/Kg for soils, sediments, and solids. Tissue samples are measured in the range of 200 to 10000ug/Kg. Detection limits will vary with the individual sample matrix, sample preparation procedures, instrument calibration range, and volume of sample analyzed. Analytes detected over these concentration ranges will be diluted and re-analyzed for accurate quantification. Reporting limits for each matrix per analyte can be viewed within the LIMS under Applications/Product Catalog

4. Interferences

4.1 Phthalate esters can be a major source of contamination if any material containing plasticizers (phthalates) comes in contact with the sample during the extraction process. Use of plastic or any material containing plasticizers (phthalates) should be avoided during extraction or analysis.

4.2 The injection port of the gas chromatograph can become contaminated with high boiling compounds resulting in the loss of sensitivity of Pentachlorophenol, 2,4-Dinitrophenol, 4-Nitrophenol, Benzoic Acid, Benzaldehyde, 4,6-dinitro-2-methylphenol, 4-chloro-3-methylphenol, 4-chloroaniline, benzyl alcohol, 2,4-Dinitrotoluene and 2, 3, and 4-Nitroaniline. It may be necessary to replace the injection port liner routinely to prevent this loss of sensitivity. Clipping off approximately four inches of the column at the injection end may also increase sensitivity of the phenolic compounds. Low instrument response can be detected during the daily tuning procedure by including pentachlorophenol and benzidine in the daily tuning mix.

4.3 Raw GC/MS data from all blanks, samples, and spikes must be evaluated for interferences or carryover. Contamination by carryover can occur whenever high-concentration and low-concentration samples are sequentially analyzed.

4.4 Solvents, reagents and glassware may introduce interferences. These must be demonstrated to be free of interferences by the analysis of a method blank. See the *Reagent, Solvent and Standard Control* SOP (1816) and *Laboratory Glassware Cleaning SOP* (1753), for additional details.

4.5 Many interferences can be removed by sample cleanup. The cleanup methods performed include those listed in Section 10.3.1. Only appropriate cleanup techniques must be performed based on the suspected interference and the compounds of interest.

4.6 Benzidine and pyridine may be subject to oxidative losses during solvent concentration and demonstrate poor chromatographic behavior.

4.7 Hexachlorocyclopentadiene and pyridine are subject to thermal decomposition in the injection inlet, and hexachlorocyclopentadiene is subject to chemical reaction with acetone,

and photochemical decomposition.

4.8 N-nitrosodimethylamine is difficult to separate from the solvent front under the chromatographic conditions described within.

N-nitrosodiphenylamine decomposes in the GC inlet and cannot be separated from diphenylamine.

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material safety data sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

Solid samples: A minimum of 100 grams of sample must be collected in a glass jar with a Teflon lined screw cap.

Water samples: A minimum of 2 liters of sample must be collected in amber glass bottles.

Tissue samples: A minimum of 20 grams of sample must be collected in a glass jar with a Teflon lined screw cap.

6.2 Sample Preservation

Solid samples: The samples must be refrigerated and maintained at 4±2°C until extraction and analysis. Sediment samples can be frozen at -20±5°C until extraction to extend hold time. The extracts must be refrigerated and maintained at 4±2°C until analysis.

Water samples: The samples must not be preserved except by refrigeration at 4±2°C until extraction and analysis. The extracts must be refrigerated and maintained at 4±2°C until analysis.

Tissue samples: The samples must be stored frozen at -20±5°C until extraction. The extracts must be refrigerated and maintained at 4±2°C until analysis.

6.3 Sample Shipping

No special shipping requirements.

6.4 Sample Handling

Solid samples: All solid samples must be extracted within 14 days from the date of collection. Frozen sample hold times are monitored up to 14 days from the date removed from the freezer. The extracts must be refrigerated and maintained at 4±2°C until analysis. Sample extracts must be analyzed within 40 days from date of extraction.

Water samples: All water samples must be extracted within 7 days from the date of collection. Sample extracts must be analyzed within 40 days from date of extraction.

Tissue samples: Frozen sample hold times are monitored up to 14 days from the date removed from the freezer. The extracts must be refrigerated and maintained at 4±2°C until analysis. Sample extracts must be analyzed within 40 days from date of extraction.

7. Equipment and Supplies

7.1 Gas chromatograph: Programmable, heating range from 40C to 350C; split-splitless-type inlet system, (Agilent 7890 or similar); mass selective detector (Agilent 5975 or similar); automatic injector (Agilent 7683 or similar).

7.2 Chromatography Column: Fused silica capillary column, 0.25mm ID x 30m length, .25um film thickness (Zebron ZB-SemiVolatiles, Phenomenex Corporation, 5% Polysilarylene - 95% Polydimethylsiloxane , or equivalent).

7.3 Data Acquisition System: Computerized system for collecting, storing, and processing detector output (Hewlett Packard Enviroquant target software) or equivalent.

7.4 Gases: Ultra high purity BIP helium (99.9995%); Compressed Nitrogen for N-Evap.

7.5 Syringes: 10uL to 1.0mL.

7.6 Glass: Class A volumetric glass with varying volumes

7.7 GC Injection Port Liner: Phenomenex Direct Connect Top Hole

8. Reagents and Standards

Use reagent grade chemicals for all reagents. Deionized (DI) water is ASTM Type II laboratory reagent grade water.

8.1 Methylene Chloride: ACS approved, Pesticide grade, see *Reagent, Solvent and Standard Control SOP* (1816) for additional details regarding solvent purity.

8.2 Acetone: ACS approved, Pesticide grade, see *Reagent, Solvent and Standard Control SOP* (1816) for additional details regarding solvent purity.

8.3 Hexane: ACS approved, Pesticide grade, see *Reagent, Solvent and Standard Control SOP* (1816) for additional details regarding solvent purity.

8.4 Methanol: ACS approved, Pesticide grade, see *Reagent, Solvent and Standard Control SOP* (1816) for additional details regarding solvent purity.

8.5 Ether: ACS approved, Pesticide grade, see *Reagent, Solvent and Standard Control SOP* (1816) for additional details regarding solvent purity.

8.6 Analytical Standards: Standards should be stored at –10°C or less, away from light when not in use. They should be discarded after 1 year unless the vendor expiration date states otherwise or if breakdown is observed. Stock standards are given a 1 year expiration from the preparation date, or the expiration of the primary vendor solution, whichever occurs

first. Working standards are given a 6 months expiration from the preparation date or the expiration of the primary solution whichever occurs first.

8.6.1 Surrogates: Base/Neutral stock surrogate (5000ug/mL) – includes Nitrobenzene-d5, 2-Fluorobiphenyl, and Terphenyl-d14. Acid stock surrogate (10000 ug/mL) - includes Phenol-d5, 2-Fluorophenol, and 2,4,6-Tribromophenol. Restek, Ultra Scientific, or equivalent.

8.6.1.1 To prepare the surrogate spiking solution mix for 8270: Add 4.0mL of the base neutral mix (5000 ug/mL) and 2.0mL of the acid surrogate mix (10000 ug/mL) to a 250mL volumetric flask. Dilute to volume with Acetone to provide an 80 ug/mL surrogate solution.

8.6.2 Stock Calibration Mix Standards: Pre-made, commercially available solutions.

- PAH Mix - ECS-A-032 (2000ug/mL)
- EPA 8270 Add-ons - ECS-A-031 (2000ug/mL)
- EPA 625 B/N Mix#1 - ECS-A-030 (2000ug/mL)
- Benzidines Mix - ECS-A-007 (2000ug/mL)
- Phenols Mix - ECS-A-006 (2000ug/mL)
- Custom Semivolatiles Mix (containing acetophenone, atrazine, benzaldehyde, biphenyl, and caprolactam) – Restek – cat # 57685 (2000ug/mL)
- PAH Two Component Mixture – C.I.L. (2000uf/mL)
- Custom Four Component Mixture - N.S.I Q-7610-O (2000ug/ml)

The surrogate stock mixes noted in sections 8.6.1 are also added to the stock standard mixture. Due to the highly reactive nature of Benzidine and Benzaldehyde and their tendency to degrade when mixed with all the other target analytes found in this method, two separate ICAL solutions are prepared.

8.6.2.1 Preparation of the first stock standard (100ug/mL) to ***10mL*** stock solution in methylene chloride is as follows:

8.6.2.1.1 EPA 8270 Add-ons (2000ug/mL): 0.5mL

8.6.2.1.2 EPA 625 B/N Mix #1 (2000ug/mL): 0.5mL

8.6.2.1.3 Phenols Mix (2000ug/mL): 0.5mL

8.6.2.1.4 PAH Mix (2000ug/mL): 0.5mL

8.6.2.1.5 Acid Surrogate (10000ug/mL): 100uL

8.6.2.1.6 B/N Surrogate (5000ug/mL): 200uL

8.6.2.1.7 Cust. Field Surrogate Mix (2000ug/mL): 0.5mL

8.6.2.1.8 Custom Four Component Mixture (2000ug/ml): 0.5ml

8.6.2.2 Preparation of the second stock standard (100ug/mL) to 10mL in methylene

chloride is as follows:

8.6.2.2.1 Benzidines Mix (2000ug/mL): 0.5mL

8.6.2.2.2 Custom Semivolatiles Mix (2000ug/mL): 0.5mL

8.6.2.3 Preparation of calibration levels using the above stock solutions. Eight levels are prepared using the first stock solution. Only 7 additional levels are prepared using the second stock solution.

8.6.2.3.1 **Level 8 (50ug/mL):** 0.5mL of Calibration Stock diluted to a final volume of 1.0mL in methylene chloride.

8.6.2.3.2 **Level 7 (25ug/mL):** 2.5mL of Calibration Stock diluted to a final volume of 10mL in methylene chloride

8.6.2.3.3 **Level 6 (15ug/mL):** 1.5mL of Calibration Stock diluted to a final volume of 10mL in methylene chloride.

8.6.2.3.4 **Level 5 (10ug/mL):** 1.0mL of Calibration Stock diluted to a final volume of 10mL in methylene chloride.

8.6.2.3.5 **Level 4 (5.0ug/mL):** 0.5mL of Calibration Stock diluted to a final volume of 10mL in methylene chloride.

8.6.2.3.6 **Level 3 (2.0ug/mL):** 0.20mL of Calibration Stock diluted to a final volume of 10mL in methylene chloride.

8.6.2.3.7 **Level 2 (1.**0ug/mL): 0.1mL of Calibration Stock diluted to a final volume of 10mL in Methylene chloride.

8.6.2.3.8 **Level 1 (0.5ug/mL):** 0.05mL of Calibration stock diluted to a final volume of 10mL in methylene chloride.

8.6.3 Initial Calibration Verification (ICV):

Initial Calibration Verification primary solutions (200ug/mL):
Benzoic Acid Solution (2000ug/mL): Restek
Benzaldehyde Solution (2000ug/mL): Restek
Benzidine solution (1000ug/mL): Restek
Custom 8270 Mix (2000ug/ml): Restek
8270 Megamix (1000ug/ml): Restek

8.6.3.1 **Initial Calibration Verification solution (10ug/mL):** 0.05mL of Custom 8270 Mix and 0.1ml of 8270 Megamix diluted to a final volume of 10mL in methylene chloride.

8.6.3.2 **Initial Calibration Verification solution** for Benzoic Acid (10ug/mL): 50 uL of Benzoic Acid Solution diluted to a final volume of 10mL in Methylene chloride.

8.6.3.3 **Initial Calibration Verification solution** for Benzidine (10ug/mL): 100uL of Benzidine Solution diluted to a final volume of 10ml in Methylene Chloride.

8.6.3.4 **Initial Calibration Verification solution** for Benzaldehyde (10ug/ml): 50uL of Benzaldehdye solution diluted to a final volume of 10ml in Methylene Chloride.

8.6.4 Continuing Calibration Verification (CCV) solution (10ug/mL):

1.0mL of Calibration Stock diluted to a final volume of 10mL in methylene chloride. This solution is also used as the Level 5 of the ICAL.

.

8.6.5 LCS1/Matrix Spiking Solution (100/500ug/mL): Prepared with the same standards and volumes used to formulate the first ICAL stock as seen in section 8.6.2.1., minus the 3 surrogate solutions, with additional Benzoic Acid. Brought to a final volume of 10ml in Methanol. Formulation Below.

8.6.5.1 EPA 8270 Add-ons (2000ug/mL): 0.5mL

8.6.5.2 EPA 625 B/N Mix #1 (2000ug/mL): 0.5mL

8.6.5.2.1 Phenols Mix (2000ug/mL): 0.5mL

8.6.5.2.2 PAH Mix (2000ug/mL): 0.5mL

8.6.5.2.3 Custom Four Component Mixture (2000ug/ml): 0.5ml

8.6.5.2.4 Benzoic Acid Solution (Restek 2000ug/ml): 2.0ml

8.6.6 LCS2/Matrix Spiking Solution (100ug/mL):: Prepared by diluting 0.5ml of the Restek Custom Semivolatiles Mix Cat# 57685(2000ug/ml) to 10mL in Methanol.

8.6.7 LCS3/Matrix Spiking Solution (100/250ug/mL): Prepared by diluting 0.5ml of Benzidines Mix (ECS-A-007 - 2000ug/mL), and 1.5ml of Benzidine Solution (Restek 31441 1000ug/ml) to 10mL in Methanol.

8.6.8 Internal Standard Primary Standard: Six component standard commercially available from Restek – PN 31206-510. 2000ug/mL solution containing 1,4-Dichlorobenzene-d4, Naphthalene-d8, Acenaphthene-d10, Phenanthrene-d10, Chrysene-d12, and Perylene-d12.

8.6.8.1 8270 IS working solution (250ug/mL): 3.125mL of Internal Standard Primary Standard diluted to a final volume of 25mL in methylene chloride. 20uL of the solution is spiked into 1mL sample and standard vials. The final concentration on column is 5.0ug/mL.

8.6.9 DFTPP Primary Standard: Four component standard commercially available from UltraScientific – PN GCM-150. 1000ug/mL solution containing Decafluorotriphenylphosphine, Benzidine, Pentachlorophenol, and 4,4'-DDT.

8.6.9.1 8270 GC/MS Tuning Solution (50ug/mL): 1.25mL of DFTPP Primary Standard diluted to a final volume of 25mL in methylene chloride.

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

9.1 Blank(s)

9.1.1 Method Blank: A method blank must be prepared once per every 20 samples or per extraction batch, whichever is more frequent.

Compounds of interest must not be detectable in the method blank at a concentration greater than the reporting limit.

Corrective Action: Extraction of the method blank and all associated samples must be performed until the blank is in control. Samples cannot be analyzed until an acceptable method blank analysis is obtained. The results are qualified with a "B" flag for any associated sample concentrations that are less then 10x the blank concentration for the analyte. For New Jersey regulatory work, all target analytes must be < RL except phthalates which must be < 5X the RL. Sample results are qualified with a "B" flag for analytes observed in the blank > RL and phthalates observed in the blank > 5X RL. Exceptions may be made with if the samples associated with the out of control method blank are non-detect for the compound of interest, or if sample concentrations are greater than 10x the blank levels. In such cases when the sample results are accepted, the client is notified in a project narrative associated with the sample results.

9.2 Laboratory Control Sample (LCS)/ Laboratory Control Sample Duplicate (LCSD)

Laboratory control sample (LCS) and laboratory control duplicate (LCSD) must be prepared once per every 20 samples or per extraction batch, whichever is more frequent. The LCS/D may contain all target compounds of interest, or a smaller subset may be analyzed, and is extracted along with the samples as verification of the accuracy of the entire extraction procedure.

Project specific requirements, QAPPs, and/or other DQOs may supersede general limits and QC requirements.

Corrective Action: Base/Neutral compounds should be recovered at 40%-140% and Acid compounds at 30%-130% unless listed in Table D. If ≤10% of the total compounds are outside of these limits, and the recovery is at least 10% for these compounds, re-extraction is not required. If the LCS recovery is still out of control, re-extract and re-analyze the LCS and all associated samples. Samples cannot be reported until an acceptable LCS is obtained. Exceptions may be made in some cases for documented difficult/poor performing compounds such as Benzidine, Benzoic Acid, 4-Nitrophenol, Aniline, Pentachlorophenol, 2,4-Dinitrophenol, 2,4-Dimethylphenol, 4,6-Dinitro-2-methylphenol, Benzaldehyde, Caprolactam and Pyridine. An explanation of any out of control LCS recovery must be included in the project narrative to the client.

9.3 Initial Calibration Verification (ICV)

The initial calibration for each compound of interest must be verified prior to sample analysis. This is accomplished by analyzing a second source calibration standard (Section 8.6.3).

Calculate the percent recovery for each analyte. If the percent recovery for each analyte is within 70%-130% of their true value, then the calibration is assumed to be valid. If any compounds do not meet this criterion, attempts should be made to locate and correct the source of the problem. 10% of all analytes are allowed to be outside of 70%-130%, but must be within 60%-140%. The ICV may be reanalyzed once. If the standard failure continues, corrective action must be taken prior to sample analysis.

A new initial calibration must be performed and acceptable ICV results obtained prior to any sample analysis.

9.4 Continuing Calibration Verification (CCV)

On a daily basis after the DFTPP has passed, a mid-level (10ug/mL) continuing calibration standard which contains all of the analytes of interest is analyzed.

Refer to Section 10.4 for further information.

9.5 Matrix Spike/ Matrix Spike Duplicate (MS/MSD)

Matrix spike / matrix spike duplicate (MS/MSD) samples will be performed per batch of 20 samples of the same matrix processed together in those cases where the client does not specify omitting the MS/MSD for the analyses of their samples. In the case where the lab does not receive enough sample volume to perform an MS/MSD, an LCS and LCSD may be performed to document precision and bias.

See Section 12 for MS/MSD recovery limits and %RPD limits. Calculate the %RPD as described in Section 9.6.

Corrective Action: Repeat analysis or check to see that an analytical error has occurred. If the % recovery and/or RPD still exceeds the control limits, and the LCS/D is compliant; include a project narrative with the results to client noting that there may be potential matrix effects on the accuracy or precision of the reported results as evidenced by MS/MSD recoveries and/or %RPD outside of QC limits.

9.6 Laboratory Duplicate

Duplicate analyses are performed upon client and/or QAPP request. *For Organic analyses, the matrix duplicate is usually in the form of the matrix spike duplicate, see Section 9.5.*

Acceptable relative percent differences (RPD) of duplicates is listed in Section12. Acceptance criterion is not applicable to sample concentrations less than 5 times the reporting limit. Calculate the RPD as follows:

$$RPD = \frac{R1 - R2}{\frac{[R1 + R2]}{2}} \times 100$$

where:
R1 = sample Replicate #1
R2 = sample Replicate #2

Corrective Action: Repeat analysis if an analytical error is suspected. If the % RPD still exceeds the control limits; include a project narrative with the results to client noting that there may be potential matrix effects on the precision of the reported organic results as evidenced by the matrix duplicate % RPD outlier.

9.7 Method-specific Quality Control Samples

9.7.1 Surrogate Spikes: Surrogate spikes must be added to QC and field samples to evaluate the extraction method performance.

See Section 12 for surrogate recovery acceptance criteria.

Corrective Action: Up to one surrogate can be out in each fraction (Acid and Base/Neutral) but not less than 10% recovery, before any corrective action is necessary. Analysis must be repeated once if an analytical error is suspected. If the percent recovery still exceeds the control limits the sample must be re-extracted and re-analyzed to confirm the sample matrix. If *obvious* matrix interferences are noted, consultation with the Semivolatiles Department Manager, Laboratory Director or QA Officer may be necessary to confirm the need for sample re-extraction. If no re-extraction occurs, the surrogate results and reasons for the no re-extract decision must be discussed in the project narrative to the client.

9.7.2 Internal Standards: Internal standards must be added to all sample extracts, QC samples and standards for quantitation purposes.

The internal standards in the samples should remain at constant area counts with respect to the continuing calibration analyzed at the beginning of the run. Sample IS areas must be 50% to 200% of the Internal Standards in the Continuing Calibration. Additionally, the RRT of the detected sample compounds must be within 0.06RRT units of the retention times of the associated continuing calibration standard.

Corrective Action: Analysis must be repeated once unless there are obvious sample matrix interferences, e.g. If the sample extract was very colored and viscous, or there are obvious chromatographic interferences. If *obvious* matrix interferences are noted, consultation with the Semivolatiles Department Manager, Laboratory Director or QA Officer may be necessary to confirm the need for sample re-analysis.

9.8 Method Sequence

- Tune
- CCV
- Method Blank
- LCS
- LCSD
- Samples

10. Procedure

10.1 Equipment Set-up

10.1.1 The **basic GC parameters** are as follows:

Injection Port Temp: 260°C
Oven Equib Time: 0.50 min
Oven Max: 350°C
Oven: On
Cryo: Off
Ambient: 45°C
Cryo Blast: Off

Initial Temp.: 40°C
Initial Time: 1.00 min

Level	Rate (°C /min)	Final Temp. (°C)	Final Time (min)
1	25.00	200	0
2	9.00	270	0
3	12.00	320	4

Final Time: 23.344

Please note that this may differ slightly from one instrument to another.

The **basic injection port parameters** are as follows:
Pulsed Splitless “Split” mode
Equilibrium Time: 0.50 minute
Temp: 260°C
Pressure: 9.2752 psi
Total Flow: 34.2mL/min
Split: NA
Split Flow: NA
Septum Purge Flow: 3mL/min
Injection Pulse Pressure: 30psi Until 0.2min
Purge Flow to Split Vent: 30mL/min at 0.6 min
Injection volume: 1uL

This may differ slightly from one instrument to another.

10.1.2 **Column conditions** parameters are as follows:

Constant Pressure: 9.1473 psi
Column flow: 1.2mL/min
Linear Velocity: 39.723 cm/sec

This may differ slightly from one instrument to another.

10.1.3 Mass Spectrometer Scan Parameters
Scan from mass 35.0 amu to 450 amu

10.1.4 Tuning

Tune acceptance must be verified at the beginning of every 12 hour analytical sequence. The DFTPP may be combined with the calibration verification standard as long as both tuning and calibration acceptance criteria are met.

Before the analytical standards are analyzed the mass spectrometer must be adjusted to meet the proper ion criteria for DFTPP. This is demonstrated by injecting into the GC/MS system 1 uL of a 50 ug/mL DFTPP solution.

Note: Within the Enviroquant software, Autofind is used first to evaluate Tune. Three scans (the peak apex scan and the scans immediately preceding and following the apex) are acquired and averaged.

Background subtraction is required, and must be accomplished using a single scan acquired within 20 scans of the elution of DFTPP. The background subtraction should be designed only to eliminate column bleed or instrument background ions. Do not subtract part of the DFTPP peak or any other discrete peak that does not coelute with DFTPP.

Average or single scan may be used, if Autofind does not pass, but caution should be used in tuning on a single scan too close to the front or back of the DFTPP peak. If the system will not tune under ideal conditions, injection port maintenance, retuning, and/or a source clean should be performed.

The response of Benzidine and Pentachlorophenol, when monitored on a daily basis, will indicate the efficiency of the chromatography system. Benzidine and Pentachlorophenol should be present at their normal responses and no peak tailing should be visible. The tailing factor of Benzidine and Pentachlorophenol must not exceed 2. DDT breakdown must be <20%. Although moderate tailing may indicate maintenance on the instrument will be required soon, these additional compounds in the DFTPP standard are included as an aid in instrument performance evaluation.

The following DFTPP mass intensity criteria should be used:

DFTPP KEY MASSES AND ABUNDANCE CRITERIA

Mass	m/z Abundance criteria
68	Less than 2% of mass 69.
70	Less than 2% of mass 69.
197	Less than 2%of mass 198.
198	Base peak, or > 50% of Mass 442.
199	5-9% of mass 198.
365	Greater than 1% of mass 198.
441	Present but less than 24% of mass 442.

442 Base Peak, or > 50% of mass 198.
443 15-24% of mass 442.

10.2 Initial Calibration

10.2.1 After the DFTPP passes criteria, a set of multi-level calibration standards listed in Section 8.6.2.3 are analyzed, from low concentration to high. A minimum of five calibration levels are analyzed. The calibration standards are stored in the standards freezer. When the Initial Calibration is typed into a sequence, the standard ID for each of the levels must be noted in the “comments” of the sequence. (Refer to the Reagent Solvent and Standard Control SOP (1816) for further information regarding standard labeling convention.)

10.2.2 Once the standards have been analyzed, they are reduced by the search software of the Enviroquant data system. Once all the components are identified, a linear curve is calculated for the components. The criteria for evaluation are as follows:

The average response factor and the response factor of the lowest calibration standard of each target analyte should be checked against the recommended minimum response factor criteria found in Table C. This information may help to quickly identify poor responding compounds and the source of failure for initial calibrations. The %RSD for each target analyte must not exceed 20%. If the %RSD for any target exceeds 20%, the fit must be ≥0.99 quadratic or ≥.995 linear fit for all targets. A minimum of 5 levels are required for a linear calibration model and a minimum of 6 levels are required for a quadratic calibration model. When calculating calibration curves using the linear regression model, a quantitiation check must be performed on the lowest calibration point, or the point that corresponds to that compound’s established reporting limit. The recalculated concentration of the low calibration point (especially where linear regression fits are used) should be within ±50% of the standard's true concentration, and the recalculated concentrations of any calibration standards above the LLOQ should be within ±30%. If this criterion is not met then corrective action must take place and a new initial calibration must be performed prior to sample analysis.

10.2.3 Once the calibration curve is accepted, the Initial Calibration Verification (ICV) must be analyzed.

Reference standards from a separate source or different lot are analyzed after every initial calibration for evaluation of the calibration standard solutions. The response factors for all compounds should be evaluated against the minimum RF listed in Table C. The percent difference should not be greater than +/-30%D of the true value for all target compounds. If any compounds do not meet this criterion, attempts should be made to locate and correct the source of the problem. 10% of all analytes are allowed to be outside of 70%-130%, but must be within 60%-140%. The ICV may be reanalyzed once. If the standard failure continues, corrective action must be taken prior to sample analysis.

A new initial calibration must be performed and acceptable ICV results obtained prior to any sample analysis.

10.2.4 Once the calibration curve is accepted and prior to processing any samples, the analyst must demonstrate through the analysis of a MB or instrument blank that equipment and reagents are free from contaminants and interferences. If a peak is found in the blank that would prevent the identification or bias the

measurement of an analyte, the analyst should determine the source of the contaminant peak and eliminate it, if possible. Blanks are generally considered to be acceptable if target analyte concentrations are less than one half the LLOQ or are less than project specific requirements. Blanks may contain analyte concentrations greater than acceptance limits if the associated samples in the batch are unaffected

10.3 Equipment Operation and Sample Processing

10.3.1 Sample Extraction and Cleanup

Samples for 8270 are generally extracted using one of the following SOPs:

- *Shaker Table Extraction* (2261)
- *Separatory Funnel Extraction* 3510C (2165)
- *Microscale Solvent Extraction* 3570 (2172)

Samples for 8270 may be cleaned up before transfer to the instrument laboratory using one of the following SOPs:

- *Gel Permeation Column Cleanup* SOP (2167)
- *Silica Gel Clean-up* SOP (2170) – limited target compounds only.

10.3.2 The preparation lab staff will transfer the samples to the instrument laboratory. The samples are generally brought to a 1.0 to 5.0mL final volume; 1.0mL is transferred and any remaining sample is put into archive. One aliquot of each sample is then logged into the Internal Chain of Custody book and placed in the sample extract holding refrigerator located in the instrument laboratory.

10.3.3 All samples and standards are spiked with the six Internal Standards (IS) compounds before analysis, Section 8.6.8.1. The internal standard is intended to be used for both quantitation and the establishment of relative retention times. Samples at a volume of 1.0mL (including the QC samples of a method blank and LCS) are spiked with 20uL of internal standard for a concentration of 5ug/mL. The samples are shaken briefly after the internal standard is added to ensure mixing. If a different volume of sample is transferred the volume of internal standard added is adjusted accordingly.

10.3.4 The analyst may decide to screen any samples to determine is an upfront dilution is needed. An analyst might decide a dilution is needed prior to analysis for high target analyte concentration or to protect the instrument from of matrix related interferences.

10.3.5 After the samples have been analyzed, the data files from the Instrument are transferred to the server. The samples are quantitated versus the proper method. The QCPRN1.MAC macro creates a form with which to easily check internal standard and surrogate criteria. The istdrpt macro may, also, be utilized to check the internal standard and surrogate criteria. The following should be reviewed initially:

10.3.5.1 Are all the surrogates within QC criteria? Please see Section 12 for surrogate information.

10.3.5.2 Are all the internal standards of the samples within 50-200% of the daily CCV standard? If not, the samples should be checked for matrix interferences that may be causing these issues. The IS peaks should also be evaluated for peak splitting or incorrect integration by the software. A sample may not need to be reanalyzed if it can be determined (with guidance from a supervisor) that the QC is exceeded due to matrix interference.

10.3.5.3 Are all target analytes within calibration range? If not, the sample should be diluted and re-analyzed. If a dilution is performed after the internal standard has already been added, it will be necessary to add additional IS in order to provide a concentration of 5ug/mL. Conversely, if a sample has been over-diluted, it may need to be analyzed at a lesser dilution to detect target analytes that may have been diluted out.

10.3.5.4 Are all analyses within 12 hour tune time? If a sample is analyzed outside tune time, it will need to be re-analyzed in another tune clock.

10.3.6 The sequence should be printed out from Environmental Data Analysis, initialed and dated, placed in the standard logbook.

10.3.7 If anything in the initial review of the data indicates that there should be a re-analysis or a re-extract, the reason for re-analysis or re-extract should be noted on the sequence.

10.3.8 If a re-extract is required, the “Organics Re-Prep Request Form” google doc should be filled out and an email should be sent to the extractions lab.

10.3.9 A standard sequence (saved as S8073001;”S” for semivolatile;”8” for BNA8; 0730 for July 30, and 01 is the first sequence that day) would appear as follows:

Tune: WG#-1, -4, etc. This is the Analytical working group number generated by the Alpha LIMS that denotes the Tune.

CCV: WG#-2, -3, etc. This is the Analytical working group number generated by the Alpha LIMS that denotes the calibration verification.

10.4 Continuing Calibration Verification (CCV)

10.4.1 On a daily basis after the DFTPP has passed, a mid-level (10ug/mL) continuing calibration standard which contains all of the analytes of interest is analyzed. The criteria for acceptance are:

10.4.1.1 The %D for all targets must be ≤20%. Up to 20% of all targets are allowed to have %D > 20% with high bias as long as all associated samples are non-detect for those analytes. In cases where compounds fail low, they may be reported as non-detects if it can be demonstrated that there was adequate sensitivity to detect the compound at the LLOQ or project specific level of interest (e.g., by calibrating below the established LLOQ to confirm the non-detect, or by analyzing a standard near that level to confirm the analyte could be qualitatively identified if it were present. The retention times of the internal standards must be

within 0.5min of the mid-level standard of the most recent ICAL.

10.4.1.2 The area counts of the internal standards within the continuing calibration must be within 50 to 200% of the mid-level in previous ICAL.

10.4.1.3 Allowances may be made if in accordance with specific regional criteria.

10.4.1.3.1 New Jersey work may follow Data of Known Quality Protocols Technical Guidance whereas the %D for all target analytes must be ≤30% or corrective action must be taken.

10.4.1.3.2 Connecticut work may follow RCP criteria whereas if %D of >10% of target analytes is >30% corrective action must be taken.

10.4.1.3.3 Massachusetts work may follow MCP criteria whereas if ≤20% of compounds exceed criteria recalibration is not required as long as %D <40%.

10.5 Preventative Maintenance

All repair and non-routine maintenance records including outside service visits are maintained in the instrument maintenance logbooks.

Injection Port Maintenance: Maintenance should be done when the daily CCAL starts to demonstrate degradation. The type of samples analyzed will have an effect on how soon maintenance should be performed.

Septum Maintenance: The septum needs to be changed approximately every two-hundred injections. Unscrew the top septum nut, remove the pierced septum, and replace with a new 11mm Thermolite green septum (Restek) or equivalent. Screw the top septum nut back on.

Column Maintenance: Maintenance should be done when the daily CCAL starts to demonstrate degradation. The type of samples analyzed will have an effect on how soon maintenance should be performed. Generally maintenance is performed by trimming 6 cm off the front of the column. The column is then installed into the injection port liner, and the inlet nut is tightened.

11. Data Evaluation, Calculations and Reporting

11.1 Qualitative Analysis

11.1.1 The qualitative identification of compounds determined by this method is based on retention time and on comparison of mass spectrum, after background correction, with characteristic ions in a reference mass spectrum. The reference mass spectrum must be generated by the laboratory using the conditions of this method. The characteristic ions from the reference mass spectrum are defined as three ions of greatest relative intensity, or any ions over 30% relative intensity, if less than three such ions occur in the reference spectrum. Compounds are identified when the following criteria are met.

11.1.2 The intensities of the characteristic ions of a compound must maximize in the same scan or within one scan of each other. A peak selected by the data system, based on the presence of target specific ions at a target specific retention time will be accepted as meeting this criteria.

11.1.3 The relative retention time of the sample component is within ± 0.06 RRT units of the RRT of the standard component, taking into consideration matrix effects which may cause retention time shifts.

11.1.4 The relative intensities of the characteristic ions agree within 30% of the relative intensities of these ions in the reference spectrum. (Example: For an ion with an abundance of 50% in the reference spectrum, the corresponding abundance in a sample spectrum can range between 20% and 80%). Outlying abundances maybe included due to the presence of non-target interference. The relative intensities are monitored daily. The relative intensities will be updated when they exceed established values from the reference spectrum.

11.1.5 Structural isomers that produce very similar mass spectra should be identified as individual isomers if they have sufficiently different GC retention times. Sufficient GC resolution is achieved if the height of the valley between two isomer peaks is less than 50% the average of the two peak heights. Otherwise, structural isomers are identified as isomeric pairs.

11.1.6 Identification is hampered when sample components are not resolved chromatographically and produce mass spectra containing ions contributed by more than one analyte. When gas chromatographic peaks obviously represent more than one sample component (i.e. a broadened peak with shoulder(s) or a valley between two or more maxima), appropriate selection of analyte spectra and background spectra is important.

11.1.7 Examination of extracted ion current profiles of appropriate ions can aid in the selection of spectra and in qualitative identification of compounds. When analytes coelute, (i.e. only one chromatographic peak is apparent), the identification criteria may be met, but each analyte spectrum may contain extraneous ions contributed by the coeluting compound.

11.1.8 For samples containing components not associated with the calibration standards, a library search may be made for the purpose of tentative identification. The necessity to perform this type of identification (TICs) will be determined by the purpose of the analyses being conducted. Data system library searches must not use normalization routines that would misrepresent the library or unknown spectra when compared to each other.

11.1.8.1 For example, the RCRA permit or waste delisting requirements may require the reporting of non target analytes. Only after a visual comparison of sample spectra with the nearest library searches may the analyst assign a tentative identification. Guidelines for tentative identification are:

11.1.8.1.1 Relative intensities of major ions in the reference spectrum (ions >10% of the most abundant ion) should be present in the sample spectrum.

11.1.8.1.2 The spectral library match must be $\geq$ 85% for a tentatively identification to be made.

11.1.8.1.3 The relative intensities of the major ions should agree within $\pm$ 20%. (Example: For an ion with an abundance of 50% in the standard spectrum, the corresponding sample ion abundance must be between 30-70%).

11.1.8.1.4 Molecular ions in the reference spectrum should be present in

the sample spectrum.

11.1.8.1.5 Ions present in the sample spectrum but not in the reference spectrum should be reviewed for background contamination or presence of co-eluting compounds.

11.1.8.1.6 Ions present in the reference spectrum but not in the sample spectrum should be reviewed for possible subtraction from the sample spectrum because of background contamination or co-eluting peaks. Data system library reduction programs can sometimes create these discrepancies.

11.2 Quantitative Analysis

11.2.1 Response factors and % RSD to evaluate Initial Calibration acceptability.

Calculate RF by:
where:

$$RF = \frac{area_{cmp}}{area_{is}} \times \frac{conc_{is}}{conc_{cmp}}$$

area cmp = Area of the characteristic ion for the compound being measured.
area is = Area of the characteristic ion for the specific internal standard.
conc. is = Concentration of the specific internal standard.
conc. cmp = Concentration of the compound being measured.
Calculate %RSD by:
where:

$$\%RSD = \frac{SD}{\bar{x}} \times 100 \qquad SD = \sqrt{\sum_{i=1}^{N} \frac{(x_i - \bar{x})^2}{N-1}}$$

%RSD = Percent Relative Standard Deviation
x = Average of RF's
SD = Standard Deviation
x_i = Analytical results of each level in the final reporting units
N=Number of results (levels)

11.2.2 For compounds in the initial calibration in which the Average of Response Factors calibration model is used:

Calculate %Difference (%D):

$$\%D = \frac{\overline{RF}_i - RF_c}{\overline{RF}_i} \times 100$$

where:

RFi - Initial Calibration average RF
RFc = Continuing Calibration RF

11.2.3 For compounds in the Initial Calibration for which the Linear Regression calibration model is used:

$$\%\ \text{Drift} = \frac{\text{Calculated [ ] – Theoretical [ ]}}{\text{Theoretical [ ]}} \times 100$$

11.2.4 Results of Water Analysis- calculation as performed in report form:

$$\text{Concentration (ug/L)} = \frac{(\text{Conc})\ (\text{Vf})\ (\text{DF})}{(\text{Vi})} \times 1000$$

where:
Conc =Raw on-column concentration obtained from the quantitation report using Initial Calibration results.
Vf = Final volume of extract (mL)
Vi = Volume of sample extracted (mL)
DF = Dilution factor, for manually prepared dilutions

11.2.5 Results of Sediment/Soil and Sludge Analysis- calculation as performed in report form:

$$\text{Concentration (ug/Kg)} = \frac{(\text{Conc})\ (\text{Vf})\ (\text{DF})}{(\text{W})\ (\%\text{S})} \times 1000$$

where:

Conc =Raw on-column concentration obtained from the quantitation report using Initial Calibration results.
DF = Dilution factor, for manually prepared dilutions, not instrumental "dilutions".
Vf = Extract final volume (mL)
W = Aliquot of sample (wet), g
%S = Sample % solid (in decimal form)

11.2.6 The calculation for percentage breakdown for DDT is:

$$\%\ \text{Breakdown DDT} = \frac{(\text{Area DDD} + \text{Area DDE})}{(\text{Area DDD} + \text{Area DDT} + \text{Area DDE})} \times 100$$

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

All results for the organic compounds of interests are reportable without qualification if extraction and

analytical holding times are met, preservation (including cooler temperatures) are met, all QC criteria are met, and matrix interference is not suspected during extraction or analysis of the samples. If any of the below QC parameters are not met, all associated samples must be evaluated for the necessity of re-extraction and/or re-analysis.

If non-compliant organic compound results are to be reported, the Semi volatile Organics Department Manager, the Laboratory Director, and/or the QA Officer must approve the reporting of these results. The laboratory Project Manager shall be notified, and may chose to relay the non-compliance to the client, for approval, or other corrective action, such as re-sampling and re-analysis. The analyst or Department Manager performing the secondary review initiates the project narrative, and the narrative must clearly document the non-compliance and provide a reason for acceptance of these results.

QC Parameter	Acceptance Criteria
Initial Calibration Curve	≤20%RSD or ≥0.99 quadratic or ≥.995 linear fit for all targets. If the linear or quadratic calibration model is used, recalculation of the lowest calibration standard is required to be within +/-30% of the true value. Average RFs and the lowest calibration standard should be checked against the recommended minimum RFs listed in Table C as a troubleshooting tool.
Independent Check Verification	+/- 30%D for all compounds; ICV is still accepted if up to 10% of all compounds that fail to meet +/-30%D, are within 60%-140%D
Continuing Calibration Verification	Analyzed every 12hr or at the minimum of every 20 samples; ≤ 20%D for all compounds. 80% of target analytes must meet criteria. (Section 10.4)
Method Blank	No analyte detected at or above the reporting limit, “B” qualify analyte if detected concentration is less than 10X the concentration found in the associated sample(s)
Laboratory Control Sample / Lab Control Sample Duplicate	40%-140% (Base/Neutral compounds) and 30%-130% (Acid compounds) for all matrices; 30% RPD for soils; 20% RPD for waters; 10% allowed out provided %Recovery is at least 10%, exception made for “difficult” compounds (Section 9.2)
Matrix Spike / Matrix Spike Duplicate	Same as for LCS/D
Sample / Sample Duplicate	30% RPD for soils; 20% RPD for waters
Surrogates	Soil: 30-130% Waters: 30-130% for BN and 15-115% for Acid
Internal Standards	50% - 200% of the daily CCV area for the Internal Standards
Project specific QAPP and DQOs supersede the above limits.	

13. Method Performance

13.1 Method Detection Limit Study (MDL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the MDL, LOD, and/or LOQ as outlined in Alpha SOP 1732. These studies performed by the laboratory are maintained on file for review.

13.2 Demonstration of Capability Studies

Refer to Alpha SOP 1739 for further information regarding IDC/DOC Generation.

13.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

14. Pollution Prevention and Waste Management

Refer to Alpha's Chemical Hygiene Plan and Waste Management and Disposal SOPs for further pollution prevention and waste management information.

15. Referenced Documents

N-Nitrosodimethylamine	27 – 70%
Hexachlorocyclopentadiene	10 – 109%

Semivolatile Organic Compounds by Gas Chromatography/ Mass Spectrometry (GC/MS)

Reference Method No.: **EPA 8270 E**

Reference: SW-846, Test Methods for Evaluating Solid Waste: Physical/Chemical Methods, EPA SW-846, Update VI (Phase II), June, 2018.

1. Scope and Application

Matrices: This method is used to determine the concentration of semivolatile organic compounds in extracts prepared from many types of solid waste matrices, soils, and wastewater samples.

This method is used to quantitate most neutral, acidic, and basic organic compounds that are soluble in methylene chloride and capable of being eluted, without derivatization, as sharp peaks from a gas chromatographic fused-silica capillary column coated with a slightly polar silicone.

Table 9 lists “difficult” compounds that may require special treatment when being determined by this method.

Approval of any method modifications is by one of the following laboratory personnel before performing the modification: Area Supervisor, Laboratory Director, or Quality Assurance Officer.

This method is restricted to use by or under the supervision of analysts experienced in the operation of a gas chromatograph/mass spectrometer and in the interpretation of mass spectra. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability (Section 13.2).

2. Summary of Method

The samples are introduced into the GC/MS by injecting 1µL of the sample extract into a gas chromatograph (GC) with a narrow-bore fused-silica capillary column. The GC column is temperature-programmed to separate the analytes, which are then detected with a mass spectrometer (MS) connected to the gas chromatograph.

Analytes eluted from the capillary column are introduced into the mass spectrometer via direct connection. Identification of target analytes is accomplished by comparing their mass spectra with the electron impact spectra of standards run on the same GC/MS system. Quantitation is accomplished by comparing the response of quantitation ion relative to an internal standard using a calibration curve.

2.1 Method Modifications from Reference

None.

3. Reporting Limits

Table 6 lists our routine reporting limits.

4. Interferences

4.1 Only high purity helium is used in the GC system to eliminate this source of possible contamination. The helium (carrier gas) is certified by the gas supplier.

4.2 Preventive instrument maintenance is performed routinely. Section 10.5 details the maintenance steps.

4.3 Glassware must be scrupulously cleaned. This procedure is detailed in the Organic Extraction Glassware Cleaning & Handling SOP/1953.

4.4 Contaminated solvents or reagents are also possible sources of contamination. All solvents used are pesticide grade or equivalent, and reagents are purchased as certified contaminant free.

4.5 Contamination by carry-over can occur whenever high-concentration and low-concentration samples are sequentially analyzed. Whenever an unusually concentrated sample is encountered (concentrations greater than 2x the highest concentration) and the next sample has reportable hits this sample should to be re-analyzed for confirmation based on analyst discretion.

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound must be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material data handling sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

5.1 Lab coats, safety glasses, and gloves must be worn when handling samples, extracts, standards or solvents.

5.2 All solvent and extract transfers must be handled in the vented bench area in the GC/MS laboratory.

5.3 All stock standards, working standards, and vialed sample extracts must be placed into the waste bucket in the lab for future disposal by the Health and Safety Officer. The container must be labeled properly with hazard warning labels indicating the container contents.

5.4 Flammable solvent bottles must be stored in the flammables cabinet.

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

Aqueous samples are collected in two 1L amber glass jars with teflon-lined lids. For LVI, aqueous samples are collected in two 275mL amber glass jars with teflon-lined lids. Solid samples are collected in 250mL wide-mouth glass jars with teflon-lined lids. All containers are purchased pre-cleaned and certified from commercial vendors.

6.2 Sample Preservation

Both aqueous and solid samples are then preserved by packing in coolers with ice or ice packs, to maintain a temperature of 4 ± 2ºC. Upon receipt at the laboratory, the samples are transferred into sample storage refrigerators to maintain at a temperature of 4 ± 2ºC.

6.3 Sample Handling

Aqueous samples must be extracted within 7 days of sample collection, solid samples within 14 days of collection. Once extracted, the samples must be analyzed within 40 days of the extraction date.

7. Equipment and Supplies

7.1 Gas Chromatograph/Mass Spectrometer System:

7.1.1 Gas Chromatograph, Hewlett Packard 6890 (or equivalent): An analytical system complete with a temperature-programmable gas chromatograph configured for split/splitless-injection and all required accessories, including syringes, analytical columns, and gases. The capillary column is directly coupled to the source.

7.1.2 Column: Rxi-5Sil MS30m x 0.32mm ID, 0.25µm film thickness or column of similar configuration.

7.1.3 Mass Spectrometer, Hewlett Packard 5973 (or equivalent): Scanning from 35 to 500 amu every 1 second or less, using 70 volts (nominal) electron energy in the electron impact ionization mode. The mass spectrometer is capable of producing a mass spectrum for decafluorotriphenylphosphine (DFTPP) which meets the criteria in Table 1 when 1 µL of the GC/MS tuning standard is injected through the GC (50ng of DFTPP).

7.1.4 Data System: A computer system is interfaced to the Mass Spectrometer. The system allows the continuous acquisition and storage on machine-readable media of all mass spectra obtained throughout the duration of the chromatographic program. The computer software allows the analyst to search for any GC/MS data file for ions of specific mass and plot such ion abundances versus time or scan number. *HP ChemServer* software is used for data acquisition and *MSD Chemstation/Enviroquant version E.02.02* is used for data reduction.

7.2 Syringe: 10 µL.

7.3 Volumetric Flasks, Class A: Appropriate sizes with ground-glass stoppers.

7.4 Vials: Glass autosampler vials with polytetrafluoroethylene (PTFE)-lined crimp top caps.

8. Reagents and Standards

8.1 Stock Standard Solutions

Certified stock standard solutions, traceable to NIST, when available, are purchased from commercial vendors. They can be replaced with different standards as long as they contain all target analytes.

All stock standards, lot number, catalog number, expiration date, preparation date and initials are recorded in a logbook. Standards are stored in the refrigerator or freezer. Store away from any light source at 6 °C when not in use (−10 °C is recommended).

Stock standard expire 6 months from the date of preparation or on the earliest expiration date of any of the stock solution used to prepare it.

Please note that the following preparation instructions and stock standards are included for illustration purposes and may be modified as needed (ex. to accommodate standard availability or client requests), however final concentrations for the initial calibration levels shall always follow the example in 8.1.4.

Vendor	Standard	Catalog#	Concentration
Restek			
	8270 Mega Mix	31850	500-1000ug/mL
	Benzoic Acid Mix	31879	2000ug/mL
	Acid Surrogate Mix	31087	10000ug/mL
	B/N Surrogate Mix	31086	5000ug/mL
	Benzaldehyde Standard	33017	2000ug/mL
	Custom AP9 ICAL Standard	571813-FL	2000ug/mL
	Custom ADP Standard	572745-FL	2000ug/mL
	Benzidine Mix	31834	2000ug/mL
	SV Internal Standard Mix	31206	2000ug/mL
	1,4-Dioxane	30287	2000ug/mL
	Custom CLP 04.1 BNA Surrogate Mix	571320-FL	1000ug/mL
Absolute	Aromatic Amines Mix	99410	2000ug/ml
Ultra	Semi-Volatiles GC/MS Tuning Standard	GCM-150-1	1000ug/mL

8.1.1 ABN Stock Standard, 200ug/mL

Use 5mL of each of the following:
- Benzoic Acid Mix
- Benzidine Mix

and use 10mL of each of the following:
- 8270 Mega Mix
- Custom CLP 04.1 BNA Surrogate Mix

Bring up to 50mL volume with DCM.

8.1.2 AP9 Additional Compounds Stock Standard, 200ug/mL

Use 5mL of each of the following:
- Custom AP9 ICAL Standard
- Benzaldehyde Standard

Bring up to 50mL volume with DCM.

8.1.3 ADP Stock Standard, 200ug/ml

Use 5ml of:
- Custom ADP Standard

Bring up to 50mL volume with DCM.

8.1.4 Calibration Standard

A minimum of 5 calibration standards must be included for each analyte:

Calibration Curve Levels	
Level	Concentration ug/mL
1	1.0
2	2.0
3	3.0
4	5.0
5	10
6	20
7	50
8	100
9	150
10	200

LVI Calibration Curve Levels	
Level	Concentration ug/mL
1	0.2
2	0.4
3	1.0
4	2.0
5	3.0
6	5.0
7	10
8	15
9	35
10	50

*LVI- Low Volume Initiative

8.2 Internal Standard Solution

The internal standards are:

1,4-dichlorobenzene-d_4
naphthalene-d_8
acenaphthene-d_{10}
phenanthrene-d_{10}
chrysene-d_{12}
perylene-d_{12}

Each 500µL of standards, blank and sample extracts are spiked with 10µL of SV Internal Standard Mix, resulting in a concentration of 40ng/ µL.

For the LVI method, a 1:10 dilution is made of the Internal Standard Stock Solution. 500µL of standards, blank and sample extracts are spiked with 10µL of this preparation, resulting in a concentration of 4ng/ µL.

8.3 GC/MS Tuning Standard

The tuning standard is a methylene chloride solution containing 50ng/µL of decafluorotriphenylphosphine (DFTPP). The standard also contains 50ng/µL each of 4,4'DDT, pentachlorophenol, and benzidine to verify injection port inertness and GC column performance.

Prepare the GC/MS Tuning Standard with 25µL GCM-150 and 475µL Dichloromethane.

8.4 Surrogate Spiking Solution

8.4.1 Extraction Surrogate Preparation

In a 1000mL volumetric flask, add 5ml of 31086 and 31087. Bring up to volume with Acetone. The final concentration is 50µg/mL for the acid surrogates and 25µg/mL for the B/N surrogates.

8.4.2 LVI Extraction Surrogate Preparation

The LVI surrogate is a 10 fold dilution of the surrogate solution prepared in 8.4.1. For example, to make 200mL of LVI surrogate, add 20mL of 8.4.1 to a 200mL volumetric flask

and fill to volume with Acetone. The resulting surrogate concentration is 5µg/mL for the acid surrogates and 2.5µg/mL for the B/N surrogates.

8.5 Spike Solution (LCS, MS, MSD)

Spike Solution Preparation

ABN SPK1:
In a 500ml volumetric flask, add 20ml of 8270 Mega Mix #31850, 10ml of Benzoic Acid Mix #31879, 10ml Custom AP9 ICAL Standard #571813-FL and 10ml Benzaldehyde Standard #33017. Bring up to volume with Acetone. The final concentration is 40µg/ml.

Note: the LVI ABN SPK1 is prepared by making an 8 fold dilution of the 40µg/ml ABN SPK (in acetone), resulting in a 5µg/ml LVI ABN SPK1.

ABN SPK2:
In a 500ml volumetric flask, add 10ml Benzidine Mix #31834 and 10mL Custom ADP Standard #572945-FL. Bring up to volume with Acetone. The final concentration is 40µg/ml.

Note: the LVI ABN SPK2 is prepared by making an 8 fold dilution of the 40µg/ml ABN SPK (in acetone), resulting in a 5µg/ml LVI ABN SPK2.

8.6 Dichloromethane (DCM): Pesticide quality.

8.7 Acetone: Pesticide quality.

9. Quality Control

9.1 Blank(s)

Extraction blanks are performed with each extraction batch of 20 or less samples. The extraction blank must not contain any of the reportable analytes above the reporting limit. Corrective actions:

- No corrective action required if concentration of contaminant in sample is >10x concentration in blank or if contaminant not detected in sample

- If the blank have reportable hits and re-extraction could not be performed due to lack of additional sample volume, the sample results are reported and qualified with “B” flag for any associated samples that concentration is less than 10x the blank concentration

For NJ regulatory work the method blank must have all the target analytes less than RL except for Phthalates which must be less than 5x of the RL. Sample results are qualified with “B” flag for analytes observed in the blank greater than RL and the Phthalates observed in the blank greater than 5x RL

The surrogate recoveries must also be within the acceptance criteria listed in Table 2. If surrogate acceptance criteria are exceeded, the extraction batch must be evaluated to determine if re-extraction or re-analysis is necessary.

9.2 Laboratory Control Sample and Laboratory Control Sample Duplicate (LCS / LCSD)

A Laboratory Control Sample/Laboratory Control Sample Duplicate pair (LCS/LCSD) are extracted and analyzed with each analytical batch of 20 or fewer samples.

The LCS/LCSD acceptance criteria are based the performance standard control limits. These performance standards are based on commonly used state programs RCP,MCP etc. See table 3. Less than 10% of total compounds may be outside of control limits provided that recoveries are >10%. Note: this does not apply to difficult analytes listed in Table 9 which may be accepted at recoveries <10. If >10% of analytes are recovered above control limits, this is deemed acceptable as long as the analytes in question are not detected in associated samples.

If these criteria are not met, the entire batch is re-extracted. If re-extraction is not possible, due to insufficient sample or holding time exceedance, the analyst must write up the failure on a narrative sheet for inclusion in the client report.

9.3 Initial Calibration Verification (ICV)

Refer to Section 10.2.7.

9.4 Continuing Calibration Verification (CCV)

Refer to Section 10.4.

9.5 Matrix Spike and Matrix Spike Duplicate (MS / MSD)

A matrix spike/matrix spike duplicate pair is extracted and analyzed for each batch of 20 or fewer samples per client request. The MS/MSD acceptance criteria are based on performance standards. See table 3 for individual control limits. If the recovery criteria are not met, but are met in the LCS/LCSD, this is noted on a narrative sheet for inclusion in the client report.

9.6 Laboratory Duplicate

Not applicable.

9.7 Method-specific Quality Control Samples

9.7.1 Surrogates

All extracted samples and associated QC are spiked with surrogates. The acceptable surrogate recovery limits are listed in Table 2.

Corrective action: Up to one surrogate can be out in each fraction (Acid and Base/Neutral) but not less than 10% recovery, before any corrective action is necessary. Otherwise, analysis must be repeated once to see if an analytical error has occurred. If the % recovery still exceeds the control limits the sample must be re-extracted and re-analyzed to confirm sample matrix. If matrix effect is confirmed, this must be noted on a narrative sheet for inclusion in the client report.

Re-extraction is not required if surrogate recoveries are high and target analytes are not detected in the sample.

9.7.2 Internal Standards

If the area for any of the internal standards in the samples changes by a factor of two (-50% to +100%) from that in the CCV, the mass spectrometer must be inspected for malfunctions and corrections must be made, as appropriate. When corrections are made, reanalysis of samples analyzed while the system was malfunctioning is required.

9.8 Method Sequence

In a 12-hour period, the typical analytical sequence is:

- Degradation Check
- DFTPP
- Continuing or Daily Standards (1 – 3)*
  (1) ABN 50 ppm
  (2) AP9 50 ppm
  (3) ADP 50 ppm
- Method/Instrument Blank
- Samples
- QC (as required)

***Additional Continuing standards may be run at the analyst's discretion or by client request.**

10. Procedure

10.1 Equipment Set-up

10.1.1 GC/MS Operating Conditions:

Typical GC/MS operating conditions are listed below, but may be altered as long as method performance criteria are met.

Mass range:	35 – 500 amu
Scan time:	3.15 second / scan
Initial temperature:	50°C, hold for 1.5 minutes
Temperature program:	28°C/minute to 250°C then 9°C/minute to 320°C
Final temperature:	320°C for 1.50 min
Injector temperature:	300°C
Transfer line temperature:	280°C
Source temperature:	230ºC
Injector:	split ratio 5:1; 11.7mL/min
Injection volume:	1µL
Carrier gas:	helium at 523 cm/second (2.0 mL/min) constant flow

GC/MS Operating Conditions for LVI method:

Mass range:	35 – 550 amu
Scan time:	3.15 second / scan
Initial temperature:	45°C, hold for 4 minutes
Temperature program:	25°C/minute to 250°C then 20°C/minute to 320°C
Final temperature:	320°C for 4.3 min
Injector temperature:	270°C
Transfer line temperature:	280°C
Source temperature:	320ºC
Injector:	split ratio 5:1; 8.57mL/min
Injection volume:	2µL
Carrier gas:	helium at 1.7148mL/min) constant flow

10.1.2 GC/MS Tune:

At the beginning of every 12 hour sequence, analyze DFTPP tuning solution (Section 8.3).

The resultant mass spectrum for DFTPP must meet the criteria given in Table 1 before sample analysis begins. The mass spectrum of DFTPP should be acquired in the following manner:

(1) Three scans (the peak apex scan, the scan immediately preceding the apex and the scan immediately following the apex) are acquired and averaged.
(2) Background subtraction is performed using a single scan of no more than 20 scans prior to the elution of DFTPP.

The GC/MS tuning standard is also used to assess GC column performance and injection port inertness. Degradation of DDT to DDE and DDD must not exceed 20%. Benzidine and pentachlorophenol must be present at their normal responses and no peak tailing must be visible.

The tailing factor for benzidine and pentachlorophenol must be calculated in every DFTPP run. (See Table 4)

If degradation is excessive and/or poor chromatography is noted, the system needs maintenance (see Section 10.5).

10.2 Initial Calibration

10.2.1 Prepare calibration standards for all target analytes at a minimum of five concentration levels as specified in Section 8.1.4.

10.2.2 Add 10µL of Internal Standard to each calibration standard directly into the autosampler vial containing 500µL of standard. Analyze each calibration standard under the conditions specified in Section 10.1.1.

10.2.3 Record the calibration standard, unique lab identifier code (lot), concentration, and analyst's initials in the analytical sequence list.

10.2.4 In each standard, calculate the response factor (RF) for each analyte, the average RF, and the relative standard deviation (RSD) of the RFs, using the Enviroquant data processing software. The calculations are performed automatically, using the formulae listed in Alpha's Quality Manual.

It is recommended that a minimum response factor for the most common target analytes, as noted in Table 8, be demonstrated for each individual calibration level as a means to ensure that these compounds are behaving as expected. In addition, meeting the minimum response factor criteria for the lowest calibration standard is critical in establishing and demonstrating the desired sensitivity.

10.2.5 Initial Calibration %RSD Criteria:

For all analytes, the RSD must be ≤ 20% for the mean response factor to be used for sample quantitation.

If the RSD for any target analyte exceeds 20%, the fit must be ≥0.99 quadratic or ≥ 0.995 linear fit for all target analytes. A minimum of 5 levels are required for a linear calibration model and a minimum of 6 levels are required for a quadratic calibration model. When calculating calibration using the linear regression model, a quantitation check must be performed on the lowest calibration point, or the point that corresponds to that compound's established reporting limit.
For RCP, the RSD must be ≤ 15% for the mean response factor to be used for sample quantitation

Percent Relative Error (%RE): For linear and quadratic fit compounds, the %RE must be calculated for the standard at or near the midpoint and at the lowest level of the initial calibration. The %RE between the calculated and expected concentration of an analyte must be ≤ 30%, otherwise recalibration is necessary.

10.2.6 Evaluation of Retention Times:

The relative retention time (RRT) of each target analyte in each calibration standard should agree within 0.06 RRT units.

10.2.7 Initial Calibration Verification (Second Source Verification)

10.2.7.1 The initial calibration (Section 10.2) for each compound of interest must be verified prior to sample analysis. This is accomplished by analyzing second source calibration standards at a concentration near the midpoint concentration for the calibrating range of the GC/MS.

10.2.7.2 Analyze the standards and calculate the % Difference for each analyte according to the formula in Alpha's Quality Manual.

If the % Difference for each analyte is ± 30%, then the calibration is assumed to be valid. If this criterion is not met, then corrective action must be taken prior to the analysis.

For RCP, if the % Difference for each analyte is ± 20%, then the calibration is assumed to be valid. If this criterion is not met, then corrective action must be taken prior to the analysis.

10.2.7.3 In cases where compounds fail (greater than 30% difference), they may still be reported as non-detects.

10.2.7.4 Once the calibration curve is accepted and prior to processing any samples, the analyst must demonstrate through the analysis of a Method Blank or Instrument Blank that equipment and reagents are free from contaminants and interferences. If a peak is found in the blank that would prevent the identification or bias the measurement of an analyte, the analyst should determine the source of the contaminant peak and eliminate it, if possible. Blank are generally considered to be acceptable if target analyte concentration are less than one half the LLOQ or are less than project specific requirements. Blanks may contain analyte concentrations are greater than acceptance limits if the associated samples in the batch are unaffected.

10.3 Equipment Operation and Sample Processing

10.3.1 GC/MS Analysis of Samples

10.3.1.1 Allow the sample extracts to warm to room temperature.

10.3.1.2 Transfer all of the sample extract to a 1.5mL vial. Remove 500µL of sample extract to another vial, and add 10µL of the internal standard solution (Section 8.2).

10.3.1.3 The autosampler is programmed to inject 1µL aliquot of the sample extract into the GC/MS system, using the same instrument conditions that were used for calibration. The injection volume of the sample must be the same as the volume used for the calibration standard.

10.3.1.4 If the response of any quantitation ion exceeds the initial calibration range of the GC/MS system, the sample extract must be diluted and reanalyzed.

10.3.2 Qualitative Identification

Perform first level data review. Obtain the primary m/z (Table 5) masses for each parameter of interest. The following criteria must be met to make qualitative identification:

- Compare the background subtracted mass spectra for the sample to the reference spectra. The characteristic masses of each parameter of interest must maximize in the same or within one scan of each other.
- The retention time must fall within ± 0.1 minutes of the retention time of the compound in the analytical standard. However, analyst experience must be used in making the qualitative identification.
- The relative peak height of the one characteristic mass must fall within 30% of the relative intensity of the mass in a reference mass spectrum. The reference spectrum is obtained from a standard analyzed on the GC/MS system.

Structural isomers that have very similar mass spectra are identified only if the resolution between authentic isomers in a standard mix is less than 25% of the sum of the two peak heights. Otherwise, structural isomers are identified as isomeric pairs.

10.4 Continuing Calibration

10.4.1 The initial calibration (Section 10.2) for each compound of interest must be verified once every 12 hours prior to sample analysis. This is accomplished by analyzing calibration standards at a concentration near the midpoint concentration for the calibrating range of the GC/MS.

10.4.2 Analyze the standards and calculate the % Difference for each analyte according to the formula in Alpha's Quality Manual.

If the % Difference for each CCV analyte is $\leq$ 20%, then the calibration is assumed to be valid. If the criterion is not met for more than 20% of the compounds then corrective action must be taken.

Due to the large number of analytes present, allowances may be made for a RF that drifts out high, as long as there are no positive hits for that particular analyte in any of the associated samples.

10.4.3 If this criterion is exceeded, inspect the gas chromatographic system to determine the cause and perform whatever maintenance is necessary before verifying calibration and proceeding with sample analysis.

10.4.4 If routine maintenance does not return the instrument performance to meet the QC requirements based on the last initial calibration, then a new initial calibration must be performed.

10.4.5 Internal Standard Retention Time

The retention times of the internal standards in the calibration verification standard is evaluated after data acquisition. If the retention time for any internal standard changes by more than 30 seconds from that in the mid-point standard of the most recent initial calibration, then the chromatographic system must be inspected for malfunctions and corrections must be made, as required. When corrections are made, reanalysis of samples analyzed while the system was malfunctioning is required.

10.4.6 Internal Standard Response

Refer to section 9.7.2

10.5 Preventive Maintenance

When poor sensitivity is observed, replacement of the injector liner and seal may solve the problem. If not, clip approximately 3 – 6 inches from the injector end of the GC column. If the sensitivity does not improve it may be necessary to replace the split line or the injector weldment assembly. If the problem persists, it may be necessary to replace the GC column.

Periodic cleaning (typically twice per year) of the mass spectrometer ion source is required. More frequent source cleaning may be needed, especially if dirty samples are analyzed.

11. Data Evaluation, Calculations and Reporting

When a parameter is identified, the quantitation of that parameter must be based on the integrated abundance of the quantitation characteristic m/z given in Table 5

Calculate the concentration in the sample using the average response factor (RF) from the initial calibration curve according to the formula in Alpha's Quality Manual.

After performing technical data review, validating that all QC criteria have been met and confirming all positive hits, the data report is sent electronically to the LIMS computer for generation of the client report. There are two levels of review of the data in the LIMS system prior to release of data. These reviews must be done by two separate individuals.

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

Holding time exceedence and improper preservation are noted on the nonconformance report form.

Perform instrument maintenance as described throughout this SOP as needed when instrument calibration criteria are not met. Record all maintenance in the instrument logbook.

All batch and sample specific QC criteria outlined in Section 9 are evaluated by the analyst prior to approval of the data. When any QC criteria fail, the cause for the failure must be identified and corrected. This may include instrument recalibration followed by sample reanalysis, sample cleanup, or sample re-extraction. If it is determined that the failure is due to sample matrix effects, a project narrative report is written by the analyst for inclusion in the data report. If there is insufficient sample

volume to perform the re-analysis for confirmation, this is also noted in the narrative and included in the client report.

13. Method Performance

13.1 Detection Limit Study (DL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the DL, LOD, and/or LOQ as outlined in Alpha SOP/1732. These studies performed by the laboratory are maintained on file for review.

13.2 Demonstration of Capability Studies

Refer to Alpha SOP/1739 for further information regarding IDC/DOC Generation.

13.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

14. Pollution Prevention and Waste Management

Refer to Alpha's Chemical Hygiene Plan and Waste Management and Disposal SOP for further pollution prevention and waste management information.

15. Referenced Documents

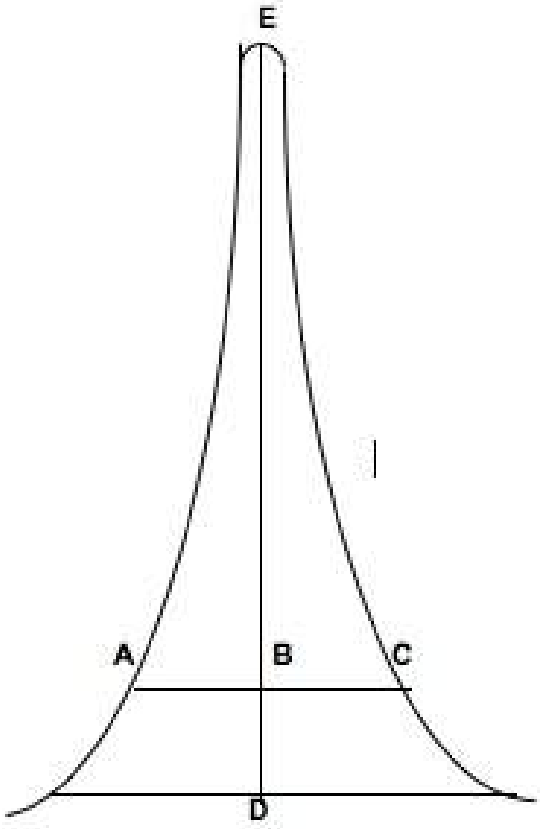
TABLE 4 – Tailing Factor Calculation



Tailing Factor = $\frac{BC}{AB}$

Example calculation:

Peak Height = DE = 100mm
10% Peak Height = BD = 10mm
Peak Width at 10% Peak Height = AC = 23mm

AB = 11mm
BC = 12mm

Therefore: Tailing Factor = $\frac{12}{11}$ = 1.1

Tailing factor for benzidine < 2.0

Tailing factor for pentachlorophenol <2.0

TABLE 5

CHARACTERISTIC IONS FOR SEMIVOLATILE COMPOUNDS

Compound	Primary Ion	Secondary Ion(s)
Acenaphthene	154	153, 152
Acenaphthylene	152	151, 153
Acetophenone	105	71, 51, 120

Specific Conductance and Salinity

Reference Methods.: **SM 2510 B, SM 2520B (Salinity),** Standard Methods for the Examination of Water and Wastewater. APHA-AWWA-WEF. Standard Methods Online.

EPA 120.1, Methods for Chemical Analysis of Water and Waste, EPA-600/4-79-020, U.S. Environmental Protection agency, 1982.

SW-846 9050A, SW-846, Test Methods for Evaluating Solid Waste: Physical/Chemical Methods, EPA SW-846, Update III, 1996.

1. Scope and Application

Matrices: This method is applicable to aqueous solutions. Soils samples can be analyzed using water based extractions for preparation prior to analysis. (Sec 2.1)

Definitions: See Alpha Quality Manual Appendix A

Conductance, G, is defined as the reciprocal of resistance, R:

$$G = 1 / R$$

Where the unit of R is ohm and G is ohm^{-1} (sometimes written mho). Conductance of a solution is measured between two spatially fixed and chemically inert electrodes. To avoid polarization at the electrode surfaces, the conductance measurement is made with an alternating current signal. The conductance of a solution, G, is directly proportional to the electrode surface area, A, cm^2, and inversely proportional to the distance between the electrodes, L, cm. The constant of proportionality, k, such that:

$$G = k (A / L)$$

is called “conductivity” (preferred to “specific conductance”). It is a characteristic property of the solution between the electrodes. The units of k are 1/ohm-cm or mho per centimeter. Conductivity is customarily reported in micromhos per centimeter (µmho/cm).

Distilled water produced in a laboratory generally has a conductivity in the range of 0.5 to 3µmhos/cm. The conductivity increases shortly after exposure to both air and the water container.

The conductivity of potable waters in the United States ranges generally from 50 to 1500µmhos/cm. The conductivity of domestic wastewaters may be near that of the local water supply, although some industrial wastes have conductivities above 10,000µmhos/cm. Conductivity instruments are used in pipeline, channels, flowing streams, and lakes and can be incorporated in multiple-parameter monitoring stations using recorders.

Laboratory conductivity measurements are used to:

- Establish the degree of mineralization to assess the effect of the total concentration of ions on chemical equilibria, physiological effect on plants or animals, corrosion rates, etc.
- Assess the degree of mineralization of distilled and deionized water.
- Evaluate variations in dissolved mineral concentration of raw water or wastewater. Minor seasonal variations found in reservoir waters contrast sharply with the daily fluctuations in some polluted river waters. Wastewater containing significant trade wastes also may show a considerable daily variation.
- Estimate sample size to be used for common chemical determinations and to check results of a chemical analysis.

- Determine amount of ionic reagent needed in certain precipitation and neutralization reactions, the end point being denoted by a change in slope of the curve resulting from plotting conductivity against buret readings.
- Estimate total dissolved solids (mg/L) in a sample, multiplying conductivity (in micromhos per centimeter) by an empirical factor. This factor may vary from 0.55 to 0.9, depending on the soluble components of the water and on the temperature of measurement. Relatively high factors may be required for saline or boiler waters, whereas lower factors may apply where considerable hydroxide or free acid is present. Even though sample evaporation results in the change of bicarbonate to carbonate, the empirical factor is derived for a comparatively constant water supply by dividing dissolved solids by conductivity.
- Approximate the milliequivalents per liter of either cations or anions in some waters by multiplying conductivity in units of micromhos per centimeter by 0.01.

Salinity is an important unit less property of industrial and natural waters. It was originally conceived as a measure of the mass of dissolved salts in a given mass of solution. The experimental determination of the salt content by drying and weighing presents some difficulties due to the loss of some components.

To determine salinity, one normally uses indirect methods involving the measurement of a physical property such as conductivity. From an empirical relationship of salinity and the physical property determined for a standard solution it is possible to calculate salinity. Because of its high sensitivity and ease of measurement, the conductivity method is most commonly used to determine salinity

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one of the following laboratory personnel before performing the modification: Area Supervisor, Laboratory Services Manager, Laboratory Director, or Quality Assurance Officer.

This method is restricted to use by or under the supervision of analysts experienced in the operation of the Conductivity Instrument and in the interpretation of data. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

2. Summary of Method

Conductivity is a measure of the ability of an aqueous solution to carry an electric current. This ability depends on the presence of ions; on their total concentration, mobility, and valence; and on the temperature of measurement. Solutions of most inorganic compounds are relatively good conductors. Conversely, molecules of organic compounds that do not dissociate in aqueous solution conduct a current very poorly, if at all.

The Corning Model 441 conductivity meter currently in use has had the traditional platonized conductivity cell replaced with sensors that operate on a 4-ring principle, where alternating voltage is applied to the 2 outer rings. This produces a current in the solution. The size of the current is determined by the quantity of ions in the solution.

2.1 Method Modifications from Reference

A Method Blank is not analyzed.

Analysis of soil samples is performed using water based extraction with ratio 1:10 soil to water.

3. Reporting Limits

The reporting limit is 10 µmho/cm for both aqueous and soil matrices. Salinity is reported in SU with RL of 2 SU

4. Interferences

4.1 Most problems in obtaining good data with conductivity-monitoring equipment are related to electrode fouling and to inadequate sample circulation.

4.2 Conductivities greater than 10,000 to 50,000µmho/cm or less than about 10µmho/cm may be difficult to measure with usual measurement electronics.

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material data handling sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

Samples are collected in either glass or plastic containers, preferably with no headspace.

6.2 Sample Preservation

None.

6.3 Sample Shipping

No special shipping requirements.

6.4 Sample Handling

Refrigerate at 4±2ºC and analyze within 24 hours of sample collection. If analysis cannot be completed within 24 hours of collection then the sample must be filtered through a 0.45micron filter and stored at 4±2ºC and analysis completed within 28 days of collection. The filter apparatus should be rinsed with DI followed by a pre-rinse with the sample before use.

7. Equipment and Supplies

7.1 Conductivity Meter: Corning Model 441, SN 001262. With auto temperature compensation from 0 – 40 °C or equivalent.

7.2 Conductivity Probe: Corning, PN 476501.

7.3 Analytical balances

7.4 Plastic cups: 150 ml

7.5 Graduated cylinder: 100 ml

8. Reagents and Standards

8.1 1413 µmhos / cm conductivity standard: Dissolve 744.7 mg of anhydrous KCl in Deionized Water and bring up to 1000mL in a volumetric flask. Alternately, Oakton, PN 00653-18, a commercially prepared standard may be used, with a certificate of analysis kept on file. Store at room temperature. Expires upon manufacturer's specified date.

8.2 84 µmhos / cm conductivity standard: Dissolve 40.38 mg of anhydrous KCl in Deionized Water and bring up to 1000mL in a volumetric flask. Alternately, Oakton, PN 00653-16, a commercially prepared standard may be used, with a certificate of analysis kept on file. Store at room temperature. Expires upon manufacturer's specified date.

8.3 Alternative conductivity standards: Standards with alternative concentrations (1500 umhos/cm, 10,049 umhos/cm , 996 umhos/com) may be used for CCV's . All standards are commercially prepared, a certificate of analysis kept on file. Standards are stored at room temperature. Expires upon manufacturer's specified date.

8.4 DI water

9. Quality Control

9.1 Blank(s)

Not applicable.

9.2 Laboratory Control Sample (LCS)

The calibration must be verified with a third party standard. When possible, choose a standard in the same range as the samples being analyzed. The LCS is analyzed at the beginning of a batch of 20 samples or less. % Recovery must be within ± 1% of the true value. If % recovery falls outside of acceptance criteria, the meter is re-calibrated and LCS is re-analyzed.

9.3 Initial Calibration Verification (ICV)

See LCS Section 9.2.

9.4 Continuing Calibration Verification (CCV)

The calibration must be verified with a third party standard. The CCV is analyzed at the end of a batch of 20 samples or less. % Recovery must be within ± 1% of the true value. If % recovery falls outside of acceptance criteria, the standard may be analyzed again. If failure continues, all samples analyzed since the last acceptable calibration verification must be reanalyzed.

9.5 Matrix Spike

Not applicable.

9.6 Laboratory Duplicate

Method 120.1: Analyze one duplicate sample per batch of 20 samples or less. Method 9050A: Analyze one duplicate sample per batch of 10 samples or less. % RPD must fall within acceptance criteria generated based on in-house performance data. If results fall outside of acceptance criteria, the data is evaluated and a narrative is included in the report.

9.7 Method-specific Quality Control Samples

Not applicable.

9.8 Method Sequence

- Calibrate conductivity sensor
- Analyze an appropriate conductivity standard, LCS
- Rinse conductivity cell with sample or DI
- Measure conductivity of samples and duplicate
- Analyze an appropriate conductivity standard, CCV

10. Procedure

10.1 Equipment Set-up

Press “On/Off” button to turn instrument on.

10.2 Initial Calibration

10.2.1 Daily Calibration of Conductivity Sensor

NOTE: The following procedure satisfies the requirement to determine the cell constant, as outlined in SM2510B.4.a and section 7.1 in 9050A

2 Point Calibration :

- Hold the sensor in air and press “CAL”.
- Place the tip of the sensor in the conductivity standard (either 84 or 1413 µmhos/cm) and press “CAL” .

  NOTE: For greater accuracy 1) calibrate using a standard close in value to the expected results of the samples and 2) have the standards at the reference temperature of 25 °C.
- The meter will automatically endpoint when the reading is stable.
- Rinse the sensor with deionized water.
- The analyst does not need to set the reference temperature.

10.3 Equipment Operation and Sample Processing

10.3.1 Rinse the conductivity cell with one or more portions of sample or DI water.

10.3.2 For soil samples: in plastic cup measure 10 g of homogenized soil material, add 100 ml of DI and stirring bar. Stir for 30 minutes, let set for 30 minutes, pour off 25 mL of extract and then proceed to section 10.3.3.

Note: Alternative weight may be used for soil preparation; in this case amount of DI water for extraction has to be adjusted to ensure 1:10 ratio for soil: H2O

For water samples pour off 25 mL of sample and proceed to section 10.3.3

10.3.3 Place the sensor in the sample and press “READ” to start the sample measurement. The decimal point will be flashing whenever the sensor is reading. The flashing will stop when the reading is stable and the instrument will “beep”. In the Laboratory notebook record the reading with the correct units as displayed on the instrument.

10.3.4 When measuring, make sure the solution is above the cell chamber slot.

10.3.5 Make sure the cell chamber is free of bubbles when measuring. To reduce air bubbles, immerse the sensor at an angle and then raise to the vertical position.

10.3.6 For greater accuracy, have the samples at the reference temperature of 25 °C.

10.4 Continuing Calibration

The calibration must be verified with a third party standard. The CCV is analyzed at the end of a batch of 20 samples or less. % Recovery must be within ± 20% of the true value. If % recovery falls outside of acceptance criteria, the standard may be analyzed again. If failure continues, all samples analyzed since the last acceptable calibration verification must be reanalyzed.

10.5 Preventative Maintenance

10.5.1 The conductivity meter is calibrated annually by an instrument service company. Certificates are kept on file.

10.5.2 Sensor maintenance:

10.5.2.1 To prevent static damage to the Model 441, avoid touching the cell chamber area of the sensor. ALWAYS disconnect the sensor from the Model 441 meter before cleaning.

10.5.2.2 Solids built up inside the cell chamber can be carefully removed with a cotton wool bud soaked in a detergent solution, then rinsing the sensor with DI water.

10.5.2.3 Do not use organic solvents to clean the sensor.

11. Data Evaluation, Calculations and Reporting

The temperature coefficient of most waters is approximately the same as that of the standard KCl solution. The more the temperature deviates from 25.0ºC, the greater the uncertainty in applying the temperature correction. Report all conductivities at 25 °C.

Results are reported directly from the Corning Model 441 instrument.

Conductivity results are used to calculate salinity using Practical Salinity Scale. This scale was developed relative to a KCl solution. A seawater with a conductivity, C, at 15°C equal to that of a KCl solution containing a mass of 32.4356 g in a mass of 1 kg of solution is defined as having a practical salinity of 35. This value was determined as an average of three independent laboratory studies. The salinity dependence of the conductivity ratio, Rt, as a function of temperature (t °C, International Practical Temperature Scale 1968) of a given sample to a standard S 35 seawater is used to determine the salinity.

$$S = a_0 + a_1 R_t^{1/2} + a_2 R_t + a_3 R_t^{3/2} + a_4 R_t^2 + a_5 R_t^{5/2} + \Delta S$$

where ΔS is given by

$$\Delta S = \left[\frac{t - 15}{1 + 0.0162\,(t - 15)}\right](b_0 + b_1 R_t^{1/2} + b_2 R_t + b_3 R_t^{3/2} + b_4 R_t^2 + b_5 R_t^{5/2})$$

and:

$a_0 = 0.0080$	$b_0 = 0.0005$
$a_1 = -0.1692$	$b_1 = -0.0056$
$a_2 = 25.3851$	$b_2 = -0.0066$
$a_3 = 14.0941$	$b_3 = -0.0375$
$a_4 = -7.0261$	$b_4 = 0.0636$
$a_5 = 2.7081$	$b_5 = -0.0144$

valid from $S = 2$ to 42, where:

$$R_t = \frac{C\,(\text{sample at } t)}{C\,(\text{KCl solution at } t)}$$

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

Holding time exceedence and improper preservation are noted on the nonconformance report form.

Perform routine preventative maintenance following manufacturer's specification. Record all maintenance in the instrument logbook.

Review of standards, blanks and standard response for acceptable performance occurs for each batch of samples. Record any trends or unusual performance on a nonconformance action form.

If the LCS recovery of any parameter falls outside the designated acceptance range, the laboratory performance for that parameter is judged to be out of control, and the problem must be immediately identified and corrected. Analysis must be repeated. If duplicate results fall outside of acceptance criteria, the data is evaluated and a narrative is included in the report.

13. Method Performance

13.1 Method Detection Limit Study (MDL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the MDL, LOD, and/or LOQ as outlined in Alpha SOP/1732. These studies performed by the laboratory are maintained on file for review.

13.2 Demonstration of Capability Studies

Refer to Alpha SOP 1739 for further information regarding IDC/DOC Generation.

13.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

14. Pollution Prevention and Waste Management

Refer to Alpha's Chemical Hygiene Plan and Waste Management and Disposal SOP for further pollution prevention and waste management information.

15. Referenced Documents

Sulfate, Turbidimetric Method

Method References: **SM 4500SO_4-E,** Standard Methods for the Examination of Water and Wastewater. APHA-AWWA-WEF. Standard Methods Online.

EPA 9038, SW-846, Test Methods for Evaluating Solid Waste: Physical/Chemical Methods, EPA SW-846, Update III, 1997.

HACH Water Analysis Handbook, Sulfa Ver 4 Method: Copyright 1989

1. Scope and Application

Matrices: This method is applicable to water and wastewater samples. The samples should be free of sediment and color. However, small amounts of color and/or sediment may be corrected for, see interference section.

Definitions: See Alpha Laboratories Quality Manual Appendix A.

Sulfate is widely distributed in nature and may be present in natural waters in concentrations ranging from a few to several thousand milligrams per liter. Mine drainage wastes may contribute large amounts of sulfate through pyrite oxidation. Sodium and magnesium sulfate exert a cathartic action.

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one or more of the following laboratory personnel before performing the modification: Area Supervisor, Department Supervisor, Laboratory Director, or Quality Assurance Officer.

This method is restricted to use by or under the supervision of trained analysts. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

2. Summary of Method

25mL of sample is mixed with 1 Sulfa Ver 4 Reagent powder pillow or ampule to react with sulfate in the sample. The sample absorbance is read on a Spectrophotometer at 420nm and calculated against a daily-made calibration curve.

2.1 Method Modifications from Reference

A HACH sulfa Ver 4 powder pillow is added to each sample in place of the individual reagents. Development time: at least 5 minutes.

Lab uses a 4 point calibration curve.

Lab is analyzing CCV and CCB after every 10 samples.

3. Reporting Limits

The reported detection limit for Sulfate is 10mg SO_4 /L for liquids, and 100mg/Kg for soils.

4. Interferences

4.1 Color or suspended matter in large amounts will interfere. Some suspended matter may be removed by filtration (Section 9.2.1). If both are small in comparison with the sulfate ion concentration, correct for interference as indicated in the procedure (Section 9.2.1). Silica in

excess of 500mg/L will interfere, and in waters containing large quantities of organic material it may not be possible to precipitate $BaSO_4$ satisfactorily.

4.2 Sulfite may be oxidized to sulfate during analysis to give a positive error.

4.3 Sample temperature control is important for reproducibility of results. Prepare calibration curve and analyze samples adjusted to room temperature. Variations over 10 °C will cause appreciable error.

4.4 In the presence of organic matter certain bacteria may reduce sulfate to sulfide. To avoid this, store all samples at low temperatures up to a maximum holding time of 28 days

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material safety data sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

Samples are collected in plastic bottles.

6.2 Sample Preservation

None.

6.3 Sample Shipping

NA

6.4 Sample Handling

Samples are stored at 4 ± 2 °C. Analyze within 28 days of collection. Bring samples to room temperature prior to analysis

7. Equipment and Supplies

7.1 Centrifuge tubes: 50mL plastic, with covers.

7.2 Spectrophotometer: For use at 420nm, with 2.5cm absorption cell.

7.3 Digital clock.

7.4 Glass fiber filters: Any size.

7.5 Membrane Filters, 0.45 μm.

7.6 Syringes

7.7 Pipets: Volumetric, various sizes.

7.8 Plastic Cups

7.9 Stirring Plate

7.10 Magnets of the same shape/size (for universal mixing)

8. Reagents and Standards

8.1 1000ppm Calibration Stock Sulfate Solution: Commercially prepared standard. A certificate of analysis is kept on file. Store at room temperature. Expires upon manufacturer's specified date.

8.1.1 Calibration Standards

Calibration standards are stored at room temperature and expire upon the manufacturer's specified date of the Stock Solution.

8.1.1.1 10ppm Calibration Standard: To a 50mL volumetric flask, add 0.5mL of the 1000ppm Stock Sulfate Solution (Section **8.1**). Bring to volume with Reagent water.

8.1.1.2 20ppm Calibration Standard: To a 50mL volumetric flask, add 1mL of the 1000ppm Stock Sulfate Solution (Section **8.1**). Bring to volume with Reagent water.

8.1.1.3 40ppm Calibration Standard: To a 50mL volumetric flask, add 2mL of the 1000ppm Stock Sulfate Solution (Section **8.1**). Bring to volume with Reagent water.

8.2 1000ppm ICV/LCS Stock Sulfate Solution: Commercially prepared standard. A certificate of analysis is kept on file. This solution is purchased as a third party standard; it is not a dilution of Section **8.1**. Store at room temperature. Expires upon manufacturer's specified date.

8.2.1 20ppm ICV/LCS Standard: To a 25mL volumetric flask, add 0.5 mL of the 1000ppm Stock Sulfate Solution (Section **8.2**). Bring to volume with Reagent water.

8.3 Sulfa Ver 4 Sulfate Reagent: HACH brand powder pillows, for a 25mL sample size. Store at room temperature. Expires upon manufacturer's specified date. Alternatively, Hanna Sulfate Reagent packets can be used (Part # HI93751-03).

8.4 Ottawa sand

8.5 Boiling Chips.

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

9.1 Blank(s)

Analyze one Blank consisting of 25 ml DI plus a Sulfa Ver4 powder pillow per batch of 20 samples or less.

For soils: weigh 5g of sand; add 50 ml of DI, stir for 30 min then let sit for 1h. Filter water portion for analysis.

The results of the Blank must be below the reporting limit. If acceptance criteria are not met, the entire batch is re-prepared and reanalyzed.

9.2 Initial Calibration Verification (ICV)

Analyze one ICV (Section **8.2.1**) at the beginning of analytical run. % Recovery must be within +/- 10% of true value. If the ICV fails this criterion, the ICV is remade and reanalyzed. If failure continues, a new calibration curve is generated.

9.3 Laboratory Control Sample (LCS)

Analyze one LCS (the same as ICV; Section **8.2.1**) per batch of 20 samples or less. % Recovery must be within +/-10% of true value. If the LCS fails this criterion, the LCS is remade and reanalyzed. If failure continues, a new calibration curve is generated.

For soils: weigh 5g of sand; add 49 ml of DI and 1.0 ml of 1000 ppm ICV/LCS stock (Section **8.2**), stir for 30 min then let sit for 1h. Filter water portion for analysis.

9.4 Continuing Calibration Verification (CCV)

Analyze one CCV (20 ppm calibration standard **8.1.1.2**) after every 10th sample and at the end of the batch to verify the calibration curve. % Recovery must be within +/- 10% of true value. If the CCV fails this criterion, the CCV is remade and reanalyzed. If failure continues, a new calibration curve is generated, and all samples analyzed since the last acceptable CCV are re-prepared and reanalyzed.

9.5 Matrix Spike

Analyze one Spike per batch of **20** samples or less for method **4500** and one Spike for every **10** samples for method **9038**.

For spiked sample: in centrifuge tube transfer 20 ml of sample, add 0.5 ml of 1000 ppm Calibration Stock (Section **8.1**), bring up to 25 ml with sample.

For soils: weigh 5g of sample; add 49 ml of DI and 1.0 ml of 1000 ppm ICV/LCS stock (Section **8.1**), stir for 30 min then let sit for 1h. Filter water portion for analysis.

% Recovery must be within in-house control chart limits. If acceptance criteria are not met, a narrative is included with the data for inclusion on the Client report.

9.6 Laboratory Duplicate

Analyze one sample in duplicate per batch of **20** samples or less for method **4500** and one Duplicate for every **10** sample for method **9038**. % RPD must be within in-house control chart limits. If acceptance criteria are not met, a narrative is included with the data for inclusion on the Client report.

9.7 Method-specific Quality Control Samples

NA

9.8 Method Sequence

1) Generate Calibration Curve, ICV/LCS and ICB.
2) Measure sample background absorbance.
3) Filter samples if necessary and dilute if necessary.
4) Measure 25mL of sample or QC sample into a centrifuge tube.
5) Add one Sulfa Ver 4 Sulfate Reagent powder pillow to each centrifuge tube and mix.
6) Wait 5 minutes.
7) Measure the sample absorbance at 420nm in 2.5cm cell.
8) If absorbance is above curve, dilute the original sample and return to .2.
9) Subtract the background absorbance from the sample absorbance.
10) Calculate final results.

10. Procedure

10.1 Equipment Set-up

10.1.1 Calibration Curve Generation

A calibration curve is prepared fresh on each day of analysis. The curve is generated using the three calibration standards from Section **8.1.1**, and Reagent water blank.

Analyze these standards and the blank according to Section **10.3.5**.

Plot the absorbance values of the standards versus the corresponding sulfate concentrations. The correlation coefficient must be $\geq$ 0.995 before analysis of samples may begin.

All calibration points are back calculated (on excel form) and should be within 10% from true concentration, except lowest point of calibration curve. %recoveries for low range will be wider, but shouldn't exceed 100% and correlation coefficient will not be worse then 0.995.

10.2 Initial Calibration

The calibration curve must be initially verified using a 20ppm LCS Solution as prepared in Section **10.3.4.1** and analyzed per Section **10.3.5**

% Recovery must be within +/- 10% of true value. If acceptance criteria are not met, a new LCS is prepared and analyzed. If failure continues, a new calibration curve is prepared.

10.3 Equipment Operation and Sample Processing

10.3.1 Sample Preparation

Samples that contain heavy suspended material are filtered prior to analysis through a glass fiber filter. If substantial turbidity or color remains, the sample may be filtered again through a 0.45μm filter. Otherwise, if samples are slightly turbid or are colored, the background absorbance is determined as in Section **10.3.3**, following the Spectrophotometer Preparation in Section **10.3.2**.

For soil samples: Weigh 5g of sample in a plastic cup; add 50mL of DI. Stir for 30 minutes, then let sit for one hour (sample may be left overnight). Filter the water portion through a 0.45um filter and then analyze below as a water sample. Samples with a high background color may need additional dilution.

10.3.2 Spectrophotometer Preparation The spec is set to zero absorbance using only DI in a 2.5cm cell at a wavelength of 420 nm.

10.3.3 Sample Background Absorbance:

Determine the background absorbance of each sample by measuring an aliquot of the sample into the 2.5cm absorption cell and recording the sample absorbance at 420nm in the laboratory notebook.

If the sample background absorbance is > 0.2 , filter sample. Record filtration information on excel Sheet.

If the background is still too high following filtration, the filtrate may be diluted with Reagent Water.

10.3.4 QC Preparation

Refer to Section 10 for QC sample frequency.

10.3.4.1 20ppm LCS / CCV: Into a centrifuge tube, pipette 0.5ml of 1000ppm LCS Stock Sulfate Solution (sect **8.2**) and bring up to 25 ml with DI.

For Soil LCS (200mg/Kg): Weigh 5g of sand; add 1mL of 1000ppm LCS Stock Sulfate Solution and 49 ml of DI in a plastic cup. Stir and filter. Analyze as a liquid LCS.

10.3.4.2 20ppm Spike: Choose a sample in the batch to spike. Add 25mL of this sample to a centrifuge tube; add 0.5mL of the 1000ppm Calibration Stock Sulfate Solution (Section **8.1**).

200mg/Kg soil spike: Weigh 5g of sample; add 1mL of 1000ppm Spike stock Sulfate Solution and 49mL of DI in a plastic cup. Stir and filter. Analyze as a liquid.

10.3.5 Sample Analysis

Measure 25mL of prepared analytical samples and QC samples into a centrifuge tubes. Add one Sulfa Ver 4 Reagent powder pillow (Section **8.3**) to each centrifuge tube, cap and shake until reagent is dissolved. Wait 5 minutes.

Determine each sample absorbance by measuring an aliquot of the mixed sample into the 2.5cm absorption cell and recording the sample absorbance in the laboratory notebook.

If the sample absorbance is greater than the absorbance of the highest calibration standard, the original sample must be diluted with Reagent water, and a new background absorbance determined. Return to Sections **10.3.3** and then **10.3.5**

10.3.6 Correction for sample color and turbidity

Subtract the sample background absorbance determined in Section **10.3.3**, from the corresponding sample absorbance determined in Section **10.3.5**. This result is the net absorbance value, which is used for calculation in Section **11**.

10.4 Continuing Calibration

The calibration curve must be verified using a 20ppm CCV Solution as prepared in Section **8.1.1.2** and analyzed per Section **10.3.5**

% Recovery must be within +/- 10% of true value.. If acceptance criteria are not met, a new CCV is prepared and analyzed. If failure continues, a new calibration curve is prepared and all samples analyzed since the last acceptable CCV are re-prepared and reanalyzed against the new curve.

10.5 Preventive Maintenance

An instrument service company calibrates the Spectrophotometers on a semi-annual basis. Certificates are kept on file.

11. Data Evaluation, Calculations and Reporting

$$\text{Sulfate as mg } SO_4 \text{ / L} = \frac{\text{Net Absorbance - Y-intercept}}{\text{Slope}} \times \text{dilution factor}$$

To calculate soils:

To calculate result in mg/kg on received basis, multiply result in mgSO4/L on Extraction (Final) volume (ml) and divide on sample weight (g)

mgSO4/kg = mgSO4/L x Extraction volume (ml) / weight (g)

To calculate final result for soil samples based on dry weight, multiply final result on 100 and divide on %TS (in %)

SO4 mg/kg (dry weight) = SO4 mg/kg x 100 / TS (%)

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

Holding time exceedence and improper preservation are noted on the nonconformance report form.

Perform routine preventative maintenance following manufacturer's specification. Record all maintenance in the instrument logbook.

Review of LCSs, blanks and spike response for acceptable performance occurs for each batch of samples. Record any trends or unusual performance on a nonconformance action form.

If the LCS recovery falls outside the designated acceptance range, the laboratory is judged to be out of control, and the problem must be immediately identified and corrected. The analytical result in the unspiked samples is suspect and is only reported for regulatory compliance purposes with the appropriate nonconformance action form. Immediate corrective action includes reanalyzing all affected samples by using any retained sample before the expiration of the holding time.

13. Method Performance

13.1 Detection Limit Study (DL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the DL, LOD, and/or LOQ as outlined in Alpha SOP ID 1732. These studies performed by the laboratory are maintained on file for review.

The quarterly method reporting limit (MRL) verification requirement is satisfied by the quarterly LOQ analysis, as per SOP/1732.

13.2 Demonstration of Capability Studies

Refer to Alpha SOP ID 1739 for further information regarding IDC/DOC Generation.

13.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

14. Pollution Prevention and Waste Management

Refer to Alpha's Chemical Hygiene Plan and Waste Management and Disposal SOP for further pollution prevention and waste management information.

15. Referenced Documents

Tannin & Lignin

References: **HACH Method 8193,** adapted from Journal American Water Works Association, vol.66 #1, p. 44, (1974).

SM 5550B, Standard Methods for the Examination of Water and Wastewater. APHA-AWWA-WEF. Standard Methods Online.

1. Scope and Application

Matrices: Drinking waters, wastewaters, boiler/cooling waters

Definitions: Refer to Alpha Analytical Labs Quality Manual.

Lignin is a plant constituent that often is discharged as a waste during the manufacture of paper pulp. Another plant constituent, tannin, may enter the water supply through the process of vegetable matter degradation or through the wastes of the tanning industry. Tannin also is applied in the so-called treatment of boiler waters, where it reduces scale formation by causing the production of a more easily handled sludge.

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one or more of the following laboratory personnel before performing the modification: Area Supervisor, Department Supervisor, Laboratory Director, or Quality Assurance Officer.

This method is restricted to use by or under the supervision of analysts experienced in the operation of the spectrophotometer and in the interpretation of spectrophotometric data. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

2. Summary of Method

This method measures all hydroxylated aromatic compounds, including tannin, lignin, phenol and cresol. Analytically these compounds are reported as Tannic Acid. Upon adding the coloring reagents, a blue color is produced which is proportional to the amount of above compounds present in the sample.

2.1 Method Modifications from Reference

The following reagents from the Hach Method 8193 are used in place of reagents described in Standard Method 5550B: 0.5 mL of Hach Tanni Ver 3 Tannin-Lignin reagent instead of 1 mL of Folin Phenol reagent and 5 mL Sodium Carbonate solution instead of 10 mL Carbonate-Tartrate reagent. Method 5550B allows using commercially prepared reagent (see sec 3.a of the method).
25min time period is used for color development (instead of 30 min).

3. Reporting Limits

The reporting limit is 0.2mg/L Tannic Acid.

4. Interferences

Any substances able to reduce Folin phenol reagent will produce a false positive response.

Organic chemicals known to interfere include hydroxylated aromatic, proteins, humic substances, nucleic acid bases, fructose and amines.

Inorganic substances known to interfere include iron II, manganese II, nitrite, cyanide, bi sulfite, sulfite, sulfide, hydrazine, and hydroxylamine hydrochloride.

Both 2 mg ferrous iron/L and 125mg sodium sulfite/L individually produce a color equivalent to 1 mg tannic acid.

Sulfide interference is eliminated by adding 1 mL of formaldehyde to the 25 mL sample size before testing.

To eliminate ferrous iron interference of up to 20mg/L, add 0.2g of sodium pyrophosphate to the sample before testing.

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound must be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material data handling sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection: Collect samples in clean plastic or glass containers.

6.2 Sample Preservation: None.

6.3 Sample Shipping: None.

6.4 Sample Handling: Store samples at 4 degrees (C) . Bring up to 20 ± 2 ° C just prior to testing. No hold time restrictions.

7. Equipment and Supplies

7.1 Genesys 10 Vis Spectrophotometer or equivalent : Capable of reading at 700nm using a 2.5cm cell.

7.2 Centrifuge

7.3 Centrifuge tubes: 50 mL

7.4 Pipets: Class A; sizes 0.5mL, 1.0ml, 2.0 mL, 5.0 mL 6.0 mL, 8.0 mL

7.5 Volumetric Flasks: Class A; sizes 25mL, 50mL and 1000 mL, with ground glass stoppers.

8. Reagents and Standards

8.1 Sodium carbonate solution: HACH Cat. # 675-49

8.2 TanniVer3 Tannin-Lignin Reagent: HACH Catalog # 2560-42; store at room temperature, use vendor's expiration date.

8.3 Tannic Acid: Fisher Cat. # A310, HACH Catalog # 791-14 or equivalent; store at room temperature no expiration date. Keep tightly sealed. (NOTE: Two different sources of Tannic Acid are required, one for preparation of Calibration Standards and Spike (Section 8.7), and the other for preparation of the LCS (Section 8.8).)

8.4 Formaldehyde solution: HACH Catalog # 2059-32. Store at room temperature, expires 6 months from date opened. Used to remove possible Sulfite interference.

8.5 Sodium pyrophosphate: HACH Catalog # 1429525. Store at room temperature. No expiration date. Keep tightly sealed.

8.6 De-ionized Water (DI)

8.7 1000ppm Tannic Acid Stock Calibration Standard and Stock Spiking Standard: To a 1000mL volumetric flask, add 500mL of DI and dissolve 1.0 g of Tannic Acid (Section 8.3). Bring to volume with DI. Prepare every 6 months. Store at room temperature.

8.7.1 40ppm Working Standard : Pipet 2 mL of 1000ppm Tannic Acid Stock Calibration Standard (Section 8.7) into a 50 mL volumetric flask. Bring to volume with DI. Prepare fresh daily. Store at room temperature.

8.7.2 Calibration Standards: Prepare these standards fresh whenever it is necessary to generate a new calibration curve.

8.7.2.1 0.1ppm Calibration Standard: Into a 200mL volumetric flask add 0.5mL of 40ppm Working Standard (Section 8.7.1). Bring to volume with DI water.

8.7.2.2 0.2 ppm Calibration Standard: Into a 200mL volumetric flask add 1.0mL of 40ppm Working Standard (Section 8.7.1). Bring to volume with DI water

8.7.2.3 0.8ppm Calibration Standard: Into a 50mL volumetric flask add 1.0mL 40ppm Working Standard (Section 8.7.1). Bring to volume with DI water.

8.7.2.4 1.6ppm Calibration Standard: Into a 50mL volumetric flask add 2.0mL 40ppm Working Standard (Section 8.7.1). Bring to volume with DI water.

8.7.2.5 4.0ppm Calibration Standard: Into a 50mL volumetric flask add 5.0mL 40ppm Working Standard (Section 8.7.1). Bring to volume with DI water.

8.7.2.6 6.4ppm Calibration Standard: Into a 50mL volumetric flask add 8.0mL 40ppm Working Standard (Section 8.7.1). Bring to volume with DI water.

8.8 1000ppm Tannic Acid Stock LCS: (NOTE: Use an alternate source of Tannic acid than that used in Section 8.7.) To a 1000mL volumetric flask, add 500mL of DI and dissolve 1.0 g of Tannic Acid (Section 8.3). Bring to volume with DI. Prepare every 6 months. Store at room temperature.

8.8.1 40ppm Working LCS / Spiking Standard: Pipet 2 mL of 1000ppm Tannic Acid Stock LCS Standard (Section 8.8) into a 50 mL volumetric flask. Bring to volume with DI. Prepare daily before each use. Store at room temperature.

8.8.1.1 1.6 ppm LCS: Pipet 1 mL of the 40ppm working LCS standard (Section 8.8.1) into a 25 mL volumetric flask and bring up to volume with DI. The 25mL aliquot of this solution is used for the LCS sample. Prepare the LCS on a daily basis or whenever the analysis is performed.

8.8.1.2 Spiking solution: To a 25 mL sample aliquot, pipet 1.0 mL of the 40ppm Working LCS Standard (Section 8.8.1).

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

9.1 Blank: The Blank QC sample consists of a 25mL aliquot of DI water. Analyze one Blank sample at the beginning of each batch of 20 or less samples. Blank sample results must be less than the Reporting Limit (RL). If results are greater than the RL, another aliquot is re-poured and re-analyzed. If results continue to be greater than the RL, the entire sample batch must be re-processed.

9.2 Laboratory Control Sample (LCS): Following the Blank, analyze one LCS (Section 8.8.1.1) at the beginning of each batch of 20 samples or less. % Recovery must be within 80-120% before continuing sample analysis. If the LCS recovery is outside of the control limits, then a new LCS sample aliquot is re-poured and re-analyzed. If the LCS failure continues, a new LCS solution is prepared (Section 8.8.1.1) and re-analyzed. If failure continues, a new calibration curve must be prepared and analyzed (Section 10.2).

9.3 Initial Calibration Verification (ICV): Refer to LCS (Section 9.2).

9.4 Continuing Calibration Verification (CCV): The LCS (Section 9.2) is utilized for the CCV in this analysis. A CCV and Continuing Calibration Blank (Section 9.1) QC sample pair are read on the spectrophotometer following every 10 samples and also at end of the sample batch. % Recovery for the CCV must be within 80-120%. If the CCV recovery is outside of the control limits, then a new CCV sample aliquot is re-poured and re-analyzed. If the CCV failure continues, a new CCV solution is prepared (Section 8.8.1.1) and re-analyzed. If failure continues, a new calibration curve must be prepared and analyzed (Section 10.2). All samples analyzed since the last acceptable CCV must be reanalyzed.

The Continuing Calibration Blank (CCB) results must be less than the Reporting Limit (RL). If results are greater than the RL, the CCB is re-poured and re-analyzed. If failure continues, the problem must be found and corrected, and all samples analyzed since the last acceptable CCB must be reanalyzed.

9.5 Matrix Spike: Analyze one Matrix Spike sample per batch of 20 samples or less. (Section 8.8.1.2.) % Recovery must be within 75-125%. If recovery is outside the acceptance criteria, the results must be narrated for inclusion on the Client report.

9.6 Laboratory Duplicate: Analyze one sample in Duplicate per batch of 20 samples or less. The RPD must be $\leq$ 25%. If the RPD is outside the acceptance criteria, the results must be narrated for inclusion on the Client report.

9.7 Method-specific Quality Control Samples: None.

9.8 Method Sequence

- Blank
- LCS/ICV
- 10 samples/QC samples
- CCV/CCB
- 10 samples
- CCV/CCB

10. Procedure.

10.1 Equipment Set-up: Turn on the spectrophotometer to warm up the instrument. Set the wavelength at 700nm.

10.2 Initial Calibration:

10.2.1 Prepare calibration standards per Section 8.7.

10.2.2 Pour 25mL of each standard and a DI blank into new centrifuge tubes. Add coloring reagents as described in Sections 10.3.2 – 10.3.4, and wait 25 minutes.

10.2.3 Using the 2.5cm cell, zero the Spectrophotometer at 700nm with an aliquot of the colored Blank sample.

10.2.4 Read each standard using the 2.5cm cell at 700nm. Record the absorbance values in the Laboratory notebook.

10.2.5 Plot the absorbance values of the standards versus the corresponding concentrations.

Correlation coefficient will be calculated. All calibration points are back calculated on excel and should be within 10% from true concentration, except lowest point of calibration curve. %recoveries for low range will be wider, but shouldn't exceed 50% and correlation coefficient must be > or = 0.995. If calibration curve criteria failed, then new calibration standards have to be re-analyzed and new calibration curve has to be generated and all calibration points have to be recalculated to meet criteria. If second calibration curve fails acceptance criteria, then analysis have to stopped, problem has to be identified; new calibration standards made and analyzed. The calibration curve is valid for a maximum of 1 year, unless the LCS % Recovery falls outside of the acceptance criteria of 80%-120% (Section 9.2).

10.3 Equipment Operation and Sample Processing:

10.3.1 Pour 25 mL of each well-homogenized sample and QC sample into a labeled centrifuge tube. Make sure that sample is brought up to 20 ± 2 ° C (see sec. 6.4)

10.3.2 Add 1 mL of Formaldehyde Solution (Section 8.4) to each centrifuge tube. Swirl to mix. Formaldehyde solution is added to remove potential Sulfite interference.

10.3.3 Add one 0.2g scoop of Sodium Pyrophosphate (Section 8.5) to each centrifuge tube and swirl until crystals dissolve.

10.3.4 Add 0.5mL of TanniVer3 Reagent (Section 8.2) and 5.0mL of Sodium Carbonate solution (Section 8.1) to each centrifuge tube. Swirl to mix.

10.3.5 Wait 25 minutes for full color development.

NOTE: If the colored sample is cloudy or turbid, cap the tube and centrifuge prior to proceeding.

10.3.6 Using the 2.5cm cell, zero the Spectrophotometer at 700nm with an aliquot of the colored Blank sample.

10.3.7 Read each sample and QC sample using the 2.5cm cell at 700nm. Record the absorbance values in the Laboratory notebook.

10.3.7.1 If a sample result is greater than the highest standard used for the calibration curve, prepare an appropriate dilution of the original sample using DI water. Proceed back to Section 10.3.1 to prepare and analyze the diluted sample.

10.4 Continuing Calibration:

Refer to Section 9.4. The continuing calibration standard and blank are processed as in Section 10.3.

10.5 Preventive Maintenance

Spectrophotometers are calibrated semiannually by an instrument service company. Certificates are kept on file.

11. Data Evaluation, Calculations and Reporting

All absorbance values obtained in Section 10.3 are recorded in the Tannin & Lignin Elecronic Laboratory notebook (ELN). Electronically prepare a record using the ELN by following the Alpha Work Instructions WI/11-01.

The ELN calculates the concentration of tannic acid in each sample and QC sample, using the following formula:

$$\text{mg Tannic Acid/L} = \frac{(\text{Absorbance}) - (\text{y-intercept})}{\text{Slope}} \times \text{Dilution factor}$$

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

Refer to Section 9 for Quality Control Criteria and processes.

13. Method Performance

13.1 Method Detection Limit Study (MDL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the MDL, LOD, and/or LOQ as outlined in Alpha SOP 1732. These studies performed by the laboratory are maintained on file for review.

13.2 Demonstration of Capability Studies

Refer to Alpha SOP 1734 and 1739 for further information regarding IDC/DOC Generation.

13.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method

14. Pollution Prevention and Waste Management

Samples and standards that have been prepared and analyzed must be disposed of in the Organic –Wet Chemistry waste stream.

Refer to Alpha's Chemical Hygiene Plan and SOP 1728 Waste Management and Disposal for further pollution prevention and waste management information.

15. Referenced Documents

TCLP Extraction

Metals and Semi-Volatile Organics

Reference Method: **EPA 1311**

Reference: **SW-846**, Test Methods for Evaluating Solid Waste, Physical/Chemical Methods, Update I, July 1992

State of Connecticut, DEP, TCLP by SW-846 Method 1311, Version 2.0, December 2006

1. Scope and Application

The TCLP is designed to determine the mobility of both organic and inorganic analytes present in liquid, solid, and multiphasic wastes.

Definitions: See Alpha Laboratories Quality Manual Appendix A.

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one of the following laboratory personnel before performing the modification: Area Supervisor, Extractions Manager, Laboratory Services Manager, Laboratory Director, or Quality Assurance Officer.

This method is restricted to use by or under the supervision of trained analysts. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

2. Summary of Method

For liquid wastes, (i.e., those containing less than 0.5% dry solid material), the waste, after filtration through a 0.6 to 0.8 μm glass fiber filter, is defined as the TCLP extract.

For wastes containing greater than or equal to 0.5% solids, the liquid, if any, is separated from the solid phase and stored for later analysis; the particle size of the solid phase is reduced, if necessary. The solid phase is extracted with an amount of extraction fluid equal to 20 times the weight of the solid phase. The extraction fluid employed is a function of the alkalinity of the solid phase of the waste. Following extraction, the liquid extract is separated from the solid phase by filtration through a 0.6 to 0.8 μm glass fiber filter.

If compatible (i.e., multiple phases will not form on combination), the initial liquid phase of the waste is added to the liquid extract, and these are analyzed together. If incompatible, the liquids are analyzed separately and the results are mathematically combined to yield a volume-weighted average concentration.

For additional detailed instruction, see TCLP and SPLP Work Instruction (ID# 17618).

2.1 Method Modifications from Reference

- 10.1.1.3.3 – Shaker table is used instead of stir bars. Samples not covered when shaking.
- 8.2 – 4N NaOH is used instead of 1N NaOH.

3. Reporting Limits

The Reported Detection Limit is determined by the amount of sample used for preparation. Therefore a review of Client requirements for Reporting Limits is necessary prior to sample preparation. Refer to analytical method SOPs.

4. Interferences

4.1 The most common cause of contamination is from improperly cleaned glassware and lab supplies. All glassware and re-useable extraction equipment must be scrupulously cleaned, following the Organic Extraction Glassware Cleaning and Handling SOP/1953 and Work Instruction 10995, Solvent rinsing guide.

4.2 Impurities in solvents and reagents may also yield artifacts and/or interferences that may compromise the results of sample analysis. All of these materials must be demonstrated to be free from interferences under the conditions of extract preparation and analysis by preparing method blanks with each extraction batch. The same solvents and reagents are used for the method blank and the associated samples.

4.3 Phthalate esters contaminate many types of products used in the laboratory. Plastic materials must not contact the samples or extracts, as phthalates could be easily leached from the plastic. The exception is in the use of various pre-packed reagent cartridges (Florisil, Silica gel) used in the extract cleanup steps. Each new lot of cartridges is checked for contamination, and is monitored on an on-going basis through the analysis of method blanks.

4.4 Additional specific interference or contamination concerns are addressed in the various analytical SOPs.

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material data handling sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents. This includes wearing personal protective equipment such as a labcoat, safety glasses, gloves and respirator (as necessary).

5.1 Lab coats, safety glasses, and gloves must be worn when handling samples, extracts, standards or solvents and when washing glassware.

5.2 All extract concentration steps must be performed in the extraction hoods. All solvent and extract transfers must also be handled in the hood.

5.3 All expired stock standards, working standards, and spent sample extracts must be placed into the waste bucket in the lab, for future disposal by the Hazardous Waste Manager. The container must be properly labeled with hazard warning labels indicating the container contents.

5.4 Bottles containing flammable solvents must be stored in the flammables cabinet or in the vented cabinets found under the hoods.

5.5 All waste solvents must be transferred to the satellite waste storage containers located in the extraction lab. Separate containers are provided for chlorinated and non-chlorinated solvents and must be used accordingly. Under no circumstances are solvents to be poured down the sink drains.

5.6 Inspect all glassware prior to use. Do not use any glassware that is chipped, cracked or etched if it could present a safety hazard. Damaged glassware is put aside for repair, otherwise discard the piece.

5.7 All Field Samples must be opened and handled in a hood.

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

Samples are collected in glass containers. Soils are collected in 8oz amber glass jars, and aqueous samples are collected in 500mL amber glass jars.

6.2 Sample Preservation

Preservatives are not added to samples before extraction.

6.3 Sample Shipping

No special shipping requirements.

6.4 Sample Handling

Samples may be refrigerated at 4 ± 2°C, unless refrigeration results in irreversible physical change to the waste. If precipitation occurs, the entire sample (including precipitate) should be extracted.

Samples must undergo TCLP extraction within the time periods listed in Table 1.

7. Equipment and Supplies

7.1 Agitation Apparatus: End-over-end 30 ± 2 rpm. Calibrated Quarterly.

7.2 Vacuum Filtration Unit

7.3 0.6 to 0.8 µm Glass Fiber Filter Paper: 70 mm, 90 mm, and 120 mm, and acid prewashed 47 mm for all metals analysis.

7.4 2 L Glass/Plastic-coated Bottles

7.5 7 L Plastic Extraction Vessel: For Lamp Extraction

7.6 pH Meter: +/- 0.01 units resolution

7.7 pH test paper: 0-14 pH range

7.8 Laboratory Balance: +/- 0.1 g tolerance

7.9 250 mL Beaker or equivalent

7.10 Watch Glass: Used with Beaker (Section 7.8)

7.11 Stir Bars

7.12 Hot Plate: 1x1 ft (120 V) Barnestead-Thermolyne – Type 2200

7.13 2 L Graduated Cylinder Class A

7.14 250 mL Graduated Cylinder Class A

7.15 Teflon coated Sieve: 9.5 mm (0.375-inch)

7.16 Oven: Capable of maintaining 100 ± 20°C

7.17 Automatic Shaker Table

7.18 Vessel to store fluid #1

7.19 Vessel to store fluid #2

7.20 Calibrated thermometer: Temperature calibration point 50°C. Range: 0-100°C.

7.21 Bottle Top Dispenser: 0-5 mL, 0-100 mL

7.22 1 L Amber Bottle: Thermo Scientific, Item # 341-0950, Jar Tall Amber WM.

7.23 120 mL Plastic Bottle: Greenwood, Product # 07-120WMF24503, Natural HDPE WM Packer assembled w/38-400 F-217 Lined Cap.

7.24 250 mL Plastic Bottle: Greenwood, Product # 07-250OB45F22603, Natural HDPE WM Oblong Bottle Assembled w/45-400 F-217 Lined Cap.

8. Reagents and Standards

8.1 Hydrochloric Acid: 1N: Dilute 83 mL conc. HCl to 1 liter with reagent water. Store at room temperature; expires one year from date of prep.

8.2 Sodium Hydroxide: 4N: Dissolve 160 grams NaOH in 1 liter of reagent water. If larger volumes are required, prepare using similar ratios. Store at room temperature; expires one year from date of prep.

8.3 Glacial acetic acid: CH_3COOH. Store at room temperature; expires according to manufacturer's specifications.

8.4 Reagent Water, (ASTM Type II): All references to water within this SOP refer to reagent water unless otherwise specified. Reagent water is interference-free.

8.5 Extraction Fluid #1: Add 5.7 mL glacial acetic acid to 500 mL of reagent water, add 64.3 mL of 4N NaOH, and dilute to a volume of 4 liters. Check the pH of the solution after preparation and record the value in the Extraction Fluid Logbook. The pH is within 4.93 $\pm$ 0.05 when correctly prepared. In addition, the pH of the fluid is verified prior to each use and the pH recorded in the extraction logbook. Store at room temperature; no expiration date, however the pH must be maintained.

NOTE: Larger volumes or extraction fluid may be prepared, provided the ratios remain the same. For example, a typical preparation of 200 L of Extraction Fluid #1:

1140 mL Glacial Acetic Acid + 3215 mL 4N NaOH diluted to 200 L with reagent water

8.6 Extraction Fluid #2: Dilute 5.7 mL glacial acetic with reagent water to a volume of 1 liter. Check pH of solution which should be 2.88 ± 0.05 when correctly prepared. Record the pH in the Extraction Fluid Logbook.

The pH is checked prior to use to ensure that this fluid is prepared accurately. If the pH is not within the above specifications, the fluid is discarded and fresh extraction fluid prepared. Store at room temperature; no expiration date, however the pH must be maintained.

NOTE: Larger volumes or extraction fluid may be prepared, provided the ratios remain the same. For example, a typical preparation of 20L or 50L Extraction Fluid #2:

19,886 mL of reagent water + 114 mL Glacial Acetic Acid = 20 L of fluid.

49,715 mL of reagent water + 285 mL Glacial Acetic Acid = 50 L of fluid

8.7 Trace Nitric Acid (1:1 HNO3): 500 mL HNO3 diluted to 1 liter with DI water. Store at room temperature in hood. Expires 3 months from prep.

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

9.1 Blank(s)

A minimum of **one blank** (using the same extraction fluid lot number as used for the samples) must be prepared and analyzed for every 20 extracts or every 48 hours, whichever comes first. The Blank vessel is a randomly selected container from the stock and is not one designated for blank use only.

9.2 Laboratory Control Sample (LCS)

Not applicable.

9.3 Initial Calibration Verification (ICV)

Not applicable.

9.4 Continuing Calibration Verification (CCV)

Not applicable.

9.5 Matrix Spike

Not applicable.

9.6 Laboratory Duplicate

Not applicable.

9.7 Method-specific Quality Control Samples

None.

9.8 Method Sequence

- Determine analysis to be performed (Metals, ABN, Pest, PCB, Herbicides)
- Check sample; ensure there is enough sample for the extraction
- Determine the %solids of the waste sample

- Determine particle size reduction requirement
- Determine the extraction fluid to be used
- Extract the sample for TCLP
- Filter the extract.
- Aliquot extract to proper preparation departments
- Prepare extracts according to analytical protocols

10. Procedure

10.1 Equipment Set-up

10.1.1 Preliminary Evaluation

Perform preliminary TCLP evaluations on a minimum of 100g aliquot of waste. If there is limited sample volume, the chemist must contact the project manager. This aliquot may not actually undergo TCLP extraction. These preliminary evaluations include:

(1) determination of the percent solids (Section 10.1.1.1);

(2) determination of whether the waste contains insignificant solids and is, therefore, its own extract after filtration (Section 10.1.1.1.2);

(3) determination of whether the solid portion of the waste requires particle size reduction (Section 10.1.1.2); and

(4) determination of which of the two extraction fluids are to be used for the nonvolatile TCLP extraction of the waste (Section 10.1.1.3)

10.1.1.1 Determine % Solids

10.1.1.1.1 If waste contains no free liquid, proceed to Section 10.1.1.2 where the waste is the solid portion. If the waste contains less than 0.5% solids, proceed to Section 10.1.1.1.2.

10.1.1.1.2 Mulitphasic waste - separate liquid and solid portion

10.1.1.1.2.1 Pre-weigh a filter. Pre-weigh a beaker or graduated cylinder that will hold the initial filtrate. Pre-weigh empty filtrate container. Record weights in the extraction logbook.

10.1.1.1.2.2 Assemble the vacuum filtration unit.

10.1.1.1.2.3 Weigh a subsample of the waste (100 g minimum), or pour 100 mL of the sample into a cylinder, and record the weight or volume in the extraction logbook.

10.1.1.1.2.4 Transfer the waste sample to the filter holder, spreading evenly over the filter.

10.1.1.1.2.5 Allow enough time for the liquid to pass through the filter (at least 15 minutes).

10.1.1.1.2.6 The material in the filter holder is defined as the SOLID PHASE of waste and the filtrate is defined as the LIQUID PHASE.

Note: The SOLID PHASE may appear liquid in some samples. Do Not replace original filter. Use only one filter.

10.1.1.1.2.7 Weigh the filtrate filled container and calculate the weight of the LIQUID PHASE as follows:

$$W_{LP} = W_F - W_C$$

Where:

W_{LP} = Weight of the LIQUID PHASE
W_F = Weight of the filtrate filled container
W_C = Weight of container

10.1.1.1.2.8 Calculate the weight of the SOLID PHASE using the following formula:

$$W_{SP} = W_W - W_{LP}$$

Where:

W_{SP} = Weight of the SOLID PHASE
W_W = Weight of the waste sample (Section 10.1.1.1.2.3)
W_{LP} = Weight of the LIQUID PHASE (Section 10.1.1.1.2.7)

10.1.1.1.2.9 Calculate the percent solids using the following formula:

$$\%\ Solids = \frac{Wsp}{Ww} \times 100$$

Where:

W_{SP} = Weight of the SOLID PHASE (Section 10.1.1.1.2.8)
W_W = Weight of the waste sample (Section 10.1.1.1.2.3)

10.1.1.1.2.10 If the % Solids determined above (section 10.1.1.1.2.9) is less than 0.5%, then the filtrate is the TCLP extract. Filter sample until enough filtrate is obtained for analysis and proceed to Section 10.3.1.3.6.

10.1.1.1.2.11 If the % Solids determined above in section is greater than or equal to 0.5%, all liquids entrained in the filter and waste must be removed to determine the % dry solids. Remove the solid phase and filter from the filtration apparatus. Heat at 100 ± 20° C in an oven (section 7.16) until two successive weights yield the same value within ±1%. Record weights in the extraction logbook.

10.1.1.1.2.12 Calculate the percent dry solids using the following formula:

$$\%\ Dry\ Solids = \frac{W_{DW} - W_F}{W_W} \times 100$$

Where:

W_{DW} = Weight of dried waste + filter (Section 10.1.1.1.2.11)
W_F = Weight of the filter (Section 10.1.1.1.2.1)
W_W = Weight of waste sample (Section 10.1.1.1.2.3)

10.1.1.1.2.13 If the % dry solids determined above (section 10.1.1.1.2.12), is less than 0.5%, then the filtrate is the TCLP extract. Filter sample until enough filtrate is obtained for analysis and proceed to Section 10.3.1.3.6.

10.1.1.1.2.14 If the % dry solids determined above is greater than or equal to 0.5%, the sample is multi-phasic. Determine the weight of the dry waste by subtracting the weight of the filter from the weight of the dry waste and filter as determined follows and record in extraction logbook:

Weight of dry solids= **W_{DW} . W_F**

Where:

W_{DW} = Weight of dried waste + filter (Section 10.1.1.1.2.11)
W_F = Weight of the filter (Section 10.1.1.1.2.1)

Proceed to Section 10.3.1.3. (**NOTE:** Do not dispose of dried waste + filter.)

10.1.1.2 Determine whether waste requires particle size reduction

Evaluate the solid phase of the waste sample (Section 10.1.1.1.2.6), to determine if particle size reduction is necessary. Particle size reduction is required unless the solid has a surface area greater than 3.1 cm^2 per gram or is smaller than 1 cm in its narrowest dimension (i.e.: will not pass through a 9.5 mm (0.375-inch) standard sieve).

If the surface area is smaller or the particle size is larger than described above, prepare the solid portion of the waste for extraction by crushing, cutting or grinding the waste to a surface area or particle size as described above.

NOTE: Surface area criteria is meant for filamentous (e.g. paper, cloth, etc.) waste materials. Actual measurement of surface area is not required, nor is it recommended. For materials that do not obviously meet the criteria, those samples should be reduced to meet the 1 cm dimension criteria.

10.1.1.3 Extraction Fluid Determination

10.1.1.3.1 Weigh out a 5 g subsample of the solid phase waste, if the sample is all solid. If the sample is multiphasic, weigh out a 5 g subsample of the solid waste from Section 10.1.1.1.2.6.

10.1.1.3.2 Transfer the 5 g aliquot to a 250 mL beaker (or equivalent) and add 96.5 mL of reagent water. (NOTE: Less weight and volume may be used, provided the ratio remains the same.)

10.1.1.3.3 Place beaker (or equivalent) in the automatic shaker (Section 7.17) for 5 minutes.

10.1.1.3.4 Measure using pH strip and record the pH in the extraction logbook.

10.1.1.3.5 If pH is less than 5.0, use extraction fluid #1, proceed to Section 10.3.

10.1.1.3.6 If pH is greater than 5.0, add 3.5 mL 1N HCl, slurry briefly, cover with a watch glass, heat to 50°C+/- 2°C on a hotplate and hold for 10 minutes.

Note: heating block load tests have shown heating times of up to 25 minutes prior to the sample reaching the specified temperature. The 10 minute hold begins only after the temperature is reached and monitored using a calibrated thermometer placed in a sample or one representative of the batch.

Cool solution to room temperature and record pH. If the pH is less than 5.0, use extraction fluid #1. Otherwise, use extraction fluid #2.

10.2 Initial Calibration

Not applicable.

10.3 Equipment Operation and Sample Processing

10.3.1 Extraction of SOLID PHASE

10.3.1.1 A 100 gram minimum aliquot of SOLID PHASE is extracted to produce the TCLP extract, as outlined below. In some cases, a larger sample size may be required in order to produce enough liquid for the required analysis. If the amount of extract generated by a single TCLP extraction will not be sufficient to perform all of the analysis, more than one extraction may be performed and the extracts combined for analysis. If there is limited sample volume, the chemist must contact the project manager.

10.3.1.2 100% Solid Waste

10.3.1.2.1 If the waste is 100% solid, homogenize the sample and weigh out an aliquot (100 gram minimum), follow Sections 10.4.1.2 (particle size reduction) and then proceed to 10.3.1.3.2 (extraction fluid amount).

10.3.1.3 Liquid or Multiphasic Waste

10.3.1.3.1 Quantitatively transfer the solid material, along with the filter (from Section 10.1.1.1.2.14), into a glass extractor bottle (plastic may be used if only metals are being analyzed).

Repeat sections 10.1.1.1.2 through .6 if additional final volume is needed for the intended analysis.

10.3.1.3.2 Determine the amount of extraction fluid to add to the extractor vessel as follows:

$$V_{EF} = \frac{20 \times \%\,Solid \times W_W}{100}$$

Where:

V_{EF} = Volume of extraction fluid required.
(Density = 0.998g/L, therefore assume volume is equivalent to weight.)
%Solid = Percent solid as determined in section 10.1.1.1.2.9
(100% if waste contains no free liquid as determined in section 10.1.1.1.1)
W_W = Weight of waste (Section 10.1.1.1.2.3)

10.3.1.3.3 Add the volume of the appropriate extraction fluid (determined in Section 10.1.1.3) to the extraction vessel. Glass amber 2.5 L for organics and metals, 2.5 L plastic if for metals only analysis. New (never used) 2.5 L HPDE plastic vessels for PFAS (Reference: PFAS by SPE and LC/MS/MS Isotope Dilution (ID#23528).

10.3.1.3.4 Close the extractor bottle tightly. Secure in rotary agitation device, and rotate at 30 ± 2 rpm for 18 ± 2 hours while maintaining room temperature at 23 ± 2° C. Record the agitation device (Tumbler) ID in the extraction logbook.

10.3.1.3.4.1 The room temperature (°C) and the extraction time are recorded in the extraction logbook at both the beginning and the end of extraction.

10.3.1.3.4.2 To verify that the proper room temperature is maintained during extraction, a Maximum/Minimum thermometer is reset at the beginning of the extraction period. This thermometer is reviewed at the end of the extraction period and the Maximum and Minimum temperatures are noted in the extraction logbook.

10.3.1.3.4.3 If proper room temperature is not maintained during the extraction period, it is considered a variation from the method and must be written into a laboratory narrative and submitted with the reported data. The Department Supervisor is immediately notified to determine the proper corrective action to be taken.

10.3.1.3.4.4 If determination is made that a MAX/MIN thermometer reading is outside of the acceptance range (21C-25C), it must be confirmed by comparison to the average temperature of the room during the extraction period recorded in the data logger records. Any MAX/MIN temperature reading that exceeds acceptance criteria must be reviewed by the department manager or team leader and QA.

10.3.1.3.5 Following extraction, vacuum filter the extract through glass fiber filters (acid precleaned for metals analysis). For this final filtration, the glass fiber filter may be changed to facilitate quicker filtration but should be kept to a minimum when practical. Use of pre-filters is prohibited for TCLP.

10.3.1.3.6 Prepare the TCLP extract as follows:

10.3.1.3.6.1 If the waste contained no initial liquid phase, the filtered extract obtained is defined as the TCLP extract. Proceed to 10.3.1.3.7.

10.3.1.3.6.2 If the waste contained a liquid phase, check its compatibility with the extraction fluid determined in Section 10.1.1.3. If the liquids are compatible (miscible), then the initial liquid phase (Section 10.1.1.1.2.6) and the filtered extract are combined and analyzed together.

10.3.1.3.6.3 If the initial liquid phase of the waste obtained in Section 10.1.1.1.2.6, is not compatible with the filtered extract, do not combine the liquids. Analyze these liquids, collectively defined as the TCLP extract, separately and mathematically combine the results, as described below. Determine the volume of the individual phases, conduct the appropriate analyses, and combine the results mathematically by using a simple volume-weighted average:

$$(\mathrm{mg/L}),\ \mathrm{Final\ Analyte\ Concentration} = \frac{(\mathbf{V_1})(\mathbf{C_1}) + (\mathbf{V_2})(\mathbf{C_2})}{\mathbf{V_1} + \mathbf{V_2}}$$

Where:

$\mathbf{V_1}$ = Volume of the first phase (L)
$\mathbf{C_1}$ = Analyte concentration first phase (mg/L)
$\mathbf{V_2}$ = Volume of the second phase (L)
$\mathbf{C_2}$ = Analyte concentration second phase(mg/L)

10.3.1.3.7 Record the pH of the TCLP extract in the extraction logbook prior to preservation of samples.

10.3.1.3.8 Metals analysis: transfer filtrate (or combined filtrates) to a 120 mL plastic bottle and add 2.5 mL of 1:1 HNO_3 preservative to all samples.

10.3.1.3.8.1 Check the pH of the preserved samples to ensure that the sample is properly preserved at a pH of less than 2.

10.3.1.3.9 Non-volatile Organics: transfer filtrate (or combined filtrates) to two 1 L glass amber bottles, adhere pre-made sample ID labels and transfer to extraction department refrigerators.

10.3.2 Extraction of Lamps

10.3.2.1 Lamps (for both TCLP extraction and 120x extraction) are broken down into small particles (See Section 10.1.1.2) and extracted using Extraction Fluid #1. The extraction procedure from Section 10.3.1.3.2 through 10.3.1.3.8 is followed with the exception that the entire lamp weight including endcaps is used. 7 L plastic extraction vessels are utilized for larger lamps that exceed 100 g total weight. The vessel size must be recorded in the logbook for lamp samples.

10.3.2.1.1 Check the sample comments for whether Mercuric Oxide (HgO) is required during the extraction. If so, make note in the logbook that the HgO packet was added to the extraction vessel prior to tumbling. Contact the project manager if HgO is requested but no packet is supplied.

10.3.2.2 The excess unfiltered extract is immediately decanted into the TCLP waste drum, making sure to leave behind in the extraction vessel the solid material that was extracted.

10.3.2.3 The remaining solid material is transferred to a plastic bag, labeled as TCLP Lamp Waste and brought to the Hazardous Waste department for proper disposal.

10.4 Continuing Calibration

Not Applicable.

10.5 Preventive Maintenance

None.

11. Data Evaluation, Calculations and Reporting

None.

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

12.1 All Holding time exceedences, improper preservation and Extraction Anomalies are to be reported to a Supervisor or Manager. Non Conformance Reports may need to be issues through the Qualtrax System.

12.2 Refer to determinative method SOPs for additional Corrective Action information.

13. Method Performance

13.1 Method Detection Limit Study (MDL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the MDL, LOD, and/or LOQ as outlined in Alpha SOP 1732 These studies performed by the laboratory are maintained on file for review.

13.2 Demonstration of Capability Studies

Refer to Alpha SOP 1739 for further information regarding IDC/DOC Generation.

TCLP/SPLP Extraction - Volatile Organics EPA 1311/1312

Reference: EPA 1311, EPA 1312 SW-846, Test Methods for Evaluating Solid Waste, Physical/Chemical Methods, Update I, July 1992.

1. Scope and Application

Matrices: The TCLP/SPLP extraction process is designed to determine the mobility of both organic and inorganic analytes present in liquid, solid, and multiphasic wastes.

Definitions: Refer to Alpha Analytical Quality Manual.

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one or more of the following laboratory personnel before performing the modification: Area Supervisor, Department Supervisor, Laboratory Director, or Quality Assurance Officer.

This method is restricted to use by or under the supervision of experienced analysts Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

2. Summary of Method

For liquid wastes, (i.e., those containing less than 0.5% dry solid material), the waste, after filtration through a 0.6 to 0.8 μm glass fiber filter, is defined as the TCLP/SPLP extract.

For wastes containing greater than or equal to 0.5% solids, the liquid, if any, is separated from the solid phase and stored for later analysis. The solid phase is extracted with an amount of extraction fluid equal to 20 times the weight of the solid phase. A special extractor vessel is used when testing for volatile analytes. Following extraction, the liquid extract is separated from the solid phase by filtration through a 0.6 to 0.8 μm glass fiber filter.

If compatible (i.e., multiple phases will not form on combination), the initial liquid phase of the waste is added to the liquid extract, and these are analyzed together. If incompatible, the liquids are analyzed separately, and the results are mathematically combined to yield a volume-weighted average concentration.

2.1 Method Modifications from Reference

None.

3. Reporting Limits

The analytical method detection limits determined by the laboratory are on file for review. See the 8260 SOP 32639.

4. Interferences

Potential interferences that may be encountered during analysis are discussed in the individual analytical methods.

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material safety data sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents. This includes wearing personal protective equipment such as a lab coat, safety glasses, gloves and respirator (as necessary).

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

When the waste is to be evaluated for volatile analytes, care shall be taken to minimize the loss of volatiles. Samples shall be collected and stored in a manner intended to prevent the loss of volatile analytes (e.g., samples are collected in Teflon-lined septum capped vials and stored at 4 ± 2° C). Samples are opened only immediately prior to extraction.

SPLP samples may be collected in 25g En Core sampling device.

6.2 Sample Preservation

Preservatives shall not be added to samples before extraction. For SPLP samples arriving in En Cores they must be extruded and tumbled within 48 hours of collection. Extrude the entire sample, but no more 25g since the vessel can only hold 500 mLs of fluid.

6.3 Sample Shipping

No specific requirements.

6.4 Sample Handling

Samples may be refrigerated unless refrigeration results in irreversible physical change to the waste. If precipitation occurs, the entire sample (including precipitate) must be extracted.

TCLP/SPLP extracts are prepared for analysis and analyzed as soon as possible following extraction. Extracts or portions of extracts for organic analyte determinations shall not be allowed to come into contact with the atmosphere (i.e., no headspace) to prevent losses.

Samples must undergo TCLP/SPLP extraction within the time periods listed in Table 1.

7. Equipment and Supplies

7.1 Agitation Apparatus: End-over-end 30 ± 2 rpm.

7.2 Zero Headspace Extraction Vessel

7.3 Glass Fiber Filters: 0.6 to 0.8µm, 90mm

7.4 50mL Gastight Syringe

7.5 Graduated Cylinder: 500 mL, 1L

7.6 Laboratory Balance: 0.01g tolerance

7.7 Pressure Gauge: 0-60 psi

7.8 Pressure Filtration Device

7.9 Drying Oven: 100 ± 2 °F

7.10 Fluid Metering Pump

7.11 pH Meter: The meter should be accurate to + 0.05 units at 25°C

8. Reagents and Standards

8.1 Analytical Standards: The standards shall be prepared according to the appropriate volatile organic analysis method 8260 SOP 32639.

8.2 Hydrochloric Acid (HCl), 1N: Dilute 83 mL conc. HCl to 1L with DI water.

8.3 Nitric Acid (HNO_3), 1N: Dilute 64 mL conc. HNO_3 to 1L with DI water.

8.4 Sodium Hydroxide (NaOH), 1N: Dissolve 40 gs NaOH in 1L of water.

8.5 Glacial acetic acid: CH_3COOH.

8.6 Ottawa sand: SiO_2

8.7 Extraction Fluid #1: Add 5.7 mL glacial acetic acid to 500 mL of DI water, add 64.3 mL of 1N NaOH, and dilute to a volume of 1L. Check pH of solution which must be 4.93 $\pm$ 0.05 when correctly prepared. The laboratory reagent number is referenced in the TCLP sample logbook.

NOTE: This extraction fluid is monitored frequently for impurities. The pH is checked prior to use to ensure that this fluid is prepared accurately. If impurities are found or the pH is not within the above specifications, the fluid shall be discarded and fresh extraction fluid prepared.

8.8 Extraction Fluid #2: Organic-free reagent water.

8.9 Methanol: Purge and Trap Grade or equivalent. Store in flammables cabinet.

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

9.1 Blank

A minimum of **one blank** must be analyzed for every batch or 20 extracts, whichever comes first. The blank is prepared by weighing 20g of Ottawa sand (SiO_2) and utilizing the same extraction fluid as used for the samples. The blank is then analyzed following the same procedures as analytical samples.

9.2 Laboratory Control Sample (LCS)

A laboratory control sample is not extracted. Refer to the 8260 procedure for the LCS information.

9.3 Initial Calibration Verification (ICV)

Not Applicable.

9.4 Continuing Calibration Verification (CCV)

Not Applicable.

9.5 Matrix Spike

Upon a client's request, a spike solution composed of all regulated compounds can be added to the TCLP/SPLP extract before analysis. See Method 8260 for more information.

9.6 Laboratory Duplicate

Not Applicable.

9.7 Method-specific Quality Control Samples

Not Applicable.

9.8 Temperature Measurement Guidelines

The ambient temperature of the tumbler rooms must be monitored from the beginning to the end of the TCLP, SPLP and ZHE extractions by use of a MIN/MAX thermometer to determine room temperature outages.

If a determination is made that a MAX/MIN thermometer reading is outside of the acceptance range (21C-25C), it must be confirmed by comparison to the average temperature of the room during the extraction period recorded in the datalogger records.

Any MAX/MIN temperature reading that exceeds acceptance criteria must be reviewed by the Department Manager or Team Leader and QA.

If a temperature exceedance is confirmed, the following narrative must be included on the Alpha job report.

Narrative # 2068

TCLP / SPLP TEMPERATURE EXCEEDANCE

[list] [qcsamplist]: The ambient temperature of the area in which the TCLP/SPLP/ZHE extraction was performed was outside the required 21-25 degrees C temperature range.

9.9 Method Sequence

The extraction sequence is:

- Disassemble ZHE; clean all parts with warm H_2O and soap; dry.
- Check sample; ensure there is enough sample for analysis.
- Determine %solids of the waste.
- Extract the TCLP/SPLP.
    - Record the temperature of the extraction room.
    - Following extraction, perform a leak test on the ZHE canisters.
- Draw sample with syringe from ZHE after extraction.
- Prepare sample for 8260 analysis

10. Procedure

10.1 Equipment Set-up

10.1.1 Preliminary Evaluation

10.1.1.1 Determine % Solids :

10.1.1.1.1 If waste contains no free liquid, proceed to Section 10.1.1.2 where the waste is the solid portion.

10.1.1.1.2 If the waste contains less than 0.5% solids, proceed to Section 10.3.2.

10.1.1.1.3 Multiphasic waste - separate liquid and solid portion

The following is performed by the Login Department.

10.1.1.1.3.1 Using a pressure filtration device pre-weigh the filter and the container to receive the initial filtrate. Record the weight in the laboratory notebook.

10.1.1.1.3.2 Assemble the pressure filter according to the manufacturer's directions.

10.1.1.1.3.3 Weigh a subsample of the waste (100 g minimum) and record the weight.

10.1.1.1.3.4 Transfer the waste sample to the filter holder spreading evenly over the filter.

10.1.1.1.3.5 Gradually apply a gentle pressure of 1-10psi until the pressurizing gas moves through the filter, proceed to Section 10.1.1.1.3.8.

10.1.1.1.3.6 If no additional liquid has passed through the filter in any 2 minute interval, slowly increase the pressure in 10psi increments.

10.1.1.1.3.7 Stop the filtration when pressurizing gas passes through the filter, or 50psi is reached and no additional liquid passes through the filter in any 2 minute interval.

10.1.1.1.3.8 The material in the filter holder is defined as the SOLID PHASE of waste and the filtrate is defined as the LIQUID PHASE.

Note: the SOLID PHASE may appear liquid in some samples. Do Not replace original filter. Use only one filter.

10.1.1.1.3.9 Weigh the filtrate filled container and record the weight in the laboratory notebook. Calculate the weight of the LIQUID PHASE as follows:

$$W_{LP} = W_F - W_C$$

Where:

W_{LP} = Weight of the LIQUID PHASE
W_F = Weight of the filtrate filled container
W_C = Weight of container

10.1.1.1.3.10 Calculate the weight of the SOLID PHASE using the following formula:

$$W_{SP} = W_W - W_{LP}$$

Where:

W_{SP} = Weight of the SOLID PHASE
W_W = Weight of the waste sample
W_{LP} = Weight of the LIQUID PHASE

10.1.1.1.3.11 Calculate the percent solids using the following formula:

$$\%Solids = \frac{W_{sp}}{W_w x 100}$$

Where:

W_{SP} = Weight of the SOLID PHASE
W_W = Weight of the waste sample

10.1.1.1.3.12 If the % Solids determined in Section 10.1.1.1.3.11, is less than 0.5%, then proceed to Section 10.3.2, where the filtrate is the TCLP/SPLP extract.

10.1.1.1.3.13 Remove the solid phase and filter from the filtration apparatus, dry at 100 ± 2° F, cool and weigh. Record the weight in the laboratory notebook.

10.1.1.1.3.14 Calculate the percent dry solids using the following formula:

$$\% \text{ dry solids} = \frac{W_{DW} - W_F}{W_W \times 100}$$

Where:

W_{DW} = Weight of dried waste + filter
W_F = Weight of the filter
W_W = Weight of waste sample

10.1.1.1.3.15 If the % dry solids determine above, 10.1.1.3.14, is less than 0.5%, then proceed to Section 10.3.2, where the filtrate is the TCLP extract.

10.1.1.2 Determine whether waste requires particle size reduction

The following is performed by the Metals Prep Department.

Using fresh portion of the waste, obtain another solid phase of the waste sample by pressure filtration as determined in Sections 10.1.1.1.1. Use enough wet sample to obtain a dry portion for tumbling: at least 100 g. Evaluate the solid phase for particle size. Particle size reduction is required unless the solid has a surface area greater to 3.1 cm^2 per g, or is smaller than 1 cm in its narrowest dimension.

10.1.1.3 Determine Compatibility of Liquids

The following is performed by the Metals Prep Department.

If a LIQUID PHASE was filtered, check its compatibility with the extraction fluid. If the liquids are compatible (miscible), then only one TCLP/SPLP extract needs to be analyzed. If the liquids are not compatible, then the two liquids will have to be analyzed separately. Record in the laboratory notebook.

10.2 Initial Calibration

Not Applicable.

10.3 Equipment Operation and Sample Processing

10.3.1 After the preliminary examination has been completed, the sample used in the following step comes from supplied VOA sample vials. The extraction for Volatile Organics is accomplished in a zero headspace extractor, ZHE.

10.3.2 Waste containing less than 5% dry solids

10.3.2.1 For waste containing less than 5% dry solids, weigh out up to a 500 g subsample and record its weight. Filter enough of the sample so that two 40 mL VOA vials may be filled with the filtered liquid. The liquid portion of the waste, after filtration, is defined as the TCLP/SPLP extract for volatile organic analysis. Proceed to Section 10.3.4.20.

10.3.3 100% Solid Waste

10.3.3.1 If particle size reduction is required (Section 10.1.1.2.), prepare the waste for extraction by crushing, cutting, or grinding the waste to a surface area or particle size as described in Section 10.1.1.2. Waste and appropriate reduction equipment should be refrigerated to 4 ± 2° C prior to particle size reduction.

10.3.3.2 Weigh 20 gs of prepared waste and record the weight. If a 25 g Encore is supplied extrude and record the weight.

10.3.3.3 Quantitatively transfer the sample to the ZHE.

10.3.3.4 Assemble the ZHE according to manufacturer's instructions. Add the appropriate type and amount of fluid using the fluid metering pump. The fluid added is 20 times the amount of sample. For example, for a 20 g sample, add 400 mL of extraction fluid for TCLPs or 400 mL of organic free DI water for SPLPs. For a 25 g sample, 500 mLs of the appropriate fluid is added.

10.3.3.5 Position the ZHE in the vertical position with the liquid inlet/outlet valve on top and open.

10.3.3.6 Gradually apply pressure to the ZHE and bleed out any headspace.

10.3.3.7 Proceed to Section 10.3.4.16.

10.3.4 Waste containing greater than 5% dry solids

10.3.4.1 Determine the amount of waste to charge into the ZHE as follows:

$$\text{Weight of waste to charge the ZHE} = \frac{20 \times 100}{\%\ \text{solids}}$$

Weigh out a subsample of the waste of the appropriate size and record the weight

10.3.4.2 If particle size reduction of the solid portion of the waste was required in Section 10.1.1.2, prepare the waste for extraction by crushing, cutting or grinding the solid portion of the waste to a surface area or particle size as described in Section 10.1.1.2. Waste and appropriate reduction equipment should be refrigerated to 4 ± 2° C prior to particle size reduction.

10.3.4.3 Quantitatively transfer the entire sample quickly to the ZHE. Assemble the ZHE in accordance with the manufacturer's instructions.

10.3.4.4 Place the device in the vertical position with the inlet/outlet valve on top and open.

10.3.4.5 Gradually apply pressure to the ZHE and bleed out any headspace quickly.

10.3.4.6 At the first appearance of liquid from the liquid inlet/outlet valve quickly close the valve.

10.3.4.7 Attach a 50mL gastight syringe to the liquid inlet/outlet valve and open the valve.

10.3.4.8 Begin applying gentle pressure to force the liquid phase of the sample into the filtrate collection container. When no additional liquid has passed through the filter in any 2-minute interval, proceed to Section 10.3.4.9.

10.3.4.9 Stop filtration by closing the liquid inlet/outlet valve.

10.3.4.10 Disconnect and weigh the 50mL gastight syringe. Record the weight in the laboratory notebook.

10.3.4.11 The material in the ZHE is defined as the solid phase of the waste and the filtrate is defined as the liquid phase.

10.3.4.12 If the liquid phase is compatible with the extract (Section 10.1.1.3), store the filtrate at 4 ± 2°C until analysis. Then combine and analyze the filtrate as one extract.

10.3.4.13 If the liquid phase is not compatible with the solid extract, then analyze the filtrates separately and mathematically combine the results (Section 10.3.4.22).

10.3.4.14 Determine the weight of extraction fluid #1 for TCLP or organic free DI water for SPLP to add to the ZHE as follows:

Weight of extraction fluid = $20(W_S + W_T - W_{TF})$

Where:

W_S = Weight Sample
W_T = Weight of pre-weighed 50mL syringe
W_{TF} = Weight of filtrate in 50mL syringe

For 100% solid samples, the above formula reduces to:

Weight of extraction fluid = 20 x weight of sample

10.3.4.15 Add extraction fluid by backing piston off the filter and sucking fluid into the ZHE. Do not open the ZHE.

10.3.4.16 Re-pressurize the ZHE to 15 psi (1.03 bar) and place in the rotary agitation apparatus. Rotate at 30 ± 2 rpm for 18 ± 2 hours.

10.3.4.17 Post-extraction measure the final pressure of the ZHE canister. If pressure has decreased below 15 PSI the sample must be reset.

10.3.4.18 Following the agitation period separate the material in the extractor vessel into its liquid and solid phases.

10.3.4.18.1 100% solid waste samples: Filter enough liquid phase to fill two 40 mL vials. The filtrate is defined as the TCLP/SPLP extract. Proceed to Section 10.3.4.20.

10.3.4.18.2 Compatible liquid phases: Filter the entire extract into a 50mL gastight syringe. Transfer the contents of the syringe into 40mL VOA vials. Combine the extracts (Section 10.3.4.22) and analyze together.

10.3.4.18.3 Non-compatible liquid phases. Filter a sufficient quantity of the solid extract to fill two 40 mL VOA vials and analyze. The two liquids are collectively defined as the TCLP/SPLP extract and results are mathematically combined after individual analysis.

10.3.4.19 Following collection of the TCLP/SPLP extract immediately prepare the extract for analysis and store with minimal headspace at 4 ± 2°C until analyzed.

10.3.4.20 Follow the volatile organic analyses method 8260 SOP 32639 to analyze the TCLP/SPLP extract.

10.3.4.21 If the individual liquid phases (i.e. non-compatible liquids) are analyzed separately, determine the volume of the individual phases, conduct the appropriate analyses, and combine the results mathematically by using a simple volume-weighted average:

$$\text{Final Analyte Concentration} = \frac{(V_1)(C_1) + (V_2)(C_2)}{V_1 + V_2}$$

Where:

V_1 = Volume of the first phase, (L)
C_1 = Analyte concentration first phase, (mg/L)
V_2 = Volume of the second phase, (L)

C_2 = Analyte concentration second phase, (mg/L)

10.4 Continuing Calibration

Not Applicable.

10.5 Preventive Maintenance

Tumbler rotation speed is verified annually and documented in the TCLP Annual Calibration Log, Form No.: 13855.

Balances are calibrated semi-annually by an instrument service company. Certificates are kept on file.

ZHEs are cleaned after extraction in soapy water. Filter screens and o-rings may be changed if they show degradation or the extraction vessel can't maintain pressure. Extremely contaminated vessels maybe further solvent rinsed with methanol

11. Data Evaluation, Calculations and Reporting

Calculations are included in Section 10.

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

Holding time exceedance, improper preservation and observed sample headspace are noted on the nonconformance report form.

Perform routine preventative maintenance following manufacturer's specification. Record all maintenance in the instrument logbook.

Review of standards, blanks and standard response for acceptable performance occurs for each batch of samples. Record any trends or unusual performance on a nonconformance action form.

13. Method Performance

13.1 Detection Limit Study (DL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the DL, LOD, and/or LOQ as outlined in Alpha SOP ID 1732. These studies performed by the laboratory are maintained on file for review.

13.2 Demonstration of Capability Studies

Refer to Alpha SOP ID 1739 for further information regarding IDC/DOC Generation.

13.2.1 Initial (IDC)

Not Applicable.

13.2.2 Continuing (DOC)

Not Applicable.

14. Pollution Prevention and Waste Management

Refer to Alpha's Chemical Hygiene Plan and Hazardous Waste Management and Disposal SOP for further pollution prevention and waste management information.

15. Referenced Documents

2121 Chemical Hygiene Plan

1. Scope and Application

Matrices: This method is applicable for solid samples (soils, sediments, sludges).

Definitions: Refer to Alpha Analytical Quality Manual.

The organic carbon in a sample consists of a variety of organic compounds in various oxidation states. Some of these compounds may be oxidized by biological or chemical processes and can be measured by the Biochemical Oxygen Demand or Chemical Oxygen Demand tests. To measure the amount of organically bound carbon, the organic carbon molecules are broken down into single carbon units, and converted into a form that can be measured quantitatively.

The PE 2400 Series II CHNS/O Analyzer can simultaneously determine carbon (C), hydrogen (H), nitrogen (N), sulfur (S), and oxygen (O) in organic material. In the CHN mode, the PE 2400 Series II CHNS/O Analyzer uses a combustion method to convert the sample elements to simple gases (CO_2, H_2O, and N_2). The resulting gases are homogenized and controlled to exact conditions of pressure, temperature, and volume. The homogenized gases are allowed to de-pressurize through a column where they are separated in a stepwise steady-state manner and detected as a function of their thermal conductivity and reported as a percentage for solid samples. Treated with hydrochloric acid prior to analysis, the Total Organic Carbon (TOC) content is determined by the amount of CO_2 in the sample. If the sample is analyzed without pretreatment, the Total Carbon (TC) content is determined. Total Inorganic Carbon can be determined by subtraction of the TOC from the TC values.

This method is applicable to the measurement of TOC and Soot in solid samples $\geq$ 100mg/Kg or $\geq$ 0.01%, dry weight. According to the instrument manufacturer, a sample of up to 70% carbon can be analyzed without dilution.

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one or more of the following laboratory personnel before performing the modification: Area Supervisor, Department Supervisor, Laboratory Director, or Quality Assurance Officer.

This method is restricted to use by or under the supervision of analysts experienced in the operation of the TOC Analyzer and in the interpretation of the data. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

2. Summary of Method

An aliquot of solid sample is dried, homogenized, weighed into a tin capsule, pre-treated with hydrochloric acid and heated to 75°C to convert the inorganic carbon (*i.e.,* carbonate and bicarbonate in the form of CO_2) prior to analysis.

Organic carbon is measured using combustion and a carbon analyzer. The sample, of approximately 5-10 (masses less than 5 mg must be avoided since balance is not calibrated below 5 mg)mg corrected sample weight (a larger aliquot may be used for heterogeneous, or low- carbon samples to improve reproducibility), is oxidized in a pure oxygen environment, introduced into a furnace by a 60-slot Autosampler, then combusted. A greater mass may be weighed if the sample observations indicate low carbon content. As much as 20-25mg may be utilized. The carrier gas (O_2) is combined with the carbon content of the combusted sample to form CO_2. Elements, such as halogens and sulfur, are removed by scrubbing reagents in the combustion zone. A thermal conductivity detector then measures the CO_2. The amount of CO_2 derived from a sample is directly proportional to the concentration of organic carbon material in the sample.

For Soot, the sample will be transferred to an aluminum tin. The tins will be placed in an oven or muffle furnace for 24 hours at 375°C. After sample is in the muffle furnace for 24hrs sample is reduced to a powder with a mortar and pestle, weighed into a tin capsule, then treated with acid then re-dried and analyzed on the TOC Analyzer.

2.1 Method Modifications from Reference

Samples are analyzed using 2 replicates unless otherwise specified by the Client. Hydrochloric acid is substituted for phosphoric acid. The use of this acid has been validated and documented by the laboratory.

3. Reporting Limits

The Practical Quantitation Limit (PQL) or Reporting Limit (RL) is 0.01 (or 100mg/Kg) for solid samples.

4. Interferences

4.1 To determine the TOC/Soot content, the inorganic fractions (carbonate and bicarbonate) must be removed prior to analysis by lowering the pH of the sample to $\leq$ 2. When removing the inorganic carbon, care must be taken in sample pretreatment to minimize the potential of loss of volatile organic carbon present in the sample.

4.2 Maintaining the samples at 4±2°C, and analyzing within the specified holding time minimizes bacterial decomposition and volatilization of the organic material.

4.3 Elements, such as halogens and sulfur, are removed by scrubbing reagents in the combustion zone. Large and/or complex organic molecules such as tannins, lignins, or humic acids may be oxidized slowly. If these compounds are suspected to be present, it is advisable to check the efficiency of the oxidation procedure with a selected representative sample, and adjust the analysis (sample size) as needed.

4.4 Oils from skin, or contact with any organic material, such as plastic containers and rubber tubing, can contaminate samples. Handle the weighing tins with tweezers.

4.5 Sample heterogeneity can be a major source of imprecision in TOC/Soot results. Recommend to clients to perform a client-specific duplicate, to evaluate precision and representativeness of the TOC/Soot results to the site.

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound must be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material data handling sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

The use of laboratory equipment and chemicals exposes the analyst to several potential hazards. Good laboratory techniques and safety practices shall be followed at all times. All relevant Material Safety Data Sheets (MSDSs) are kept on file.

Approved PPE, which includes Safety Glasses, Gloves and Lab Coats, must be worn at ***all*** times when handling samples, reagents, chemicals, or when in the vicinity of others handling these items, so that dermal contact is avoided. All standards, reagents and solvents shall be handled using the proper PPE. All flammable solvents must be kept in the flammable storage cabinet, and returned to the cabinet immediately after use. When transporting chemicals, use a secure transporting device and/or secondary outer container. Chemical storage is properly segregated and adequately ventilated to reduce the possibility of hazardous reactions. Chemical storage in work areas shall be kept to a minimum. Storage on bench tops or other work surfaces, except temporary, is not permitted.

All standards and reagents shall be prepared in a hood while using the proper PPE.

Analytical instrumentation poses the unique possibility of exposure to high voltages. Other than the *routine* instrument maintenance, as listed in the front of every Instrument Maintenance Logbook, at no time shall an instrument operator attempt to maintenance an instrument alone, or without the proper training, supervision or instruction. Caution must always be used in the presence of moving parts (autosamplers) and hot surfaces (injection ports).

All additional company safety practices shall be followed at all times as written in the *Chemical Hygiene Plan*.

All TOC standard solutions must be handled with caution. See pages 5-3 through 5-5 of the PE 2400 Series II CHNS/O Analyzer User's Manual for additional and specific Warnings and Precautions.

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

A minimum of 5 grams of sample must be collected in a glass jar.

6.2 Sample Preservation

Soil samples must be refrigerated and maintained at 4°±2°C until drying and analysis.

Sediment samples are either processed within 28 days (or can be frozen (for programs with an EPA approved holding time extension for frozen storage) at -15C to -20C until processing.

6.3 Sample Shipping

The *Sample Receipt & Login SOP* (1559) describes how samples are normally shipped or obtained by the laboratory, precautions to be used in opening sample shipments, and sample storage conditions.

6.4 Sample Handling

Soil samples must be refrigerated and maintained at 4°±2°C until drying and analysis.

Sediment samples are either processed within 28 days or can be frozen at -15C to -20C until processing (for programs with an EPA approved holding time extension for frozen storage)

All solid samples must be analyzed within 28 days from the date of collection unless extended hold times are provided in client specific QAPP.

The *Sample Receipt & Login SOP* (1559) describes the responsibilities of sample custody including all proper documentation, verification, and tracking procedures, following Chain of Custody (COC) protocols and sample receipt procedures using the *Sample Receipt Checklist*, which includes the check for proper sample preservation and cooler temperature verification.

Internal COC procedures for sample tracking include the use of sample tracking logbooks. These procedures are also described in the *Sample Receipt & Login SOP* (1559).

7. Equipment and Supplies

7.1 Instrument: Perkin Elmer 2400 Series II CHNS/O Analyzer with computer and PE software

7.2 Detector: Thermal Conductivity

7.3 Mortar and pestle

7.4 Oven: 75 +/- 2 °C

7.5 Muffle Furnace: Capable of maintaining temperature of 375°C

7.6 Dessicator

7.7 Volumetric Flasks: Class-A, various volumes

7.8 Microbalance: Perkin-Elmer, Model AD-6. See the Manufacturer User's Manual, Section 1.2, pages 3-4, for Microbalance and weighing instructions. The Microbalance calibration is verified every day using 5.0mg - 200mg weights, in the range of daily use, and be accurate within +/1%. If the balance needs to be re-calibrated, see the Manufacturer User's Manual SOP, Section 1.1, page 3, for details.

7.9 Tweezers: Anti-Magnetic

7.10 Tin Boats: 5 X 8 mm.

7.11 Polypropylene beakers: 50 mL, for weighing wet samples.

7.12 Glass Beads: Filter Aid 400, High-density; from Perkin Elmer or 3M. Used as the CCB/Method Blank media. Beads must be muffled at 375°C prior to use to remove any trace carbon.

7.13 Gas-tight syringes: Various measuring sizes, including 10μL for direct sample spiking

7.14 Transfer pipets and/or Eppendorf pipettor for delivering HCl: Polypropylene.

7.15 Printer : OKIDATA Microline 320 Turbo-9 Pin or equivalent

Note: All maintenance records including routine upkeep and outside service visits are maintained in the instrument maintenance logbooks. See the Manufacturers User's Manual for detailed troubleshooting instructions and routine maintenance, as needed.

8. Reagents and Standards

Use reagent grade chemicals for all reagents. All reagents and standards are stored at room temperature and expire 6 months from preparation, unless otherwise indicated below.

8.1 Deionized (DI) water: All references to DI water refer to ASTM Type II reagent grade water which has been boiled, cooled and capped to eliminate CO_2. Water must be replaced weekly.

8.2 10% Hydrochloric Acid solution: Add 300mL of concentrated HCl (34-37%) to 700mL of DI water. Mix thoroughly and cool to room temperature before use. Store in a glass bottle and keep at room temperature. This solution is stable for 6 months.

8.3 Potassium Hydrogen Phthalate (KHP), CCV or K-Factor for TOC:

CCV- 10,000mg/L equivalent to 10,000mg/Kg Carbon, or 1.0 % TOC:

Dry potassium hydrogen phthalate (KHP) (primary standard grade) at 110°C for 1 hour. Cool to room temperature in a dessicator. Dissolve 2.128g of KHP (primary standard grade) in ASTM DI water, and dilute to 100mL in a volumetric flask. This standard is good for 6 months, stored at room temperature. Discard solution if discoloration or any signs of bacterial growth are observed.

8.4 Potassium Hydrogen Phthalate (KHP) Spiking Solution/MS/ICV: 10,000mg/L equivalent to 10,000mg/Kg Carbon, or 1.0 % TOC. From a separate source than the solution in Section 8.3, Sigma Aldrich or equivalent.

Dry KHP (primary standard grade) at 110°C for 1 hour. Cool to room temperature in a dessicator. Dissolve 2.128g of KHP (primary standard grade) in ASTM DI water, and dilute to 100mL in a volumetric flask. *Use a separate source or different lot of KHP from that used to prepare the calibration standards.*

This stock may be stored up to six months at room temperature. Discard solution if discoloration or any signs of bacterial growth are observed. Use at 1.0 % TOC concentration for solid samples, and at 10,000mg/L for aqueous samples.

8.5 Solid Standard Reference Materials: Standard Reference Material (SRM) NIST 1944, a separate source from the calibration standard that is certified at the concentration of 4.4% TOC for solid samples. SRM 1650b for Soot, this material has no certified value, however has a reference value of 78% soot carbon. ("Quantification of the Dilute Sedimentary Soot Phase: Implications for PAH Speciation and Bioavailability" published in Environmental Science and Technology, Vol. 31, No. 1, 1997 by Gustafsson, Haghseta, Chan, McFarlane and Gschwend.)

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

9.1 Blank(s)

9.1.1 Method Blank: A method blank must be analyzed once per every 20 samples or per TOC/Soot batch, whichever is more frequent. The Blank consists of 30-50mg of Filter Aid acidified with HCl and dried. (Section 7.11).

TOC must not be detectable in the method blank at a concentration greater than the reporting limit for the given matrix (Section 3).

Corrective Action: Analysis of the method blank and all associated samples must be performed until the blank is in control. Samples cannot be analyzed until an acceptable method blank analysis is obtained. Exceptions may be made with approval of the Department Manager, if the samples associated with the out of control method blank are non-detect for TOC/Soot, or if sample TOC/Soot concentrations are greater than 10X the blank levels. In such cases, the sample results are accepted without corrective action for the high method blank and the client is notified in a project narrative associated with the sample results.

9.1.2 Continuing Calibration Blank: A CCB must be analyzed immediately after every CCV. The CCB is 30-50mg of Filter Aid acidified with HCl and dried. (Section 7.10).

The CCB concentration must not be greater than the reporting limit for the given matrix (Section 3).

Corrective Action: Repeat analysis once to see if an analytical error occurred. If the CCB still exceeds the control limits, re-calibrate and/or re-analyze a fresh

blank. All samples associated with the out of control CCB must be re-analyzed (since the last acceptable CCB). Exceptions may be made with approval of the Department Manager if the samples associated with the out of control method blank are non-detect for TOC/Soot or if sample TOC/Soot concentrations are greater than 10X the blank levels. In such cases, the sample results are accepted without corrective action for the high CCB and the client is notified in a project narrative associated with the sample results.

9.1.3 Instrument Blank: An Instrument Blank must be analyzed during Calibration.run2. The Instrument Blank consists of 30-50mg of Filter Aid acidified with HCl and dried at 75°C. (Section 7.10).

9.2 Laboratory Control Sample (LCS)

Laboratory control sample (LCS) must be from a second source or lot number to verify the accuracy of the standard curve. The LCS is analyzed along with the samples. A LCS must be analyzed once per every 20 samples or per TOC batch, whichever is more frequent. For *solid* samples, the LCS is the NIST SRM at 4.4% TOC. The LCS is treated identically as samples with HCl and dried at 75°C.

LCS consists of approximately 5.0mg of SRM 1944 with a true value of 4.4% TOC (Section 8.6). This SRM is NOT evaluated for Soot since no certified concentration for Soot is published.

The acceptable recovery QC range is 75%-125% for the LCS.

Corrective Action: Repeat analysis once to see if an analytical error has occurred. If the LCS recovery is still out of control, re-calibrate and re-analyze the LCS and all associated samples. Samples cannot be analyzed until an acceptable LCS is obtained. Exceptions may be made with approval of the Department Manager if the samples associated with the out of control LCS are also associated with a matrix spike that is in control. This is an acceptable measure of accuracy of the analytical procedures. An explanation of this out of control LCS recovery must be included in the project narrative to the client and the sample data reported with the acceptable MS results as batch QC.

9.3 Initial Calibration Verification (ICV)

Second source analyzed at the beginning of the run. Sample matrix of ICV is a 1.0% carbon solution of KHP.

The acceptable recovery QC range for the ICV is 80-120%.

The **ICV** is prepared by adding 10μL of *Spiking Solution* (Section 8.4), (with a 1% TOC true value). The weight recorded is the Calibration Solution only. (10μL of solution should weigh approximately 10mg).

Corrective Action: Repeat analysis once to see if an analytical error occurred. If the ICV still exceeds the control limits, re-calibrate and re-analyze all samples since last acceptable ICV.

9.4 Continuing Calibration Verification (CCV)

A CCV must be analyzed at a minimum of every 10 burns and at the close of an analytical sequence. This standard monitors instrument performance throughout the duration of the analytical run. Sample matrix of CCV is a 1.0% carbon solution of KHP.

The **CCV** is prepared by adding 10µL of *Calibration Solution* (Section 8.3), (with a 1% TOC true value). The weight recorded is the Calibration Solution only. (10µL of solution should weigh approximately 10mg).

The acceptable recovery QC range for the CCV is 80-120%.

Corrective Action: Repeat analysis once to see if an analytical error occurred. If the CCV still exceeds the control limits, re-calibrate and re-analyze all samples since last acceptable CCV.

9.5 Matrix Spike

A matrix spike must be performed once per 10 samples (10% frequency). When project specifications dictate, a Matrix Spike Duplicate (MSD) may also need to be performed at the same frequency as the MS. Prepare the MS according to Section 8.4 for the given matrix.

A **Matrix Spike** sample is spiked with 10µL of *Spiking Solution* (Section 8.4), at a 1.0 % TOC true value. The weight recorded is the sample weight prior to spiking.

The acceptable recovery QC range is 75%-125% for the MS/MSD. Calculate the %RPD as in Section 9.6 when analyzing a MS/MSD pair. The acceptable %RPD is $\leq$ 25% for solid samples.

Corrective Action: If sample concentration exceeds 4X the spike amount, narrate. Repeat analysis once to see if an analytical error has occurred. If the % recovery or %RPD still exceeds the criteria and the LCS is compliant; include a project narrative with the results to the client noting that there may be potential matrix effects on the accuracy or precision of the TOC/Soot results as evidenced by matrix spike recovery or %RPD outside of QC limits.

9.6 Laboratory Duplicate

Duplicate analyses (matrix duplicate) must be performed once per 20 samples (5% frequency).

Acceptable relative percent difference (RPD) of duplicates is $\leq$ 25%. Acceptance criterion is not applicable to sample concentrations less than 5X the reporting limit. Calculate RPD as follows:

$$\%RPD = \frac{R1 - R2}{\frac{[R1 + R2]}{2}} \times 100$$

where:

R1 = highest result
R2 = lower result

Corrective Action: Repeat analysis once to see if an analytical error has occurred. If the % RPD still exceeds the control limits; include a project narrative with the results to the client noting that there may be potential matrix effects on the precision of the TOC/Soot results as evidenced by the matrix duplicate RPD exceedance.

9.7 Method-specific Quality Control Samples

High level Initial Calibration Verification (HLICV - linearity check):

This sample consists of 4% carbon solution (high calibration point).

Aliquot 50 µL using a syringe into a tin boat, record weight and analyze. (Equivalent to a 5 mg sample containing 40% TOC).

The acceptable recovery QC range for the HLICV is 80-120%.

Corrective Action: Repeat analysis once to see if an analytical error occurred. If the HLICV still exceeds the control limits, re-calibrate.

9.8 Method Sequence

- Calibration Curve generation
- ICV
- ICB
- HLICV
- Method Blank
- LCS
- Laboratory Duplicate
- Matrix Spike
- Samples 1 – 8
- CCV
- CCB
- Samples 9 – 18
- CCV
- CCB

10. Procedure

10.1 Equipment Set-up

Samples are prioritized by the Department Manager for analysis based on hold time and client due date. Section 15.5 outlines the steps for final TOC reporting that will contain the sample analysis final results.

The analyst initials, date, sample ID #'s, sample weights (solids), or volumes (aqueous), of all Standards, QC samples and field samples, are entered into the TOC logbook. Include the standard, LCS and MS IDs and concentrations. Use TOC weight spreadsheet to record all information.

10.1.1 Pretreatment for Total Organic Carbon:

This procedure is used to remove the inorganic compounds in the sample prior to the determination of Total Organic Carbon. If Total Carbon is to be determined, addition of the acid solution is omitted.

10.1.1.1 Aliquot 10-15g of wet solid sample into a weighing vessel. Remove shells, rocks and other large non-representative materials with tweezers. Record weight of vessel and vessel + wet sample.

10.1.1.2 Heat for 4 hours at 75 +/- 2 °C. Return sample to oven if additional drying time is required(in ½ hour increments) Record time in and out of oven. Cool sample to room temperature in dessicator. Record weight of vessel + dry sample.

10.1.1.3 Add 10% HCl (Section 8.2) dropwise to dry sample to induce effervescence (removal of inorganic carbon). Do not use excessive acid.. Only add enough acid to exhaust the effervescence. In lieu of additional acid, use DI water to wet the sample in order to form a slurry if necessary, to distribute the acid throughout the sample. Record the volume of HCl used for each sample.

10.1.1.4 Return the sample to the oven. Heat for 4 hours at 75 +/- 2 °C. Return sample to oven if additional drying time is required(in ½ hour increments) Record time in and out of oven. Cool to room temperature in dessicator. Record final weight of dry sample + vessel. The change in weight of dry sample after acidification is used to adjust the weight of the aliquots used for analysis.

10.1.1.5 Take a sub-aliquot of approximately 2-3 g of dry sample and perform moisture content using SM2540D. The corrected sample weight (CSW, see Section 11.4) is corrected using this result (see Section 11.4 for calculations)

10.1.1.6 Grind sample with mortar and pestle to homogenize. Place ground sample into a 4 mL vial.

10.1.1.6.1 If Soot analysis is required, take a portion of the dried sample aliquot(prior to acidification), approximately 5-10 gm, and place into a muffle furnace at 375°C for 24 hours. Once the sample aliquot is cooled to room temperature, proceed to the acid addition step, Section 10.1.1.3. Samples for Soot are read analytically in the same way as Routine TOC.

10.1.1.7 Weigh (and record weight of) each replicate into a tin capsule (see Section 10.3 for appropriate weight range). Record the weight and use the TOC weight spreadsheet to calculate the corrected sample weight (CSW) which is entered into the analyzer.

10.2 Initial Calibration

On the accompanying computer, or "PC", Perkin Elmer software has been loaded to collect and save sample and standard analysis data. Create a file to store the data from each day's analytical sequence by clicking on the PE 2400 icon, go to "new" and "save" the file "as" the name of the date of the analysis (*i.e.,* 060503.chn). Data from each standard or sample analysis will be automatically stored in this file for future reference

10.2.1 Follow the instrument Manufacturers User's Manual for instrument set up and see Sections below for an outline of the initial, daily calibration procedure.

See the Manufacturers User's Manual, page 5-69, for the default instrument conditions when in the CHN operating mode.

10.2.2 *Routine* TOC/Soot Calibration Method:

TOC analyses use K-Factors (3 repeat analyses of a 1.0% TOC standard, Section 8.3) and Blanks, calculated and averaged by the instrument when the calibration is being performed. Follow the instrument Manufacturer's User's Manual, page 4-67. Calibration of the instrument using K-Factors and Blanks is performed once per day of analysis.

Load the Autosampler (Section 10.3.2) for combustion to analyze Blanks and Standards in the order listed below. All "Blanks" and "K-Factors" are prepared in the same way. Analyze the standards following the procedure in Section 10.3.

- **Instrument "Primer"** (~3.5mg of SRM 1944, with true value of 4.4% TOC) only if new column.
- **Blank 1** (30-50mg of Filter Aid) only if new column
- **K-Factor 1** (10µl of *Calibration Solution*, Section 10.3,)
  The weight recorded is the Calibration Solution, only.
- **Blank 2** (30.0mg of Filter Aid)
- **K-Factor 2** (10µl of *Calibration Solution*, Section 10.3,)
  The weight recorded is the Calibration Solution, only.
- **K-Factor 3** (10µl of *Calibration Solution*, Section 10.3,)
  The weight recorded is the Calibration Solution, only.

The K-Factors must reproduce from the mean value within +/- 15% of known K factor for each instrument for carbon. The calculation involves the comparison among the latest K-Factor run, the prior K-Factor run, and the current running average K-Factor. An "out of tolerance" message will be displayed if this criterion is not met.

The ICV/LCS and Method Blank are prepared to run immediately following the third K-Factor, given the instrument is “in tolerance”.

Corrective Action: If, at any time during the 6–step process of calibration, one of the K-Factors or Blanks fail, repeat analysis of failing sample.

10.3 Equipment Operation and Sample Processing

Prepare a Calibration per Section 10.2.

An ICV/ICV and LCS/Method Blank are analyzed immediately following the third K-Factor of the Routine Calibration, provided the instrument is “in tolerance”. The LCS and method blank must be run with the same number of replicates that are required for the samples in the run.

Remove all pretreated samples from the oven, and allow to cool in a dessicator.

Weigh approximately 5-10mg (to an accuracy of 0.01 mg) (masses less than 5 mg must be avoided since balance is not calibrated below 5 mg) of sample into a tin boat using the Perkin-Elmer Microbalance, Model AD-6, which is linked to the instrument. Samples that are known to be high in TOC may use a lesser sample aliquot. Samples where it is observed that the TOC may be low, weight as much as 20-25mg. Record the weights in the TOC/Soot logbook. Matrix Duplicate and Matrix Spike samples are weighed as separate samples, with their own replicates. As noted in Section 10.1.1.6, use the TOC weight spreadsheet to correct the sample weights for all replicates and re-analyses.
Any observations regarding the sample composition must be noted in the TOC/Soot logbook such as: sandy, contains shells or rocks, contains grass or roots, is light/white in coloration, etc.

Analyze a CCV/CCB (Section 9.4 and 9.1.3) after every 10 “burns”, and at the end of the analytical sequence.

If following the *Lloyd Kahn* Calibration method, analyze the first set of batch QC samples, the ICV/LCS and Method Blank, followed by field samples with a CCV/CCB analyzed every 10 “burns”, and at the end of the analytical sequence.

10.3.1 Multiple Sample Instrument Loading:

10.3.1.1 Each tin boat is carefully folded with anti-magnetic tweezers, and placed into its respective holding tray position. (See the Manufacturer User’s Manual SOP, Section 1.2, page 4, for tin boat folding details.) Weights, sample tray position and Autosampler location are recorded in the TOC/Soot logbook. The analyst must be very careful when transferring samples. Documentation of sample consistency is very important. See Figure 1 for an example logbook page.

10.3.1.2 Adjust the Autosampler tray to begin sampling at auto-slot #1 and carefully transfer the folded tins containing the samples to the correct auto-slot, using tweezers. All Instrument Calibration Standards (Blanks, K-Factors and/or *Lloyd Kahn* Calibration Standards) are loaded first. Immediately following will be the first batch QC samples, the ICV/LCS and Method Blank for the run, followed by field samples. Rotate the Autosampler in a *counter clockwise* manner.

10.3.1.3 A maximum of 60 tins can be held on the Autosampler at one time. The instrument only allows for 100 total samples (including calibration/blank samples) to be programmed for any given run.

10.3.2 Sample Analysis

10.3.2.1 Select the *Auto Run* option on the keypad on the instrument. The following menu appears:

AUTO RUN NO. 1
1B 2K 3S
where: B = Blank
K = K-Factor
S = Sample

Assuming the *Instrument Standardization* occupies auto-slots 1-6, Enter "3" for Sample, then select "Enter". Enter the weight of the "Primer" Standard (position 1) and select "Enter".

10.3.2.2 You will be prompted for AUTO RUN NO. 2 as in Section 10.3.3.1, except now there is a function "4NP" which allows the analyst to stop/erase everything by selecting this feature.

- Enter "1" for the Blank. The weight will not be asked for.
- Enter "2" for the first K-Factor, then select "Enter". Enter the weight of your K-Factor (the standard weight should be ~ 10mg). Select "Enter".
- Enter "1" for the second Blank, then "Enter".
- Enter "2" for the second K-Factor, then "Enter". Enter the weight, then "Enter".
- Enter "2" for the third K-Factor, then "Enter". Enter the weight, then "Enter".

10.3.2.3 All remaining sample weights are added by entering "3" for Sample, and then by entering the sample weight. Continue adding all information to the run sequence, using the keypad. When entering sample identifications, and letters are necessary, refer to the Manufacturer's User's Manual, page 3-4, for instructions for converting numbers to letters.

10.3.2.4 When all sequence information is entered and complete, select "Start". The analyses will begin. The computer will continue to display the "AUTO RUN" menu during sample analysis.

10.3.2.5 The Standard and Sample data prints out as it is collected on the line printer, and is also collected on the linked computer using the PE 2400 software. The data on the computer is saved in a file named as the date of the analysis (*i.e.,* 060503.chn) for future reference, as noted in 10.2.

10.3.2.6 When all analyses are complete, refer to the Manufacturers User's Manual SOP, Section 3.1, page 7, for instructions to "Shut Down" the instrument.

10.3.2.7 Evaluate all batch QC samples first, to confirm or exclude the need for re-analyses. The ICV/LCS/HLICV, Method Blank, CCB/CCV samples must meet the acceptance criteria in Section 9. Follow the corrective action for any QC failures.

10.3.2.8 Evaluate the field samples, LCS/SRM, and MS/Duplicates next. If replicate "burns" vary by more than 30%, re-weigh two additional aliquots similar to the initial weights used, and re-analyze the sample. For a 2-replicate analysis, this provides a total of four burns/samples. If the second set of replicates also has RPD > 30%, report the first set. If the re-analysis has an RPD which passes, report the re-analysis. Three and four replicate analysis may be requested, and the average of the multiple burns is reported, unless otherwise indicated by the client. Analysts should use judgement in cases where there may have been an error with the autosampler or other factor (incorrect loading, etc.) which may have led to RPD failure. The Lloyd Kahn method requires that quadruplicate analysis be performed on one sample per batch of up to 20 samples and that the RSD must meet precision criteria of 3 times the standard deviation of laboratory generated sample data. One sample per batch of up to 20 must be analyzed in quadruplicate. RSD criteria is 40%. This value was generated using 30 data points of quadruplicate analysis of various concentrations and multiple instruments. The RSD was calculated for each sample in quadruplicate, and the RSD limit is based on 3 times the average standard deviation. Failure to meet this criteria requires that the entire batch be re-analyzed.

10.4 Continuing Calibration

A CCV must be analyzed as outlined in Section 10.3.3 at a minimum of every 10 burns and at the close of an analytical sequence.

10.5 Preventive Maintenance

The reduction column is changed after every 100-200 runs. The combustion column is replaced as needed.

11. Data Evaluation, Calculations and Reporting

11.1 Procedures for data and record management for TOC/Soot analysis must adhere to the Quality Systems Manual, other subordinate documents covering record keeping, and the *Document Control* SOP, 08-01. All records are stored in such a manner as to be safe and accessible for at least 10 years.

11.2 The relevant TOC/Soot laboratory notebooks must follow the specifications in the *Laboratory Notebook Usage* Work Instruction 1556, and all record keeping and document control practices.

11.3 Sample results for TOC/Soot are directly reported from the instrument printout.

11.4 Calculations: The following calculations are applied by the instrument when determining the percentage of Total Organic Carbon or Soot: Note: sample weights are corrected for sample mass changes due to acidification prior to analysis and entered into the instrument software as the corrected weights, therefore, no correction is required after analysis.

Corrected Sample Weight(CSW): Weight that is entered at the instrument, corrected for sample mass change after acidification.

CSW = aliquot wt (mg) * total sample dry wt (g) (prior to acidification) * dry wt.@ (75°C)
Total sample dry wt (g) (post acidification) *dry wt.@(105°C)

Carbon Blank (CB): Used to make all other determinations, namely, K-Factor and weight percent calculations. When run alternately with samples, the instrument averages the blank values.

Carbon Blank (CB) = Carbon Read – Nitrogen Read

Carbon K-Factor (C KF): K-Factor, or detector calibration factor, is determined when a known standard is analyzed to calibrate the analyzer in terms of micrograms of carbon. This calibration factor is then used to determine unknowns.

C KF = ((CR – NR) – CB x 100) / (CSW x C Theory Wt. %)

where: CR = Carbon Read
NR = Nitrogen Read
CB = Carbon Blank
CSW= Corrected Sample Weight (mg) (using corrected weight recorded in Section 10.3)
C Theory Wt % = 1% (based on the concentration of the K-Factor standard)

Carbon (mg/Kg):

Carbon (mg/Kg) = (((CR – NR) – CB) x 1000) / (SW x C KF)

where: CR = Carbon Read
NR = Nitrogen Read
CB = Carbon Blank
CSW = Corrected Sample Weight (mg)
C KF = Carbon K-Factor

To convert to % C divide result in mg/Kg by 10000

Example Calculation of Percent TOC/Soot from the instrument, converted to mg of TOC/Soot:

If the result from the instrument is 1.083% and the sample weight is 10.76mg:

1.083% = 100 x [**X** / 10.76mg] (to solve for **X,** divide each side by 100)
0.01083 = **X** / 10.76mg (multiply each side by 10.76mg)
0.116mg = **X**

11.5 Reporting Results

The following procedures must be followed for reporting of TOC/Soot results:

Go to the next page in the bound TOC/Soot logbook.

Retain all computer printouts for the standard and sample analyses of this sequence.

Print the sequence from the computer and review it to make sure that no weight or sample ID transcription errors were made.

Calculate the recoveries for the QC samples (IVC/LCS, CCV, MS and RPD between the duplicate samples) and ensure the Method Blank and CCB meet the criteria. Remember any "QC Failures" require corrective action. See Section 9.0 or 12.0.

After reviewing the final logbook entries, make a copy of the logbook page for secondary review.

Go to the LIMS and "batch" and "associate" the set of QC samples and field samples that were just analyzed.

Enter the Final Results into the LIMS report sheet and check for transcription errors.

Transfer all associated sample paperwork to the Department Manager for the second level review and approval.

All TOC/Soot results are reportable without qualification if analytical holding times are met, preservation (including pH and cooler temperatures) are met, all QC criteria defined in the table below are met, and matrix interference was not suspected during analysis of the TOC/Soot samples. If any of the below QC parameters are not met, all associated samples must be evaluated for re-analysis.

QC Parameter	Acceptance Criteria
Initial Calibration Curve, *Lloyd Kahn*	r $\geq$ 0.995 and slope ± 10% the historical curves
Initial Calibration Verification	80-120% of True Value
Linearity check (high level ICV)	80-120% of True Value
Method Blank	< reporting limit for matrix
Laboratory Control Sample	75-125% R
Matrix Duplicate	25%RPD for results <5x reporting limit
Replicate burns (each sample)	30% RPD
Quadruplicate analysis(1 per batch)	< 40 % RSD
Matrix Spike	75-125% R
Matrix Spike Duplicate if requested	75-125%R/25%RPD
Continuing Calibration Verification	80-120% of True Value
Continuing Calibration Blank	< reporting limit for matrix

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

Section 9 outlines sample batch QC acceptance criteria. If non-compliant TOC/Soot results are to be reported, the Department Manager and/or the Laboratory Director, and the QA Manager must approve the reporting of these results. The laboratory Project Manager is notified, and may chose to relay the non-compliance to the client, for approval, or other corrective action, such as re-sampling and re-analysis. The analyst or Department Manager performing the secondary review initiates the project narrative, and the narrative must clearly document the non-compliance and provide a reason for acceptance of these results.

13. Method Performance

13.1 Method Detection Limit Study (MDL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the MDL, LOD, and/or LOQ as outlined in Alpha SOP/1732. These studies performed by the laboratory are maintained on file for review.

13.2 Demonstration of Capability Studies

Refer to Alpha SOP/1739 for further information regarding IDC/DOC Generation.

13.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

14. Pollution Prevention and Waste Management

The *Hazardous Waste and Sample Disposal* SOP (1797) must be referenced for disposal of used standards, solvents, acids, reagents or other chemicals.

Once satisfactory TOC results have been generated, the sample containers must be scanned back into LIMS and returned to the appropriate sample refrigerator and held for 30 days.

All waste generated must be transferred to the waste disposal area. Dispose all solid samples in solid waste container. Aqueous samples must be poured into a 55-gallon drum marked acidic/non-chlorinated waste.

Refer to the *Chemical Hygiene Plan* and the *Hazardous Waste & Sample Disposal SOP* (1797) for further pollution prevention and waste management information.

1. Scope and Application

Matrices: This method is applicable for solid samples (soils, sediments, sludges).

Definitions: Refer to Alpha Analytical Quality Manual.

The organic carbon in a sample consists of a variety of organic compounds in various oxidation states. Some of these compounds may be oxidized by biological or chemical processes and can be measured by the Biochemical Oxygen Demand or Chemical Oxygen Demand tests. To measure the amount of organically bound carbon, the organic carbon molecules are broken down into single carbon units and converted into a form that can be measured quantitatively.

The PE 2400 Series II CHNS/O Analyzer can simultaneously determine carbon (C), hydrogen (H), nitrogen (N), sulfur (S), and oxygen (O) in organic material. In the CHN mode, the PE 2400 Series II CHNS/O Analyzer uses a combustion method to convert the sample elements to simple gases (CO_2, H_2O, and N_2). The resulting gases are homogenized and controlled to exact conditions of pressure, temperature, and volume. The homogenized gases are allowed to de-pressurize through a column where they are separated in a stepwise steady-state manner and detected as a function of their thermal conductivity and reported as a percentage for solid samples. Treated with hydrochloric acid prior to analysis, the Total Organic Carbon (TOC) content is determined by the amount of CO_2 in the sample. If the sample is analyzed without pretreatment, the Total Carbon (TC) content is determined. Total Inorganic Carbon can be determined by subtraction of the TOC from the TC values.

This method is applicable to the measurement of TOC and Soot in solid samples $\geq$ 500mg/Kg or $\geq$ 0.05%, dry weight. According to the instrument manufacturer, a sample of up to 70% carbon can be analyzed without dilution.

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one or more of the following laboratory

personnel before performing the modification: Area Supervisor, Department Supervisor, Laboratory Director, or Quality Assurance Officer.

This method is restricted to use by or under the supervision of analysts experienced in the operation of the TOC Analyzer and in the interpretation of the data. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

2. Summary of Method

An aliquot of solid sample is dried, homogenized, weighed into a tin capsule, pre-treated with hydrochloric acid and heated to 75°C to convert the inorganic carbon (*i.e.,* carbonate and bicarbonate in the form of CO_2) prior to analysis.

Organic carbon is measured using combustion and a carbon analyzer. The sample, of approximately 5-10 mg corrected weight(masses less than 2 mg must be avoided since balance is not calibrated below 2 mg) Aa larger aliquot may be used for heterogeneous, or low- carbon samples to improve reproducibility, is oxidized in a pure oxygen environment, introduced into a furnace by a 60-slot Autosampler, then combusted. A greater mass may be weighed if the sample observations indicate low carbon content. As much as 20-25mg may be utilized. The carrier gas (O_2) is combined with the carbon content of the combusted sample to form CO_2. Elements, such as halogens and sulfur, are removed by scrubbing reagents in the combustion zone. A thermal conductivity detector then measures the CO_2. The amount of CO_2 derived from a sample is directly proportional to the concentration of organic carbon material in the sample.

For Soot, the sample will be transferred to an aluminum tin. The tins will be placed in an oven or muffle furnace for 24 hours at 375°C. After sample is in the muffle furnace for 24hrs sample is reduced to a powder with a mortar and pestle, weighed into a tin capsule, then treated with acid then re-dried and analyzed on the TOC Analyzer.

2.1 Method Modifications from Reference

Samples are analyzed using 2 replicates unless otherwise specified by the Client. Hydrochloric acid is substituted for phosphoric acid. The use of this acid has been validated and documented by the laboratory.

3. Reporting Limits

The Practical Quantitation Limit (PQL) or Reporting Limit (RL) is 0.05% (or 500mg/Kg) for solid samples.

4. Interferences

4.1 To determine the TOC/Soot content, the inorganic fractions (carbonate and bicarbonate) must be removed prior to analysis by lowering the pH of the sample to $\leq$ 2. When removing the inorganic carbon, care must be taken in sample pretreatment to minimize the potential of loss of volatile organic carbon present in the sample.

4.2 Maintaining the samples at 4±2°C and analyzing within the specified holding time minimizes bacterial decomposition and volatilization of the organic material.

4.3 Elements, such as halogens and sulfur, are removed by scrubbing reagents in the combustion zone. Large and/or complex organic molecules such as tannins, lignins, or humic acids may be oxidized slowly. If these compounds are suspected to be present, it is advisable to check the efficiency of the oxidation procedure with a selected representative sample and adjust the analysis (sample size) as needed.

4.4 Oils from skin, or contact with any organic material, such as plastic containers and rubber tubing, can contaminate samples. Handle the weighing tins with tweezers.

4.5 Sample heterogeneity can be a major source of imprecision in TOC/Soot results. Recommend to clients to perform a client-specific duplicate, to evaluate precision and representativeness of the TOC/Soot results to the site.

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound must be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material data handling sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

The use of laboratory equipment and chemicals exposes the analyst to several potential hazards. Good laboratory techniques and safety practices shall be followed at all times. All relevant Material Safety Data Sheets (MSDSs) are kept on file.

Approved PPE, which includes Safety Glasses, Gloves and Lab Coats, must be worn at all times when handling samples, reagents, chemicals, or when in the vicinity of others handling these items, so that dermal contact is avoided. All standards, reagents and solvents shall be handled using the proper PPE. All flammable solvents must be kept in the flammable storage cabinet and returned to the cabinet immediately after use. When transporting chemicals, use a secure transporting device and/or secondary outer container. Chemical storage is properly segregated and adequately ventilated to reduce the possibility of hazardous reactions. Chemical storage in work areas shall be kept to a minimum. Storage on bench tops or other work surfaces, except temporary, is not permitted.

All standards and reagents shall be prepared in a hood while using the proper PPE.

Analytical instrumentation poses the unique possibility of exposure to high voltages. Other than the *routine* instrument maintenance, as listed in the front of every Instrument Maintenance Logbook, at no time shall an instrument operator attempt to maintenance an instrument alone, or without the proper training, supervision or instruction. Caution must always be used in the presence of moving parts (autosamplers) and hot surfaces (injection ports).

All additional company safety practices shall be followed at all times as written in the *Chemical Hygiene Plan*.

All TOC standard solutions must be handled with caution. See pages 5-3 through 5-5 of the PE 2400 Series II CHNS/O Analyzer User's Manual for additional and specific Warnings and Precautions.

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

A minimum of 5 grams of sample must be collected in a glass jar.

6.2 Sample Preservation

Soil samples must be refrigerated and maintained at 4 ± 2 °C until drying and analysis.

Sediment samples are either processed within 28 days (where citing 9060 hold time reference) (or 14 days for Lloyd Kahn) or can be frozen (for programs with an EPA approved holding time extension for frozen storage) at -15 °C to -20 °C until processing.

6.3 Sample Shipping

The *Sample Receipt & Login SOP* (1559) describes how samples are normally shipped or obtained by the laboratory, precautions to be used in opening sample shipments, and sample storage conditions.

6.4 Sample Handling

All solid samples (NOT requiring the *Lloyd Kahn* Calibration method) must be analyzed within 28 days from the date of collection unless extended hold times are provided in client specific QAPP. **Note:** If samples require the *Lloyd Kahn* Calibration method, the hold time is 14 days unless otherwise indicated by client.

The *Sample Receipt & Login SOP* (1559) describes the responsibilities of sample custody including all proper documentation, verification, and tracking procedures, following Chain of Custody (COC) protocols and sample receipt procedures using the *Sample Receipt Checklist*, which includes the check for proper sample preservation and cooler temperature verification.

Internal COC procedures for sample tracking include the use of sample tracking logbooks. These procedures are also described in the *Sample Receipt & Login SOP* (1559).

7. Equipment and Supplies

7.1 Instrument: Perkin Elmer 2400 Series II CHNS/O Analyzer with computer and PE software

7.2 Detector: Thermal Conductivity

7.3 Mortar and pestle

7.4 Oven: 75 ± 2 °C

7.5 Muffle Furnace: Capable of maintaining temperature of 375°C

7.6 Desiccator

7.7 Volumetric Flasks: Class-A, various volumes

7.8 Microbalance: Perkin Elmer, Model AD-6. See the Manufacturer User's Manual, Section 1.2, pages 3-4, for Microbalance and weighing instructions. The Microbalance calibration is verified every day using 5.0mg - 200mg weights, in the range of daily use, and be accurate within ±1%. If the balance needs to be re-calibrated, see the Manufacturer User's Manual SOP, Section 1.1, page 3, for details.

7.9 Tweezers: Anti-Magnetic

7.10 Tin Boats: 5 X 8 mm.

7.11 Polypropylene beakers: 50 mL, for weighing wet samples.

7.12 Glass Beads: Filter Aid 400, High-density; from Perkin Elmer or 3M. Used as the CCB/Method Blank/LFB media. Beads must be muffled at 375°C prior to use to remove any trace carbon.

7.13 Gas-tight syringes: Various measuring sizes, including 10µL for direct sample spiking

7.14 Transfer pipets and/or Eppendorf pipettor for delivering HCl: Polypropylene.

Note: All maintenance records including routine upkeep and outside service visits are maintained in the instrument maintenance logbooks. See the Manufacturers User's Manual for detailed troubleshooting instructions and routine maintenance, as needed.

8. Reagents and Standards

Use reagent grade chemicals for all reagents. All reagents and standards are stored at room temperature and expire 6 months from preparation, unless otherwise indicated below.

8.1 Deionized (DI) water: All references to DI water refer to ASTM Type II reagent grade water which has been boiled, cooled and capped to eliminate CO_2. Water must be replaced weekly.

8.2 10% Hydrochloric Acid solution: Add 300mL of concentrated HCl (34-37%) to 700mL of DI water. Mix thoroughly and cool to room temperature before use. Store in a glass bottle and keep at room temperature. This solution is stable for 6 months.

8.3 Potassium Hydrogen Phthalate (KHP), CCV or K-Factor for TOC:

CCV- 10,000mg/L equivalent to 10,000mg/Kg Carbon, or 1.0 % TOC:

Dry potassium hydrogen phthalate (KHP) (primary standard grade) at 110°C for 1 hour. Cool to room temperature in a desiccator. Dissolve 2.128g of KHP (primary standard grade) in ASTM DI water and dilute to 100mL in a volumetric flask. This standard is good for 6 months, stored at room temperature. Discard solution if discoloration or any signs of bacterial growth are observed.
Calibration Standards-
Dry KHP (primary standard grade) at 110°C for 1 hour. Cool to room temperature in a desiccator.

- 0.1% (1000mg/Kg) – Add 10 mL of the 1.0% calibration solution (see below) to a 100 mL volumetric flask. Dilute to 100 mL using ASTM DI water.

- 0.5% (5000 mg/Kg) - Dissolve 1.064g of KHP (primary standard grade) in ASTM DI water and dilute to 100mL in a volumetric flask. This standard is good for 6 months, stored at room temperature. Discard solution if discoloration or any signs of bacterial growth are observed.

- 1.0% (10000mg/Kg) - Dissolve 2.128g of KHP (primary standard grade) in ASTM DI water and dilute to 100mL in a volumetric flask. This standard is good for 6 months, stored at room temperature. Discard solution if discoloration or any signs of bacterial growth are observed.

- 2.0% (20000mg/Kg) - Dissolve 4.256g of KHP (primary standard grade) in ASTM DI water and dilute to 100mL in a volumetric flask. This standard is good for 6 months, stored at room temperature. Discard solution if discoloration or any signs of bacterial growth are observed.

- 4.0% (40000mg/Kg) - Dissolve 8.512g of KHP (primary standard grade) in ASTM DI water and dilute to 100mL in a volumetric flask. This standard is good for 6 months, stored at room temperature. Discard solution if discoloration or any signs of bacterial growth are observed.

8.4 Potassium Hydrogen Phthalate (KHP) Spiking Solution/MS/ICV: 10,000mg/L equivalent to 10,000mg/Kg Carbon, or 1.0 % TOC. From a separate source than the solution in Section 8.3, Sigma Aldrich or equivalent.

Dry KHP (primary standard grade) at 110°C for 1 hour. Cool to room temperature in a desiccator. Dissolve 2.128g of KHP (primary standard grade) in ASTM DI water and dilute to 100mL in a volumetric flask. *Use a separate source or different lot of KHP from that used to prepare the calibration standards.*

This stock may be stored up to six months at room temperature. Discard solution if discoloration or any signs of bacterial growth are observed. Use at 1.0 % TOC concentration for solid samples, and at 10,000mg/L for aqueous samples.

8.5 Solid Standard Reference Materials (when requested): Standard Reference Material (SRM) NIST 1944, a separate source from the calibration standard that is certified at the concentration of 4.4% TOC for solid samples. SRM 1650b for Soot, this material has no certified value, however, has a reference value of 78% soot carbon. ("Quantification of the Dilute Sedimentary Soot Phase: Implications for PAH Speciation and Bioavailability" published in Environmental Science and Technology, Vol. 31, No. 1, 1997 by Gustafsson, Haghseta, Chan, McFarlane and Gschwend.)

The recovery range for SRM 1944 --3.3 - 5.5%C and SRM1650(soot) 80%-120%C (low 62.40%-high 93.60%). Corrective action for recoveries outside of the expected range: re-run once, if still failing criteria, recalibrate and rerun after confirming the calibration (passing ICV,ICB). If the SRM continues to fail, contact the department supervisor or manager.

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

9.1 Blank(s)

9.1.1 Method Blank: A method blank must be weighed out alongside samples during the pretreatment process once per every 20 samples or per TOC/Soot batch, whichever is more frequent. The Blank consists of 10-15g of Filter Aid that has been dried in the muffle furnace to remove any trace amounts of Carbon

TOC must not be detectable in the method blank at a concentration greater than the reporting limit for the given matrix (Section 3).

Corrective Action: Analysis of the method blank and all associated samples must be performed until the blank is in control. Samples cannot be analyzed until an acceptable method blank analysis is obtained. Exceptions may be made with approval of the Department Manager, if the samples associated with the out-of-control method blank are non-detect for TOC/Soot, or if sample TOC/Soot concentrations are greater than 10X the blank levels. In such cases, the sample results are accepted without corrective action for the high method blank and the client is notified in a project narrative associated with the sample results.

9.1.2 **Continuing Calibration Blank:** A CCB must be analyzed immediately after every CCV. The CCB is 30-50mg of Filter Aid acidified with HCl and dried. (Section 7.10).

The CCB concentration must not be greater than the reporting limit for the given matrix (Section 3).

Corrective Action: Repeat analysis once to see if an analytical error occurred. If the CCB still exceeds the control limits, re-calibrate and/or re-analyze a fresh blank. All samples associated with the out-of-control CCB must be re-analyzed (since the last acceptable CCB). Exceptions may be made with approval of the Department Manager if the samples associated with the out-of-control method blank are non-detect for TOC/Soot or if sample TOC/Soot concentrations are greater than 10X the blank levels. In such cases, the sample results are accepted without corrective action for the high CCB, and the client is notified in a project narrative associated with the sample results.

9.1.3 **Instrument Blank:** An Instrument Blank must be analyzed during Calibration.run2. The Instrument Blank consists of 30-50mg of Filter Aid acidified with HCl and dried at 75°C. (Section 7.10).

9.2 Laboratory Control Sample (LCS)

Laboratory control sample (LCS) must be from a second source or lot number to verify the accuracy of the standard curve. The LCS is analyzed along with the samples. A LCS must be analyzed once per every 20 samples or per TOC batch, whichever is more frequent. The LCS is an aliquot of the filter aid prepared alongside the samples and spiked at a known value. The recovery limits are 80%-120%.

Corrective Action: Repeat analysis once to see if an analytical error has occurred. If the LCS recovery is still out of control, re-calibrate and re-analyze the LCS and all associated samples. Samples cannot be analyzed until an acceptable LCS is obtained.

9.3 Initial Calibration Verification (ICV)

Second source analyzed at the beginning of the run. Sample matrix of ICV is a 1.0% carbon solution of KHP.

The acceptable recovery QC range for the ICV is 80-120%.

The **ICV** is prepared by adding 10µL of *Spiking Solution* (Section 8.4), (with a 1% TOC true value). The weight recorded is the Calibration Solution only. (10µL of solution should weigh approximately 10mg).

Corrective Action: Repeat analysis once to see if an analytical error occurred. If the ICV still exceeds the control limits, re-calibrate and re-analyze all samples since last acceptable ICV.

9.4 Continuing Calibration Verification (CCV)

A CCV must be analyzed at a minimum of every 10 burns and at the close of an analytical sequence. This standard monitors the instrument's performance throughout the duration of the analytical run. Sample matrix of CCV is a 1.0% carbon solution of KHP.

The CCV is prepared by adding 10µL of *Calibration Solution* (Section 8.3), (with a 1% TOC true value). The weight recorded is the Calibration Solution only. (10µL of solution should weigh approximately 10mg).

The acceptable recovery QC range for the CCV is 80-120%.

Corrective Action: Repeat analysis once to see if an analytical error occurred. If the CCV still exceeds the control limits, re-calibrate and re-analyze all samples since last acceptable CCV.

9.5 Matrix Spike

A matrix spike must be performed once per 20 samples (5% frequency). When project specifications dictate, a Matrix Spike Duplicate (MSD) may also need to be performed at the same frequency as the MS. Prepare the MS according to Section 8.4 for the given matrix.

A **Matrix Spike** sample is spiked with 10µL of *Spiking Solution* (Section 8.4), at a 1.0 % TOC true value. The weight recorded is the sample weight prior to spiking.

The acceptable recovery QC range is 75%-125% for the MS/MSD. Calculate the %RPD as in Section 9.6 when analyzing a MS/MSD pair. The acceptable %RPD is $\leq$ 25% for solid samples.

Corrective Action: If sample concentration exceeds 4X the spike amount, narrate. Repeat analysis once to see if an analytical error has occurred. If the % recovery or %RPD still exceeds the criteria and the LCS is compliant; include a project narrative with the results to the client noting that there may be potential matrix effects on the accuracy or precision of the TOC/Soot results as evidenced by matrix spike recovery or %RPD outside of QC limits.

9.6 Laboratory Duplicate

Duplicate analyses (matrix duplicate) must be performed once per 20 samples (5% frequency).

Acceptable relative percent difference (RPD) of duplicates is $\leq$ 25%. Acceptance criterion is not applicable to sample concentrations less than 5X the reporting limit. Calculate RPD as follows:

$$\%RPD = \frac{R1 - R2}{\frac{[R1 + R2]}{2}} \times 100$$

where:

R1 = highest result

R2 = lower result

Corrective Action: Repeat analysis once to see if an analytical error has occurred. If the % RPD still exceeds the control limits; include a project narrative with the results to the client noting that there may be potential matrix effects on the precision of the TOC/Soot results as evidenced by the matrix duplicate RPD exceedance.

9.7 Method-specific Quality Control Samples

9.7.1 High Level Initial Calibration Verification (HICV) or Linearity Check

This sample consists of 4% carbon solution prepared at the high calibration point.

Aliquot 50 µL using a syringe into a tin boat, record weight and analyze. (Equivalent to a 5 mg sample containing 40% TOC).

The acceptable recovery QC range for the HICV is 80-120%.

Corrective Action: Repeat analysis once to see if an analytical error occurred. If the HICV still exceeds the control limits, re-calibrate. If any sample exceeds the HICV the sample is re-injected with a smaller sample weight that renders a measurement within range. Alternate HICV may be used to test the higher levels of quantification when needed as typically found in soot analysis.

9.7.2 Standard Reference Material (SRM)

If an SRM is required per project plan, 5.0mg of NIST 1944 with a true value of 4.4% TOC (Section 8.6) is used. It is treated with the same lot of HCl as the associated samples and dried at 75° C. The SRM must recover within 75-125% of the true value.

9.8 Method Sequence

- Calibration Curve generation
- ICV
- ICB
- HICV
- Method Blank
- LCS
- SRM (Optional)
- Laboratory Duplicate
- Matrix Spike
- Samples 1 – 5
- CCV
- CCB
- Samples 6 – 15

- CCV
- CCB

10. Procedure

10.1 Equipment Set-up

Samples are prioritized by the Department Manager for analysis based on hold time and client due date. Section 15.5 outlines the steps for final TOC reporting that will contain the sample analysis final results.

The analyst initials, date, sample ID #'s, sample weights (solids), or volumes (aqueous), of all Standards, QC samples and field samples, are entered into the TOC logbook. Include the standard, LCS and MS IDs and concentrations. Use TOC weight spreadsheet to record all information.

10.1.1 Pretreatment for Total Organic Carbon:

This procedure is used to remove the inorganic compounds in the sample prior to the determination of Total Organic Carbon. If Total Carbon is to be determined, addition of the acid solution is omitted.

10.1.1.1 Aliquot 10-15g of wet solid sample into a weighing vessel. Remove shells, rocks and other large non-representative materials with tweezers. Record weight of vessel and vessel + wet sample.

10.1.1.2 Heat for at least 4 hours at 75 +/- 2 °C. Return sample to oven if additional drying time is required(in ½ hour increments) Record time in and out of oven. Cool sample to room temperature in desiccator. Record weight of vessel + dry sample.

10.1.1.3 Add 10% HCl (Section 8.2) dropwise to dry sample to induce effervescence (removal of inorganic carbon). Do not use excessive acid. Only add enough acid to exhaust the effervescence. In lieu of additional acid, use DI water to wet the sample in order to form a slurry, if necessary, to distribute the acid throughout the sample. Record the volume of HCl used for each sample.

10.1.1.4 Return the sample to the oven. Heat for 4 hours at 75 +/- 2 °C. Return sample to oven if additional drying time is required(in ½ hour increments) Record time in and out of oven. Cool to room temperature in desiccator. Record final weight of dry sample + vessel. The change in weight of dry sample after acidification is used to adjust the weight of the aliquots used for analysis.

Note: If the % change post acidification is a negative value this indicates the initial drying step prior to acidification was incomplete. The sample prep must be repeated.

10.1.1.5 Take a sub-aliquot of approximately 2-3 g of dry sample and perform moisture content using SM2540G. The corrected sample weight (CSW, see Section 11.4) is corrected using this result (see Section 11.4 for calculations)

10.1.1.6 Grind sample with mortar and pestle to homogenize. Place ground sample into a 4 mL vial.

10.1.1.6.1 If Soot analysis is required, take a portion of the dried sample aliquot(prior to acidification), approximately 5-10 gm, and place into a muffle furnace at 375°C for 24 hours. Once the sample aliquot is cooled to room temperature, proceed to the acid addition step, Section 10.1.1.3. Samples for Soot are read analytically in the same way as Routine TOC.

10.1.1.7 Weigh (and record weight of) each replicate into a tin capsule (see Section 10.3 for appropriate weight range). Record the weight and use the TOC weight spreadsheet to calculate the corrected sample weight (CSW) which is entered into the analyzer.

10.2 Initial Calibration

On the accompanying computer, or "PC", Perkin Elmer software has been loaded to collect and save sample and standard analysis data. Create a file to store the data from each day's analytical sequence by clicking on the PE 2400 icon, go to "new" and "save" the file "as" the name of the date of the analysis (*i.e.,* 060503.chn). Data from each standard or sample analysis will be automatically stored in this file for future reference

10.2.1 Follow the instrument Manufacturers User's Manual for instrument set up and see Sections below for an outline of the initial, daily calibration procedure.

See the Manufacturers User's Manual, page 5-69, for the default instrument conditions when in the CHN operating mode.

10.2.2 *Lloyd Kahn* Calibration Method: **Note:** The *Routine* instrument calibration procedure (Section 10.2.2) must be established before the Linear Regression method is used, otherwise, the raw data will not reflect results that approximate the results from the curve.

Prepare a curve for *Lloyd Kahn* calibration as outlined below. Additionally, see page 5-82 and 5-83 of the Manufacturers User's Manual for proper set-up of this calibration method.

Analyze each point of the calibration curve following Section 10.3. On an Excel spreadsheet, plot *Carbon (mg*) vs. *Instrument Response*, using five standards and a blank covering the analytical range of interest. See Section 8.3 for Calibration Standard preparation. Standards are solutions of KHP.

Blank = 10 ul of DI water from Barnstead

Point 1 = 0.1% (1,000mg/Kg) Standard

Point 2 = 0.5% (5,000mg/Kg) Standard Point 3 = 1.0% (10,000mg/Kg) Standard Point 4 = 2.0% (20,000mg/Kg) Standard

Point 5 = 4.0% (40,000 mg/Kg) Standard

This is the calibration curve for Linear Regression analysis. The corrected response (Y-axis) is calculated by subtracting the nitrogen response from the carbon response. This is plotted against concentration.

The correlation coefficient (r) of the initial calibration curve must be ≥0.995. For any calibration other than average response the laboratory shall evaluate Relative Error. The

evaluation will be done on a mid-level calibration point and the lowest calibration point. The lowest point must recover within 50% and the mid-level within 30%. This information will be noted on the calibration check spreadsheet and scanned with the raw data stored at the laboratory.

For Lloyd Kahn analysis, one sample per 20 (or per batch) must be analyzed in quadruplicate.

Corrective Action: If the correlation coefficient criteria is not met, the standard curve must be re-prepared and re-analyzed until the correlation coefficient is acceptable.

10.3 Equipment Operation and Sample Processing

Prepare a Calibration Curve per Section 10.2.

An ICV/ICV and LCS/Method Blank are analyzed immediately following the third K-Factor of the Routine Calibration, provided the instrument is “in tolerance”. The LCS and method blank must be run with the same number of replicates that are required for the samples in the run.

Remove all pretreated samples from the oven, and allow to cool in a desiccator.

Weigh approximately 5-10mg (to an accuracy of 0.01 mg) (masses less than 5 mg must be avoided since balance is not calibrated below 5 mg) of sample into a tin boat using the Perkin-Elmer Microbalance, Model AD-6, . Samples that are known to be high in TOC may use a lesser sample aliquot. Samples where it is observed that the TOC may be low, weight as much as 20-25mg. Record the weights in the TOC/Soot logbook. Matrix Duplicate and Matrix Spike samples are weighed as separate samples, with their own replicates. As noted in Section 10.1.1.6, use the TOC weight spreadsheet to correct the sample weights for all replicates and re-analyses. Any observations regarding the sample composition must be noted in the TOC/Soot logbook such as: sandy, contains shells or rocks, contains grass or roots, is light/white in coloration, etc.

Analyze a CCV/CCB (Section 9.4 and 9.1.3) after every 10 “burns”, and at the end of the analytical sequence.

If following the *Lloyd Kahn* Calibration method, analyze the first set of batch QC samples, the ICV/LCS and Method Blank, followed by field samples with a CCV/CCB analyzed every 10 “burns”, and at the end of the analytical sequence.

10.3.1 Multiple Sample Instrument Loading:

10.3.1.1 Each tin boat is carefully folded with anti-magnetic tweezers, and placed into its respective holding tray position. (See the Manufacturer User’s Manual SOP, Section 1.2, page 4, for tin boat folding details.) Weights, sample tray position and Autosampler location are recorded in the TOC/Soot logbook. The analyst must be very careful when transferring samples. Documentation of sample consistency is very important. See Figure 1 for an example logbook page.

10.3.1.2 Adjust the Autosampler tray to begin sampling at auto-slot #1 and carefully transfer the folded tins containing the samples to the correct auto-slot, using tweezers. All Instrument Calibration Standards (Blanks, K-Factors and/or *Lloyd Kahn* Calibration Standards) are loaded first. Immediately following will be the first batch QC samples, the ICV/LCS and Method Blank for the run, followed by field samples. Rotate the Autosampler in a counterclockwise manner.

10.3.1.3 A maximum of 60 tins can be held on the Autosampler at one time. The instrument only allows for 100 total samples (including calibration/blank samples) to be programmed for any given run.

10.3.2 Sample Analysis

10.3.2.1 Select the *Auto Run* option on the keypad on the instrument. The following menu appears:

AUTO RUN NO. 1
1B 2K 3S
where: B = Blank
K = K-Factor
S = Sample

Assuming the *Instrument Standardization* occupies auto-slots 1-6, Enter "3" for Sample, then select "Enter". Enter the weight of the "Primer" Standard (position 1) and select "Enter".

10.3.2.2 You will be prompted for AUTO RUN NO. 2 as in Section 10.3.3.1, except now there is a function "4NP" which allows the analyst to stop/erase everything by selecting this feature.

- Enter "1" for the Blank. The weight will not be asked for.
- Enter "2" for the first K-Factor, then select "Enter". Enter the weight of your K-Factor (the standard weight should be ~ 10mg). Select "Enter".
- Enter "1" for the second Blank, then "Enter".
- Enter "2" for the second K-Factor, then "Enter". Enter the weight, then "Enter".
- Enter "2" for the third K-Factor, then "Enter". Enter the weight, then "Enter".

10.3.2.3 All remaining sample weights are added by entering "3" for Sample, and then by entering the sample weight. Continue adding all information to the run sequence, using the keypad. When entering sample identifications, and letters are necessary, refer to the Manufacturer's User's Manual, page 3-4, for instructions for converting numbers to letters.

10.3.2.4 When all sequence information is entered and complete, select "Start". The analyses will begin. The computer will continue to display the "AUTO RUN" menu during sample analysis.

10.3.2.5 The Standard and Sample data prints out as it is collected on the line printer, and is also collected on the linked computer using the PE 2400 software. The data on the computer is saved in a file named as the date of the analysis (*i.e.,* 060503.chn) for future reference, as noted in 10.2.

10.3.2.6 When all analyses are complete, refer to the Manufacturers User's Manual SOP, Section 3.1, page 7, for instructions to "Shut Down" the instrument.

10.3.2.7 Evaluate all batch QC samples first, to confirm or exclude the need for re-analyses. The ICV/LCS/HICV, Method Blank, CCB/CCV samples must meet the acceptance criteria in Section 9. Follow the corrective action for any QC failures.

10.3.2.8 Evaluate the field samples, LCS/SRM, and MS/Duplicates next. If replicate "burns" vary by more than 30% and are greater than 5 times the RL, re-weigh two additional aliquots similar to the initial weights used and re-analyze the sample. For a 2-replicate analysis, this provides a total of four burns/samples. If the second set of replicates also has RPD > 30%, report the first set. If the re-analysis has an RPD which passes, report the re-analysis. Three and four replicate analyses may be requested, and the average of the multiple burns is reported, unless otherwise indicated by the client. Analysts should use judgement in cases where there may have been an error with the autosampler or other factor (incorrect loading, etc.) which may have led to RPD failure. The Lloyd Kahn method requires that quadruplicate analysis be performed on one sample per batch of up to 20 samples and that the RSD must meet precision criteria of 3 times the standard deviation of laboratory generated sample data. One sample per batch of up to 20 must be analyzed in quadruplicate. RSD criteria is 40%. This value was generated using 30 data points of quadruplicate analysis of various concentrations and multiple instruments. The RSD was calculated for each sample in quadruplicate, and the RSD limit is based on 3 times the average standard deviation. Failure to meet these criteria requires that the entire batch be re-analyzed.

10.4 Continuing Calibration

A CCV must be analyzed as outlined in Section 10.3.3 at a minimum of every 10 burns and at the close of an analytical sequence.

10.5 Preventive Maintenance

The reduction column is changed after every 100-200 runs or as needed. The combustion column is replaced as needed.

11. Data Evaluation, Calculations and Reporting

11.1 Procedures for data and record management for TOC/Soot analysis must adhere to the Quality Systems Manual, other subordinate documents covering record keeping, and the *Document Control* SOP, 08-01. All records are stored in such a manner as to be safe and accessible for at least 10 years.

11.2 The relevant TOC/Soot laboratory notebooks must follow the specifications in the *Laboratory Notebook Usage* Work Instruction 1556, and all record keeping and document control practices.

11.3 Sample results for TOC/Soot are directly reported from the instrument printout.

11.4 Calculations: The following calculations are applied by the instrument when determining the percentage of Total Organic Carbon or Soot: Note: sample weights are corrected for sample mass changes due to acidification prior to analysis and entered into the instrument software as the corrected weights, therefore, no correction is required after analysis.

Corrected Sample Weight(CSW): Weight that is entered at the instrument, corrected for sample mass change after acidification.

CSW = aliquot wt (mg) * total sample dry wt (g) (prior to acidification) * dry wt.@ (75°C)
Total sample dry wt (g) (post acidification) *dry wt.@(105°C)

Carbon Blank (CB): Used to make all other determinations, namely, K-Factor and weight percent calculations. When run alternately with samples, the instrument averages the blank values.

Carbon Blank (CB) = Carbon Read – Nitrogen Read

Carbon K-Factor (C KF): K-Factor, or detector calibration factor, is determined when a known standard is analyzed to calibrate the analyzer in terms of micrograms of carbon. This calibration factor is then used to determine unknowns.

C KF = ((CR – NR) – CB x 100) / (CSW x C Theory Wt. %)

where: CR = Carbon Read
NR = Nitrogen Read
CB = Carbon Blank
CSW = Corrected Sample Weight (mg) (using corrected weight recorded in Section 10.3)
C Theory Wt % = 1% (based on the concentration of the K-Factor standard)

Carbon (mg/Kg):

Carbon (mg/Kg) = (((CR – NR) – CB) x 1000) / (SW x C KF)

where: CR = Carbon Read
NR = Nitrogen Read
CB = Carbon Blank
CSW = Corrected Sample Weight (mg)
C KF = Carbon K-Factor

To convert to % C divide result in mg/Kg by 10000

Example Calculation of Percent TOC/Soot from the instrument, converted to mg of TOC/Soot:

If the result from the instrument is 1.083% and the sample weight is 10.76mg:

1.083% = 100 x [**X** / 10.76mg] (to solve for **X,** divide each side by 100)
0.01083 = **X** / 10.76mg (multiply each side by 10.76mg)
0.116mg = **X**

11.5 Reporting Results

The following procedures must be followed for reporting of TOC/Soot results:

Go to the next page in the bound TOC/Soot logbook.

Retain all computer printouts for the standard and sample analyses of this sequence.

Print the sequence from the computer and review it to make sure that no weight or sample ID transcription errors were made.

Calculate the recoveries for the QC samples (IVC/LCS, CCV, MS and RPD between the duplicate samples) and ensure the Method Blank and CCB meet the criteria. Remember any "QC Failures" require corrective action. See Section 9.0 or 12.0.

After reviewing the final logbook entries, make a copy of the logbook page for secondary review.

Go to the LIMS and "batch" and "associate" the set of QC samples and field samples that were just analyzed.

Enter the Final Results into the LIMS report sheet and check for transcription errors.

Transfer all associated sample paperwork to the Department Manager for the second level review and approval.

All TOC/Soot results are reportable without qualification if analytical holding times are met, preservation (including pH and cooler temperatures) are met, all QC criteria defined in the table below are met, and matrix interference was not suspected during analysis of the TOC/Soot samples. If any of the below QC parameters are not met, all associated samples must be evaluated for re-analysis.

QC Parameter	Acceptance Criteria
Initial Calibration Curve, *Lloyd Kahn*	r $\geq$ 0.995
Initial Calibration Verification	80-120% of True Value
High-Level ICV (Linearity Check)	80-120% of True Value
Relative Error Calibration Verification	Low Standard: 50-150% Mid Standard: 70-130%
Method Blank	< reporting limit for matrix
Laboratory Control Sample/SRM	80-120% LCS 75-125% SRM
Matrix Duplicate	25%RPD for results >5x reporting limit
Replicate burns (each sample)	30% RPD for results >5x reporting limit
Quadruplicate analysis(1 per 20 samples)	< 40 % RSD
Matrix Spike	75-125% R
Matrix Spike Duplicate if requested	75-125%R/25%RPD
Continuing Calibration Verification	80-120% of True Value
Continuing Calibration Blank	< reporting limit for matrix

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

Section 9 outlines sample batch QC acceptance criteria. If non-compliant TOC/Soot results are to be reported, the Department Manager and/or the Laboratory Director, and the QA Manager must approve the reporting of these results. The laboratory Project Manager is notified, and may chose to relay the non-compliance to the client, for approval, or other corrective action, such as re-sampling and re-analysis. The analyst or Department Manager performing the secondary review initiates the project narrative, and the narrative must clearly document the non-compliance and provide a reason for acceptance of these results.

13. Method Performance

13.1 Method Detection Limit Study (MDL) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the MDL, LOD, and/or LOQ as outlined in Alpha SOP/1732. These studies performed by the laboratory are maintained on file for review.

13.2 Demonstration of Capability Studies

Refer to Alpha SOP/1739 for further information regarding IDC/DOC Generation.

13.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

14. Pollution Prevention and Waste Management

The *Hazardous Waste and Sample Disposal* SOP (1797) must be referenced for disposal of used standards, solvents, acids, reagents or other chemicals.

Once satisfactory TOC results have been generated, the sample containers must be scanned back into LIMS and returned to the appropriate sample refrigerator and held for 30 days.

All waste generated must be transferred to the waste disposal area. Dispose all solid samples in solid waste container. Aqueous samples must be poured into a 55-gallon drum marked acidic/non-chlorinated waste.

Refer to the *Chemical Hygiene Plan* and the *Hazardous Waste & Sample Disposal SOP* (1797) for further pollution prevention and waste management information.

Method 9014 (Modified). SW-846, Test Methods for Evaluating Solid Waste: Physical / Chemical Methods, EPA SW-846, Update III, 1997

1. Scope and Application

Matrices: This method is applicable to waters, liquids, solids, soils and sludges

Definitions: Refer to Alpha Analytical Quality Manual.

The following SOP is a reflux-distillation procedure used to extract soluble cyanide salts and many insoluble cyanide complexes from wastes and leachates. It is based on the decomposition of nearly all cyanides by a reflux distillation procedure using a strong acid and a magnesium catalyst. Cyanide, in the form of hydrocyanic acid (HCN) is purged from the sample and captured into an alkaline scrubber solution. The concentration of cyanide in the scrubber solution is then determined by flow injection analysis on a Lachat Analyzer.

This method was designed to address the problem of “trace” analyses (<1000ppm). The method may also be used for “minor” (1000ppm – 10,000ppm) and “major” (>10,000ppm) analyses by adapting the appropriate sample dilution. However, the amount of sodium hydroxide in the standards and the sample analyzed must be the same.

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one or more of the following laboratory personnel before performing the modification: Area Supervisor, Department Supervisor, Laboratory Director, or Quality Assurance Officer.

This method is restricted to use by or under the supervision of analysts experienced in the operation of the Lachat and in the interpretation of Lachat data. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

2. Summary of Method

The cyanide, as hydrocyanic acid (HCN), is released from samples containing cyanide by means of a reflux-distillation operation under acidic conditions and absorbed in a scrubber containing sodium hydroxide solution. The cyanide concentration in the absorbing solution is then determined colorimetrically by Lachat flow injection analysis.

2.1 Method Modifications from Reference

The sample size used is 50mL. The Midi distillation unit has demonstrated the ability to achieve the same RDL using 50mL instead of 500mL sample volume. Refer to EPA Method 335.4.

Modification for Method 9014: An automated determination of cyanide using the Lachat instrument is used instead of manual spectrophotometric determination.

Modification for amenable cyanide: Analysis is not prepped under amber light.

3. Reporting Limits

The Reported Limit for aqueous samples is 0.005mg/L; soil and solid samples is 1mg/Kg

4. Interferences

4.1 Interferences are eliminated or reduced by using the distillation procedure. However, chlorine and sulfide are interferences. Refer to Section 10.1.1.

4.2 High results may be obtained for samples that contain nitrate and/or nitrite. During the distillation, nitrate and nitrite will form nitrous acid, which will react with some organic compounds to form oximes. These compounds once formed will decompose under test conditions to generate HCN. The possibility of interference of nitrate and nitrite is eliminated by pretreatment with sulfamic acid just before distillation. Nitrate and nitrite are interferences when present at levels higher than 10mg/L and in conjunction with certain organic compounds.

4.3 Thiocyanate is reported to be an interference when present at very high levels. Levels of 10mg/L were not found to interfere.

4.4 Fatty acids, detergents, surfactants, and other compounds may cause foaming during the distillation when they are present in high concentrations. Add anti-foaming agent to the sample during the distillation procedure (Section 10.3.1).

4.5 Carbonates and aldehydes are possible interferences.

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material safety data sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

The following chemicals have the potential to be highly toxic or hazardous. For detailed explanations consult the MSDS:

- Cyanide
- Sulfuric acid
- Pyridine
- Chloramine-T

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

Samples are collected in plastic or glass containers. All containers must be thoroughly cleaned and rinsed.

Oxidizing agents such as chlorine decompose most cyanides. Testing for chlorine must be done in the field prior to sample preservation.

6.2 Sample Preservation

Prior to preservation, samples must be tested for chlorine (Section 6.1).

Aqueous samples are preserved with 50% sodium hydroxide in the field to a pH $\geq$ 12 at the time of collection.

Samples and distillates are stored in the refrigerator at 4 ±2 °C.

6.3 Sample Shipping

No specific requirements.

6.4 Sample Handling

When properly preserved, cyanide samples are stored for up to 14 days prior to sample preparation steps.

Distillates must be analyzed within 14 days of distillation. Samples must be analyzed within 14 days of receipt.

Note: for MCP-TCN samples must be analyzed within 24h after distillation

7. Equipment and Supplies

7.1 Cyanide Midi Distillation Unit: Lab Crest, BGL or comparable midi distillation unit. With reaction vessels, collection vessels, cold fingers and impingers.

7.2 pH paper: Range 1-14

7.3 Lead Acetate Paper

7.4 Vacuum source

7.5 50mL centrifuge tubes: New, plastic, with caps.

7.6 KI starch paper: Residual Chlorine sensitivity

7.7 Class A volumetric flasks: 25, 50, 100, 500 and 1000mL

7.8 Graduated cylinders: 50mL glass or plastic

7.9 Eppendorf pipettor or pipets: 0.5, 1, 2, and 5mL

7.10 Lachat 8500 Flow Analyzer: Including Quick Chem software, autosampler, pump and accessories.

7.11 Balance: Capable of weighing to 0.0001gram

7.12 Beakers: 100mL

7.13 Chiller

7.14 Stir plate

7.15 Stir bars

7.16 Dilution vials

8. Reagents and Standards

Reagent grade chemicals are used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. Other grades may be used, provided it is first ascertained that the reagent is of sufficient high purity to permit its use without lessening the accuracy of the determination.

8.1 Standards and Reagents for Distillation

8.1.1 Reagent Water: All references to water in this method refer to Deionized Water (DI) from Alpha's water treatment system.

8.1.2 Ascorbic Acid, $C_6H_8O_6$: Powder. Store at room temperature. Expires upon manufacturer's specified date.

8.1.3 Sodium hydroxide solution (1N), NaOH: In a 1L volumetric flask, dissolve 40g of NaOH. Bring to volume with DI water. Store at room temperature. Expires one month from date of preparation.

8.1.4 Sulfamic acid (0.4N), H_2NSO_3H: In a 1L volumetric flask, dissolve 40g H_2NSO_3H. Bring to volume with DI water. Store at room temperature. Expires 6 months from date of preparation.

8.1.5 Sulfuric acid (1:1), H_2SO_4: To a 1L volumetric flask, add 500mL DI water. Slowly and carefully add 500mL of concentrated H_2SO_4. Store at room temperature. Expires one month from date of preparation.

8.1.6 Magnesium chloride solution (2.5M), $MgCl_2 \cdot 6H_2O$: In a 1L volumetric flask, dissolve 510g of $MgCl_2 \cdot 6H_2O$. Bring to volume with DI water. Store at room temperature. Expires 6 months from date of preparation.

8.1.7 LCS, 1000ppm cyanide stock solution: Commercially available standard with a certificate of analysis and from a different source than the Lachat calibration standards. Purchased from Ricca, Catalog # 2543-32. Store refrigerated at 4 ± 2 °C. Expires upon manufacturer's specified date.

8.1.8 LCS 10ppm cyanide working solution: Pipet 1mL of 1000ppm cyanide stock solution (Section 8.1.7) into a 100mL volumetric flask. Add 10mL of 1N NaOH (Section 8.1.3). Bring to volume with DI water. Prepare each day of use.

8.1.8.1 This can also be made by taking 5mL of 10ppm (Section 8.1.8) up to 500mL with 0.1N NaOH. This would be distilled as a whole volume (50mL). Prepare daily.

8.1.9 1000ppm Stock Spiking Solution: 1000ppm cyanide standard available commercially with a certificate of analysis. This is from a different source than the LCS (8.1.7). Purchased from LabChem Inc., Catalog # LC13545. Store refrigerated at 4 ± 2 °C. Expires upon manufacturer's specified date.

8.1.10 10ppm Working Cyanide Spiking Solution: Pipet 1mL of the 1000ppm Stock Spiking Solution (Section 8.1.9) into a 100mL volumetric flask. Add 10mL 1N NaOH (Section 8.1.3). Bring to volume with DI water. Prepare fresh each day of use.**pH 4 Acetate Buffer solution:** In a 500mL volumetric flask, dissolve 410g of sodium acetate trihydrate. Bring to volume with DI water. Adjust to pH of 4.5 with acetic acid (Section 8.1.13). Store at room temperature. Expires 6 months from date of preparation.

8.1.11 Lead Carbonate Powder, [Pb (CO3)]

8.1.12 LCS 0.5 ppm Cyanide Working Solution: Pipet 5mL of the 10ppm Working Cyanide Spiking Solution (Section 8.1.10) into a 100mL volumetric flask . Add 1mL of 10N NaOH (Section 8.1.16). Bring to volume with DI water. Prepare each day of use.

8.1.13 Concentrated Acetic Acid: Store at room temperature. Expires upon manufacturer's specified date.

8.1.14 Ottawa Sand or Boiling chips

8.1.15 Sodium hydroxide solution (10N), NaOH: In a 1L volumetric flask, dissolve 400g of NaOH. Bring to volume with DI water. Store at room temperature. Expires 6 months from date of preparation.

8.1.16 Sodium hydroxide solution (0.1N), NaOH: In a 10L carboy mix 100mL of 10N NaOH. Bring to volume with DI water. Store at room temperature. Expires daily.

8.1.17 Total Cyanide SRM: ERA catalog # 541. Store in room temperature. Expires upon manufacturer's specified date.

8.1.18 Calcium Hypochlorite Solution: Dissolve 5g Ca(OCl)2 in 100mL Deionized water. Store in an amber colored bottle in the dark. Expires monthly.

8.2 Standards and Reagents for Lachat Analysis

8.2.1 Helium gas: To prevent bubble formation, degas all solutions except the standards with helium. Use He at 140kPa (20 lb/in^2) through a helium degassing tube (Lachat part number 50100). Bubble He vigorously through the solution for one minute.

8.2.2 Reagent 1. Carrier, 0.1N Sodium Hydroxide: In a 1L plastic container add 10mL of 10N NaOH (Section 8.1.16). Bring to 1L volume with DI. Store at room temperature. Prepare fresh bi-weekly.

8.2.3 Reagent 2. Acetate Buffer, 2.68M: In a 1L volumetric flask, dissolve 163g spdium acetate trihydrate (acetic acid, sodium salt trihydrate, $CH_3CO_2NA•H_2O$) in approximately 800mL of water. Add 40mL of acetic acid to solution. Dilute to the mark and invert to mix. Store at room temperature. Prepare fresh monthly.

8.2.4 Reagent 3. Chloramine-T: Dissolve 2.0g chloramine-T hydrate in 500mL DI. Prepare fresh daily.

8.2.5 Reagent 4. Pyridine-Barbituric Acid Reagent: Under a fume hood, place 15g barbituric acid in a 1L beaker and add 100mL water, rinsing down the sides of the beaker to wet the barbituric acid. Add 75mL pyridine (C_5H_5N) while stirring and mix

until the barbituric acid dissolves. Add the 15mL concentrated hydrochloric acid (12M HCl) and mix. Store at room temperature. Prepare fresh weekly.

8.2.6 **0.5ppm Calibration standard:** Pipet 5mL of the 10ppm working cyanide spiking solution (Section 8.1.10) into a 100mL volumetric flask. Bring to volume with 0.1N NaOH. Prepare each day of use.

8.2.7 **0.2ppm Calibration standard:** Pipet 2mL of the 10ppm working cyanide spiking solution (Section 8.1.10) into a 100mL volumetric flask. Bring to volume with 0.1N NaOH. Prepare each day of use.

8.2.8 **0.1ppm Calibration standard:** Pipet 1mL of the 10ppm working cyanide spiking solution (Section 8.1.10) into a 100mL volumetric flask. Bring to volume with 0.1N NaOH. Prepare each day of use. This calibration standard is also used as the Continuing Calibration Verification sample.

8.2.9 **0.04ppm Calibration standard:** Pipet 5mL of the 0.2ppm calibration standard (Section 8.2.7) into a 25mL volumetric flask. Bring to volume with 0.1N NaOH. Prepare each day of use.

8.2.10 **0.02ppm Calibration standard:** Pipet 1mL of the 0.5ppm calibration standard (Section 8.2.6) into a 25mL volumetric flask. Bring to volume with 0.1N NaOH. Prepare each day of use.

8.2.11 **0.01ppm Calibration standard:** Pipet 10mL of the 0.02ppm calibration standard (Section 8.2.10) and 10mL of 0.1N NaOH into a container and mix. Prepare each day of use.

8.2.12 **0.004ppm Calibration standard:** Pipet 5mL of 0.04ppm calibration standard (Section 8.2.9) into a 50mL volumetric flask. Bring to volume with 0.1N NaOH. Prepare each day of use.

8.2.13 **0.1ppm ICV standard:** Pipet 1mL of the 10ppm LCS cyanide working solution (8.1.8) into a 100mL volumetric flask. Bring to volume with 0.1N NaOH. Prepare each day of use.

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

9.1 Blank

A minimum of one method blank is distilled and analyzed per batch of 20 or less samples. The Method Blank is utilized to determine if contamination or any memory effects are occurring. (Section 10.3.1.1) The blank result must be less than the reporting limit of 0.005 mg/L for liquids and 1 mg/kg for soils. If the blank result is outside of acceptance criteria, it is injected another time. If failure continues, sample analysis is terminated and the source of the problem is found and corrected. All samples analyzed since the last acceptable blank analysis must be reanalyzed.

9.2 Laboratory Control Sample (LCS)

Distill and analyze two LCSs per batch of 20 samples. A Low LCS is analyzed at 0.1mg/L and a high LCS is analyzed at 0.2mg/L. (Section 10.3.1.2)

LCS measurements for Method SM 4500 CN-CE must be within ±10%. For Method 9010C/9012B, the LCS measurements must be within ± 15% for liquids and +/- 20% for soils.

Samples for Method 9010C/9012B: LCSDs are distilled and analyzed along with the LCSs, as described above. The RPD between LCS and LCSD must be ≤ 20% for liquids and <35% for soils.

For soil samples: LCS and LCSD recovery must be within vendor specified acceptance criteria (it will be different for different lots of SRM)

If any LCS fails acceptance criteria for either % Recovery or RPD, analysis is terminated and samples are redigested and analyzed

9.3 Initial Calibration Verification (ICV)

The Initial Calibration Verification Standard (ICV) (Section 8.2.13) is analyzed immediately following the calibration to verify the curve. If the measurements exceeds ±10% of 0.1ppm, the analysis is terminated and recalibration must occur. An acceptable result for the ICV must be obtained prior to any sample analysis.

9.4 Continuing Calibration Verification (CCV)

The Continuing Calibration Verification Standard (CCV) (Section 8.2.8) is analyzed after every 10 injections. The CCV measurements cannot exceed ±10% of the 0.1ppm. If the CCV is not within acceptance criteria, the standard is injected again. If failure continues, sample analysis is terminated and the source of the problem is found and corrected. All samples analyzed since the last acceptable calibration verification must be reanalyzed.

9.5 Matrix Spike

Distill and analyze one spike per batch of 20 samples. For Method 9010C/9012B distill and analyze one spike per batch of 10 samples.

For Method 9010C/9012B, the % Recovery must be within ±20% for liquids and ±35% for solids. For SM 4500CN-CE, the % Recovery must be within ±10%. (Section 10.3.1.4).

Samples for Method 9010C/9012B: A Matrix Spike Duplicate (MSD) is distilled and analyzed along with the MS, as described above. The RPD between MS and MCSD must be ≤ 20% for liquids and <35% for soils

9.6 Laboratory Duplicate

Analyze one duplicate sample for every 20 samples. A duplicate sample is a sample brought through the entire sample preparation and analytical process. (Section 10.3.1.5)

The RPD must be 20% or less for liquids and 35% or less for soils and solids. See Section 12 for Corrective Action if these criteria are not met.

9.7 Method-specific Quality Control Samples

None.

9.8 Method Sequence

The analytical sequence is:

- Screening of samples for chlorine and sulfide
- Prep of amenable cyanide, if needed
- Distillation:
    - Samples

- LCS Low
- LCS High
- Blank
- Matrix Spike
- Duplicate

- Analysis:
  - Calibration and Standardization of Lachat Instrument
  - CCV
  - CCB
  - ICV
  - ICB
  - 10 samples
  - CCV
  - CCB
  - 10 samples
  - CCV
  - CCB
  - Calculation of sample cyanide concentration

10. Procedure

10.1 Equipment Set-up

10.1.1 Screening for Chlorine and Sulfide Interference

10.1.1.1 Chlorine Interference

Oxidizing agents, such as chlorine, decompose most cyanides. Test by placing a drop of sample on a strip of potassium iodide (KI) - starch paper previously moistened with acetate buffer solution, pH 4. If positive indication is noted, then treat an aliquot of sample with Ascorbic Acid (Section 8.1.2). Repeat this test until the KI paper is negative. Immediately inform the Department Supervisor of this interference.

Manganese dioxide, nitrosyl chloride, etc., if present also may cause discoloration of the test paper

10.1.1.2 Sulfide Interference

Oxidized products of sulfide convert CN- to SCN- rapidly, especially at high pH. Test for S^{-2} by placing a drop of sample on lead acetate test paper previously moistened with acetic acid buffer solution, pH 4 (Section 8.1.11). Darkening of the paper indicates presence of S^{-2}. Add powdered lead carbonate [Pb (CO3)] in 1g increments to the whole sample volume. Re-test with acetate paper. Repeat test until a drop of treated sample no longer darkens the acidified lead acetate test paper. Record in the sample prep logbook the amount of lead carbonate added to the sample.

10.1.2 Amenable Cyanide Prep

10.1.2.1 Add 25mL, or 1g and 25mL of DI (8.1.1), to a 100mL beaker with a stir bar.

10.1.2.2 Add 1mL of 10ppm LCS cyanide working solution (8.1.8) to beaker.

10.1.2.3 Prep one sample in duplicate.

10.1.2.4 Add 1-2mL of calcium hypochlorite solution (8.1.18) to all samples and QC under the hood.

10.1.2.5 Check for the presence of chlorine by placing a drop of the sample on a KI-starch paper (7.6). It should turn blue if there is sufficient chlorine.

10.1.2.6 Check samples every 15 minutes for one hour for the presence of chlorine and add more calcium hypochlorite if needed.

10.1.2.7 After one hour of digesting, add ascorbic acid (8.1.2) until KI strip no longer turns blue.

10.1.2.8 Bring sample volume up to 50mL and distill following steps 10.3.1.6 thru 10.3.1.15.

10.2 Initial Calibration

10.2.1 Allow 15 minutes for heating unit to warm up to 60 °C.

10.2.2 Prepare a series of 7 calibration standards (Sections 8.2.6 – 8.2.12) and a 0.1N NaOH blank. Alternatively, calibration standards may be prepared by auto-diluting a 0.5ppm calibration standard (Section 8.2.6). Perform this function per the Lachat manufacturer's instructions for the Quick Chem 8500.

10.2.3 Set up manifold as shown in Table 1.

10.2.4 Input data system parameters as shown in Table 2.

10.2.5 Place standards and blank in the autosampler, per the manufacturer's instructions. Input the information required by the data system, such as concentration, replicates and QC scheme.

10.2.6 Inject the standards, per the manufacturer's instructions.

10.2.7 Prepare a standard curve by plotting instrument response against standard concentration values. A calibration curve is fitted to the calibration solution concentration/response data using the computer. The calibration coefficient of the curve must be greater than or equal to 0.995 before sample analysis can begin.

Calibration coefficient will be calculated using Lachat software. All calibration points are back calculated by Lachat software and should be within 10% from true concentration, except 2 lowest points of calibration curve. %recoveries for low range will be wider, but shouldn't exceed 100% and correlation coefficient will not be worse than 0.995.

10.3 Equipment Operation and Sample Processing

10.3.1 Distillation

10.3.1.1 Add 50mL of shaken liquid sample, or 1gram of a well-homogenized solid sample and 50mL of DI, to the 50mL reaction vessel.

10.3.1.2 For the Liquid High LCS, fill one 50mL reaction vessel with 50mL DI. For the soil High LCS, add 1g Ottawa Sand (Section 8.1.15) and 50mL of DI. After the system has been charged with air, add 1mL of 10ppm LCS cyanide working solution (8.1.8) to the closed system. (Final concentration equals 0.2mg/L.)

For the Liquid Low LCS, fill one 50mL reaction vessel with 50mL of DI. For a soil Low LCS, add 0.2-0.3 g (depending on actual SRM stock concentration) of SRM (sec 8.1.17) and 50mL of DI. Record exact SRM weight. For liquid samples: After

the system has been charged with air, add 0.5mL of 10ppm LCS cyanide working solution (Section 8.1.8) to the closed system. (Final concentration equals 0.1mg/L.) **Don't add liquid Cyanide Standard for soil samples!** Final LCS soil concentration will change based on SRM lot
Samples for Method 9010C/9012B: Prepare a LCS Duplicate along with the LCSs described above.

10.3.1.3 For the method blank for liquid samples, fill one 50mL reaction vessel with 50mL of DI. For the method blank for soil samples, fill a 50mL reaction vessel with 1g of Ottawa Sand (Section 8.1.15) and 50mL DI.

10.3.1.4 For the matrix spike, fill a 50mL reaction vessel with 50mL of sample that has been chosen to be spiked. For soil samples, use 1g of soil and add 50mL of DI water. After the system has been charged with air, add 1mL of 10ppm working cyanide spiking solution (8.1.10) to the closed system.

Samples for Method 9010C/9012B: Prepare a Matrix Spike Duplicate (MSD) in the same manner as the MS, as described above.

10.3.1.5 For the duplicate, fill a 50mL reaction vessel with a duplicate aliquot of 50mL, or 1g soil and 50mL DI water of a sample that has been chosen to be duplicated.

10.3.1.6 Into the receiver or scrubber tube add 5mL of a 1N NaOH solution and add 40mL of DI water.

10.3.1.7 Arrange tubes in the distillation unit noting in the logbook which sample is in which glassware. The glassware is numbered and consistently placed in the same position in the distillation unit.

10.3.1.8 Assemble the unit completely. Turn on the pump. There must be gas bubbling in each tube. Check to make sure all connections are tight and bubbles are flowing at an equal rate in each sample tube. If not, adjust flow rate with the knobs in front of each receiver tube and/or check lines to ensure they are not obstructed.

10.3.1.9 Add 5mL of 0.4N sulfamic acid (8.1.4) to each sample tube and rinse the closed 50mL reaction vessel with a squirt of DI. No residue is to be left of the vessel wall.

10.3.1.10 Add 5mL of 1:1 H_2SO_4 (8.1.5) to each sample tube and rinse the closed 50mL reaction vessel with a squirt of DI. No residue is to be left on the vessel wall. Turn on the heat. Samples are to come to a boil on all of the midi-still units.

10.3.1.11 After 2 minutes of heating, add 2mL of 2.5M $MgCl_2$ Solution (8.1.6) to each sample tube, followed by a rinse with DI. If foaming occurs, an additional 2mL of $MgCl_2$ Solution may be added. If foaming continues, stop the distillation for that sample and reduce the sample size by 2 – 5x (as determined by the severity of the foaming). Contact the Inorganics Supervisor for guidance.

10.3.1.12 Turn on the chiller.

10.3.1.13 Set the timer-dial on the distillation unit to "110".

10.3.1.14 After 110 minutes the unit will shut off; leave the chiller running for an additional 30 minutes while the tubes cool down.

10.3.1.15 Pour contents of the scrubber tube into a new, labeled, centrifuge tube (Section 7.5). Carefully rinse the scrubber tube with DI water and add rinseate to the centrifuge tube to bring to 50mL volume. Cap and refrigerate for later analysis by the Lachat Instrument.

10.3.2 Lachat Analysis

10.3.2.1 Following initial calibration and standardization, (Section 10.2 and 10.4), place the samples in the autosampler, per the manufacturer's instructions. Input the information required by the data system, such as concentration, replicates and QC scheme.

10.3.2.2 Inject the samples, per the manufacturer's instructions.

10.3.2.3 The data system calculates sample concentration using the regression equation. Results are mg/L for Aqueous samples and mg/Kg for soil and solid samples.

10.3.2.4 If sample concentrations are greater than the highest calibration standard, the distilled sample is diluted with 0.1N sodium hydroxide (NaOH) diluent (Section 8.2.2), and reanalyzed. When the automated diluter is used, 0.1N NaOH is also used. **Do not dilute distilled samples or standards with DI water.**

10.4 Continuing Calibration

10.4.1 After the calibration has been established, it must be verified by the analysis of an Initial Calibration Verification Standard (ICV) (Section 8.2.13). The ICV of 0.1ppm must be made from a different source than the calibration standards. If the measurements exceed ±10% of 0.1ppm, the analysis is terminated. See Section 9.3 for Corrective Actions.

10.4.2 A Blank and a Continuing Calibration Verification (CCV) sample (Section 8.2.8) are analyzed after every 10 injections. The CCV measurements cannot exceed ±10% of the CCV value of 0.1ppm and the blank result must be less than the reporting limit of 0.005 mg/L. See Section 9.4 for CCV Corrective Actions and Section 9.1 for Blank corrective actions.

10.5 Preventive Maintenance

Preventative maintenance is recorded in the instrument maintenance logbook and is performed on the Lachat instrument as follows:

Daily:

1) Clean the autosampler
2) Clean the surfaces on the auto-dilutor
3) Prime the dilutor with fresh DI water
4) Clean the pump surfaces
5) Clean the detector with DI and dry with Kim-Wipes
6) Clean the instrument surfaces with DI, wipe clean with a paper towel

Bi-weekly:

1) Clean the injection ports with DI. Take apart the injection valve and inspect it for corrosion. Make sure that the valve connectors are tight and the o-rings are not worn. If the O-rings look worn replace with new ones.

Monthly:

1) Using DI water, clean the unions and the tees that are associated with the manifold.
2) Delete Temporary files on the computer

Every 6 months:

1) Replace the o-rings in the injection valve.
2) Replace the o-rings in the manifold

3) Back up the files on the computer

11. Data Evaluation, Calculations and Reporting

11.1 The Lachat data system calculates sample concentration using the regression equation.

11.2 Report only those values that fall between the lowest and the highest calibration standards.

11.3 Report results in mg CN/L for liquids and in mg CN/kg for soils.

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

Holding time exceedance and improper preservation are noted on the nonconformance report form. The analyst narrates the nonconformance when the project is turned in for review. The narration must state what the nonconformance was and any corrective action taken.

Perform routine preventative maintenance according to Section 10.5. Record all maintenance in the instrument logbook. Notify the Department Manager if the instrument problems are not routine in nature. The Department Manager determines whether the problem can be corrected with in-house technical staff or if the instrument vendor should be contacted to schedule service. All service calls are documented in the Instrument logbook, and a copy of the service report is given to the Department Manager.

Review of standards, blanks and standard response for acceptable performance occurs for each batch of samples. If any part of batch quality control does not meet acceptance criteria, the Department Manager is notified. If enough sample remains and holding time has not expired, then the batch is redistilled and reanalyzed. If there is not sufficient sample remaining to allow redistillation, then that analysis is repeated and both sets of data are reported with the nonconformance narrated on the final report.

If either the ICV, ICB, Method Blank, LCS, LCSD, CCV, or CCB recovery falls outside the designated acceptance range, the laboratory performance is judged to be out of control, and the problem must be immediately identified and corrected. The analytical result in the unspiked samples is suspect and is only reported for regulatory compliance purposes with the appropriate nonconformance action form.

Immediate corrective action for a failing CCV/CCB includes reanalyzing the failing standard. If the standard passes the second time then the analysis may be continued. The raw data is noted. If the standard fails again, the problem must be found and corrected. The CCV/CCB standard is remade and reanalyzed. If the standard passes, all samples analyzed since the previous passing standard are reanalyzed. The raw data is noted and all data associated with the failing standard must have one line drawn through the data, indicating it's unable.

If the standard fails after instrument maintenance, the instrument is recalibrated. A new ICV/ICB is performed, and all samples analyzed since the previous passing CCV/CCB are reanalyzed.

If following reanalysis of the LCS, it is found to still be outside acceptance criteria, the entire sample batch must be redistilled and reanalyzed. If the %RPD between the LCS/LCSD fails after reinjection, then the entire sample batch must be redistilled and reanalyzed.

If the Method Blank fails it is re-poured and reinjected. If failure continues, the associated sample data is evaluated as follows: Sample results below the detection limit may be reported with a narrative included. If samples have positive results, and the results are greater than 10x the concentration found in the method blank, the data may be reported with a narrative included. Any positive samples with results less than 10x the concentration found in the method blank must be redistilled and reanalyzed.

If the Matrix Spike recovery does not meet acceptance criteria, and the LCS recovery is acceptable, matrix interference may be assumed. The associated data may be reported with a narrative included.

If sample Duplicates are outside of the acceptance criteria, the analyst examines the sample for homogeneity. If the sample is not homogenous, this is narrated on the final report. Clean, homogenous samples are redistilled and reanalyzed within holding time.

Sample nonconformance regarding a Matrix Spike recovery or a duplicate %RSD is narrated on the final report along with the corrective action(s) taken.

13. Method Performance

13.1 Detection Limit Study (DL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the DL, LOD, and/or LOQ as outlined in Alpha SOP ID 1732. These studies performed by the laboratory are maintained on file for review.

The quarterly method reporting limit (MRL) verification requirement is satisfied by the quarterly LOQ analysis, as per SOP/1732.

13.2 Demonstration of Capability Studies

Refer to Alpha SOP ID 1739 for further information regarding IDC/DOC Generation.

13.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

14. Pollution Prevention and Waste Management

Refer to Alpha's Chemical Hygiene Plan and Hazardous Waste Management and Disposal SOP for further pollution prevention and waste management information.

EPA Method 9060 A, SW-846, Test Methods for Evaluating Solid Waste: Physical/Chemical Methods, EPA SW-846, Update III B, 2004.

1. Scope and Application

Matrices: This method may be applied to water and wastewater samples containing minimum amounts of particulates and phase-separated organics.

Definitions: See Alpha Laboratories Quality Manual Appendix A

The organic carbon in water and wastewater is composed of a variety of organic compounds in various oxidation states. Some of these carbon compounds can be oxidized further by biological or chemical processes, and the bio-chemical oxygen demand (BOD) and chemical oxygen demand (COD) may be used to characterize these fractions. The presence of organic carbon that does not respond to either the BOD or COD test makes these methods unsuitable for the measurement of total organic carbon. Total organic carbon (TOC) is a more convenient and direct expression of total organic content than either BOD or COD, but does not provide the same kind of information. If a repeatable empirical relationship is established between TOC and BOD or COD, then TOC can be used to estimate the accompanying BOD or COD. This relationship must be established independently for each set of matrix conditions, such as various points in a treatment process. Unlike BOD or COD, TOC is independent of the oxidation state of the organic matter and does not measure other organically bound elements, such as nitrogen and hydrogen, and inorganics that can contribute to the oxygen demand measured by BOD and COD. TOC measurement does not replace BOD and COD testing.

To determine the quantity of organically bound carbon, the organic molecules must be broken down to single carbon units and converted to a single molecular form that can be measured quantitatively. TOC methods utilize heat and oxygen, ultraviolet irradiation, chemical oxidants, or combinations of these oxidants to convert organic carbon to carbon dioxide (CO_2). Within this method, the CO_2 is measured directly by a nondispersive infrared analyzer.

The methods and instruments used in measuring TOC analyze fractions of total carbon (TC) and measure TOC by two or more determinations. These fractions of total carbon are defined as:

- Inorganic carbon (IC) - the carbonate, bicarbonate, and dissolved CO_2 total organic carbon (TOC) - all carbon atoms covalently bonded in organic molecules.
- Dissolved organic carbon (DOC) - the fraction of TOC that passes through a 0.45µm filter.
- Particulate organic carbon (POC) – also referred to as nondissolved organic carbon, the fraction of TOC retained by a glass fiber filter.
- Volatile organic carbon (VOC) also referred to as purgeable organic carbon, the fraction of TOC removed from an aqueous solution by gas stripping under specified conditions.

- Nonpurgeable organic carbon (NPOC) the fraction of TOC not removed by gas stripping.

In most water samples, the IC fraction is many times greater than the TOC fraction. Eliminating or compensating for IC interferences requires multiple determinations to measure true TOC. IC interference can be eliminated by acidifying samples to pH 2 or less to convert IC species to CO_2. Subsequently, purging the sample with a purified gas removes the CO_2 by volatilization. Sample purging also removes POC so that the organic carbon measurement made after eliminating IC interferences is actually an NPOC determination; determine VOC to measure true TOC. In many surface and ground waters, the VOC contribution to TOC is negligible. Therefore, in practice, the NPOC determination is substituted for TOC.

Alternatively, IC interferences may be compensated for by separately measuring total carbon (TC) and inorganic carbon. The difference between TC and IC is TOC.

The purgeable fraction of TOC is a function of the specific conditions and equipment employed. Sample temperature and salinity, gas-flow rate, type of gas diffuser, purging-vessel dimensions, volume purged, and purging time affect the division of TOC into purgeable and nonpurgeable fractions. When separately measuring VOC and NPOC on the same sample, use identical conditions for purging during the VOC measurement as in purging to prepare the NPOC portion for analysis. Consider the conditions of purging when comparing VOC or NPOC data from different laboratories or different instruments.

Many instruments utilizing persulfate oxidation of organic carbon are available. They depend on ultraviolet irradiation activation of the reagents. The persulfate-ultraviolet oxidation method is a rapid, precise method for the measurement of trace levels of organic carbon in water and is of particular interest to the electronic, pharmaceutical, and steam-power generation industries where even trace concentrations of organic compounds may degrade ion-exchange capacity, serve as a nutrient source for biological growth, or be detrimental to the process for which the water is being utilized.

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one of the following laboratory personnel before performing the modification: Area Supervisor, Laboratory Director, or Quality Assurance Officer.

This method is restricted to use by or under the supervision of analysts experienced in the operation of the TOC Analyzer and in the interpretation of TOC data. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

2. Summary of Method

Organic carbon is oxidized to carbon dioxide, CO_2 by persulfate in the presence of ultraviolet light. The CO_2 produced may be measured by a nondispersive infrared analyzer.

The TOC Analyzer utilizes an ultraviolet lamp submerged in a continuously gas-purged reactor that is filled with a constant-feed persulfate solution. The samples are introduced serially into the reactor by an autosampler. The CO_2 produced is sparged continuously from the solution and is carried in the gas stream to an infrared analyzer that is specifically tuned to the absorptive wavelength of CO_2. The instrument's microprocessor calculates the area of the peaks produced by the analyzer, compares them to the peak area of the calibration standard stored in its memory, and prints out a calibrated organic carbon value in milligrams per liter.

2.1 Method Modifications from Reference

2.1.1 Method 9060 requires that samples be analyzed in quadruplicate (4 replicates). Alpha analyzes samples in quadruplicate with a % RSD required to be ≤15%.

3. Detection Limits

The Reported Detection Limit for TOC is 0.5mg / L and for DOC is 1.0mg/L.

4. Interferences

4.1 Instrumental

The intensity of the ultraviolet light reaching the sample matrix may be reduced by highly turbid samples or with aging of the ultraviolet source, resulting in sluggish or incomplete oxidation. Large organic particles or very large or complex organic molecules such as tannins, lignins, and humic aid may be oxidized slowly because persulfate oxidation is rate-limited.

4.2 Parameters

Excessive acidification of sample, producing a reduction in pH of the persulfate solution to 1 or less, can result in sluggish and incomplete oxidation of organic carbon.

Persulfate oxidation of organic molecules is slowed in samples containing significant concentrations of chloride by the preferential oxidation of chloride; at a concentration of 0.1% chloride, oxidation of organic matter may be inhibited completely. If chloride interference is suspected, then the sample is diluted.

With any organic carbon measurement, contamination during sample handling and treatment is a likely source of interference. This is especially true of trace analysis. Take extreme care in sampling, handling, and analysis of samples with TOC below 1mg/L.

Removal of carbonate and bicarbonate by acidification and purging with purified gas results in the loss of volatile organic substances. The volatiles also can be lost during sample blending, particularly if the temperature is allowed to rise. Another important loss can occur if large carbon-containing particles fail to enter the needle used for injection. Filtration, although necessary to eliminate particulate organic matter when only DOC is to be determined, can result in loss or gain of DOC, depending on the physical properties of the carbon-containing compounds and the adsorption of carbonaceous material on the filter, or its desorption from it. Check filters for their contribution to DOC by analyzing a filtered blank. Note that any contact with organic material may contaminate a sample. Avoid contaminated glassware, plastic containers, and rubber tubing. Method Blanks are analyzed with each batch to verify a clean system.
The presence of large amounts of particulate material will cause problems with the determination of carbon. The TOC analyzers are not equipped for the analysis of samples with large amounts of particulate matter. Small amounts may be compensated for by dilution (refer to Section 10.3.2).

5. Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by

whatever means available. A reference file of material data handling sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

Collect samples in two (for method -5310) or three (for method -9060) 40mL amber vials with or without Teflon septa. Minimal headspace is desirable.

6.2 Sample Preservation

6.2.1 If samples are to be analyzed for Dissolved Organic Carbon (DOC), they must be filtered within 24 hours of collection, and prior to preservation. Refer to Section 10.1.1 for filtration procedure.

6.2.2 Within two hours of sampling, the samples are preserved with 1:1 H_2SO_4 to a pH $\leq$2 and refrigerated at 4 $\pm$ 2 ºC until analysis.

6.3 Sample Shipping

No special shipping requirements other than the samples should be on ice.

6.4 Sample Handling

Samples to be filtered by the laboratory for DOC analyses, must be filtered upon receipt at the laboratory (within 24 hours from collection time).

Preserved samples must be analyzed within a 28-day holding time.

7. Equipment and Supplies

7.1 Filtering Apparatus.

7.2 0.45 µm Filters.

7.3 40mL Amber Glass Vials: with or without Teflon septa.

7.4 Glass Syringes: 100µL and 200µL volumes.

7.5 Pipettor: **1-10ml**, with disposable tips.

7.6 Volumetric Flasks: Class A 1 L and 250 mL sidearm filtering flask

7.7 AAL: "TOC-3": Shimadzu TOC-V WP Total Organic Carbon Analyzer with autosampler.

7.7.1 Computer and related accessories capable of running associated software: TOC-Control V ver. 1.07.00. c2000-2004 by Shimadzu Corp.

7.8 AAL: "TOC-4", "TOC-5", "TOC-6": Shimadzu TOC-V WP Total Organic Carbon Analyzer with autosampler.

7.8.1 Computer and related accessories capable of running associated software: TOC-Control V ver. 2.30

7.9 10ml disposable syringes:
BD 10ml syringe with Luer-Lok Tip, P/N 309604

7.10 0.45u acrodisc for use with disposable syringe:
Pall LIfe Sciences Acrodisc 25mm syrringe filter with 0.45u Nylon membrane, P/N 4438 T

8. Standards and Reagents

8.1 Reagent Water: Deionized water (DI).

8.2 10% Persulfate + 5% Phosphoric Acid Reagent Mixture: Measure 50g 98^{+}% sodium persulfate ($Na_2S_2O_8$) into a rinsed bottle. Add 18mL of 85% phosphoric acid (H_3PO_4). Add 426mL of reagent water (DI). Mix well. This mixture must be prepared monthly. Label bottle with date made, date of expiration, reagent lot number, and store at room temperature. (Use AAL unique ID: example: TOC-030917-R2).

8.3 21% Acid Reagent: Measure 74mL of 85% phosphoric acid (H_3PO_4) into a rinsed bottle. Add 376mL of reagent water (DI). Mix well. This mixture must be prepared monthly. Label bottle with date made, date of expiration, and reagent lot number and store at room temperature. (Use AAL unique ID: example: TOC-030917-R1)..

8.4 2000ppm Organic Carbon Stock Calibration Standard: In a 1L volumetric flask, add 4.25g of Potassium Hydrogen Phthalate (KHP) and 1mL H_3PO_4. Bring to volume with DI and agitate to mix well. Transfer to a 1L Amber glass bottle. Prepare every six months. Label bottle with standard lot number, date made, and date of expiration. Store at 4 $\pm$ 2 °C. (Use AAL unique ID: example: TOC-030917-C).

8.4.1 4.0ppm CCV: To a 100mL volumetric flask, add 200µL of 2000ppm stock calibration standard (Section 8.4) and bring to volume with DI. Prepare fresh on each day of use. (Use AAL unique ID: example: TOC-030917-CCV).

8.4.2 50ppm Calibration Standard: To a 100mL volumetric flask, add 2.5mL of 2000ppm stock standard (Section 8.4) and bring to volume with DI. Prepare fresh for each calibration curve generated.

8.4.3 10ppm Calibration Standard: To a 100mL volumetric flask, add 0.5mL of 2000ppm stock standard (Section 8.4) and bring to volume with DI. Prepare fresh for each calibration curve generated.

8.4.4 5.0ppm Calibration Standard: To a 100mL volumetric flask, add 10mL of 50ppm calibration standard (Section 8.4.2) and bring to volume with DI. Prepare fresh for each calibration curve generated.

8.4.5 1.0ppm Calibration Standard: To a 100mL volumetric flask, add 2mL of 50ppm calibration standard (Section 8.4.2) and bring to volume with DI. Prepare fresh for each calibration curve generated.

8.4.6 0.5ppm Calibration Standard: To a 100mL volumetric flask, add 1mL of 50ppm calibration standard (Section 8.4.2) and bring to volume with DI. Prepare fresh for each calibration curve generated.

8.5 2000ppm Organic Carbon Stock Check Standard: In a 1L volumetric flask, add 4.25g of Potassium Hydrogen Phthalate (KHP) and 1mL H_3PO_4. Bring to volume with DI and agitate to mix well. Transfer to a 1L Amber glass bottle. Prepare every six months. Label bottle with standard lot number, date made, and date of expiration. Store at 4 ± 2 °C. (Use AAL unique ID: example: TOC-030917-W).

The KHP used for this solution must be from a different source and lot number than that used in Section 8.4.

8.5.1 Initial Calibration Verification Standard (ICV)

4.0ppm ICV: To a 100mL volumetric flask, add 200µL of 2000ppm stock check standard (Section 8.5) and bring to volume with DI. This is analyzed at the start of each daily run. Prepare fresh on each day of use. (Use AAL unique ID: example: TOC-030917-ICV).

8.5.2 Calibration Verification Blank (ICB)

One ICB is analyzed at the start of each daily run. The ICB consists of 40mL of DI. The DI must be from the same source as was used to prepare the Calibration Verification samples. Results must be < 0.5mg/L, but preferably ≤ 0.2mg/L. If this criterion is not met, the instrument must be internally cleaned again (Refer to Section 10.1.4) to ensure that the system is clean prior to sample analysis.

8.6 400ppm TOC IC Stock Standard:

To a 100mL volumetric flask, add 0.3545g sodium carbonate (Na2CO3) anhydrous powder. Bring to volume with DI water. Store at room temperature. Prepare annually or as needed. (Use AAL unique ID: example: TOC-030917-IC400).

8.6.1.1 10ppm TOC IC Working Check Standard (Negative LCS): Into a 100mL volumetric flask, add 2.5mL of 400ppm TOC IC Stock Standard. Bring to volume with DI water. Store at room temperature. Prepare weekly or as needed. Also referred to as the 10ppm IC CK STD (Inorganic Check Standard). (Use AAL unique ID: example: TOC-030917-IC10).

8.7 Purging / Carrier Gas: Nitrogen, ultra-high purity.

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

9.1 Blank (MB)

9.1.1 Method Blank (MB)

One MB is analyzed per batch of 20 samples or less. The MB consists of 40mL of DI. The DI must be from the same source as was used to prepare the Calibration Verification samples. Results must be < 0.5mg/L, but preferably ≤ 0.2mg/L. If this criterion is not met, the instrument must be internally cleaned again (Refer to Section 10.1.4) in order to ensure that the system is clean prior to sample analysis.

In the case of DOC, the MB (or also referred to as the Filter Blank) consists of DI that was filtered through a 0.45µm filter (Section 7.2). Results must be <1.0mg/L. If this criterion is not met, first ensure as stated above, that the instrument system is clean.

Next: there are two options regarding the sample:

1. The sample and associated Filter Blank are refiltered. This must depend on sample holdtime, and available volume.
2. If the sample result is greater than 10x the result of the Filter Blank, then the reported data can be accompanied by a narrative stating this.

9.2 Laboratory Control Sample (LCS)

9.2.1 **4.0ppm LCS:** To a 100mL volumetric flask, add 200µL of 2000ppm stock check standard (Section 8.5) and bring to volume with DI. The 2.0ppm LCS is analyzed for each batch of 20 or less samples (per instrument and per day). Therefore, a new LCS should be analyzed for each additional batch of 20 or less samples, when multiple batches are run on the same instrument and daily analytical sequence. Refer to Section 9.3 (Use AAL unique ID: example: TOC-030917-LCS).

9.2.2 **Negative LCS Standard (LCSN):** A negative LCS (LCSN) is analyzed before the Calibration Blank (ICB) to demonstrate that there is no Inorganic Carbon contribution to the Organic Carbon analysis. The analysis of the 10ppm LCSN (also referred to as the 10ppm IC CK STD) (8.6.1) must yield a result of < 0.5mg/L

(Use AAL unique ID: example: TOC-030917-IC).

If the LCSN fails these criteria, the data is inspected to determine the cause of the failure. The standard is reanalyzed. If failure continues, the standard is remade and reanalyzed. If failure continues, there is a system malfunction and sample analysis cannot take place. The following instrument parameters are investigated: UV Lamp function, sparger function and acid delivery to the sparger. If the problem persists, contact the Department Supervisor. Analysis cannot begin until the 10ppm LCSN is within acceptance criteria.

Note: Also referred to as the 10ppm “IC CK STD” (Inorganic Check Standard).

9.3 Initial Calibration Verification (ICV)

An ICV is analyzed at the beginning of the analytical sequence, at a concentration of 4.0ppm. (For preparation instructions, refer to Section 8.5.1.)

The ICV must be recovered within ± 10% of the true value. If this criterion is not met, the system must be cleaned again, and the ICV must be re-analyzed. If failure continues, remake

the ICV (Section 8.5.1) and/or generate a new calibration curve (Section 10.1.6). Sample analysis cannot proceed until an acceptable ICV is obtained.

9.4 Continuing Calibration Verification (CCV)

A Continuing Calibration Verification standard is analyzed after every 10 or less samples (inclusive of the method blank, lcs, duplicate and matrix spike samples).

To a 100mL volumetric flask, add 200µL of 2000ppm stock calibration standard (Section 8.4) and bring to volume with DI. Prepare fresh on each day of use.

9.4.1 This CCV is at a concentration of 4.0ppm TOC (Section 8.4.1) and must be recovered within ±10% of the true value. If the CCV fails this criterion, it is re-made and re-analyzed.

If failure continues, all samples analyzed since the last valid CCV, are considered invalid and must be re-analyzed. However, prior to re-analysis, a new calibration curve must be generated. (Refer to Section 10.1.6.)

9.4.2 Continuing Calibration Blank (CCB)

A Continuing Calibration Blank is analyzed after every 10 samples (inclusive of the method blank, lcs, duplicate and matrix spike samples). This CCB consists of 40mL DI water and must be recovered below the detection limit. If the CCB fails this criterion, it is re-poured and re-analyzed.

If failure continues, all samples analyzed since the last valid CCB, are considered invalid and must be re-analyzed. However, prior to re-analysis, a new calibration curve must be generated. (Refer to Section 10.1.6.)

9.5 Matrix Spike

One Matrix Spike (MS) is analyzed per batch of 10 samples or less. Measure 40mL of the well-homogenized sample to be spiked into a 40mL amber glass vial with Teflon cap. Using a glass syringe, add 80µL of the 2000ppm Stock Check Standard (Section 8.5). Invert to mix. The true value of the spike prepared accordingly, is 4ppm. The matrix spike must be recovered within 80 – 120% for method 9060 and 85-115% for method 5310.

If the matrix spike recovery is outside of acceptance criteria, the sample and its MS are reanalyzed upon dilution with DI water for TOC analysis. If failure repeats, the data is reported, and a narrative submitted for inclusion on the Client report.

9.6 Laboratory Duplicate

One Duplicate sample is analyzed per batch of 10 samples or less. Samples are routinely collected in two 40mL amber glass vials; therefore, the second vial may be used as the sample duplicate. It must, however, be analyzed as if it were a separate sample. The %RPD between the sample and its duplicate must be <20% for method 9060 and <15% for method 5310.

If the % RPD is outside of acceptance criteria, the duplicate is reanalyzed. If failure repeats, the data is reported, and a narrative submitted for inclusion on the Client report.

9.7 Method-specific Quality Control Samples

Refer to Section 9.2.2.

9.8 Method Sequence

- TOC-3, TOC- 4, TOC-5 and TOC-6: DI (Rinse water)

- TOC-3 & TOC-4, TOC-5 and TOC-6:
- Calibration curve generation (if necessary)
- DI water (to check system stability)
- IC CK STD (10ppm Negative LCS)
- ICV 4.0ppm
- ICB
- MB (per 20 samples or less)
- LCS 4ppm (per 20 samples or less)
- Samples 1-8
- CCV 4.0ppm
- CCB

If Method 5310, then proceed with samples 9-18 (dup/spk required per 10 samples)

- CCV 4.0ppm
- CCB
- Duplicate
- Matrix Spike 4ppm
- CCV 4.0ppm
- CCB
- Shut down

If Method 9060, then proceed with dup and spk (dup/spk required per 10 samples)

- Duplicate
- Matrix Spike 4ppm
- CCV 4.0ppm
- CCB
- Shut down

10. Procedure

10.1 Equipment Set-up

10.1.1 Sample Preparation for Dissolved Organic Carbon (DOC) Analysis

Prior to preservation, samples to be analyzed for dissolved organic carbon (DOC) are filtered through a 0.45µm filter (Section 7.2) as follows:

- Prior to filtration of the sample, filter 1L of DI through a 0.45µm filter and discard.
- Filter sample through the same 0.45µm filter:
  - For method -5310: 100ml of sample for two vials
  - For method -9060: 150ml of sample for three vials
- Transfer filtered sample to two 40mL amber vials and preserve accordingly.
- Prepare a DOC method blank following the same procedure listed above. Filter enough to fill two to three 40mL amber vials, dependent on which method is being filtered for.

Another method of filtration of DOC samples can be the following: Use 0.45 µm filtering discs with a 10 or 20mL disposable syringe. Each syringe and disc must be rinsed thoroughly first by filling with DI and discarding PRIOR to any Filter Blanks or samples.

Record all necessary information in the filtration logbook: sample ID, date and time of filtration, analyst's initials, the lot number of the vials and syringe discs used, and the preservative used.

10.1.2 Instrument Set-Up

Follow the manufacturer's instructions for proper instrument set-up procedures. For TOC-3, TOC- 4, TOC-5, and TOC-6 instruments, refer to Table A.

10.1.3 Reagent Preparation

10.1.3.1 Verify that the reagents (Sections 8.2 and 8.3) have not expired and that there is adequate Nitrogen gas supply. If necessary, prepare reagents and/or alert Tech Support if gas manifold has a malfunction.

10.1.3.2 Ensure that the DI supply to the instrument is fresh for each day of analysis.

10.1.3.3 Prepare the 4.0ppm ICV (Section 8.5.1) and CCV standard (Section 8.4.1) each day of analysis.

10.1.4 Instrument Preparation

10.1.4.1 (TOC-3, -4, -5, -6)

Set instrument to analysis 1 vial of Rinse water, entitled DI, to ensure system is stable and clean before analyses.

Proceed to section 10.1.5

10.1.5 If a valid calibration curve is already in place, proceed to Section 10.2.

10.1.6 Calibration Curve Generation

A new calibration curve is generated every six months. However, if there has been a major change to the system, a new calibration curve must be generated following the change and prior to sample analysis.

NOTE: For TOC/DOC Method 5310 with samples originating from Massachusetts, a new calibration curve must be generated DAILY prior to the analysis of these samples.

A calibration curve of 5 points will be used for this: Blank (0ppm, DI), 0.5ppm, 1.0ppm, 5.0ppm, and 10.0ppm (refer to Section 8.4 for instructions).

Prepare five calibration standards per Section 8.4.2 through Section 8.4.6 and two DI water blanks.

Analyze the five calibration standards and blanks:

(TOC-3, -4, -5, -6) with the TOC Shimadzu TOC-V WP software program, Set the range at 0.1 – 10ppm for TOC.

After analysis, the software program for TOC-3, 4, 5, 6 will allow the user to select the calibration standards and blank desired to include in the calibration curve calculation.

All of the standards must be chosen, and also the second blank (the first blank is considered a rinse). The correlation coefficient (r) must be $\geq$ 0.995. If this criterion is not met, the calibration standards are re-made, and the calibration curve is re-analyzed.

All calibration points are back calculated by software and should be within 10% from true concentration, except lowest points of calibration curve. % Recoveries for low range will be wider,but shouldn't exceed 100% and correlation coefficient will not be worse than 0.995.

Samples and QC samples may not be analyzed until a valid Calibration Curve is obtained.

10.2 Initial Calibration

10.2.1 Before any analyses, verify that the system is clean.

10.2.2 Run one DI (Rinse water) sample to check for system stability. (Note: Only at initial instrument startup. This also acts as a TOC water screen to ensure the lab water being used is acceptable (resulting value is below the reporting limit of 0.5ppm for TOC and 1.0ppm for DOC) prior to use).

Per the manufacturer's instructions, set up the autosampler to analyze the following:

TOC-3, TOC-4, TOC-5, TOC-6 = DI (Rinse water)

10.2.3 Negative LCS Standard (LCSN) (also referred to as the IC CK STD): Prior to sample analysis and following the ICV and ICB, a negative LCS (LCSN) is analyzed to demonstrate that there is no Inorganic Carbon contribution to the Organic Carbon analysis. The analysis of the 10ppm LCSN (8.6.1) must yield a result of < 0.5mg/L.

If the LCSN fails this criteria, the data is inspected to determine the cause of the failure. The standard is reanalyzed. If failure continues, the standard is remade and reanalyzed. If failure continues, there is a system malfunction and sample analysis cannot take place. The following instrument parameters are investigated: UV Lamp function, sparger function and acid delivery to the sparger. If the problem persists, contact the Department Supervisor. Analysis cannot begin until the 10ppm LCSN is within acceptance criteria.

10.2.4 Initial Calibration Verification (ICV) and Initial Calibration Blank (ICB)

Prior to sample analysis, the calibration curve must be verified.

Analyze an ICV and an ICB to confirm stability and cleanliness.

4.0ppm ICV (Section 8.5.1)

ICB (DI water)

The ICV must have a % Recovery ± 10% of the true value. The results for the ICB must be less than 0.5mg/L, but preferably less than or equal to 0.2mg/L. If these criteria are not met, the system must be cleaned again (Section 10.1.4) and the ICV and ICB must be re-analyzed. If failure continues, remake the ICV (Section 8.5.1) and/or generate a new calibration curve (Section 10.1.6).

10.3 Equipment Operation and Sample Processing

10.3.1 Samples and QC samples are analyzed according to the manufacturer's instructions for TOC Shimadzu TOC-V WP software program (TOC-3, 4, 5, 6) instructions, using

the valid calibration curve in the TOC Shimadzu TOC-V WP software program range of "0.1 – 10ppm TOC". (As generated in Section 10.1.6).

10.3.1.1 Dissolved Organic Carbon: If samples are to be analyzed for DOC, the same procedure is followed as for TOC.

10.3.2 The samples to be analyzed must have a minimum amount of sediment. Initial dilution of samples with sediment may be necessary to facilitate analysis by either instrument. Dilutions are prepared volumetrically (or with a graduated cylinder and calibrated auto-pipettor) with DI water. However, prior to dilution, consider the history of the samples and the detection limit requirements of the client. If questions arise due to sample matrix, consult with the Department Supervisor and/or the Laboratory Director before proceeding with analysis.

10.3.3 Samples are to be analyzed with 3 Reps each. The TOC Software will calculate the standard deviation, the %RSD, and the mean. The %RSD must be $\leq$ 15% for method 9060 and <10% for method 5310. If this criterion is not met, the sample must be re-analyzed with 2 Reps. If failure continues, consult with the Department Supervisor and/or the Laboratory Director before proceeding.

TOC Method 9060: Samples (including all batch QC) must be analyzed with 4 Reps each.

10.3.4 Similarly, a duplicate sample and a matrix spike sample are to be analyzed in replicate. Prepare the duplicate and matrix spike samples according to Sections 9.6 and 9.5.

10.3.4.1 For Method 5310, a duplicate and matrix spike is required for every **10** samples or less in a batch.

10.3.4.2 For Method 9060, a duplicate and matrix spike is required for every **10** samples or less in a batch.

10.3.5 If the sample results are above 10mg/L TOC, they are above the high end of the calibration curve. In this instance, the sample must be manually diluted volumetrically (or with a graduated cylinder and calibrated auto-pipettor) with DI water and re-analyzed. A timeout message or baseline drift might also necessitate a dilution of the sample even if the sample is < 10mg/L.

While setting up the diluted sample in the batch, the analyst must include the dilution factor in the Sample ID field.

10.4 Continuing Calibration

10.4.1 Continuing Calibration Verification (CCV) and Continuing Calibration Blank (CCB)

A Continuing Calibration Verification standard and a Continuing Calibration Blank pair are analyzed after every 10 samples (inclusive of the duplicate and matrix spike samples).

10.4.1.1 The CCV is at a concentration of 4.0ppm TOC (Section 8.4.1) and must be recovered within ±10% of the true value. If the CCV fails this criterion, it is re-made and re-analyzed.

If failure continues, all samples analyzed since the last valid CCV, are considered invalid and must be re-analyzed. However, prior to re-analysis, a new calibration curve must be generated. (Refer to Section 10.1.6.)

10.4.1.2 The results for the CCB must be less than 0.5mg/L, but preferably less than or equal to 0.2mg/L. If the CCB fails this criterion, it is reanalyzed.

If failure continues, all samples analyzed since the last valid CCB, are considered invalid and must be re-analyzed. However, prior to re-analysis, a new calibration curve must be generated. (Refer to Section 10.1.6.)

10.5 Preventive Maintenance

The instrument is primed and cleaned internally prior to analysis. Tubing, copper/tin scrubber, and autosampler syringe are inspected routinely to ensure they are in proper working order. The external autosampler is kept clean and free of dust. Extra parts are kept on hand in the event they are necessary. All instrument maintenance is recorded in the Instrument Maintenance Logbook.

If continual bubbling in the gas/liquid separator tube occurs during analysis, lift the back, right cover of the instrument body (carefully so as not to disturb any connected fan wiring), and gently tap the line from the separator tube until all the bubbles are released. Any sample currently running may need reanalysis due to failed detection. (i.e. instrument message “no sample detected”.)

11. Data Evaluation, Calculations and Reporting

The TOC Shimadzu TOC-V WP software program calculates the area of the peaks produced by the analyzer, compares them to the peak area of the calibration standard stored in its memory, and calculates a mean TOC value in mg/L.

If the sample was manually diluted prior to analysis, the calculated mean must be manually multiplied by the dilution factor. The Reported Detection Limit is also multiplied by the same dilution factor.

If the sample result is <0.5mg/L for TOC, it is reported as ND (Not Detected). Likewise, if the sample result is <1.0mg/L for DOC, it is reported as ND (Not Detected).

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

Refer to Section 9 for corrective actions.

13. Method Performance

13.1 Method Detection Limit Study (MDL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the MDL, LOD, and/or LOQ as outlined in Alpha SOP/1732. These studies performed by the laboratory are maintained on file for review.

The quarterly method reporting limit (MRL) verification requirement is satisfied by the quarterly LOQ analysis, as per SOP/1732.

13.2 Demonstration of Capability Studies

Refer to Alpha SOP/1739 for further information regarding IDC/DOC Generation.

13.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

14. Pollution Prevention and Waste Management

Refer to Alpha's Chemical Hygiene Plan and Waste Management and Disposal SOP for further pollution prevention and waste management information.

15. Referenced Documents

Chemical Hygiene Plan

SOP/1732 MDL/LOD/LOQ Generation

SOP/1739 IDC/DOC Generation

SOP/1728 Waste Management and Disposal SOP

16. Attachments

Table A: TOC-VW (TOC-3 , TOC-4, TOC-5, TOC-6 INSTRUMENTS)

Table A:

TOC-VW (TOC 3, 4, 5, 6 INSTRUMENT)

STARTING THE INSTRUMENT:

Turn on nitrogen ultra-pure nitrogen gas tank.

Push the on/off button on the bottom right front of the instrument to on (green light will be visible).

With the computer on, use the mouse to double click on the TOC-CONTROL V icon on the desktop.

Double click on “Sample Table Editor”

Enter user’s initials, hit OK

At Sample Table page:

Go to File “New”

Double click on “Sample Run”

Select System “TOC-VW”, hit OK

At Save As page:

For File name, overwrite existing to say current date as month/day/year (00/00/0000), hit SAVE

At Dated Run page:

Click on yellow lightning bolt icon @ top to connect to system

At Parameter Confirmation Dialog page:

Click on “Use Settings on PC”

At Sequence Box page:

Wait for system to initialize (page box will disappear once initialized)

Once initialized, click on white square box @ top (just left of yellow lightning bolt), to see Background Monitor

Wait for NDIR: baseline pos., baseline fluc., and baseline noise -> all 3 items should have a green checkmark before instrument can run analyses.

When all 3 items are green, close this box by clicking on the “X” on the top right of the box.

At the Dated Run page again:

Adjust columns to include: Analysis//Sample Name//Result//Status//Date/Time//Vial

NOTE: Prior to analyzing samples, generate a new Calibration Curve according to the Instrument's User Manual,

TO SET UP AN ANALYSIS RUN:

At top of Dated Run page:

Go to Insert, Autogenerate

Sample group wizard (page 1): sample source:

Bullet calibration curve, push rectangular button w/ dots within it

Next to file name, type toc3curve120211a (for example)

Select current dated curve from choices below

Hit OPEN

Then hit NEXT

Sample group wizard (page 2):

Number of samples = enter number of samples to analyze

Start vial = vial number to begin analyzing

Erase sample name/leave blank, hit NEXT

Page 3: hit NEXT

Page 4: hit NEXT

Page 5: hit FINISH

Sparging/acid addition with autosampler pie display, hit OK

Back at Dated Run page:

Type in information for each sample name in the appropriate column

TO BEGIN ANALYSIS:

Click on the green stoplight icon at top of screen:

Standby box should have "keep running" bullet

Hit Standby button

Then hit OK on sparging/acid addition autosampler pie display page

Then @ start ASI measurement box, UNCHECK the external acid addition box, hit START

TO TURN OFF INSTRUMENT AFTER ANALYSIS IS COMPLETED:

At the end of the run, hit the round clock icon at the top of the screen

Mare sure “shut down instrument” is bulleted

Hit “standby”

Turn off instrument power button so that the green light is now off.

Turn off gas tank.

TO PRINT ANALYSIS PAPERWORK:

File, Print, sample report

Close all pages on screen by hitting the “X” at the top right of each page.

Total Phosphorous

Dissolved Phosphorus

Colorimetric, Combined Reagent

1. Scope and Application

Matrices: Water and wastewater samples and soils.

Definitions: See Alpha Laboratories Quality Manual Appendix A

Phosphorus occurs in natural waters and in wastewaters almost solely as phosphates. These are classified as orthophosphates, condensed phosphates (pyro-, meta-, and other polyphosphates), and organically bound phosphates. They occur in solution, in particles or detritus, or in the bodies of aquatic organisms.

These forms of phosphate arise from a variety of sources. Small amounts of certain condensed phosphates are added to some water supplies during treatment. Larger quantities of the same compounds may be added when the water is used for laundering or other cleaning, because these materials are major constituents of many commercial cleaning preparations. Phosphates are used extensively in the treatment of boiler waters. Orthophosphates applied to agricultural or residential cultivated land as fertilizers are carried into surface waters with storm run-off and to a lesser extent with melting snow. Organic phosphates are formed primarily by biological processes. They are contributed to sewage by body wastes and food residues, and also may be formed from orthophosphates in biological treatment processes or by receiving water biota.

Phosphorus is essential to the growth of organisms and can be the nutrient that limits the primary productivity of a body of water. In instances where phosphate is a growth-limiting nutrient, the discharge of raw or treated wastewater, agricultural drainage, or certain industrial wastes to that water may stimulate the growth of photosynthetic aquatic micro- and macro-organisms in nuisance quantities.

Phosphates also occur in bottom sediments and in biological sludges, both as precipitated inorganic forms and incorporated into organic compounds.

Phosphorus analyses embody two general procedural steps: (a) conversion of the phosphorus form of interest to dissolved orthophosphate, and (b) colorimetric determination of dissolved orthophosphate. The separation of phosphorus into its various forms is defined analytically but the analytical differentiations have been selected so that they may be used for interpretive purposes.

Filtration through a 0.45-µm-pore-diameter membrane filter separates dissolved from suspended forms of phosphorus. No claim is made that filtration through 0.45-µm filters is a true separation of suspended and dissolved forms of phosphorus; it is merely a convenient and replicable analytical technique designed to make a gross separation.

Phosphates that respond to colorimetric tests without preliminary hydrolysis or oxidative digestion of the sample are termed “reactive phosphorus.” While reactive phosphorus is largely a measure of orthophosphate, a small fraction of any condensed phosphate present usually is hydrolyzed unavoidably in the procedure. Reactive phosphorus occurs in both dissolved and suspended forms.

Acid hydrolysis at boiling-water temperature converts dissolved and particulate condensed phosphates to dissolved orthophosphates. The hydrolysis unavoidably releases some phosphate from organic compounds, but this may be reduced to a minimum by judicious selection of acid strength and hydrolysis time and temperature. The term “acid-hydrolyzable phosphorus” is preferred over “condensed phosphate” for this fraction.

The phosphate fractions that are converted to orthophosphate only by oxidation destruction of the organic matter present are considered “organic” or “organically bound” phosphorous. The severity of the oxidation required for this conversion depends on the form of, and to some extent on the amount of, the organic phosphorus present. Like reactive phosphorus and acid hydrolyzable phosphorus, organic phosphorus occurs both in the dissolved and suspended fractions.

The total phosphorus as well as the dissolved and suspended phosphorus fractions each may be divided analytically into the three chemical types that have been described: reactive, acid hydrolyzable, and organic phosphorus. Determinations usually are conducted only on the unfiltered and filtered samples. Suspended fractions generally are determined by difference.

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one of the following laboratory personnel before performing the modification: Area Supervisor, Laboratory Director, or Quality Assurance Officer.

This method is restricted to use by or under the supervision of trained analysts. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

2. Summary of Method

Digestion Method: Because phosphorus may occur in combination with organic matter, a digestion method to determine total phosphorus must be able to oxidize organic matter effectively to release phosphorus as orthophosphate. This digestion is performed by using the persulfate oxidation technique.

Colorimetric Method: The ascorbic acid method is used for the determination of orthophosphate in environmental samples. An extraction step is recommended for the lower levels and when interferences must be overcome. Ammonium molybdate and potassium antimonyl tartrates react in acid medium with orthophosphate to form a heteropoly acid-phosphomolybdic acid that is reduced to intensely colored molybdenum blue by ascorbic acid. The absorbance of this complex is measured photometrically at 880nm.

2.1 Method Modifications from Reference

Glassware is acid rinsed with room temperature 1:1 HCl, instead of hot dilute HCl.

Initial testing of samples with phenolphthalein has been eliminated since samples are received already preserved with H_2SO_4 and are pH checked by the Login Department upon receipt.
Soil samples are analyzed using the same digestive procedure.

3. Reporting Limits

The Reported Detection Limit is 0.01mg/L for waters and 5.0mg/kg for soils

4. Interferences

Correction for Turbidity or Interfering Color: The natural color of water generally does not interfere at the high wavelength used. For highly colored or turbid waters, prepare a blank by adding all reagents except ascorbic acid and potassium antimonyl tartrate to the digested sample aliquot. Subtract the blank absorbance from the absorbance of each sample.

Arsenates react with the molybdate reagent to produce a blue color similar to that formed with phosphate. Concentrations as low as 0.1mg As/L interfere with the phosphate determination.

Hexavalent chromium and NO_2 interfere to give results about 3% low at concentrations of 1mg/L and 10 to 15% low at 10mg/L.

Sulfide (Na_2S) and silicate do not interfere at concentrations of 1.0 and 10mg/L.

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material data handling sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

Water samples are collected in 500mL plastic bottles, soil samples may be collected in plastic or glass jars.

6.2 Sample Preservation

If samples are for Dissolved Phosphorus analysis, filtration must take place prior to preservation with H_2SO_4 to a pH < 2.

All samples are preserved with H_2SO_4.

6.3 Sample Shipping

No special shipping requirements.

6.4 Sample Handling

Samples are stored under refrigeration at 4 ± 2 °C. Analysis must be performed within 28 days of collection. All samples should be analyzed as soon as possible after digestion. If a prolonged period passes in between, sample extracts are refrigerated at 4 ± 2 °C.

7. Equipment and Supplies

7.1 Spectrophotometer, with infrared phototube for use at 880nm, providing a light path of 2.5cm.

7.2 Acid-washed Glassware: Use acid-washed glassware for determining low concentration of phosphorus. Phosphate contamination is common because of its absorption on glass surfaces. Avoid using commercial detergents containing phosphate. Clean all glassware with 1:1 HCl two times followed by two DI water rinses. Preferably, reserve the glassware only for phosphate determination. Only disposable syringes and filters are to be used for filtering samples for Dissolved Phosphorus analysis.

7.3 Centrifuge Tubes: 50mL volume. (Must be new and disposable.)

7.4 Hot Plate: A 30cm x 50cm heating surface is adequate.

7.5 Scoop, 0.5gm To hold required amounts of persulfate crystals.

7.6 Erlenmeyer Flasks: 125mL volume.

7.7 0.45µm membrane filters: For Dissolved Phosphorus sample preparation.

7.8 Borosilicate Glass beads

7.9 SEAL AQ2 Discrete Analyzer, with all associated reagent wedges, sample tubes, and reaction segments. The SEAL has a light and filter capable of maintaining a 880nm wavelength.

7.10 Boiling Chips ultra-pure, non-reactive.

7.11 Syringes to use with membrane filters.

7.12 Pipettes Class A glass or automated.

8. Reagents and Standards

8.1 Calibration Curve and Spike, Stock Complex Phosphate Standard: 1000 mgP/L This stock solution is certified and purchased commercially prepared. Stored at room temperature per manufacturer's specifications. Expires upon manufacturer's specified date.

8.2 Calibration Curve and Spike, Intermediate Complex Phosphate Standard: 50 mgP/L Dilute 5.0mL stock complex phosphate solution to 100mL with DI water. Store at 4 ± 2°C. Expires 6 months after date of preparation.

8.3 Calibration Curve, Working Standard: 1.0 mgP/L Add 2mL of 50 mgP/L intermediate standard (Section 8.2) to 100mL volumetric flask and dilute to volume with DI water. Prepare fresh on each day of use.

8.4 Calibration Standards: Follow table below. Prepare fresh on each day of use.

Volume of 1.0 mg/L Working Standard (Section 8.3)	Final Volume (mL)	Calibration Standard Final Concentration (mgP/L)
0 mL	50	0
0.5 mL	50	0.010
2 mL	50	0.040
5 mL	50	0.100
25mL	50	0.500
50mL	50	1.000

8.5 ICV-LCS-CCV Stock Complex Phosphate Standard: 1000 mgP/L Second, independent, source standard. Stored at room temperature per manufacturer's specifications. Expires upon manufacturer's specified date.

8.6 ICV-LCS-CCV Intermediate Complex Phosphate Standard: 50 mgP/L Add 5mL of 1000 mgP/L stock standard (Section 8.5) to 100mL volumetric flask and dilute to volume with DI water. Store at 4 ± 2°C. Expires 6 months after date of preparation.

8.7 ICV-LCS-CCV Working Standard: Prepare fresh each day of use.

8.7.1 0.5 mgP/L: Add 0.5mL of 50 mg/L intermediate standard (Section 8.6) to 50mL centrifuge tube and dilute to the 50mL mark with DI water.

8.8 Matrix Spike: Intermediate Phosphate Standard (Section 8.2) is utilized for matrix spike solution. Pipet 0.5mL of the 50 mgP/L standard into 50mL of sample to result in a 0.5mg/L spike concentration.

8.9 Sulfuric Acid, H_2SO_4, 5N: Dilute 140mL concentrated sulfuric acid to 1L with DI. Store at room temperature. Expires 6 months from date of preparation.

8.10 Potassium Antimonyl Tartrate Solution: Dissolve 1.3715g $K(SbO)\ C_4H_4O_6 \cdot ½H_2O$ in 400mL DI water in a 500mL volumetric flask and dilute to volume. Store at 4 ± 2°C. Expires one month from date of preparation.

8.11 Ammonium Molybdate Solution: Dissolve 10g $(NH_4)_6Mo_7O_{24} \cdot 4H_2O$ in 250mL distilled water. Store at 4 ± 2°C. Expires one month from date of preparation.

8.12 Ascorbic Acid, 0.1M: Dissolve 3.52g ascorbic acid in 200mL DI water. The solution is stable for about 1 week at 4 ± 2°C.

8.13 Orthophosphate 1000ppm solution Independent, source standard. Store at 4 ± 2°C. Expires upon manufacturer's specified date.

8.14 Orthophosphate 25ppm spike solution Add 2.5mLs 1000ppm Orthophosphate solution to a clean, glass 100mL volumetric and dilute to volume with DI. Store at 4 ± 2°C. Expires 6 months from date of preparation.

8.15 SEAL Working Ascorbic Acid, 15g/L (with orthophosphate spike): Dissolve 1.5g of ascorbic acid in about 80mL DI water. Spike with .15mL 25ppm Orthophosphate standard to produce a spike level of .025mg P/L. Dilute to 100mL and mix well. The solution is stable for one week if stored at 4 ± 2°C. Discard if the solution becomes yellowed.

8.16 Combined Reagent: Mix 8.9, 8.10, 8.11, and 8.12 in the following proportions for 100mL of the combined reagent: 50mL 5N H_2SO_4 (Section 8.9), 5mL potassium antimonyl tartrate solution (Section 8.10), 15mL ammonium molybdate solution (Section 8.11), and 30mL ascorbic acid solution (section 8.12). Mix after addition of each reagent. Let all reagents reach room temperature before they are mixed and mix in the order given. If turbidity forms in the combined reagent, shake and let stand for a few minutes until turbidity disappears before proceeding. The reagent is stable for 4 hours. Discard reagent if it turns blue or black in color.

8.17 SEAL Working Coloring Reagent: To a clean 100mL volumetric flask, add 40mL sulfuric acid (8.9), followed by 6.5 mL antimony potassium tartrate (8.10) and swirl to mix. Then, add 20 mL ammonium molybdate (8.11). Swirl the contents, fill the flask up to the mark with DI water and mix well. Expires three weeks from day of preparation if stored at 4 ± 2°C. Discard if the reagent turns blue or becomes turbid.

8.18 Sodium Hydroxide, 6N: Dissolve 240 grams of NaOH pellets in 1000mL of DI water. Store at room temperature. Expires one month from date of preparation.

8.19 Phenolphthalein Indicator: Aqueous solution, commercially available. Store at room temperature. Expires upon manufacturer's specified date.

8.20 11N Sulfuric Acid Solution: Dilute 308mL concentrated sulfuric acid to 1000mL with DI. Store at room temperature. Expires 6 months from date of preparation.

8.21 Potassium Persulfate ($K_2S_2O_8$): Commercially available. Store at room temperature. Expires upon manufacturer's specified date.

8.22 Deionized Water

8.23 Soil LCS/SRM ERA Standard Reference Material for Nutrients in soil, catalog no. 542

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

9.1 Blank(s)

Method Blank/Calibration Blank - One method blank, which consists of DI water brought through the entire method, must be analyzed per batch of 20 samples or less. The CCB is analyzed after every 10 samples and at the end of the sequence.

Results of the Blanks must be less than the reporting limit. Otherwise the entire batch of samples must be re-prepared and reanalyzed. Exceptions are samples with results of more than 10 times the positive blank value.

Soil blanks are made with 0.1gm boiling chips and 50mLs of DI water and are analyzed like water blanks.

9.2 Laboratory Control Sample (LCS)

Analyze one per batch of 20 samples or less. The calibration curve must be verified by a second source standard prior to performing any sample analysis. For Total and Dissolved Phosphorus, the LCS is the ICV.

The ICV/LCS for aqueous samples must be recovered within 90-110% of the true value. If the ICV/LCS fails, re-analyze. If failure continues, stop analysis, correct problem and re-calibrate.

The Soil LCS made with approximately 0.15g of Standard Reference Material (SRM) brought up to 50mL with DI water. The soil LCS recovery criteria will vary per Lot of SRM, according to the SRM manufacturer's criteria listed on the certificate of analysis.

9.3 Initial Calibration Verification (ICV)

The calibration curve must be verified by a second source standard prior to performing any sample analysis. For Total and Dissolved Phosphorus, the ICV is the LCS.

The ICV/LCS must be recovered within 90-110% of the true value for water samples and be within vendor criteria for SRM. If the ICV/LCS fails, re-analyze. If failure continues, stop analysis, correct problem and re-calibrate.

9.4 Continuing Calibration Verification (CCV)

The calibration curve must be verified by a second source standard. The CCV is analyzed after every 10 samples and at the end of the sequence to verify the curve.

The CCV must be recovered within 90-110% of the true value. If the CCV fails, re-analyze. If failure continues, stop analysis, correct problem and re-calibrate.

9.5 Matrix Spike

Analyze one per batch of 20 samples or less. Concentration is 0.5 mgP/L. The matrix spike must be recovered within 75 – 125% of the true value. If the matrix spike recovery is outside acceptance criteria, and the LCS is acceptable, a narrative is submitted with the data for inclusion on the client report.

9.6 Laboratory Duplicate

Analyze one sample in duplicate per batch of 20 samples or less. The RPD must be ≤ 20%. If this criterion is not met, a narrative is submitted with the data for inclusion on the client report.

9.7 Method-specific Quality Control Samples

Not applicable.

9.8 Method Sequence

9.8.1 Using spectrophotometer:

- Acid-rinse all glassware
- Calibration curve generation.
- Filter samples if analysis is for Dissolved Phosphorus, then preserve with H_2SO_4.
- Add 50mL of water sample or 0.1g of soil sample and 50mL DI water to an Erlenmeyer flask.
- Add 1mL H_2SO_4 solution and scoop solid $K_2S_2O_8$ and glass beads
- Boil down to 10mL or less.
- Cool and dilute to 30mL with DI.
- Add 1 drop phenolphthalein indicator solution.
- Neutralize to faint pink color with NaOH.
- Add sample aliquot to a new centrifuge tube and bring up to 50mL with DI.
- Add 4 mL combined reagent to a 25mL aliquot of sample.
- Read sample absorbance after 10-30 minutes.
- Analyze CCV and CCB after every 10 samples to verify curve.
- End sequence with CCV and CCB.
- Calculate results.

9.8.2 Using SEAL AQ2 analyzer:

- Acid-rinse all glassware
- Filter samples if analysis is for Dissolved Phosphorus, then preserve with H_2SO_4.
- Add 50mL of water sample (soils are not done on the SEAL) to an Erlenmeyer flask, along with a 1.0ppm calibration standard for the calibration curve.
- Add 1mL H_2SO_4 solution and scoop solid $K_2S_2O_8$ and glass beads
- Boil down to 10mL or less.
- Cool and dilute to 50mL with DI.
- Turn on the SEAL AQ2 analyzer.
- Fill out a run sequence and save it.
- Fill cups, including a cup of 1.0ppm digested standard for the curve
- Start the analysis.
- Change names of blank and LCS to be what the LIMS will recognize (ie, what is on the batch sheet).
- Export the data to LIMS by dropping it into the “SEAL on bowzer” folder.

10. Procedure

10.1 Equipment Set-up

10.1.1 Sample Preparation for Dissolved Phosphorus Analysis

Prior to preservation, samples to be analyzed for dissolved phosphorus are filtered using new disposable syringes and new 0.45um filter discs. 100mL of sample is filtered, poured into two new centrifuge tubes and preserved with H_2SO_4.

10.2 Initial Calibration

10.2.1:

Preparation of calibration curve, with spectrophotometer: Prepare individual calibration curve from a series of six digested standards (0 mgP/L to 1.0 mgP/L) on each day of analysis. The curve must be digested. Use DI water without the combined reagent to zero the Spectrophotometer. Plot absorbance vs. phosphate concentration to give a straight line. The correlation coefficient must be 0.995 or greater for the curve to be considered valid. Analyze at least one phosphate standard with each batch of 20 samples or less.

All calibration points are back calculated (on excel) and should be within 10% from true concentration, except 2 lowest points of calibration curve. %recoveries for low range will be wider, but shouldn't exceed 100% and correlation coefficient will not be worse then 0.995.

10.2.2:

Preparation of calibration curve, with SEAL AQ2 analyzer: Prepare and digest a 1.0 mgP/L standard and put it into the first slot in the auto-sampler. When prompted, click on "Auto-calibrate" to start calibration. Once the curve is finished, it may be checked in the "calibration" section. The correlation coefficient must be 0.995 or greater for the curve to be considered valid.

. All calibration points are back calculated by SEAL software and should be within 10% from true concentration, except 2 lowest points of calibration curve. %recoveries for low range will be wider, but shouldn't exceed 100% and correlation coefficient will not be worse then 0.995.

10.3 Equipment Operation and Sample Processing, with spectrophotometer

10.3.1 Add 50mL or a suitable portion of thoroughly mixed sample to a prepared (Section 7.2) 125mL Erlenmeyer flask. Use 0.1g of soil sample with 50 ml of DI for soil samples.

10.3.2 Add 1mL H_2SO_4 solution, one scoop solid $K_2S_2O_8$ and 3 to 5 glass beads.

10.3.3 Boil gently on a preheated hot plate until a final volume of 10mL or less is reached. Organophosphorus compounds such as AMP may require as much as 1-1/2 to 2 hours for complete digestion.

10.3.4 Cool, dilute to 30mL with DI water.

10.3.5 Add 0.05mL (1 drop) phenolphthalein indicator solution.

10.3.6 Neutralize to a faint pink color with NaOH.

10.3.7 Pour pink liquid sample into a new (unused) centrifuge tube and bring volume to 50mL with DI. Pour back into a 125mL Erlenmeyer flask.

10.3.8 Swirl the sample to mix and pour off 25mL digested sample into centrifuge tube.

10.3.9 Add 4.0mL combined reagent to all 25mL sample and QC sample aliquots and mix thoroughly.

10.3.10 After at least 10 minutes but no more than 30 minutes, use DI as the reference solution to zero the spectrophotometer at 880nm. Measure absorbance of each sample and record in the electronic laboratory notebook. If samples seem to have high background color before the addition of the coloring reagent, a background color may be checked for (see section 4).

If the sample concentration is greater than the highest concentration of the calibration curve (1.0mg/L), the digested sample is diluted with DI water to a concentration within the range of the calibration curve.

10.4 Equipment Operation and Sample Processing, with SEAL AQ2 Analyzer

10.4.1 Acid rinse all glassware twice with 1:1 hydrochloric acid and then twice with DI water.

10.4.2 Pour out 50mLs of mixed samples and QC samples, including a 1.0ppm calibration standard.

10.4.3 Add 1mL H_2SO_4 solution, one scoop solid $K_2S_2O_8$ and 3 to 5 glass beads.

10.4.4 Boil gently on a preheated hot plate until a final volume of 10mL or less is reached. Organophosphorus compounds such as AMP may require as much as 1-1/2 to 2 hours for complete digestion.

10.4.5 Cool and dilute to 50mLs.

10.4.6 Turn on SEAL AQ2 analyzer by flipping first the small, and then the large switch in the back.

10.4.7 Give the instrument at least half an hour to warm up.

10.4.8 If it has not yet been done that day, go through daily start-up, check voltages, and test aspiration.

10.4.9 Double click on scheduling to open the schedule form, and insert samples, Method Blanks, LCSs, Duplicates, and Matrix Spikes (the CCVs and CCBs populate automatically) NB: leave the first spot for the calibration curve.

10.4.10 Pour a small (approximately 1 mL) aliquot into small tubes and put them into the instrument. Put the 1.0ppm standard into the first spot.

10.4.11 Check to see that all the reagent wedges are in the correct spots and that there are sufficient reaction segments.

10.4.12 Save the sequence and double click on “run”; check the boxes for curve analysis.

10.4.13 Once the instrument is done analyzing the run, check and approve the results in the Data Review section. Then, change the Blank and LCS names to be whatever they are on the batch sheet (ex: WG123456-1) and save the run in the “out” folder.

10.4.14 Open the “SEAL on bowzer” folder and drop the run into it from the “out” folder. This saves the data to LIMS.

10.5 Continuing Calibration

The method blank and LCS are used as the CCB/CCV and should be read after every ten samples and at the end of the batch. Recovery for the CCV must be between 85-115% of the true value. Recovery for the CCB must be between the RL and its negative, (i.e: within -.01mg/L and .01mg/L for waters).

10.6 Preventative Maintenance

The Spectrophotometers are calibrated on a semi-annual basis by an instrument service company. Certificates are kept on file.

11. Data Evaluation, Calculations and Reporting

Calculate the concentration value of the sample directly from the standard curve. (Section 10.2).

$$\text{mg } P_{Total}/L = \frac{\text{absorbance} - \text{y-intercept}}{\text{slope}} \times \text{Dilution factor}$$

If samples were filtered prior to preservation, report as mg $P_{Dissolved}$ / L.

For soil samples, convert results to mg/kg, by multiplying result in mg/l by extraction volume and dividing by weight. All results must by reported based on dry weight.

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

Holding time exceedances or improper preservation are noted on the nonconformance report form.

Perform routine preventative maintenance following manufacturer's specification. Record all maintenance in the instrument logbook.

Review of standards, blanks and standard response for acceptable performance occurs for each batch of samples. Record any trends or unusual performance on a nonconformance action form.

If the CCV or LCS recovery of any parameter falls outside the designated acceptance range, the laboratory performance for that parameter is judged to be out of control, and the problem must be immediately identified and corrected. The analytical result for that parameter in the unspiked samples is suspect and is only reported for regulatory compliance purposes with the appropriate nonconformance action form. Immediate corrective action includes reanalyzing all affected samples by using any retained sample before the expiration of the holding time.

13. Method Performance

13.1 Method Detection Limit Study (MDL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the MDL, LOD, and/or LOQ as outlined in Alpha SOP/1732. These studies performed by the laboratory are maintained on file for review.

The quarterly method reporting limit (MRL) verification requirement is satisfied by the quarterly LOQ analysis, as per SOP/1732.

13.2 Demonstration of Capability Studies

Refer to Alpha SOP/1739 for further information regarding IDC/DOC Generation.

13.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

14. Pollution Prevention and Waste Management

Refer to Alpha's Chemical Hygiene Plan and Waste Management and Disposal SOP for further pollution prevention and waste management information.

15. Referenced Documents

Chemical Hygiene Plan

SOP/1732 MDL/LOD/LOQ Generation

SOP/1739 IDC/DOC Generation

SOP/1728 Waste Management and Disposal SOP

16. Attachments

None.

Total Solids in Solid and Semisolid Samples

(Percent Solids)

Reference Method: **SM 2540 G,** Standard Methods for the Examination of Water and Wastewater. APHA-AWWA-WEF. Standard Methods Online.

1. Scope and Application

Matrices: Soils, solids and sludges.

Definitions: See Alpha Analytical Quality Manual

This method is applicable to the determination of total solids in such solid and semisolid samples as river and lake sediments, sludges separated from water and wastewater treatment processes, and sludge cakes from vacuum filtration, centrifugation, or other sludge dewatering processes.

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one of the following laboratory personnel before performing the modification: Area Supervisor, Laboratory Services Manager, Laboratory Director, or Quality Assurance Officer.

This method is restricted to use by or under the supervision of trained analysts. Each analyst must demonstrate the ability to generate acceptable results by completing an initial demonstration of capability

2. Summary of Method

A homogenized aliquot of sample is weighed in a tared dish and set in a 103º - 105ºC oven until dry. The sample and dish are cooled and re-weighed, thus the percent of solids in the original sample can be calculated.

2.1 Method Modifications from Reference

Aluminum pans are used instead of porcelain dishes. However, if the sample is corrosive, then the porcelain dishes are used.

5-10 grams of sample are used for soil and solid matricies.

One duplicate is analyzed per batch of 20 samples or less.

3. Reporting Limits

The Reported Detection Limit is 0.1%.

4. Interferences

4.1 Humidity: Humidity in the laboratory may cause samples to pick up moisture. When not being weighed, samples should be kept tightly capped or in a dessicator.

4.2 Large rocks / debris: Large rocks or debris may cause false high results and therefore should not be included in the sample aliquot.

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material safety data sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents. Personal protective equipment is to be worn at all times within the laboratory areas. At a minimum, a labcoat, gloves and safety glasses are worn.

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

Samples are collected in glass or plastic containers with minimal headspace. Containers are covered immediately to minimize the loss of sample moisture.

6.2 Sample Preservation

Samples are refrigerated at 4 ºC.

6.3 Sample Shipping

No special shipping requirements.

6.4 Sample Handling

Samples are kept refrigerated at 4 ºC until the time of analysis.

For samples received, marked and commented as **Foreign Soils** reference SOP 2296 Treatment of Foreign Soils.

For samples received, marked and commented as **Containing or May contain Asbestos** reference WI 2535 Asbestos Handling Procedures.

7. Equipment and Supplies

7.1 Analytical Balance: Capable of weighing to 0.01g

7.2 Aluminum Weighing Dishes or Pans

7.3 Porcelain Evaporation Dishes

7.4 Dessicator: With a color-indicator dessicant.

7.5 Drying Oven: Capable of maintaining 103 – 105 ºC.

7.6 Oven Trays

7.7 Computer: with connection to LIMS and the Analytical Balance (Sect. 7.1)

7.8 Baked Sand: created by and available in the extractions department

8. Reagents and Standards

None.

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

9.1 Blank(s)

One blank is analyzed per batch of 20 samples or less from the state of Maine. Blank recovery must be between 95%-105%. If this criterion is not met, the sample and it's duplicate are reanalyzed. Sand, baked to dryness in the extractions laboratory, is used for the blank sample.

9.2 Laboratory Control Sample (LCS)

Not applicable.

9.3 Initial Calibration Verification (ICV)

Not applicable.

9.4 Continuing Calibration Verification (CCV)

Not applicable.

9.5 Matrix Spike

Not applicable.

9.6 Laboratory Duplicate

One duplicate is analyzed per batch of 20 samples or less. Duplicate determinations must agree within 20%. If this criterion is not met, the sample and it's duplicate are reanalyzed.

If sample, used for batch duplicate, is non-homogeneous, then data may be reported with a narrative.

9.7 Method-specific Quality Control Samples

Not applicable.

9.8 Method Sequence

- Create a Workgroup in LIMS
- Locate Samples and take possession of them in LIMS
- Create an ELN for the Workgroup
- Homogenize Sample
- Record the Tare weight of the evaporation dish, then the Gross weight for each sample one at a time
- Dry samples in the oven 3+ hours.
- Cool samples in the dessicator
- Record the Net Weight (1)
- Dry samples again for 1+ hour(s), unless samples were originally dried overnight. Due to running of analysis 24 hours a day overnight is interpreted to mean a minimum of 5 hours.

Samples from the State of Maine logged for ME-TS-2540 must always be dried again regardless of the length of time dried.

- Cool samples in the dessicator
- Record the Net Weight (2)
- Save and Send Data to LIMS

10. Procedure

10.1 Equipment Set-up

10.1.1 LIMS Knowledge: Prior to utilizing this SOP, the analyst must first be familiar with the operation of the Laboratory Information Management System (LIMS) and the generation of a sample batch or workgroup.

10.1.2 Porcelain Dish Preparation: Porcelain evaporation dishes are used only if a sample is corrosive to aluminum. To prepare the porcelain dishes, bake them in the 103 – 105 ºC drying oven for a minimum of 1 hour before placing them in the dessicator. Cool in the dessicator for a minimum of one hour.

10.1.3 Matrix and Volume Evaluation: Total Solids analysis should not be performed on plastic, caulking or oil. If logged for total solids analysis see login staff for assistance in altering the login in LIMS.

When taking an aliquot of sample for analysis, it is important that the sample volume is not exhausted to perform total solids before all other analysis has been performed. If the container has analysis printed on the alpha applied label other than total solids, ensure those tests have been performed prior to utilizing the remainder of the sample for total solids analysis.

10.2 Initial Calibration

Not applicable.

10.3 Equipment Operation and Sample Processing

10.3.1 Prioritizing Work and Selecting Samples to Analyze

Using the Pivot Table located in the Login folder on the network drive (Login_TS_#.#) identify the next samples to be analyzed. Rushes must be prioritized by due date and priority level (P1, P2, P3 or null), followed by non-rush samples by due date and priority level. Gather the samples to be run from sample custody prior to batching into workgroups.

10.3.2 Generating a LIMS Batch

Utilizing a computer (Sect. 7.7), generate a LIMS batch of samples and assign a Workgroup (WG) number to the batch. When generating the batch, choose a sample that will be duplicated. Print out a copy of the LIMS batchsheet. For samples from the state of Maine, a blank must be analyzed. Use the “Scan to Batch” function in LIMS to scan the barcodes of samples you are batching to ensure no typographical errors are made. When selecting the DUP (and Blank for samples from Maine) also use the barcode scanner to ensure accuracy.

10.3.2 Creating a Gravimetric Laboratory Notebook

From the menu bar in LIMS select: “Sample Data”, “Data”, “Logbooks”, “ELN-Wet Chem” and enter the workgroup number in the space provided. If this is the first time you have attempted to open a lab notebook for this workgroup a window will pop up confirming you wish to create a new gravimetric laboratory notebook.

Once you create the laboratory notebook the samples will populate in the spreadsheet with the Duplicate at the top. Above the list of samples. The reference sample for the Duplicate can be confirmed by double clicking the Sample Number of the Duplicate.

10.3.3 Taking the Tare Weight

10.3.3.1 With the cursor on the tare weight field in the ELN, weigh the corresponding empty dish on a tared balance. When the weight is stable, push the “Print” button on the balance. This will transfer the weight of the empty dish into the ELN.

10.3.4 Taking the Gross Weight

10.3.4.1 Homogenize the sample by mixing with a spatula or spoon.

10.3.4.2 Remove a 5 – 10g aliquot of soil sample or 20 – 25g of a sludge sample and place it in the weighing dish.

10.3.4.3 With the cursor on the cell for the “Gross Weight” corresponding to the sample to be weighed, zero the balance and weigh the dish plus the sample. When the weight is stable, push the “Print” button on the balance. This will transfer the weight into the ELN.

10.3.4.4 Place the dish onto an oven tray.

10.3.5.5 Once the samples have all been weighed and the weights recorded in the ELN, click save.

10.3.6 Drying the Samples : Phase I

10.3.6.1 Place the oven tray in the 103 – 105 ºC drying oven. In the ELN double click the Time In (1) field to populate the current time, edit as needed to reflect the time the samples were placed in the oven. Enter the temperature reading on the oven into the Temperature field.

10.3.6.2 After a minimum of three hours (samples with state of origin ME must be dried at least five hours), if samples appear dry, move the oven tray of dried samples to a dessicator. Allow to cool completely.

10.3.7 Taking the First Net Weight

10.3.7.1 In the ELN with the cursor on the “Net Weight (1)” field corresponding to the sample to be weighed, zero the balance and weigh the dish plus the sample. When the weight is stable, push the “Print” button on the balance. This will transfer the weight into the ELN.

10.3.7.2 Repeat Section 10.3.7.1 until the Net Weight (1) for all samples has been recorded.

10.3.7.3 Click on the “Save” button to save the weights.

10.3.8 Drying the samples : Phase II

10.3.8.1 If the samples were dried in the oven for less than five (but at least three) hours, the tray of samples must be placed back in the 103 – 105 ºC drying oven for a minimum of one hour. If the samples are from the state of Maine the samples must always be placed back in the oven for a minimum of one hour.

10.3.8.2 After drying, move the oven tray of samples to a dessicator. Allow to cool completely.

10.3.9 Taking the Second Net Weight

10.3.9.1 In the ELN with the "Net Weight(2)" field selected corresponding to the sample to be weighed, zero the balance and weigh the dish plus the sample. When the weight is stable, push the "Print" button on the balance. This will transfer the weight into the ELN.

10.3.9.2 Repeat Sections 10.3.9.1 until the Net Weight (2) for all samples has been recorded.

10.3.9.3 Click on the "Save" button to save the weights.

10.3.9.4 If Net Weight (1) and Net Weight (2) are within 4% or 50mg, the ELN will highlight the values light pink and display. If this is the case for all samples in the batch, proceed to Section 10.3.10.

10.3.9.5 If Net Weight (1) and Net Weight (2) are not within 4% or 50mg the ELN will highlight the values red and the words "Not Acceptable" will be displayed, repeat Sections 10.3.8 and 10.3.9 for those samples. This will allow the chemist to record a Net Weight (3), (4) or (5), until the values are within the acceptable range.

If the samples have been dried ≥ 24 hours, and the weights are still not within 4% or 50mg, consult the Department Supervisor as to how to proceed.

10.3.10 Saving the Batch

10.3.10.1 Click on the "Save" button to save the weights in the ELN.

10.3.10.2 Click on the "Send to LIMS" button in the ELN.

10.4 Continuing Calibration

Not applicable.

10.5 Preventative Maintenance

The temperature of the laboratory ovens is recorded constantly on the data logger. The chart recorder and the laboratory ovens are calibrated on an annual basis by an instrument service company. Certificates are kept on file.

Analytical balances are calibrated on a semi-annual basis by an instrument service company. Certificates are kept on file. The calibration of the balances is verified on a daily basis and records are kept in a Logbook.

11. Data Evaluation, Calculations and Reporting

The Excel Spreadsheet is programmed to calculate the Percent Solids results. This is the formula that is used for calculation:

$$\% \text{ Total Solids} = \frac{(A - B)}{} \times 100$$

(C - B)

Where: A = Final Net Weight (weight of dried residue + dish, g)
B = Tare weight (weight of dish, g)
C = Initial Gross Weight (weight of wet sample + dish, g)

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

Improper preservation is noted on the Sample Delivery Group form.

Perform routine preventative maintenance following manufacturer's specification. Record all maintenance in the instrument logbook.

13. Method Performance

13.1 Method Detection Limit Study (MDL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the MDL, LOD, and/or LOQ as outlined in Alpha SOP/1732. These studies performed by the laboratory are maintained on file for review.

13.2 Demonstration of Capability Studies

Refer to Alpha SOP/1739 for further information regarding IDC/DOC Generation.

13.2.1 Initial **(IDC)**

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

14. Pollution Prevention and Waste Management

Unless the containers are labeled as hazardous material (i.e. low flashpoint, ignitable, containing asbestos or high levels of toxic materials), the dried samples are disposed of into the trash.

If sample containers are labeled as hazardous, refer to the Chemical Hygiene Plan for waste handling and disposal instructions.

Refer to Alpha's Chemical Hygiene Plan and Waste Management and Disposal SOP for further pollution prevention and waste management information.

Total Sulfide, Methylene Blue Method

References: **SM 4500S2-D:** Standard Methods for the Examination of Water and Wastewater. APHA-AWWA-WEF. Standard Methods Online.

EPA 9030B: SW-846, Test Methods for Evaluating Solid Waste: Physical/Chemical Methods, EPA SW-846, Update III, 1997.

1. Scope and Application

Matrices: This method is applicable to water, wastewater and seawater samples.

Definitions: Refer to Alpha Analytical Quality Manual.

Sulfide often is present in groundwater, especially in hot springs. Its common presence in wastewaters comes partly from the decomposition of organic matter, sometimes from industrial wastes, but mostly from the bacterial reduction of sulfate. Hydrogen sulfide escaping into the air from sulfide-containing wastewater causes odor nuisances. The threshold odor concentration of H_2S in clean water is between 0.025 and 0.25µg/L. H_2S is very toxic and has claimed the lives of numerous workers in sewers. It attacks metals directly and has indirectly caused serious corrosion of concrete sewers because it is oxidized biologically to H_2SO_4 on the pipe wall.

From an analytical standpoint, three categories of sulfide in water and wastewater are distinguished:

- Total sulfide includes dissolved H_2S and HS-, as well as acid-soluble metallic sulfides present in suspended matter. The S_{-2} is negligible, amounting to less than 0.5% of the dissolved sulfide at pH 12, less than 0.05% at pH 11, etc. Copper and silver sulfides are so insoluble that they do not respond in ordinary sulfide determinations; they can be ignored for practical purposes.
- Dissolved sulfide is that remaining after suspended solids have been removed by flocculation and settling.

Un-ionized hydrogen sulfide may be calculated from the concentration of dissolved sulfide, the sample pH, and the practical ionization constant of H_2S.

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one or more of the following laboratory personnel before performing the modification: Area Supervisor, Department Supervisor, Laboratory Director, or Quality Assurance Officer.

This method is restricted to use by or under the supervision of trained analysts. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

2. Summary of Method

Sulfide is separated from the sample matrix by suspending the sample in a hydrochloric acid solution and vigorous agitation. Hydrogen sulfide gas is released from the sample and collected in a gas scrubbing bottle containing sodium hydroxide. The methylene blue method is based on the reaction of sulfide, mild oxidizing agent potassium dichromate, and dimethyl-p-phenylenediamine to produce methylene blue.

2.1 Method Modifications from Reference

Soil samples don't require preservation and have hold time of 7 days

For water samples: whole sample is filtered and filter with sediment is being analyzed.

Lab is purchasing commercially available coloring reagents from HACH.

Lab is using DI instead of dagassed reagent water.

3. Reporting Limits

The reported detection limit is 0.1 mg/L for liquid samples and 0.5 mg/kg for soils samples

4. Interferences

4.1 Strong reducing agents interfere in the methylene blue test by preventing formation of the blue color. Thiosulfate at concentrations about 10mg/L may retard color formation or completely prevent it. Sulfide itself prevents the reaction if its concentration is very high, in the range of several hundred milligrams per liter. To avoid the possibility of false negative results, use the antimony method to obtain a qualitative result in industrial wastes likely to contain sulfide but showing no color by the methylene blue method. Iodide, which is likely to be present in oil-field wastewaters, may diminish color formation if its concentration exceeds 2mg/L. Ferrocyanide produces a blue color; distillation will minimize interference.

4.2 Eliminate interferences due to sulfite, thiosulfate, iodide, and many other soluble substances (but not ferrocyanide), by precipitating ZnS.

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material safety data sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

Take samples with minimum aeration in either a glass or plastic bottle. Fill the bottle completely and cover. Aqueous samples are collected in a 250mL plastic bottle, soil/solid samples are collected in an amber glass container.

6.2 Sample Preservation

All samples must be preserved with 2N zinc acetate (Section 8.5) and 6N sodium hydroxide (Section 8.6).

Use four drops of 2N zinc acetate solution per 100mL aqueous sample. Adjust the pH to greater than 9.0 with 6N NaOH.

Soils require no preservative.

6.3 Sample Shipping

No specific requirements.

6.4 Sample Handling

Samples are stored refrigerated at 4 ± 2° C. Aqueous and soil samples are analyzed within a 7-day holding time.

7. Equipment and Supplies

7.1 Spectrophotometer, Genesys 10vis (or equivalent): For use at a wavelength of 664nm with cells providing light paths of 1cm.

7.2 Test Tubes (centrifuge tubes): 25mL capacity

7.3 Pipets: Glass, volumetric, various volumes or Auto-pippets.

7.4 Volumetric Flasks: 100mL and 1L volumes, 250 ml ,200 ml and 50 ml

7.5 Erlenmeyer Flasks: 125mL volume

7.6 Three-neck Flask: 500mL volume, 24/40 standard taper joints.

7.7 Dropping funnel: 250mL volume, 24/40 joint.

7.8 Purge gas inlet tube: 24/40 joint with coarse frit.

7.9 Purge gas outlet: 24/40 joint reduced to ¼ in. tube.

7.10 Gas scrubbing bottles: 125mL volume, with ¼ inch o.d. inlet and outlet tubes.

7.11 Tubing: ¼ inch o.d. polytetrafluoroethylene (PTFE) or polypropylene.

7.12 Magnetic Stirrer

7.13 Nitrogen gas: 5.0 Ultra pure.

7.14 Nitrogen regulator

7.15 Flowmeter

7.16 Teflon-coated stirring bar

7.17 Analytical Balance: Capable of weighing 0.1g.

7.18 Glass fiber filter disks: 90mm

7.19 Filtration Apparatus: With membrane filter funnel.

7.20 Suction flask

7.21 Vacuum pump

7.22 Graduated cylinders

8. Reagents and Standard

8.1 2 different sources. Stock Sulfide Solution, approximately 1097 mg/L: In 200 ml volumetric flask weigh 1.5779 grams of $Na_2S \cdot 9H_2O$ (Section 8.8) and bring volume up to 200 ml of DI Store in the refrigerator. Final concentration is 1097 mg/L. Stable for 2 weeks.. Standard has to be re-made, if degradation of LCS and ICV is noticeable.

8.1.1 LCS/ICV/CCV/ Spike Working Solution (65.82 mg/l): In 50 ml volumetric flask add 10 ml of 1N NAOH (8.6) solution, then adds 3 ml of Stock Sulfide Solution (8.1), bring volume up to 50 ml with DI. Gently mix; can not be mixed vigorously. Different stocks are used to prep ICV/ LCS solution and CCV / Spike solution. Solution is stable for one week.

8.1.2 Intermediate calibration standard 10.97 mg/l: Pipet 1 ml of Stock Sulfide Calibration Solution (8.1) into 100ml volumetric flask. Bring volume up to 100ml with DI. Make daily.

8.2 Sulfide 1 Reagent: Available commercially from HACH Company. Store at 4 ± 2°. Reagent expires upon manufacturer's specified date.

8.3 Sulfide 2 Reagent: Available commercially from HACH Company. Store at 4 ± 2°. Reagent expires upon manufacturer's specified date.

8.4 Sulfide Calibration Solutions: These solutions are used to generate the calibration curve in Section 10.1. Prepare a series of sulfide solutions by diluting the Intermediate Calibration Sulfide Standard second source (Section 8.1.2). These solutions are prepared fresh prior to generating a calibration curve.

Into seven 100mL volumetric flasks containing 20ml of 1N NaOH pipet 0mL, 0.5 ml 1mL, 2.0mL, 4mL, and 8mL,12 ml and 16 ml of Intermediate Calibration Sulfide Solution (Section 8.1.2). Bring each to volume with DI.

8.5 Zinc Acetate Solution: Dissolve 220g $Zn(C_2H_3O_2)_2 \cdot 2H_2O$ in 500mL water. This solution is used as the preservative during sampling. Store at room temperature. Solution is stable for one year.

8.6 Sodium Hydroxide Solution, NaOH, 1N, 6N and 0.2N: For 1N NaOH, dissolve 40g NaOH in 1L of DI water. For 6N, dissolve 240g NaOH in 1L of DI water. This solution is used as a preservative during sampling. Store at room temperature. Solution is stable for 6 month. For 0.2N NaOH, add 200 ml of 1.0 N NaOH in 1L of DI water. Stable for 1 month.

8.7 HCL Solution, 2N: Add 175mL concentrated HCL (Section 8.10) to 500mL of DI water. Dilute to 1L with DI water. Store at room temperature. Make daily.

8.8 $Na_2S \cdot 9H_2O$: Store at 4 +/- 2 degrees C, out of direct light.

8.9 Concentrated HCL: Store at room temperature.

8.10 Ottawa sand or equivalent.

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

9.1 Blanks

9.1.1 **Method Blank:** Distill and analyze one Method Blank of DI water (for liquid samples) or 10g of Ottawa sand (for soil samples) per batch of 20 samples or less. The Method Blank results must be less than the Reporting Limit. Refer to Section 12 for any corrective actions.

9.1.2 **ICB/CCB:** The ICB/CCB is not distilled. It consists 25 ml of 0.02N NaOH and is analyzed following each ICV/CCV. Results must be less than the Reporting Limit. Refer to Section 12 for any corrective actions.

9.2 Laboratory Control Sample (LCS)

Distill and analyze one LCS (Section 8.1.1) per batch of 20 samples or less.

For waters: in 250 ml volumetric flask add approximately 50 ml of DI, 6 drops on 2N Zn Acetate, swirl and add 1 ml of LCS working Solution (8.1.1), adjust pH with 6N NaOH solution (@ 6 drops) to pH greater then 9. Bring volume up to 250 ml with DI. Let solution to sit for several minutes prior to preparation (filtration).

For soils: weigh 10g of Ottawa sand and add 1ml of LCS working solution (8.1.1) directly to reaction flask.

Follow distillation and colorimetric process.

% Recovery must be within 75 – 125%. Refer to Section 12 for any corrective actions.

9.3 Initial Calibration Verification (ICV)

The ICV is not distilled. In 100 ml volumetric flask add 20 ml of 1N NAOH solution, 1 ml of LCS working solution; bring volume up to 100 ml with DI. Done fresh prior to analysis

ICV is analyzed at the beginning of analytical batch.

% Recovery must be within 75 – 125%. Refer to Section 12 for any corrective actions.

9.4 Continuing Calibration Verification (CCV)

The CCV is not distilled. In 100 ml volumetric flask add 20 ml of 1N NAOH solution, 1 ml of CCV working solution; bring volume up to 100 ml with DI. Done fresh prior to analysis. It consists of the CCV Standard (Section 8.1.1) and is analyzed after every 10 samples and at the end of the batch.

% Recovery must be within 75 – 125%. Refer to Section 12 for any corrective actions.

9.5 Matrix Spike

Prepare and analyze one matrix spike per batch of 20 samples or less. The matrix spike consists of the 2ml of Working spike solution (8.1.1) added directly to reaction flask prior to distillation. % Recovery must be within in-house control limits. Refer to Section 12 for any corrective actions.

9.6 Laboratory Duplicate

Prepare and analyze one sample in duplicate per batch of 20 samples or less. %RPD must be $\leq$ 25%. Refer to Section 12 for any corrective actions.

9.7 Method-specific Quality Control Samples

Upon client specification

9.8 Control Limits

The laboratory maintains performance records to document the quality of data that is generated. Method accuracy for samples is assessed and records maintained. After the analysis of 20 spiked samples, and 20 laboratory control samples, calculate the average percent recovery (R) and the standard deviation of the percent recovery (S).

Control limits for the method parameters are generated. The control limits are calculated based on in-house performance data. The limits are compared to the control limits found in the reference method.

9.9 Method Sequence

- Generate a calibration curve.(done once a year)
- Filter water samples or weigh out soil samples
- Add turned filters (for water samples) or aliquot of soil to reaction flask
- Assemble distillation system and distill for at least an hour.
- Disassemble distillation unit and bring distillate up to final volume.
- Start colorimetric procedure.
- Add 1mL Sulfide 1 Reagent to 25mL of sample and swirl gently to mix.
- Add 1mL of Sulfide 2 Reagent.
- Wait 5 – 15 minutes.
- Read the absorbance of samples and QC samples.
- Calculate results.

10. Procedure

10.1 Initial Calibration

Prepare a calibration curve using the selected standards from Section 8.4

Analyze the standards as in Section 10.2.2 and 10.2.3 below, and plot concentration vs. absorbance. Determine the slope and the y-intercept. The correlation coefficient must be $\geq$ 0.995. A calibration curve is generated once a year of when significant changes are noted.

10.2 Equipment Operation and Sample Processing

10.2.1 Sample Preparation

10.2.1.1 **Soil samples:** Weigh 10 grams of the sample add to the reaction flask with a clean stir bar. Record the weight on excel form/ prep book.

10.2.1.2 **Aqueous samples:** Filter entire sample volume through a 90mm glass fiber filter and rinse with DI water. Place filter into the reaction flask with a clean Teflon stir bar. Record the volume of sample filtered on excel form/ prep book.

10.2.1.3 Add 200mL of 2N HCL Solution (Section 8.7) into the thistle tube, making sure that the stopcock is closed.

10.2.1.4 Add 20mL of 1N NaOH (Section 8.6) and 50mL of DI to the 250mL collection vessel.

10.2.1.5 Assemble the distillation train.

10.2.1.6 Connect the thistle flask to the center position of the reaction flask

10.2.1.7 Connect the collection vessel to the left side of the reaction flask, and the impinger tube to the collection vessel. The impinger tube must be below the surface of the NaOH solution. Make sure that all ground glass joints are sealed.

10.2.1.8 Connect the Nitrogen gas to the right side of the collection vessel. The gas inlet must be below the surface of the reaction flask solution.

10.2.1.9 Making sure that the train is a closed system, purge the train with Nitrogen for 5 minutes. Open the valve on the Nitrogen tank (Section 7.13) and open up the regulator so that 45 psi of Nitrogen is flowing (this will effectively give a flow rate of about 150mL/min).

10.2.1.10 Once the system has been purged for 5 minutes, open the stopcock fully on the thistle tube and release the 2N HCL solution into the reaction vessel. At this point the sample should be stirring. Close the stopcock as soon as all of the 2N HCL solution has been delivered to the reaction flask. Let the reaction progress for 1 hour.

10.2.1.11 After one hour has passed, dissemble the train and bring the total volume of the collection vessel to 100mL with DI**.**

10.2.2 Color Development: Transfer 25mL sample to a test tube. Add 1.0mL Sulfide 1 reagent (Section 8.2) and swirl to mix. Add 1mL of Sulfide 2 reagent (Section 8.3). Let the reaction continue for 5 minutes. Excessive mixing causes low results by loss of H_2S as a gas before it has had time to react. The presence of sulfide will be indicated by the appearance of blue color. Color development usually is complete in about 1 minute, but a longer time is often required for fading out of the initial pink color. Wait 5 to 15 minutes and make color comparisons. If zinc acetate was used, wait at least 10 minutes before making a visual color comparison.

10.2.3 Absorbance Determination: Set the spectrophotometer to a wavelength of 664nm. Zero the instrument with a portion of the reagent blank sample using a 1 cm cell. Read the absorbance of the samples and QC samples and record this information on the excel format.

If the absorbance is greater than the highest standard in the calibration curve, the sample must be diluted with 0.2N NaOH and reanalyzed. Record on excel format any dilutions that are prepared.

10.3 Continuing Calibration

See Sections 9.4

10.4 Preventive Maintenance

An instrument service company calibrates the spectrophotometers on a semi-annual basis. Certificates are kept on file.

11. Calculations

Calculate sulfide concentration using the calibration curve generated in Section 10.1:

$$\text{Sulfide (mg/L)} = \frac{\text{Absorbance} - \text{y intercept}}{\text{Slope}} \times \text{Dilution factor}$$

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

Holding time exceedance and improper preservation are noted on the nonconformance report form.

Perform routine preventative maintenance following manufacturer's specification. Record all maintenance in the instrument logbook.

Review of standards, blanks and standard response for acceptable performance occurs for each batch of samples. Record any trends or unusual performance on a nonconformance action form.

If the ICV, CCV or LCS recovery of any parameter falls outside the designated acceptance range, the laboratory performance for that parameter is judged to be out of control, and the problem must be immediately identified and corrected. The analytical result for that parameter in the unspiked samples is suspect and is only reported for regulatory compliance purposes with the appropriate nonconformance action form. Immediate corrective action includes reanalyzing all affected samples by using any retained sample before the expiration of the holding time.

If the Method Blank result is greater than the reporting limit, and all associated sample results are non-detect, or greater than 10x the concentration of the Method Blank, the data may be reported and a narrative submitted for inclusion on the final report. If associated sample results are positive, but at a concentration less than 10x the concentration of the Method Blank, those samples are re-distilled and reanalyzed.

If the LCS fails acceptance criteria, the entire batch must be redigested and reanalyzed. If there is insufficient sample volume to redigest, then the Client Services Department is notified and the sample results are reported as estimated, with a narrative to be included on the final report.

If the Matrix Spike fails acceptance criteria, the non-conformance is narrated and included on the final report.

If %RPD for the Duplicate fails acceptance criteria, the non-conformance is narrated and included on the final report.

13. Method Performance

13.1 Method Detection Limit Study (MDL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the MDL, LOD, and/or LOQ as outlined in Alpha SOP/1732 These studies performed by the laboratory are maintained on file for review.

The quarterly method reporting limit (MRL) verification requirement is satisfied by the quarterly LOQ analysis, as per SOP/1732.

13.2 Demonstration of Capability Studies

Refer to Alpha SOP 1739 for further information regarding IDC/DOC Generation.

13.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

14. Pollution Prevention and Waste Management

Refer to Alpha's Chemical Hygiene Plan and Waste Management and Disposal SOP for further pollution prevention and waste management information.

15. Referenced Documents

Chemical Hygiene Plan

SOP/1732 MDL/LOD/LOQ Generation
SOP/1739 IDC/DOC Generation

TPH- Diesel Range Organics

References: **Maine 4.1.25,** Maine Health and Environmental Testing Laboratory, 09/06/1995.

EPA 8015D (Modified), SW-846, Test Methods for Evaluating Solid Waste: Physical/Chemical Methods, EPA SW-846, Update IV, June 2003.

1. Scope and Application

Matrices: Diesel Range Organics can be determined in water, soil, sludge and product samples.

Definitions: See Alpha Laboratories Quality Manual Appendix A

TPH-DRO is used to identify and determine the concentration of Diesel Range Organics. This corresponds to the hydrocarbon range of C10 – C28, inclusive (Alpha LIMS products Maine-DRO and TPH-DRO). Alpha also reports the hydrocarbon ranges of C10 – C36 as (Alpha LIMS modified product TPH-DRO-D) and C9 – C44 as (Alpha LIMS modified product TPH-DROD-C44) by this method. TPH-DRO-D can be also used to report Oil Range Organics (ORO), C20-C36, and Residual Range Organics (RRO), C24-C36, TPH C10-C20 and TPH C20-C34.

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one of the following laboratory personnel before performing the modification: Area Supervisor, Laboratory Services Manager, Laboratory Director, or Quality Assurance Officer.

This method is restricted to use by or under the supervision of trained analysts experienced in the operation of the Gas Chromatograph and in the interpretation of Gas Chromatograph data. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

2. Summary of Method

TPH-DRO provides GC conditions for the detection petroleum fractions. Prior to use of this method, appropriate sample extraction techniques must be used. Both neat and diluted organic liquids may be analyzed by direct injection. A 1µL or 2µL aliquot of the extract is injected into a GC using the solvent flush technique, and compounds are detected by a FID.

2.1 Method Modifications from Reference, EPA 8015D

2.1.1 Alkane Standard Calibration is performed instead of Fuel Oil Calibration.

2.1.2 Quality control samples consist of a Blank, LCS and a Duplicate. MS/MSD is performed upon Client request only.

2.1.3 Alpha LIMS product TPH-DROD product includes C10-C36 and TPH-DROD-C44 product includes C9-C44.

3. Reporting Limits

The reported detection limit for this procedure as outlined is as follows:

- For the Maine DRO Method: 50µg/L for aqueous samples and 3.33mg/kg for soil/solid samples.
- For TPH-DRO and TPH-DROD-C44 Methods: 500µg/L for aqueous samples and 33.3mg/kg for soil/solid samples. For TPH-DROD: 200µg/L for aqueous samples and 33.3mg/kg for soil/solid samples.

4. Interferences

Solvents, reagents, glassware, and other sample processing hardware may yield discrete artifacts and/or elevated baselines causing misinterpretation of gas chromatograms. All of these materials must be demonstrated to be free from interferences, under the conditions of the analysis, by analyzing method blanks. Specific selection of reagents and purification of solvents by distillation in all-glass systems may be required.

Interferences co-extracted from samples will vary considerably from source to source, depending upon the waste being sampled.

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound must be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material data handling sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

Samples must be collected in glass containers with Teflon-lined caps. Plastic containers or lids may not be used for the storage of samples due to the possibility of sample contamination from phthalate esters and other hydrocarbons within the plastic.

Samples must be kept cool until receipt at the Laboratory.

6.2 Sample Preservation

Samples for Maine DRO are preserved with 1:1 HCl to a pH < 2. Samples for TPH-DRO, TPH-DRO-D and TPH-DROD-C44 are not preserved.

6.3 Sample Handling

Samples must be stored under refrigeration to 4 ± 2°C.

Liquid samples must be extracted within 7 days from collection, and soils must be extracted within 14 days from collection.

The extracts must be stored under refrigeration and must be analyzed within 40 days of extraction.

7. Equipment and Supplies

7.1 Gas Chromatograph, Hewlett Packard 6890 (or equivalent): An analytical system suitable for on-column injections. All required accessories, including: detectors, column supplies, recorder, gases and syringes. A data system for measuring peak area and/or peak heights.

7.2 GC Columns
Column 1: RTX-5 – 30m x 0.32mm ID, 0.25µm
Column 2: RTX-5MS – 30m x 0.32mm ID, 0.25µm

7.3 Class A Volumetric Flask: 10, 50, and 100mL with ground glass stopper.

7.4 Microsyringe: 10µL.

7.5 Helium: Compressed Helium, 5.0 ultra high purity.

7.6 Pipets: 9 inch glass pipets.

7.7 Analytical Balance: 0.0001g sensitivity

7.8 Pasteur Pipets: Borosilicate glass

7.9 Autosampler vials: 2mL volume with Teflon-lined septum crimp caps.

8. Reagents and Standards

8.1 Solvents, pesticide quality: Hexane, methylene chloride, acetone and pentane. Store in a flammables cabinet. Expires upon manufacturer's specified date.

8.2 o-Terphenyl, 2000µg/mL Stock Standard in methylene chloride: Vendor purchased stock solution used to prepare calibration standards. This solution is used only for Calibration Standards preparation. Expires upon manufacturer's specified date. Store at room temperature.

8.3 99.5% pure Nonane: Vendor purchased. Two sources are purchased. One source is used for the calibration standard and the other source is used for the continuing calibration standard. Store per vendor recommendations. Expires upon manufacturer's specified date.

8.4 Combination of CT-ETPH Alkane Standard and n-tetratetracontane, 1000ug/mL: Vendor purchased stock solution. This solution is used for LCS/MS spiking solution preparation. Expires upon manufacturer's specified date if unopened. Once opened, standard expires 6 months from the date of opening or the manufacturer's specified date, whichever is sooner. Store 20± 2°C.

8.5 Stock Calibration Standards

8.5.1 n-Nonane (c9), 2000µg/mL Stock Working Standard: To a 50mL volumetric flask, add 140µL of vendor purchased 99.5% pure Nonane (Section 8.3). Bring to volume with methylene chloride. Standard expires 6 months from the date of preparation. Store in the refrigerator at 4 ± 2°C.

Use one source for the calibration standards and the other source for the continuing calibration standards.

8.5.2 Calibration/Window defining Hydrocarbon Stock Standard, 1000µg/mL. Vendor purchased stock solution used to prepare calibration standards. Two sources are purchased: One is used for the Calibration Standards, and the other is used for the Continuing Calibration Standards. Contains the following alkanes in methylene chloride:

n-Octane	(c8)	n-Hexacosane	(c26)
n-Decane	(c10)	n-Octacosane	(c28)
n-Dodecane	(c12)	n-Triacontane	(c30)
n-Tetradecane	(c14)	n-Dotriacontane	(c32)
n-Hexadecane	(c16)	n-Tetratriacontane	(c34)
n-Octadecane	(c18)	n-Hexatriacontane	(c36)
n-Eicosane	(c20)	n-Octatriacontane	(c38)
n-Docosane	(c22)	n-Tetracontane	(c40)
n-Tetracosane	(c24)		

Expires upon manufacturer's specified date if unopened. Once opened, standard expires 6 months from the date of opening or the manufacturer's specified date, whichever is sooner. Store in the refrigerator at 20± 2°C .

NOTE: n-Octane (c8), and c38 through c40 are not used in the calculation of the DRO calibration standards, but are present in the solution.

The calibration/window defining hydrocarbon standard also serves: a) to demonstrate sufficient separation between the solvent and C8-alkane peak, b) to ensure that the last component, C36, is eluted within a reasonable amount of time (30minutes), and c) to serve as a retention time marker for oil identification.

8.5.3 n-Tetratetracontane Stock Working Standard: Vendor purchased stock solution used to prepare calibration standards. Two sources are purchased: One is used for the Calibration Standards, and the other is used for the Continuing Calibration Standards. Contains n-Tetratetracontane in carbon disulfide (c44).

Expires upon manufacturer's specified date if unopened. Once opened, standard expires 6 months from the date of opening or the manufacturer's specified date, whichever is sooner. Store in the refrigerator at 20± 2°C .

8.6 Working Calibration Standards: **(Also refer to Table 1)**

Working calibration standards are stored in the refrigerator at 4 ± 2°C and expire 6 months from the date of preparation.

8.6.1 Level 1 Calibration Standard for TPH-DRO/TPH-DRO-D (3µg/mL): To 994uL of methylene chloride add 6 uL of L6 calibration standard (Section 8.6.6)

8.6.2 Level 2 Calibration Standard for TPH-DRO/TPH-DRO-D (20µg/mL): To 960 uL of methylene chloride add 40 uL of L6 calibration standard (Section 8.6.6)

8.6.3 Level 3 Calibration Standard for TPH-DRO/TPH-DRO-D (50µg/mL): To 900 uL of methylene chloride add 100 uL of L6 calibration standard (Section 8.6.6)

8.6.4 Level 4 Calibration Standard for TPH-DRO/TPH-DRO-D (100µg/mL): To 800 uL of methylene chloride add 200 uL of L6 calibration standard (Section 8.6.6)

8.6.5 Level 5 Calibration Standard for TPH-DRO/TPH-DRO-D (200µg/mL): To 600 uL of methylene chloride add 400 uL of L6 calibration standard (Section 8.6.6)

8.6.6 Level 6 Calibration Standard for TPH-DRO/TPH-DRO-D (500µg/mL): To a 5mL volumetric flask add 1.25mL of n-Nonane Stock Solution (Section 8.5.1) and 1.25mL o-Terphenyl I Stock Solution (Section 8.2) and 2.5mL of Calibration/Window Defining Hydrocarbon Solution (Section 8.5.2).

8.7 Working Calibration Standards: (Also refer to Table 2)

Working calibration standards are stored in the refrigerator at 4 ± 2°C and expire 6 months from the date of preparation.

8.7.1 Level 1 Calibration Standard for TPH-DROD-C44 (3µg/mL): To 988uL of methylene chloride add 12 uL of L5 calibration standard (Section 8.6.6)

8.7.2 Level 2 Calibration Standard for TPH-DROD-C44 (20µg/mL): To 920 uL of methylene chloride add 80 uL of L5 calibration standard (Section 8.6.6)

8.7.3 Level 3 Calibration Standard for TPH-DROD-C44 (50µg/mL): To 800 uL of methylene chloride add 200 uL of L5 calibration standard (Section 8.6.6)

8.7.4 Level 4 Calibration Standard for TPH-DROD-C44 (100µg/mL): To 600 uL of methylene chloride add 400 uL of L5 calibration standard (Section 8.6.6)

8.7.5 Level 5 Calibration Standard for TPH-DROD-C44 (250µg/mL): To a 5mL volumetric flask add 1.00mL of n-Nonane Stock Solution (Section 8.5.1) and 1.00mL o-Terphenyl Stock Solution (Section 8.2) and 2.00mL of Calibration/Window Defining Hydrocarbon Solution (Section 8.5.2) and 2.00mL of n-Tetratetracontane (Section 8.5.3).

8.7.6 Level 6 Calibration Standard for TPH-DROD-C44 (500µg/mL): To a 10mL volumetric flask add 2.50mL o-Terphenyl Stock Solution (Section 8.2).

8.8 o-Terphenyl: Vendor purchased. Used to prepare extraction surrogate. Expires upon manufacturer's specified date. Store in the refrigerator at 4 ± 2°C.

8.8.1 Surrogate Standard Solution, 330ug/L: To a 500mL volumetric flask, add 15mL of 10000ug/mL o-terphenyl solution. Bring to volume with acetone. The surrogate standard solution expires 6 months from the date of preparation. Store in the refrigerator at 4 ± 2°C.

8.9 LCS / MS spiking solution, 100µg/mL

To a 100mL volumetric flask, add 10mL of the CT-ETPH Alkane Standard (Section 8.4) and 10mL of second source of n-Tetratetracontane (Section 8.5.3) using a 1mL syringe. Bring to

volume with pentane. This solution is stored in a refrigerator at 4 ± 2°C and expires 6 months from the date of preparation.

8.10 Continuing Calibration Standards

8.10.1 n-Nonane (c9), 2000µg/mL Stock Working Standard: Refer to Section 8.5.1.

8.10.2 Continuing Calibration Standard, 100µg/mL: To a 50mL volumetric flask, add 5mL of second source, vendor purchased 1000ug/mL o-Terphenyl solution, 2.5mL Nonane solution (Section 8.5.1 alternate source) and 5mL of Calibration/Window defining Hydrocarbon Stock Standard (1000µg/mL, Section 8.5.2) and add 5mL of second source of n-tetratetracontane (1000ug/mL, Section 8.5.3). Bring to volume with methylene chloride. This standard is stored in a refrigerator at 4 ± 2°C and expires 6 months from the date of preparation.

8.11 Fuel Degradation Standard

To a 20mL volumetric flask of methylene chloride, add 500 uL of a 2000 ug/mL of a vendor prepared Fuel Oil Degradation Mix. Adjust to volume with methylene chloride.

9. Procedure

9.1 SET-UP

9.1.1 Extraction

In general, water samples are extracted at a neutral pH with methylene chloride, using Method 3510. Solid samples are extracted using either Method 3540, 3545 or 3546 to achieve maximum sensitivity. The extract must be concentrated to a final volume of 1mL.

9.1.2 Typical Gas Chromatography Conditions

Set helium carrier gas flow at 30mL min^{-1}, column temperature at 45°C for 2 minutes, then 12°C min^{-1} to 320°C, hold for 10.0 minutes. Injection volume can be either 1uL or 2uL depending on the instrument utilized. The same injection volume for all calibration standards and samples extracts must be used.

9.2 Initial Calibration

9.2.1 Calibration Curve Generation:

A curve consisting of the 6 different concentrations (Table 1), each containing C8, C9 and C10 through C40 even numbered alkanes (Section 8.5), is analyzed under the conditions listed in Section 9.1.2.

The %RSD for MEDRO and TPH-DRO (C10-C28) must be < 20% for the initial calibration. The %RSD for Alpha LIMS product TPH-DROD (C10-C36) and TPH-DROD-C44 (C9-C44 must be < 25% for the initial calibration. Once this is achieved, a continuing calibration standard (Section 9.3) is analyzed. If the Maine DRO method is to be analyzed at any point after Initial Calibration, a Fuel Degradation Standard is added after the continuing calibration verification.

9.3 Continuing Calibration

9.3.1 As a minimum requirement, the working calibration curve and retention times must be verified at the beginning of each 12-hour work shift, or every 20 samples, followed by an acceptable bracketing continuing calibration verification standard. Additional analyses of the verification standard(s) throughout a 12-hour work shift are strongly recommended, especially if the samples being analyzed contain visible concentrations of oily material.

9.3.2 Calculate the % Difference of the standard from the calibration curve.

9.3.2.1 If the response for the MEDRO or TPH-DRO C10-C28 range is within ± 20% of the response obtained during the initial calibration then the initial calibration is still considered valid, and the analyst may continue to use the mean CF or RF values from the initial calibration to quantitate the sample results. Individual alkanes may exceed %D of ± 20, as long as the range is ± 20%.

9.3.2.2 If the response for the Alpha LIMS product TPH-DROD (C10-C36) and TPH-DROD-C44 (C9-C44) range is within ± 25 of the response obtained during the initial calibration then the initial calibration is still considered valid, and the analyst may continue to use the mean CF or RF values from the initial calibration to quantitate the sample results. Individual alkanes may exceed %D of ± 25, as long as the range is ± 25%

9.3.2.3 If the % difference exceeds then preventative maintenance must be performed (Section 9.5).

Once maintenance is complete, another standard is analyzed. If the % difference still exceeds the method requirements, a new initial calibration must be performed (Section 9.2).

9.3.2.4 The alkanes for the opening and ending Containing calibration cannot be over 50% and 10% must be within the criteria.

9.3.3 **Maine DRO, Fuel Degradation Check Standard**

For Maine-DRO analysis, each analytical sequence ends with a demonstration that the resolution criteria have been met for all the samples run in that sequence. (i.e. The system must resolve pristane from C17 and phytane from C18 at 50ug/mL total commercial diesel fuel oil, or at the minimum reporting level. This is typically analyzed after an ICAL or analytical sequence containing samples. Peaks are considered to be resolved when 60% resolution has been achieved.

If any of the above criteria are not met, the problem must be corrected before further samples are analyzed. Any samples analyzed between the last acceptable QC samples must be reanalyzed. If reanalysis is not possible (e.g. due to holding time exceedences or limited volume, etc.) the data must be flagged and a narrative included on the final report.

9.4 Sample Analysis and Quantitation

9.4.1 The same GC operating conditions used for the initial calibration must be employed for sample analyses, including sample injection volume (Section 9.1.2).

9.4.2 Tentative identification occurs when a peak from a sample extract falls within the retention time window for the compound.

9.4.3 The sample ranges are quantitated according to the product requested by the Client (TPH-DRO, Maine-DRO, TPH-DRO-D or TPH-DROD-C44). Refer to Table 1 for carbon ranges.

9.4.4 The concentration reported for an extract is calculated using the Environquant data processing software. Proper quantitation requires the appropriate selection of a baseline from which the peak area or height can be determined. See the Manual Integration SOP for integration guidelines.

9.4.5 If the sample concentration exceeds the highest concentration of the respective calibration curve, the sample extract must be diluted with methylene chloride and reanalyzed.

9.5 Preventative Maintenance

Preventive maintenance is performed at the discretion of the GC analyst.

9.5.1 Cool the oven to 25°C; turn off both the front and back inlet pressure and temperature.

9.5.2 Remove the septum retaining nut and the old septum. Use forceps to insert a new septum, pressing it firmly into the fitting. Replace the septum retaining nut, and tighten finger-tight.

9.5.3 Using a septum nut wrench, loosen the split/splitless insert nut located under the septum retaining nut. Remove and replace the pre-packed glass wool liner from injection ports using forceps.

9.5.4 To replace the inlet seal base, remove the column from the inlet using a ¼-inch wrench. Remove the insulation cup using either a Phillips-head or star-head screwdriver, or a ½ –inch wrench to loosen the reducing nut. The seal is placed in the nut first, followed by the seal, making sure the raised portion is facing downwards. Replace the reducing nut and tighten.

9.5.5 **Capillary Column Replacement**

9.5.5.1 To prepare the capillary column for installation, score the column using a glass or ceramic scribing tool. Break off the column end by supporting it against the column cutter opposite the scribe. Ensure there are no jagged edges. Position the column through the column nut and 0.5 mm graphite Restek ferrule, making sure it extends 4 to 6mm to the end of the ferrule. Insert the column in the inlet and slide the nut and ferrule up the column to the inlet base. Finger-tighten the column nut until it starts to grab the column. Adjust the column position accordingly. Tighten the column nut with a ¼-inch wrench until the column is firmly in place.

9.5.5.2 Reload the method either on the instrument or at the computer terminal. Set the oven temperature to 270 °C for approximately one-half hour.

9.5.5.3 A new calibration curve must be analyzed following capillary column replacement.

9.6 Calculations

Quantitation: The total area under all peaks and any baseline rise is determined for the sample and standard.

For liquids:

$$C = \frac{[(R_S)(V_E)(D)]}{[(V_S)(m)]}$$

Where:

C = Concentration of Standard, µg/L
D = Dilution Factor
Vs = Volume of water sample, L
V_E = Total Volume of sample extract, mL
R_S = GC Response in DRO window
m = Slope of the curve

For solids:

$$C = \frac{[(R_S)(V_E)(D)]}{[(W)(m)]}$$

Where:

C = Concentration of Standard, mg/Kg
D = Dilution Factor
W = Weight of water sample, Kg
V_E = Total Volume of sample extract, mL
R_S = GC Response in DRO window
m = Slope of the curve

10. Quality Control and Data Assessment

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

10.1 Demonstration of Capability

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method. Each time a method modification is made, the analyst is required to repeat the procedure.

When one or more of the parameters tested fail at least one of the acceptance criteria, the analyst must locate and correct the source of the problem and repeat the test for failed parameters of the method.

Repeated failure confirms a general problem with the measurement system or analytical technique of the analyst. If the failure repeats, locate and correct the source of the problem and repeat the test for all parameters listed in the method.

10.2 Method Blanks

Method blanks are extracted and analyzed with each analytical batch of 20 or less samples. The result of the method blank must be less than the reporting limit.

If results are detected above the reporting limit and the associated samples are non-detect, a narrative is submitted for inclusion on the final report. If results are detected above the reporting limit and the associated samples also have positive results, all samples in the extraction batch must be reextracted and reanalyzed.

10.3 Laboratory Control Samples (LCS)

A Laboratory Control Sample is extracted with each sample batch. The LCS consists of an aliquot of clean (control) matrix similar to the sample matrix, and of the same weight or volume, and a known amount of analyte spike. The LCS must be recovered between 60 – 140% for Maine-DRO and TPH-DRO products. For the TPH-DRO-D and TPH-DROD-C44 product, the LCS must be recovered between 40 – 140%.

If the LCS recovery is outside of acceptance criteria, all samples in the extraction batch must be reextracted and reanalyzed.

10.4 Duplicates

A duplicate aliquot of a sample is extracted and analyzed to ensure the consistency of the extraction. The relative percent difference (%RPD) must be $\leq$ 20% for the Maine-DRO product. For TPH-DRO and TPH-DRO-D and TPH-DROD-C44 products, the relative percent difference (%RPD) must be $\leq$ 40%.

If the % RPD is outside of acceptance criteria, the Duplicate sample is reextracted and reanalyzed, unless there is obvious sample non-homogeneity. If there is obvious sample non-homogeneity, a narrative is submitted for inclusion on the final report.

10.5 Matrix Spike (MS)

For the Maine-DRO product, a MS is extracted and analyzed with each analytical batch. The MS consists of an aliquot of sample matrix and a known amount of analyte spike. The MS must be recovered between 60 – 140%.

If the MS recovery is outside of acceptance criteria and the LCS is within acceptance criteria, a narrative is submitted for inclusion on the final report. If the MS and the LCS are outside or acceptance criteria, all samples in the extraction batch must be reextracted and reanalyzed.

10.6 Control Limits

The laboratory maintains performance records to document the quality of data that is generated. Method accuracy for samples is assessed and records maintained.

Control limits for the method parameters are generated. The control limits are calculated based on in-house performance data. The limits are compared to the control limits found in the reference method.

10.7 Surrogate Standards

Surrogate recoveries are calculated for all samples and QC samples and must recover within 40 – 140%. If any surrogate recovers outside acceptance criteria, the sample is reextracted and reanalyzed for confirmation.

If any surrogate recovers above acceptance criteria and the sample is non-detect, a narrative is submitted for inclusion on the client report.

If the surrogate in a sample duplicate recovers outside of acceptance criteria and the surrogate in the sample recovers within acceptance criteria, the data may be reported with a narrative submitted for inclusion on the client report.

10.8 Analytical Sequence

A typical 12-hour analytical sequence:

- Continuing Calibration Standard
- Method Blank
- LCS
- Samples (up to 20)
- Bracketing Continuing Calibration Standard

11. Method Performance

The method detection limit (MDL) is defined as the minimum concentration of a substance that can be measured and reported with 99% confidence that the value is above zero. The MDL concentrations were obtained using a diesel fuel mixture that is calculated against the DRO component standard. The MDL actually achieved in a given analysis will vary depending on instrument sensitivity and matrix effects.

Method performance data is on file in the laboratory QC department. Comparison of method performance data for the laboratory to the reference method criteria occurs when laboratory in-house acceptance limits are generated. In-house generated data must be within the specifications of the reference method or the analysis is not continued until corrective action is completed.

12. Corrective Actions

Holding time exceedence, improper preservation and observed sample headspace are noted on the nonconformance report form.

Perform routine preventative maintenance following manufacturer's specification. Record all maintenance in the instrument logbook.

Review of standards, blanks and standard response for acceptable performance occurs for each batch of samples. Record any trends or unusual performance on a nonconformance action form.

If the CCV or LCS recovery of any parameter falls outside the designated acceptance range, the laboratory performance for that parameter is judged to be out of control, and the problem must be immediately identified and corrected. The analytical result for that parameter in the un-spiked samples is suspect and is only reported for regulatory compliance purposes with the appropriate nonconformance action form. Immediate corrective action includes reanalyzing all affected samples by using any retained sample before the expiration of the holding time.

13. Pollution Prevention

See Chemical Hygiene Plan for pollution prevention operations.

14. Waste Management

See Chemical Hygiene Plan for waste handling and disposal.

TPH-Gasoline Range Organics 8015D

Reference: Maine 4.2.17, Maine Health and Environmental Testing Laboratory, 09/06/1995.

EPA 8015D (Modified), SW-846, Test Methods for Evaluating Solid Waste: Physical/Chemical Methods, EPA SW-846, Update IV, June 2003

1. Scope and Application

Matrices: This method is suitable for the analysis of waters, soils, or wastes.

Definitions: Refer to Alpha Analytical Quality Manual.

This method is designed to measure the concentration of gasoline range organics, from MTBE through naphthalene inclusive, in both water and soil. This corresponds to a boiling point range between approximately 60 ºC and 220 ºC.

The analytical procedure is based on a purge-and-trap, Gas Chromatography (GC) procedure.

With the optional PID/FID in series, the method can be extended for the specific determination of petroleum volatile organic compounds (PVOCs) as specified in the current edition of EPA Method 8020.

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one or more of the following laboratory personnel before performing the modification: Area Supervisor, Department Supervisor, Laboratory Director, or Quality Assurance Officer.

This method is restricted to use by or under the supervision of analysts experienced in the operation of the Gas Chromatograph and in the interpretation of Gas Chromatograph data. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

2. Summary of Method

This method provides gas chromatographic conditions for the detection of volatile petroleum fractions such as gasoline, Stoddard solvent, or mineral spirits. Samples are analyzed utilizing purge-and-trap sample concentration. The gas chromatograph is temperature programmed and utilizes a capillary column to facilitate separation of organic compounds. Detection is achieved by a flame ionization detector (FID) or FID with photoionization detector (PID) in series (photoionization detector first in the series). Quantitation is based on FID detector response to a gasoline component standard.

This method is suitable for the analysis of waters, soils, or wastes. Water samples can be analyzed directly for gasoline range organics by purge-and-trap extraction and gas chromatography. Soil or waste samples are dispersed in methanol to dissolve the volatile organic constituents. A portion of the methanolic solution is then analyzed by purge-and-trap GC.

This method is based in part on (1) API's Petroleum Hydrocarbon Methods (Revised August 1993); (2) work by the Wisconsin Ad-Hoc Committee on LUST Program Analytical Requirements and Wisconsin State Laboratory or Hygiene; and (3) work by the Maine Laboratory Hydrocarbon Study Committee

2.1 Method Modifications from Reference

Soil samples do not have extraction surrogates or spikes added to them at the time of methanol preservation. Surrogates and spikes are added directly to the 5mL syringe containing water and the appropriate volume of the methanol extract.

GRO is defined as all chromatographic peaks eluting from methyl-tertiary-butyl ether through naphthalene.

3. Reporting Limits

The Reported Limit for water is 50 µg/L and for soil is 2.5 mg/Kg.

4. Interferences

4.1 Heavier petroleum products such as diesel fuel may contain some volatile components producing a response within the retention time range for GRO. Other compounds that respond to the FID, such as chlorinated and oxygenated hydrocarbons, are detected by this method and will be included in the concentration. Spills of known specific constituents are analyzed and quantified by a method specific for those constituents. If the chromatogram exhibits the characteristics of fuel oil, the GRO is reported but flagged with a recommendation for DRO analysis.

4.2 Samples can be contaminated by diffusion of volatile organics through the sample container septum during shipment and storage, or by dissolution of volatiles into the methanol used for preservation. Trip Blanks prepared from both reagent water and methanol should be carried through sampling and subsequent storage and handling to serve as a check on such contamination.

4.3 Contamination by carryover can occur whenever high-level and low-level samples are sequentially analyzed. To reduce carryover, the sample syringe and/or purging device must be rinsed between samples with reagent water or solvent. For volatile samples containing high concentrations of water-soluble materials, suspended solids, high boiling compounds or organohalides, it may be necessary to wash the syringe or purging device with a detergent solution, rinse with distilled water, and then dry in a 105ºC oven between analyses. The trap and other parts of the system are also subject to contamination, therefore frequent bake-out and purging of the entire system may be required. A screening step is recommended to protect analytical instrumentation. Whenever an unusually concentrated sample is encountered, it should be followed by analysis of a water blank to check for cross-contamination.

4.4 The retention time window definition (methyl tert-butyl ether through naphthalene inclusive) introduces a negative bias, however, it improves comparability between laboratory data. Note that gasoline blends often contain 10% ethanol, which could be responsible for a portion of this negative bias.

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material safety data sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

Aqueous samples are collected in duplicate, without agitation and without headspace in VOA vials with Teflon-lined septa screw caps. The Teflon liner must contact the sample.

A reagent water trip blank accompanies each batch of water samples.

Methanol (purge and trap grade) must be added to soil sample vials before or immediately after sample collection. In lieu of the in-field preservation of samples with methanol, soil samples may be collected in specially designed, air tight sampling devices. Samples that have not been preserved in the field are preserved in the lab as soon as possible after arrival in the lab. Date and time of preservation is noted on the Chain of Custody or final report.

A methanol trip blank accompanies each batch of soil samples.

6.2 Sample Preservation

Aqueous samples are acidified to a pH of 2.0 or less at the time of collection. This is typically accomplished by adding 3 or 4 drops (0.1 to 0.2mL) of 1:1 HCL (one part reagent water and one part concentrated hydrochloric acid) to a 40mL sample. The laboratory must determine the pH of all water samples at the time of analysis and if the pH is found to be greater than 2.0, it must be noted.

Aqueous and soil samples must be cooled to 4 ± 2 ºC immediately after collection

6.3 Sample Shipping

No specific requirement.

6.4 Sample Handling

Water and soil samples must be analyzed within 14 days of collection.

7. Equipment and Supplies

7.1 Gas Chromatograph: Agilent 6890 or equivalent, Data system Enviroquant Software in conjunction with Nelson Intelligent 900 Series Interface.

7.1.1 Column: Restek RTX-502.2 Capillary Column, 105m X .53mm I.D., 3.0 micron film thickness or equivalent. The column must be capable of achieving a 60% resolution of all 10 components, with the exception of m/p-xylene. It must also be capable of separating methyl tert-butyl ether from the methanol solvent peak. The Resolution is defined as:

$$\frac{(\text{Height of smallest peak} - \text{Height of valley}) \times 100\%}{(\text{Height of smallest peak})}$$

7.1.2 Detector: FID (in series with a PID detector, optional)

7.1.3 Purge-and-trap Device: The purge and trap device consists of two separate pieces of equipment: a purging device coupled to a desorber (Autosamplers: Centurion. Concentrators: Encon evolution).

7.1.3.1 Purge/carrier gas = Helium, analytical grade (99.999% pure) or Nitrogen analytical grade (99.999%).

7.1.3.2 Traps are conditioned, desorbed, and baked according to manufacturer's guidelines. The trap may be vented to the analytical column during daily conditioning, however, the column must be run through the temperature program prior to analysis of the samples.

7.1.3.3 The desorber must be capable of rapidly heating the trap to 260ºC.

7.2 Analytical Balance: A top-loading balance capable of weighing to the nearest 0.01 g (for weighing soil samples).

7.3 Ultrasonic Bath

7.4 VOA Vials: 40mL amber VOC vials with Teflon/silicone septa.

7.5 Syringes: 5mL gas-tight syringe with shutoff valve.

7.6 Volumetric Flask (class A): 10mL, 50mL, 100mL, 500mL, 1000mL with a ground-glass or screw-top stopper.

7.7 Micro syringes: 1µL, 5µL, 10µL, 25µL, 100µL, 250µL, 500µL, and 1000µL.

7.8 Spatula: Stainless steel.

7.9 Ottawa Sand: SiO2.

8. Reagents and Standards

8.1 Reagent Water: Organic-free water; municipal tap water filtered through carbon.

8.2 Methanol: Purge-and-trap grade or equivalent. Store away from other solvents.

8.3 Gasoline Component Stock Standard: Purchased from Ultra Scientific UST-100, GRO PVOC/WISC mix. Refer to Table 1 for concentrations. Store with minimal headspace at -10°C to -20°C. Expires 6 months from the date of opening or upon signs of degradation or evaporation.

8.3.1 GRO Calibration Stock Standard: To a 10mL volumetric flask, add 1mL of Gasoline Component Stock Standard (Section 8.3), Add 500µL of 4-bromofluorobenzene (Section 8.5.2) and 500µL of a,a,a-trifluorotoluene (Section 8.5.1). Bring to volume with methanol. Store with minimal headspace at -10°C to -20°C. Expires 6 months from the date of preparation or upon signs of degradation or evaporation.

8.3.1.1 GRO Working Calibration Standards

Store standards with minimal headspace at -10°C to -20°C. Standards expire 6 months from the date of preparation or upon signs of degradation or evaporation.

8.3.1.1.1 Level 1, 50ng ranges, 5ng surrogates: To a 100mL volumetric flask, add 1µL of GRO Calibration Stock Standard (Section 8.3.1). Bring to volume with reagent water.

8.3.1.1.2 Level 2, 100ng ranges, 10ng surrogates: To a 100mL volumetric flask, add 2µL of GRO Calibration Stock Standard (Section 8.3.1). Bring to volume with reagent water.

8.3.1.1.3 Level 3, 500ng ranges, 50ng surrogates: To a 100mL volumetric flask, add 10µL of GRO Calibration Stock Standard (Section 8.3.1). Bring to volume with reagent water.

8.3.1.1.4 Level 4, 2000 ng ranges, 200ng surrogates: To a 5mL syringe containing reagent water, add 2µL of GRO Calibration Stock Standard (Section 8.3.1).

8.3.1.1.5 Level 5, 5000ng ranges, 500ng surrogates: To a 5mL syringe containing reagent water, add 5µL of GRO Calibration Stock Standard (Section 8.3.1).

8.3.1.1.6 Level 6, 10000ng ranges, 1000ng surrogates: To a 5mL syringe containing reagent water, add 10µL of GRO Calibration Stock Standard (Section 8.3.1).

8.3.1.1.7 Level 7, 20000ng ranges, 2000ng surrogates: To a 5mL syringe containing reagent water, add 20µL of GRO Calibration Stock Standard (Section 8.3.1).

8.4 Gasoline Component Stock Standard (second source for LCS, MS):

Purchased from Accustandard GRH-003S-Pak. Store with minimal headspace at -10°C to -20°C. Standard expires 6 months from the date of preparation or upon signs of degradation or evaporation.

8.4.1 Continuing Calibration Standard, water LCS, MS: To a 10mL volumetric flask, add 200µL of second source Gasoline Component Stock Standard (Section 8.4). Add 200µL 4-BFB (Section 8.5.2) and 200µL a,a,a-trifluorotoluene (Section 8.5.1). Bring to volume with methanol.

CCV/LCS for water: Spike 5µL of this solution into 5mL of reagent water.

MS: Spike 5µL of this solution into 5mL of a second aliquot of sample.

8.4.2 Continuing Calibration Standard, soil LCS:

CCV/LCS for soil: Weigh 15g of Ottawa sand into 15ml methanol. Spike with 15ul Gasoline Component Stock Standard (8.4). Take 100ul aliquot and add to 5ml reagent water, add 5ul working surrogate standard solution (8.6).

8.5 Surrogate Control Stock Standards

Standards expire 6 months from the date of opening or upon signs of degradation or evaporation. These standards are stored with minimal headspace at -10°C to -20°C.

8.5.1 a,a,a-trifluorotoluene: 2000µg/mL, purchased from Ultra Scientific, Cat # STS-220N

8.5.2 4-bromofluorobenzene: 2000µg/mL, purchased from Ultra Scientific, Cat # STS-110N.

8.6 Working Surrogate Standard Solution:

To a 10mL volumetric flask, add 200µL 4-BFB (Section 8.5.2) and 200µL a,a,a-trichfluorotoluene (Section 8.5.1). Bring to final volume with MeOH for a final concentration of 40ug/L. Standard expires 6 months from the date of preparation or upon signs of degradation or evaporation. Store with minimal headspace at -10°C to -20°C.

Spike 5µL of this solution into 5mL of each sample and Blank.

8.7 Gasoline Stock Standard (MDL): Purchased from Ultra Scientific, Cat # RGO-600-1. Standard expires 6 months from the date of opening or upon signs of degradation or evaporation. This standard is stored with minimal headspace at -10°C to -20°C.

8.8 Ohio Gasoline Component Stock Standard: Purchased from Absolute Standards Cat #96018, n-Hydrocarbon Mix C5-C8. Refer to Table 2 for concentrations. Store with minimal headspace at -10°C to -20°C. Expires 6 months from the date of opening or upon signs of degradation or evaporation.

8.8.1 Ohio Calibration Stock Standard: To a 10mL volumetric flask, add 1mL of Ohio Gasoline Component Stock Standard (Section 8.8), Add 500µL of 4-bromofluorobenzene (Section 8.5.2) and 500µL of a,a,a-trifluorotoluene (Section 8.5.1). Bring to volume with methanol. Store with minimal headspace at -10°C to -20°C. Expires 6 months from the date of preparation or upon signs of degradation or evaporation.

8.8.1.1 Ohio GRO Working Calibration Standards

8.8.1.1.1 Level 1, 40 ng ranges, 5ng surrogates: To a 100mL volumetric flask, add 1µL of Ohio Calibration Stock Standard (8.8.1). Bring to volume with reagent water.

8.8.1.1.2 Level 2, 80 ng ranges, 10ng surrogates: To a 100mL volumetric flask, add 2µL of Ohio Calibration Stock Standard (8.8.1). Bring to volume with reagent water.

8.8.1.1.3 Level 3, 400 ng ranges, 50ng surrogates: To a 100mL volumetric flask, add 10µL of Ohio Calibration Stock Standard (8.8.1). Bring to volume with reagent water.

8.8.1.1.4 Level 4, 1600 ng ranges, 200ng surrogates: To a VOA vial, add 5 mL of water and 2µL of Ohio Calibration Stock Standard (8.8.1).

8.8.1.1.5 Level 5, 4000 ng ranges, 500ng surrogates: To a VOA vial, add 5 mL of water and 5µL of Ohio Calibration Stock Standard (8.8.1).

8.8.1.1.6 Level 6, 8000 ng ranges, 1000ng surrogates: To a VOA vial, add 5 mL of water and 10µL of Ohio Calibration Stock Standard (8.8.1).

8.8.1.1.7 Level 7, 16000 ng ranges, 2000ng surrogates: To a VOA vial, add 5 mL of water and 20µL of Ohio Calibration Stock Standard (8.8.1).

8.9 Ohio Gasoline Component Stock Standard (second source for LCS, MS): Purchased from Sigma Aldrich Cat #, UST157, Aliphatics Mix (C5-C12). Store with minimal headspace at -10°C to -20°C. Standard expires 6 months from the date of preparation or upon signs of degradation or evaporation.

8.9.1 Ohio Continuing Calibration Standard, water LCS, MS: To a 10mL volumetric flask, add 200µL of second source Ohio Gasoline Component Stock Standard (Section 8.9). Add 200µL 4-BFB (Section 8.5.2) and 200µL a,a,a-trifluorotoluene (Section 8.5.1). Bring to volume with methanol.

CCV/LCS for water: Spike 5µL of this solution into 5mL of reagent water.

MS: Spike 5µL of this solution into 5mL of a second aliquot of sample.

8.9.2 Ohio Continuing Calibration Standard, soil LCS:

CCV/LCS for soil: Weigh 15g of Ottawa sand into 15ml methanol. Spike with 15ul Ohio Gasoline Component Stock Standard (8.9). Take 100ul aliquot and add to 5ml reagent water, add 5ul working surrogate standard solution (8.6).

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

9.1 Blanks

9.1.1 A water blank must be run with every analytical sequence containing water samples, utilizing the same water used to prepare standards and make dilutions. The concentration of the blank should not exceed the laboratory reporting level.

Water blanks are analyzed after samples suspected of being highly concentrated, to prevent carryover.

9.1.2 A reagent methanol blank must be run with each analytical sequence containing soil samples. The methanol blank is created by adding 15g of Ottawa sand to 15ml reagent methanol. Take 100ul aliquot and add to 5ml reagent water, add 5ul working surrogate standard solution (8.6) The amount of material in the blank should not exceed the laboratory reporting level.

9.2 Laboratory Control Sample (LCS)

The calibration curve must be verified with each analytical sequence by running a mid-level calibration standard in the beginning and end of the sequence.
See section 8.4.2 for LCS preparation.

NOTE: For soil batches the LCS is also injected with 100 µL methanol.

The response must fall within 20% of the expected response. If the response for the standard varies from the predicted response by more than 20%, the analytical system is examined to determine the cause and corrective action is performed and/or a new continuing calibration standard is prepared and analyzed. If the 20% criteria is still not met, the system must be recalibrated.

Any samples that were analyzed following the opening standard and before a closing standard that did not meet calibration criteria must be reanalyzed. If reanalysis is not possible, the data must be flagged and a narrative submitted for inclusion on the Client report

LCS Duplicates are run at a frequency of 5%. Alternatively, duplicate samples and spike samples can be substituted for the laboratory spiked duplicates at a frequency of 5%. Care must be taken to ensure that the samples are homogenous before analyzing duplicates and spikes.

9.3 Initial Calibration Verification (ICV)

9.4 Continuing Calibration Verification (CCV)

9.5 Matrix Spike

For every 20 samples analyzed, the lab will analyze a Gasoline Component Spike. The spike must be run through the method in the same manner as samples. The accuracy must be within

± 20% of the known concentration. If the accuracy is outside of acceptance criteria, and the LCS is acceptable, the data is reported and the MS failure is narrated.

A Matrix Spike Duplicate is performed only upon Client request.

If requested, for every 20 samples analyzed, the lab will analyze a set of Duplicate Gasoline Component Spikes. The duplicate spikes must be run through the method in the same manner as samples. The accuracy of the 2 spikes must be within 20% of the known concentration and the %RPD must be 20% or less. If these criteria are not met, and the LCS is acceptable, the data is reported and the MS failure is narrated

9.6 Laboratory Duplicate

A duplicate sample is analyzed once for every 20 samples. The duplicate aliquot is taken from the same sample container and analyzed separately under the same conditions. The %RPD between the sample and duplicate results is calculated and must be ≤ 20%. If this criterion cannot be met, the duplicate is reanalyzed. If failure continues, the data is reported and the nonconformance is narrated.

9.7 Method-specific Quality Control Samples

9.7.1 Surrogates

If surrogate recovery is outside of the established limits of 70 – 130%, verify calculations, dilutions, and standard solutions. Verify instrument performance, including checking for leaks and purge problems if the recovery is low. Low recovery may be due to the sample matrix. The analysis is repeated. If the recovery is less than 70% or, if the analyses cannot be repeated, the data is flagged and a narrative submitted for inclusion on the Client report.

High recoveries may be due to coeluting matrix interference. Surrogate recoveries may be reported as “masked” in high-level samples exhibiting matrix interference.

9.1 Method Sequence

The analytical sequence is:

- Calibration Standards (initial) or mid-range Calibration Check Standard (LCS)
- LCS Duplicate (as needed)
- Laboratory Method Blank
- Samples
- Duplicate sample (as needed)
- Matrix Spike (as needed)
- Matrix Spike Duplicate (as requested)
- Closing mid-range Calibration Check Standard (LCS) – Note: This may be used as an opening CCAL (LCS) for the next sequence.

10. Procedure

10.1 Equipment Set-up

10.1.1 Gas Chromatography Conditions: Agilent 6890 or equivalent.

PID Temperature	250 ºC
FID Temperature	250 ºC

Column	12.5 mL/min
Carrier /Makeup Gas	Helium, 99.999 grade @ 12.5 mL/min
	Air @ 350 mL/min
	Hydrogen @ 30 mL/min
Injection Port	250 ºC

10.1.2 Oven Conditions: 45 ºC for 2 minutes to 100 ºC at 3 ºC/min, to 160 ºC at 8 ºC/min, to 230 ºC at 20 ºC/min for 11.6 minutes.

10.1.3 Typical Purge and Trap Conditions:

Purge Gas:	Helium
Purge Gas Flow Rate:	40 mL/min
Purge Temperature:	35 ºC or less
Purge Time:	11.0 ± 0.1minutes
Dry purge:	4 minutes
Desorb Preheat:	220 ºC
Desorb temp:	225 ºC
Desorb Time:	6 minutes
Bake temp:	260 ºC
Bake time:	15 minutes

10.2 Initial Calibration

10.2.1 Per Section 10.3 and under the conditions listed in Section 10.1, analyze the Gasoline Component Standard at the seven concentration levels (1 µg/L, 2µg/L, 10µg/L, 40µg/L, 100µg/L, 200µg/L and 400µg/L) listed in Section 8.3.1.1. Whenever a calibration curve is analyzed, an independent check standard (Section 8.4.1) is also analyzed to validate the curve (the LCS serves as a second source verification).

10.2.2 Relative Response Factors

The external standard calibration technique is used.

A collective calibration factor must be established for the GRO hydrocarbon range. The GRO marker compounds that determine the GRO range are MTBE through naphthalene, inclusive.

10.2.3 Initial Calibration Criteria

If the RSD for an individual analyte is ≤ 20%, then the response for this compound is considered linear over the range and the mean calibration factor is used to quantitate sample results. If the RSD criterion is not met for an analyte, linearity through the origin cannot be assumed. The calibration is repeated for any compounds that fail, or a calibration curve is generated for this compound and used for sample quantitation.

10.2.3.1 Percent Relative Error (%RE): For linear fit compounds, the %RE must be calculated for the standard at or near the midpoint and at the lowest level of the initial calibration. The %RE between the calculated and expected concentration of an analyte must be ≤ 30%, otherwise recalibration is necessary.

10.2.4 Retention Time Windows and Quantitation

10.2.4.1 All chromatographic peaks eluting from methyl tert-butyl ether through naphthalene, inclusive, are used to calculate the retention time window. Quantitation is based on a direct comparison of the area within this range to the

total area of the 10 components in the Gasoline Component Standard. (Using a "baseline to baseline" integration as opposed to a "valley to valley" integration.)

10.2.4.2 The retention time window is defined as beginning approximately 0.1 minutes before the retention time of methyl tert-butyl ether and ending 0.1 minutes after the retention time of naphthalene in the calibration run.

10.2.4.3 The laboratory must determine retention time windows for the first and last standard on each GC column and whenever a new GC column is installed. This data must be retained by the laboratory.

10.2.4.4 Quantify by summing all peak areas eluting from methyl tert-butyl ether through naphthalene, inclusive.

10.3 Equipment Operation and Sample Processing

10.3.1 Gas Chromatographic Analysis of Water Samples and Soil Samples

10.3.1.1 Retrieve sample VOA vials from the sample bank refrigerator just prior to loading onto the Purge and Trap. Soilsamples preserved with methanol and QC samples must be vortexed to extract the volatile components into the methanol. Let sample settle prior to taking methanol aliquot.

10.3.1.2 Rinse a 5mL Luerlock syringe with reagent water. For aqueous samples, add appropriate amount of sample (typically 5mL) to the syringe after pouring off approximately 2 – 3 mL of sample to waste. For soil samples, fill the syringe with 5mL of reagent water. Add the appropriate amount of the methanol extract (typically 100µL) to the syringe containing the reagent water. Less sample (water or methanol) may be used if sample history or screening information indicates high concentrations of target or non-target analytes. Add 5 µL of surrogate standard solution (Section 8.5) to the sample. Transfer the sample to a VOA vial and load on the autosampler.

10.3.1.3 If sample dilutions are necessary, they may be made in volumetric flasks (10mL to 100mL). Dilutions are made without delay. If aliquots of sample less than 1mL are required, use microliter syringes to transfer the sample aliquot to the flask. Dilute to the mark with reagent water.

Alternatively, the dilutions may be made directly in a gas tight syringe to avoid further loss of volatiles.

All dilutions must ensure that the response of the major constituents is within the linear range of the curve.

10.3.1.4 If the initial analysis of a sample or a dilution of the sample has a concentration of analytes that exceeds the initial calibration range, the sample must be reanalyzed at a higher dilution. When a sample is analyzed that has a saturated response from a compound, this analysis must be followed by a blank reagent water analysis. If the blank analysis is not free of interferences, the system must be decontaminated. Sample analysis may not resume until a blank can be analyzed that is free of interferences at less than the reporting limit.

10.4 Continuing Calibration

The working calibration curve must be verified on each 12-hour period, by the injection of a midpoint Gasoline Component Standard (or an LCS) in the beginning of the analytical sequence. If the response for the Gasoline Component Standard varies from the predicted response by more than 20%, the analytical system is examined to determine the cause and corrective action is performed and/or a new continuing calibration standard is prepared and

analyzed. If the 20% criteria are still not met, the system must be recalibrated. Any samples that were analyzed following the opening standard that did not meet calibration criteria must be reanalyzed. If reanalysis is not possible, the data must be flagged and a narrative submitted for inclusion on the Client report.

10.5 Preventive Maintenance

If the response of the PID detector decreases significantly, perform a cleaning of the PID lamp per the manufacturer's instructions. If the response is still low, the PID lamp is replaced with a new one (PID lamp life is typically 30 – 90 days).

Additional maintenance is performed to maintain GC system performance. This includes periodic replacement of injector septa, replacement of injector liner(s), and clipping several inches off the injector end of the capillary column. The trap used in the Purge and Trap equipment will also need periodic replacement, when system performance degrades.

All maintenance and repair is recorded in the appropriate Instrument Maintenance Log.

11. Data Evaluation, Calculations and Reporting

11.1 Calculations

The concentration of Gasoline Range Organics in the sample is determined from a summation of the total peak area of all chromatographic peaks eluting from methyl tert-butyl ether through naphthalene, inclusive, and comparing to the calibration curve. (Using a "baseline to baseline" integration as opposed to a "valley to valley" integration.) Refer to Section 10.2.4**.**

Quantification is based on the average response from the calibration curve. The %RSD of the RF's must not exceed 20%.

Linear regression: From the calibration standards GC responses, R, and their known concentrations, C, the following linear equation is derived [R is plotted on the y-axis; C is plotted on the x-axis]:

$$R = mC + b; \text{ which can be rearranged to } C = (R - b) / (m)$$

Using the slope (m) and the intercept (b) from this equation, the concentration of sample can be calculated from the following equations:

Water Samples:

$$Cs = (Rs - b)(D) / (m)$$

Soil Samples:

$$Cs = [(Rs-b)(D)(Vt)(K)] / [(Vp)(W)(m)]$$

Where:

Cs = Concentration of sample in µg/L for waters and mg/Kg on a dry weight basis for soils. (Note: Wet weight basis can be used upon Client request.)

m = slope of the calibration curve

Rs = GC response of sample in the GRO retention time window

b = intercept of calibration curve

D = dilution factor if water sample or soil extract was diluted

Vp = volume of soil extract purged (units must be the same as those used for Vt)

Vt = total volume

K = 5 x 10^{-6} L mg/µg (this constant adjusts for both conversion from µg/Kg to mg/Kg and for the dilution of the volume of extract purged up to the 5mL used for purging).

W = total dry weight of soil sample in Kg. (This weight can be the wet weight if requested by the Client.)

11.2 Blank areas cannot be subtracted from the sample areas. Chromatographic baseline rises due to temperature programming are corrected for by using baseline correction. The baseline correction is performed by the most convenient method that the data handling system allows.

11.3 If the water blank concentration (this does not include trip blanks) exceeds 50µg/L, (or the minimum reporting level if lower) all samples associated with this blank (samples run since the last blank that was below 50 µg/L) with reportable hits must be rerun. If the associated samples are non-detect to the reporting limit, the data is reported and the nonconformance is narrated.

11.4 If a methanol blank concentration (this does not include trip blanks) exceeds 2.5mg/L, all soil samples associated with this blank (samples that have concentrations greater than 2.5mg/Kg since the last blank that was below 2.5mg/L) must be rerun. If the associated samples are non-detect to the reporting limit, the data is reported and the nonconformance is narrated.

NOTE: The blank level is equivalent to 50µg/L in the water sample prepared by spiking 100µL of the methanol blank into 5mL of water. This is also equivalent to 2.5mg/Kg in soil

11.5 To ensure that peaks outside the GRO window are not missed, run the chromatogram out 5 minutes past the last component in the GRO component standard. All significant peaks (and baseline rises) outside the window should be qualitatively assessed and reported.

11.6 Soil concentration is reported on a dry-weight basis unless specified by the Client. The report indicates whether results are on a wet or dry weight basis.

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

Holding time exceedance, improper preservation and observed sample headspace are noted on the nonconformance report form.

Perform routine preventative maintenance following manufacturer's specification. Record all maintenance in the instrument logbook.

Review of standards, blanks and standard response for acceptable performance occurs for each batch of samples. Record any trends or unusual performance on a nonconformance action form.

If the CV or LCS recovery of any parameter falls outside the designated acceptance range, the laboratory performance for that parameter is judged to be out of control, and the problem must be immediately identified and corrected. The analytical result for that parameter in the unspiked samples is suspect and is only reported for regulatory compliance purposes with the appropriate

nonconformance action form. Immediate corrective action includes reanalyzing all affected samples by using any retained sample before the expiration of the holding time.

13. Method Performance

13.1 Detection Limit Study (DL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the DL, LOD, and/or LOQ as outlined in Alpha SOP ID 1732. These studies performed by the laboratory are maintained on file for review.

13.2 Demonstration of Capability Studies

Refer to Alpha SOP ID 1739 for further information regarding IDC/DOC Generation.

13.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

14. Pollution Prevention and Waste Management

Refer to Alpha's Chemical Hygiene Plan and Hazardous Waste Management and Disposal SOP for further pollution prevention and waste management information.

15. Referenced Documents

Volatile Organic Compounds by Gas Chromatography/Mass Spectrometry (GC/MS)

References: **Method 8260D**, SW-846, Test Methods for Evaluating Solid Waste: Physical/Chemical Methods, EPA SW-846, Update VI (Phase II), June 2018.

Method 5035A, SW-846, Closed System Purge & Trap and Extraction for Volatile Organics in Soil and Waste Samples. Test Methods for Evaluating Solid Waste: Physical/Chemical Methods, Draft Revision I, July 2002.

Method 5030B, Purge & Trap for Aqueous Samples. SW-846, Test Methods for Evaluating Solid Waste: Physical/Chemical Methods, EPA SW-846, Update III, December 1996.

Method 5030C, Purge & Trap for Aqueous Samples. SW-846, Test Methods for Evaluating Solid Waste: Physical/Chemical Methods, EPA SW-846, Update IV, May 2003.

1. Scope and Application

Matrices: Method 8260 is used to determine volatile organic compounds in a variety of solid waste matrices. This method is applicable to nearly all types of samples, regardless of water content, including various air sampling trapping media, ground and surface water, aqueous sludges, caustic liquors, acid liquors, waste solvents, oily wastes, mousses, tars, fibrous wastes, polymeric emulsions, filter cakes, spent carbons, spent catalysts, soils, and sediments.

Definitions: Refer to Alpha Analytical Quality Manual.

The compounds listed in Table 5 may be determined by this method.

There are various techniques by which these components may be introduced into the GC/MS system. Purge-and-trap, by Methods 5030C (aqueous samples) and 5035A (solid and waste oil samples), is the most commonly used technique for volatile organic analytes. However, other techniques are also appropriate and necessary for some analytes. One technique is direct injection of an aqueous sample (concentration permitting).

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one or more of the following laboratory personnel before performing the modification: Department Manager, Department Supervisor, Laboratory Director, or Quality Assurance Officer.

This method is restricted to use by or under the supervision of analysts experienced in the operation of the gas chromatograph/mass spectrometers and in the interpretation of mass spectra and their use as a quantitative tool. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

2. Summary of Method

The volatile compounds are introduced into the gas chromatograph by the purge-and-trap method or by direct injection. The analytes are introduced to a narrow-bore capillary column for analysis. The Gas Chromatograph (GC) is temperature-programmed to separate the analytes, which are then detected with a mass spectrometer (MS) interfaced to the GC.

Analytes eluted from the capillary column are introduced into the mass spectrometer via a direct connection. Identification of target analytes is accomplished by comparing their mass spectra with the electron impact (or electron impact-like) spectra of authentic standards. Quantitation is accomplished by comparing the response of a major (quantitation) ion relative to an internal standard, comparing sample response to the calibration standards.

2.1 Method Modifications from Reference

None.

3. Reporting Limits

Table 1 lists our typical reporting limits.

4. Interferences

4.1 Impurities in the purge gas, organic compounds out-gassing from the plumbing ahead of the trap, and solvent vapors in the laboratory account for the majority of contamination problems. The analytical system must be free from contamination under the conditions of the analysis. Running laboratory reagent blanks as described in Section 9.1 and 10.3 demonstrates the system is free of contamination. The use of non-Teflon plastic tubing, non-Teflon thread sealants, or flow controllers with rubber components in the purge and trap system must be avoided.

4.2 Sample contamination occurs by diffusion of volatile organics (particularly fluorocarbons and methylene chloride) through the septum seal into the sample during shipment and storage. A trip blank or a field reagent blank prepared from reagent water and carried through the sampling and handling protocol serves as a check on such contamination.

4.2.1 Storage blanks shall be analyzed if contamination is suspect. If contamination is confirmed by positive detections in the sample storage blanks, all data from samples contained in the relative refrigerator or freezer shall be evaluated for possible contamination. If the samples contain suspected contamination, the Client Services department shall be notified in order to contact the necessary clients regarding the contamination. Samples shall be reanalyzed if so desired by the client. If suspected contamination is not confirmed by storage blanks, no further action shall be pursued concerning said blanks. It is recommended that further action be taken to determine the possible cause of suspected contamination.

4.3 Contamination by carry-over can occur whenever high level and low level samples are sequentially analyzed. Whenever a highly concentrated sample is being encountered, it should be followed by an analysis of reagent water (instrument blank) to check for potential contamination. If carry-over is suspected, then numerous instrument blanks may be required; additionally, all affected samples are rerun for confirmation. In case of severe contamination, preventive maintenance of the entire system may be required.

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of safety data sheets (SDS) is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

The following method analytes have been tentatively classified as known or suspected human or mammalian carcinogens: benzene, carbon tetrachloride, 1,4-dichlorobenzene, 1,2-dichloroethane, hexachlorobutadiene, 1,1,2,2-tetrachloroethane, 1,1,2-trichloroethane, chloroform, 1,2-dibromoethane, tetrachloroethene, trichloroethene, and vinyl chloride. Pure standard materials and stock standard solutions of these compounds should be handled in a hood. A NIOSH/MESA approved toxic gas respirator should be worn when the analyst handles high concentrations of these toxic compounds.

5.1 Lab coats, safety glasses, and gloves must be worn when handling samples, standards, or solvents.

5.2 All stock solution standard preparation must be performed in the volatiles hood. Initial calibration, continuing calibration, laboratory control sample and client sample dilutions do not need to be performed in the hood.

5.3 All expired standards must be placed into the waste bucket in the lab for future disposal. The container must be labeled properly with hazard warning labels indicating the container contents.

5.4 Bottles containing Methanol must be stored in the flammables cabinet.

6. Sample Collection, Preservation, Storage, Shipping and Handling

6.1 Sample Collection and Preservation

6.1.1 Aqueous Samples

Grab samples are collected in standard 40mL glass screw-cap vials with Teflon lined silicon septa (VOA vial). Two or more VOA vials should be filled per sample location. EPA Method 8260 requires that samples be acidified to eliminate the possibility of biological degradation. Unless otherwise directed for project-specific reasons, all VOA vials are delivered to the client with approximately 2 – 4 drops of 1:1 HCl added to the vial, which is sufficient to adjust the pH of the sample to < 2. Prepared trip blanks are provided to the client to accompany field samples for QC purposes.

Fill the sample vial to the point of overflowing so that no headspace is contained within. Samples must be introduced into the vials gently to reduce agitation, which might drive off volatile compounds or cause loss of the HCl preservative.

Seal the bottle so that no air bubbles are in the VOA vial. If preservative has been added, shake vigorously for one minute. Invert the bottle and tap to check for air bubbles. Recollect the samples if any air bubbles are present.

Maintain the hermetic seal on the VOA vial until time of analysis.

6.1.2 Soil Samples

The recommended sampling method for soil samples is EPA 5035A. Method 5035A provides for two distinct sampling procedures, depending on the required reporting limits and suspected or known concentration levels of target analytes. These methods are referred to as the High Level and Low Level methods. Both are listed below but depending on the samples only one of the methods may be required. If concentration levels are unknown, it is recommended that samples be collected using both procedures.

The Lab will analyze the high level sample first, followed by the low level sample if the results from the high level analysis show that the sample is clean or contains analytes at low levels. The typical reporting levels of the two methods are listed in Table 1.

6.1.2.1 High Level Soil Samples

Collect sample in a standard 40mL glass screw-cap vial with Teflon lined silicon septa (VOA vial). The vial is provided containing 15mL of Purge and Trap Grade methanol and is labeled and weighed prior to addition of sample. Record the weight of the vial with methanol on the vial label. Prepared trip blanks are provided to the client to accompany field samples for QC purposes.

Approximately 15g of soil is added to the vial in the field, making sure that the sample is completely covered by the methanol.

Maintain the hermetic seal on the VOA vial until the time of analysis.

An additional sample of the soil must also be obtained (without methanol) to be used for the determination of soil moisture content to allow for the calculation of the dry weight results, and to calculate the methanol dilution effect. (See Sections 11.2.2.2 and 11.2.2.2.1)

6.1.2.2 Low Level Soil Samples

Collect sample in a standard 40mL glass screw-cap vials with Teflon lined silicon septa (VOA vial). Two samples should be taken per sample location. Vials are provided containing a magnetic stirring bar and 5 mL of either 200g/L sodium bisulfate solution or water, prepared by a certified vendor. These vials are labeled and weighed prior to addition of sample. Record the weight of the vial with the stirring bar and preservative on the vial label.

Approximately 5g of soil is added to the vial in the field, making sure that the sample is completely covered by the sodium bisulfate solution or water.

Maintain the hermetic seal on the VOA until the time of analysis.

6.2 Sample Handling and Storage

Document client specific sample handling, preservation and collection criteria in the project file. The laboratory Log-in staff documents sample temperature at the time of receipt.

Record deviations from this SOP or client specific criteria on the chain of custody form.

Record holding time exceedance, improper preservation and observed sample headspace on the nonconformance report form.

6.2.1 Aqueous Samples

Ice or refrigerate all samples from the time of collection until analysis, maintaining the sample temperature between 1 and 4 °C. Sample receiving personnel must note on the sample delivery group form when samples received at the laboratory are not within the temperature criteria. If more than one vial is received for a sample, the vials are stored in separate refrigerators. Storing the vials apart provides a useful check if laboratory contamination of a sample is suspected. Samples must be analyzed within 14 days of collection. Unpreserved samples must be analyzed within 7 days of collection.

6.2.2 High Level Soil Samples

Ice or refrigerate all samples from the time of collection until analysis, maintaining the sample temperature between 2 and 6 °C. Sample receiving personnel note on the

nonconformance report form when samples received at the laboratory are not within the temperature criteria. Samples must be analyzed within 14 days of collection.

6.2.3 Low Level Soil Samples

Ice or refrigerate samples preserved with water or sodium bisulfate from the time of collection until analysis, maintaining the sample temperature between 2 and 6 °C. Samples preserved with water are to be immediately frozen after sampling. Sample receiving personnel note on the nonconformance report form when samples received at the laboratory are not within the temperature criteria. Samples must be analyzed within 14 days of collection.

6.3 Sample Shipping

Samples requiring shipment to the laboratory are shipped in ice-packed coolers via an overnight delivery service in accordance with applicable Department of Transportation regulations.

7. Equipment and Supplies

7.1 Purge and Trap System (For Aqueous samples): The purge-and-trap system consists of two separate pieces of equipment: a purging device (autosampler) (TekmarAtomxXYZ, EST Centurion or equivalents) coupled to the desorber (concentrator) (EST Encon or Encon EV, or equivalents).

7.1.1 Purge gas = Helium analytical grade (99.999%) or Nitrogen analytical grade (99.999%).

7.1.2 The purging device is configured with 25 mL sample purge tubes, and the purge gas is introduced at the bottom of the water column as finely divided bubbles.

7.1.3 The trap used in the desorber is typically a Supelco “K” trap. Different traps may be used if equivalent performance is demonstrated.

7.1.4 The desorber is capable of rapidly heating the trap to 260^{o}C. The trap is not heated above manufacturer’s specifications.

7.2. Purge and Trap System (For Low Level and High Level Soil Samples): The purge and trap system consists of two separate pieces of equipment: a purging device (autosampler) (Tekmar AtomxXYZ, EST Centurion or equivalents) coupled to the desorber (concentrator) (Tekmar Velocity or Atomx, or EST Encon or Encon EV, or equivalents).

7.2.1 Purge gas = Helium analytical grade (99.999%) Nitrogen analytical grade (99.999%).

7.2.2 The autosampler purging device is a closed system, designed to accept the 40mL VOA vials. The VOA vial, containing the soil sample, water (or sodium bisulfate), and stirring bar is placed into the autosampler tray. The instrument automatically adds reagent water, internal standards, and surrogates to the unopened VOA vial. The vial is heated to 40 °C, and the purge gas is introduced into the aqueous portion to purge the volatile components onto the trap.

7.2.3 The trap used in the desorber is typically a Supelco “K” trap. Different traps may be used if equivalent performance is demonstrated.The desorber is capable of rapidly heating the trap to 260 °C. The trap is not heated above manufacturer specifications.

7.3 Gas Chromatography/Mass Spectrometer/Data System:

7.3.1 Gas Chromatograph, Agilent 6890/7890 or equivalent: An analytical system complete with a temperature-programmable gas chromatograph with appropriate

interface for sample introduction device. The system includes all required accessories, including syringes, analytical columns, and gases. The capillary column is directly coupled to the source of the GC/MS system.

7.3.2 Typical Gas Chromatographic Columns:

7.3.2.1 Column 1: Restek 502.2, 40 meter, 0.18mm ID, 1.0um, or equivalent.

7.3.2.2 Column 2: Restek RTX-VMS, 30 meter, 0.25mm ID, 1.4um, or equivalent.

7.3.2.3 Column 3: Restek RTX-VMS, 20 meter, 0.18mm ID, 1.5um, or equivalent.

7.3.3 Mass Spectrometer, Agilent 5973/5975/5978 or equivalent: Capable of acquiring mass spectra from mass/charge (m/z) 35 to 270 at a rate fast enough to acquire at least five (but preferably 10 or more) mass spectra across each chromatographic peak of interest, using 70 volts (nominal) electron energy in the electron impact ionization mode. The mass spectrometer must be capable of producing a mass spectrum for 4-Bromofluorobenzene (BFB) which meets all of the criteria in Table 3, when 50ng of the GC/MS tuning standard (BFB) are injected through the GC. For all SIM analysis, the mass spectrometer must also be able to acquire data in a dual acquisition mode (SIM and full scan).

7.3.4 Data System: Hewlett-Packard EnviroQuant software is used for data acquisition and allows the continuous acquisition and storage on machine-readable media of all mass spectra obtained throughout the duration of the chromatographic program.

EnviroQuant E.02.02 (or equivalent) is used for data processing and allows searching of any GC/MS data file for ions of a specified m/z, and plotting such ion abundances versus time or scan-number.

The most recent version of the EPA/NIST Mass Spectral Library is loaded onto the Target / EnviroQuant data system.

7.4 Wiretrol or Micro syringes: 10µL - 1,000µL.

7.5 Syringes: 5mL, 10mL, or 25mL, glass with Luerlock tip.

7.6 Balances: Top-loading, capable of weighing 0.01g.

7.7 Vials: 2mL, 4mL.

7.8 Disposable Pipets.

7.9 Volumetric Flasks: Class A, appropriate sizes, with ground-glass stoppers.

7.10 Eppendorf pipets.

7.11 Ottawa Sand: SiO_2

8. Reagents and Standards

Reagent grade organic chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all organic reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

Great care must be taken to maintain the integrity of all standard solutions. Standards in methanol are stored at –10ºC or less, in amber vials with PTFE-lined screw-caps.

8.1 Organic-free Reagent Water:

All references to water in this method refer to organic-free reagent water, which is tap water passed through activated carbon and air bubbled through.

8.2 Methanol:

Purge and Trap Grade or equivalent. Store in flammables cabinet.

8.3 Stock Solutions:

All stock standards are purchased from commercial vendors as certified ampule solutions. When an ampule of stock solution is opened, it is transferred to a labeled amber screw-cap vial with minimal headspace. The expiration date of the stock solution is either the vendor specified expiration date or 6 months from the date the ampule was opened, whichever is sooner. Typical stock standard concentrations are listed in Table 4.

8.4 Intermediate Standards: Intermediate standards are prepared volumetrically by diluting the appropriate stock standard(s) with methanol. Initial Calibration solutions expire 2 months from the date of preparation, or sooner if daily continuing calibration checks do not achieve the method acceptance criteria. If the Intermediate Standards are used as a second source to verify a valid Initial Calibration solution, there is no expiration date.

8.4.1 Internal Standard Solutions:

The internal standards are Fluorobenzene, Chlorobenzene-d_5, and 1,4-Dichlorobenzene-d_4. The intermediate IS solution is prepared by diluting the stock solution(s) with methanol to a concentration of 100 µg/mL. The appropriate amount of IS solution is added to the water or soil sample or QC sample to achieve a final concentration of 100 ng/sample or standard. Internal standard is added at the same concentration to all standards, samples, and QC samples.

8.4.2 Surrogate Standard Solutions:

The surrogate standards are Dibromofluoromethane, 1,2-Dichloroethane-d_4, Toluene-d_8, and 4-Bromofluorobenzene. The intermediate surrogate solution is prepared by diluting the stock solution(s) with methanol to a concentration of 100 µg/mL. The appropriate amount of surrogate solution is added to the water or soil sample or QC sample to achieve a final concentration of 100 ng/sample.

8.4.3 Target Compound Solutions:

The target analytes routinely reported by this method are listed in Table 1 and 4. The intermediate target compound solutions are prepared by diluting the stock solution(s) with methanol. This set of solutions, at concentrations of 200 µg/mL, is used for preparation of the calibration standards.

8.4.4 4-Bromofluorobenzene (BFB) Tune solution:

8.4.4.1 A solution containing BFB at a concentration of 50 µg/mL is prepared by volumetrically diluting the BFB stock solution. 1 µL of this solution is direct-injected or purged into the GC/MS system to verify system performance prior to any standard or sample analysis.

8.4.4.2 BFB may be analyzed in full scan mode while standards, samples, and QC are analyzed in SIM

8.5 Calibration Standards:

There are two types of calibration standards used for this method – initial calibration standards and calibration verification standards.

8.5.1 Initial Calibration Standards:

Initial calibration standards can be prepared at the levels listed in Table 4 (other/different levels are allowed). The Initial Calibration needs to have a minimum of 5 standards, 6 if a quadratic curve fit is used. Prepare these solutions in organic-free reagent water. The standards correspond to the range of concentrations found in typical samples and do not exceed the working range of the GC/MS system. Initial calibration should be mixed from fresh stock standards and dilution standards when generating an initial calibration curve.

8.5.2 Initial Calibration Verification Standard (ICV):

The initial calibration verification standard is at the same concentration as the level 3 for liquids and level 4 for soils initial calibration standard. This standard is prepared from source materials from a second manufacturer or from a manufacturer's batch prepared independently from the batch used for calibration. A second lot# from the same manufacturer may be adequate to meet this requirement. The standard must contain all calibrated target analytes that will be reported for the project, if readily available.

8.5.3 Continuing Calibration Verification Standard:

The continuing calibration verification standard, or calibration check standard, should be analyzed near the action level of the project. Since most projects are focused on achieving low reporting limits, the continuing calibration verification standard is at the same concentrations as the level 3 for liquids and level 4 for soils initial calibration standard. This standard is run at the beginning of each analytical sequence, following the BFB tune standard, to verify system performance.

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

9.1 Blank(s)

9.1.1 Before processing any samples, the analyst must demonstrate through the analysis of a method blank (MB) or instrument blank that equipment and reagents are free from contaminants and interferences. The blank must contain the internal standards and surrogates and must be from the same source of water used for preparing the standards, QC samples and sample dilutions.

9.1.2 Analyze a matrix-specific blank, i.e. methanol samples need to have methanol in the blank; sodium bisulfate samples need to have a sodium bisulfate blank analyzed;

TCLP samples need a TCLP blank, after each ICAL and CCV, and prior to any sample analysis to demonstrate that interferences from the analytical system are under control.

9.1.3 Low level soil blanks must include 5g of Ottawa sand and be vortexed.

9.1.4 Blanks are considered to be acceptable if target analyte concentrations are less than one half the LOQ or are less than project-specific requirements. Blanks may contain analyte concentrations greater than acceptance limits if the associated samples in the batch are unaffected (i.e., target analytes are not present in samples or sample concentrations/responses are >10X the blank).

9.1.5 If an analyte of interest is found in a sample in the batch near a concentration detected in the blank, the presence and/or concentration of that analyte should be considered suspect and may require qualification. Reanalysis is not necessary if the analyte concentration falls well below the action or regulatory limit or if the analyte is deemed not important for the project.

9.1.6 The laboratory must not subtract the results of the MB (or any blank) from those of any associated samples.

9.2 Laboratory Control Sample (LCS)/ Laboratory Control Sample Duplicate (LCSD)

An LCS/LCSD pair is analyzed at the beginning of each analytical sequence. Since the LCS contains the same compounds at the same concentrations as the continuing calibration check standard, the same analysis is used to satisfy both QC elements. The LCS/LCSD acceptance criteria are based on in-house control limits, unless specified by project/regulation. Less than 10% of total compounds may be outside of control limits if recoveries are >10%. (Note: this does not apply to difficult analytes listed in Table 7 which may be accepted at recoveries <10.) If >10% of analytes are recovered above control limits, this is deemed acceptable as long as the analytes in question are not detected in associated samples. If these criteria are not met, the entire batch is re-extracted. If re-extraction is not possible, due to insufficient sample or holding time exceedance, the analyst must write up the failure on a narrative sheet for inclusion in the client report.

9.3 Initial Calibration Verification (ICV)

Refer to 12

9.4 Continuing Calibration Verification (CCV)

Refer to Section 11.2.

9.5 Matrix Spike/ Matrix Spike Duplicate

Upon Client Request or state mandate, a matrix spike/matrix spike duplicate pair may be analyzed with each batch of 20 or less samples. The MS/MSD are sample aliquots spiked with the target compounds at the same concentration as the continuing calibration standard for water analysis and level 6 for soils. The MS/MSD acceptance criteria are based on in-house control limits. If the MS/MSD does not meet the criteria, but the LCSD does, the failure may be attributed to sample matrix. Report the MS/MSD, including a narrative sheet for inclusion with the client report.

9.6 Laboratory Duplicate

Not applicable.

9.7 Method-specific Quality Control Samples

9.7.1 Internal Standards

Area counts of the internal standard peaks in all samples and QC samples must be between 50-200% of the areas of the internal standards in the QC check standard.

If any individual percent recovery falls outside the range, that parameter has failed the acceptance criteria. For calibration standards, CCVs, LCS/LCSD or blanks the internal standard must be within the range for data to be reported to the clients. For samples, matrix spikes and duplicates: if the data is not within the range, the sample is rerun to confirm that the failure is due to sample matrix. A nonconformance report form is completed to ensure client notification and reporting if matrix effect is confirmed.

9.7.2 Surrogates

Surrogates are added to each field sample and QC sample. The laboratory must evaluate surrogate recovery data from individual samples versus the surrogate control limits developed by the laboratory. The surrogate acceptance criteria are listed in Table 2. Since the SIM analysis is acquired in dual mode, the surrogates from the full scan are used to evaluate the entire sample (SIM and full scan).

9.8 Method Sequence

In a 12-hour period, the typical analytical sequence is as follows:

- BFB
- QC Check Standard/Laboratory Control Sample/LCSD
- Method Blank
- Samples
- MS/MSD (upon Client request, may be run any time after the Method Blank)

10. Procedure

10.1 Equipment Set-up

Typical instrument operating conditions are listed below. Alternate conditions are allowed if method performance criteria can be met.

10.1.1 GC Conditions:

Temperature 1:	35°C	Carrier gas:	Helium 99.999% or Nitrogen 99.999%
Hold Time 1:	4 minutes	Carrier mode:	Constant flow
Ramp 1:	6°C/minute	Carrier flow:	1 mL/minute
Temperature 2:	150°C		
Hold Time 2:	0 minutes		
Ramp 2:	8°C/minute		
Temperature 3:	220°C		
Final Time:	1 minute		

10.1.2 MS Conditions:

Mass range:	m/z of 35 – 270 amu
Scan time:	0.5 minutes/scan
Source temperature:	230°C or according to manufacturer's specifications.

10.1.3 Velocity Concentrator Purge and Trap Conditions:

Purge time:	11 minutes
Dry purge:	2 minutes
Desorb preheat:	250°C
Desorb temp:	255°C
Desorb time:	2 minutes
Bake temp:	290°C
Bake time:	10 minutes

10.1.4 Encon Concentrator Purge and Trap Conditions:

Purge time:	11 minutes
Dry purge:	1 minute
Desorb preheat:	245°C
Desorb temp:	255°C
Desorb time:	1 minute
Bake temp:	270°C
Bake time:	10 minutes

10.2 Initial Calibration

10.2.1 The initial calibration is performed at a minimum of five (5) concentration levels listed in Table 4, the low level either at or below the reporting limit. The calibration is performed using instrument conditions listed in 10.1.

BFB must be analyzed prior to analysis of the initial calibration standards and must pass the criteria listed in Table 3. The mass spectrum of BFB should be acquired in the following manner:

(1) Three scans (the peak apex scan, the scan immediately preceding the apex and the scan immediately following the apex) are acquired and averaged.
(2) Background subtraction is performed using a single scan of no more than 20 scans prior to the elution of BFB.

This is done automatically with the EnviroQuant software.

10.2.1.1 Low Level/High Level Soil Curve on Centurion: To prepare a calibration standard, add the appropriate volume of standard solution(s) to a 50mL volumetric flask using a micro syringe. Remove the needle quickly and mix by inverting the flask 3 times. Pour several mLs of the aqueous standard into the waste vessel, then gently fill a 5mL syringe with standard and transfer to a 40mL VOA vial containing a magnetic stir bar. Load the vial onto autosampler.

10.2.1.2 Aqueous/High Level Soil Curve on Solatek or Centurion: To prepare a calibration standard, add the appropriate volume of standard solution(s) to a 100mL volumetric flask using a micro syringe. Remove the needle quickly and mix by inverting the flask 3 times. Pour several mLs of the aqueous standard into the waste vessel, and then gently fill a 40mL VOA vial to the top. Load the vial onto the autosampler.

10.2.2 Establish the GC operating conditions by loading the appropriate GC method. Typical instrument conditions are listed in Section 10.1. The same operating conditions are used for calibration and sample analyses. Create the analytical sequence using the HP EnviroQuant data acquisition software.

Relative Response Factors: The internal standard calibration technique is used. In each calibration standard, calculate the relative response factor for each analyte and the relative standard deviation (RSD) of the response factors using the EnviroQuant data processing software. The response factors are calculated using the areas of the characteristic (quantitation) ion for each target analyte and internal standard. The calculations are performed automatically using the EnviroQuant software, using the formulae listed in Alpha's Quality Manual.

10.2.3 Initial Calibration Criteria: The following sections outline the method acceptance criteria for an initial calibration curve. All criteria must be met for the calibration to be deemed acceptable, and for sample analysis to proceed. For MCP and CT projects see the related project specific addenda for modifications.

10.2.3.1 Relative Standard Deviation Criteria: If the RSD for each target analyte is less than or equal to 20%, then the response for this compound is considered linear over the calibration range and the mean calibration factor can be used to quantitate sample results. If the 20% RSD criterion is not met for an analyte linear regression may be used if $\mathbf{r^2} \geq 0.990$, weighted linear with a weighting factor of 1/SD2 and r > 0.995, or quadratic fit if $\mathbf{r^2} \geq 0.990$. A minimum of five points are required for linear fit and six points is required for quadratic fit. The calibration must be repeated for any compounds that fail. If more than 10% of the compounds exceed the 20% RSD limit and do not achieve the minimum correlation coefficient for alternative curve fits, sample analysis cannot proceed.

10.2.3.1.1 Percent Relative Error (%RE): For linear and quadratic fit compounds the %RE relative error must be calculated for the standard at or near the midpoint of the initial calibration and at the lowest level. The %RE between the calculated and expected amounts of an analyte should be ≤ 30% for all standards, otherwise recalibration is necessary.

10.2.4 Evaluation of Retention Times: The relative retention times used for identification of target analytes are +/- 0.06 RRT (Relative Retention Time) units, based on the most recent standard run. It has been determined that these limits work well, being wide enough to eliminate false-negative results while being tight enough to eliminate false positive results. Due to the selectivity of the mass spectrometer, compound identification is more definitive than when using a less selective detector.

10.2.5 Initial Calibration Verification: After each calibration and before the analysis of samples, an ICV must be analyzed at or near the midpoint of the curve. The ICV must be prepared using a different source than the Initial Calibration and must contain all target analytes. The percent recoveries must be between 70% and 130% for target analytes

except for “difficult” analytes (Table 7), which must exhibit percent recoveries between 40% and 160%. Corrective action is required if greater than 10% of all analytes are outside the prescribed criteria.

10.2.5.1 The ICV used for the initial calibration can be used as the continuing calibration verification. See Section 10.4 for criteria.

10.2.6 Additional considerations for SIM analysis

10.2.6.1 SIM may be useful for applications requiring quantitation limits below the normal range of electron impact quadrupole mass spectrometry, and both are allowable options for this method. Using the primary m/z for quantitation and at least one secondary m/z (or product ion) for confirmation, set up the descriptor windows based on their retention times. The selected m/z values should include any mass defect noted in the target analyte mass spectra acquired on the instrument, usually less than 0.2 amu. The dwell time for each ion may be automatically calculated by the instrument software or may be calculated based on the peak widths of the analytes of interest, the number of spectra needed to be acquired across each peak, and the number of concurrent ions that need to be acquired in each segment. When fewer m/z values are monitored in each segment, the acquisition time for each m/z can be increased, thereby increasing the sensitivity of the system. The total cycle time for the MS should be short enough that at least five, but preferably ten or more, spectra are acquired per chromatographic peak.

10.2.6.2 When compounds are analyzed in SIM mode, the following best practices are recommended:

10.2.6.2.1 Monitor at least two ions for each target analyte and use the mid-point of the calibration curve to establish proper ion ratios for each compound. The ratios of primary and secondary ions are the only qualitative tools available in SIM runs (other than RT), which increases their importance in proper identification. When interferences are expected or observed in a given matrix, acquiring multiple secondary ions may aid in qualitative identification.

10.2.6.2.2 Verify that all monitored ions are correctly integrated in order to achieve proper ion ratios. Update the primary/secondary ion ratios and reference mass spectra after each ICAL using a mid-range ICAL standard.

10.3 Equipment Operation and Sample Processing

The same GC, MS, and Purge and Trap conditions used for the initial calibration must be employed for sample analysis. After verification of system performance by analysis of BFB, the continuing calibration standard and method blank, samples are analyzed and processed as described below.

10.3.1 All samples are initially screened using Tekmar 7000 Headspace Autosamplers.

10.3.2 Retrieve sample VOA vials from the sample refrigerator just prior to loading onto the purge and trap system.

10.3.3 Aqueous samples:
Load the VOA vial directly on the sampling rack. Dilutions may be prepared volumetrically and poured into VOA vials ensuring there is no headspace left in the vial. The autosampler will then sample 10mL from the VOA vial.

10.3.4 Low level soil samples:

Low level soil sample should be shaken briefly to ensure that the stir bar is loose, and will spin on the autosampler unit. Take the low level VOA vial and place directly into the rack of the autosampler unit. Surrogate and internal standards are added automatically by the autosampler prior to sample purging.

10.3.5 High level soil samples:

Shake or vortex the sample for 15 seconds, ensuring the methanol has completely penetrated the soil in the vial. Let sample settle prior to taking methanol aliquot.

10.3.5.1 Through liquid path

Load a maximum of 860µL or appropriate dilution of the methanol into a half-full VOA vial. Fill the VOA vial up to the top with water and cap with no headspace. Allow the auto-sampler to sample 10mL out of the VOA vial which would be equivalent to injecting 100µL of the methanol extract. Prepare dilutions accordingly.

10.3.5.2 Through soil path

Into a VOA vial with a stir bar added, load 4.9mL of water plus a maximum of 100 µL of methanol or appropriate dilution of methanol extract from a 5mL luerlock syringe. Cap the vial and load onto the auto-sampler.

10.3.6 Qualitative Analysis:

10.3.6.1 The qualitative identification of each compound is based on retention time and on comparison of the sample mass spectrum with the reference mass spectrum. The reference mass spectrum must be generated by the laboratory on the same GC/MS system. The characteristic ions from the reference mass spectrum are defined to be the three ions of greatest relative intensity, or any ions over 30% relative intensity if less than three such ions occur in the reference spectrum. Compounds are identified as present when the following criteria are met:

10.3.6.1.1 The intensities of the characteristic ions of a compound maximize in the same scan or within one scan of each other. The EnviroQuant data system is configured to make this check.

10.3.6.1.2 The relative retention time (RRT) of the sample component is within ±0.06 RRT units of the RRT of the standard component.

10.3.6.1.3 The relative intensities of the characteristic ions agree within 30% of the relative intensities of these ions in the reference spectrum. (Example: For an ion with an abundance of 50% in the reference spectrum, the corresponding abundance in a sample spectrum can range between 20% and 80%.)

10.3.6.1.4 Structural isomers that produce very similar mass spectra should be identified as individual isomers if they have sufficiently different GC retention times. Sufficient GC resolution is achieved if the height of the valley between two isomer peaks is ≤ 50% of the average of the two peak heights. Otherwise, structural isomers are identified as isomeric pairs (i.e., m and p-xylene).

10.3.6.1.5 Identification is hampered when sample components are not resolved chromatographically and produce mass spectra containing ions contributed by more than one analyte. When gas chromatographic peaks obviously represent more than one sample component (i.e., a broadened peak with shoulder(s) or a valley between two or more maxima), appropriate selection of analyte spectra and background spectra is important.

10.3.6.1.6 Examination of extracted ion current profiles of appropriate ions can aid in the selection of spectra, and in qualitative identification of compounds. When analytes coelute (i.e., only one chromatographic peak is apparent), the identification criteria may be met, but each analyte spectrum will contain extraneous ions contributed by the coeluting compound.

10.3.6.2 For samples containing non-target analytes, a library search will be performed at client request. Compound identification will be classified as “tentative”, and the concentration will be reported as an estimate as no quantitative standards are run for these compounds.

10.3.6.2.1 Relative intensities of major ions in the reference spectrum (ions greater than 10% of the most abundant ion) are present in the sample spectrum.

10.3.6.2.2 The relative intensities of the major ions should agree within ±20%. (Example: For an ion with an abundance of 50% in the standard spectrum, the corresponding sample ion abundance must be between 30 and 70%.)

10.3.6.2.3 Molecular ions present in the reference spectrum are present in the sample spectrum. If the molecular ion is not present, carefully review library matches in order to avoid misidentification.

10.3.6.2.4 Ions present in the sample spectrum but not in the reference spectrum should be reviewed for possible background contamination or presence of coeluting compounds.

10.3.6.2.5 Ions present in the reference spectrum but not in the sample spectrum are reviewed for possible subtraction from the sample spectrum because of background contamination or coeluting peaks.

10.3.6.2.6 Mass spectral library search algorithms typically assign a match factor to the peak identity based on comparison of an unknown mass spectrum to library spectra. For spectra meeting the above conditions, match factors greater than 0.85 (85%) may be considered confirming evidence. Where a known limitation in data collection is identified (e.g., the presence of an incompletely resolved spectral interference), a lower match factor may be considered confirmatory. For multiple library spectra with similar match factors (e.g., for hydrocarbons with low abundance molecular ions, or structural isomers), the tentative identification assigned to the unknown may be better represented as a more generic structure (e.g., unknown hydrocarbon, C4 benzene structural isomer).

10.3.7 Quantitative Analysis:

10.3.7.1 Quantitation of a target compound detected in a sample is performed automatically by the EnviroQuant data processing software, using the formulae found in Alpha’s Quality Manual. Either the average response factor or calibration curve will be used for sample quantitation, depending on how the particular analyte was processed in the initial calibration curve. If non-target

compounds are to be reported, the quantitation is performed automatically by the EnviroQuant software using the total area of the compound and the nearest internal standard, and assuming a relative response factor of 1.0.

10.4 Continuing Calibration

Calibration verification consists of three steps that are performed at the beginning of each 12-hour analytical shift. For MCP and CT projects see the related project specific addenda for modifications.

10.4.1 Prior to the analysis of samples or calibration standards, inject or purge 1 µL (50 ng) of the 4-Bromofluorobenzene standard (Section 8.4.4) into the GC/MS system. The resultant mass spectra for the BFB must meet the criteria given in Table 3 before sample analysis begins.

10.4.2 The initial calibration curve for each compound of interest must be verified once every 12 hours prior to sample analysis. This is accomplished by analyzing the continuing calibration check standard (Section 8.5.3).

10.4.3 A method blank must be analyzed prior to any samples, typically immediately following the continuing calibration check standard, to ensure that the analytical system is free of contaminants. The method blank must not contain any target analytes at or above the required compound reporting limits.

10.4.4 The percent difference or drift for each target analyte must be less than or equal to 20% (30% for all SIM compounds). If greater than 20% of target analytes exceed the %D criteria corrective action must be taken prior to the analysis of samples. If less than or equal to 20% of compounds exceed the criteria, corrective action is not required.

10.4.5 Internal Standard Retention Time:

The absolute retention times of the internal standards in the calibration verification standard are evaluated after data acquisition. If the absolute retention time for any internal standard changes by more than 30 seconds from that in the mid-point standard level of the most recent initial calibration sequence, then the chromatographic system must be inspected for malfunctions and corrections must be made, as required. When corrections are made, reanalysis of samples analyzed while the system was malfunctioning is required.

10.4.6 Internal Standard Response:

If the area for any of the internal standards in the calibration verification standard changes by a factor of two (50% to 200%) from that in the mid-point standard level of the most recent initial calibration sequence, the mass spectrometer must be inspected for malfunctions and corrections must be made, as appropriate. When corrections are made, re-analysis of samples analyzed while the system was malfunctioning is required.

10.5 Preventive Maintenance

Routine preventive maintenance should be performed on the analytical system. This includes replacement of GC septa and periodic rinsing or replacement of purge and trap tubes and sparge needles. The trap should be replaced every six months or sooner if performance criteria

cannot be met. Periodic cleaning (typically twice per year) of the mass spectrometer ion source is required. More frequent source cleaning may be needed, especially if dirty samples are analyzed.

If system performance deteriorates, additional maintenance may be required. This includes replacement of injector ports and seals, clipping several inches off of the front end of the GC column, or in extreme cases the replacement of the GC column. Flushing or replacement of purge and trap lines may be necessary if they become contaminated or develop active sites.

Perform routine preventative maintenance as described throughout this SOP. Record all maintenance in the instrument logbook.

11. Data Evaluation, Calculations and Reporting

11.1 LIMS Data Corrections

Please note that the Laboratory Information Management System (LIMS) automatically adjusts soil sample results to account for the % Total Solids of the sample (as determined per Alpha SOP/07-38) and the methanol preservation dilution effect.

11.2 Data Calculations

11.2.1 Results of Aqueous Sample Analysis:

$$Concentration\ (ug/L) = \frac{(Conc.)\ (Vp)\ (DF)}{(Vs)}$$

where:

Conc. = On-column concentration obtained from the quantitation report.
Vp = Volume purged, 10 mL is standard
Vs = Volume of sample purged
DF = Dilution factor, for manually prepared dilutions, not instrumental "dilutions".

11.2.2 Results of Sediment/Soil, Sludge, and Waste Analysis:

All solids including soils, sediments, and sludges must be reported on a dry-weight basis.

11.2.2.1 Low-Level Samples:

$$Concentration\ (ug/Kg) = \frac{(Conc.)\ (Vp)\ (DF)}{(W)\ (\%S)}$$

11.2.2.2 High-Level Samples:

$$\text{Concentration (ug/Kg)} = \frac{(\text{Conc.})\,(Vp)\,(5000)\,(DF)}{(W)\,(Ve)\,(\%S)}$$

where:

Conc. = On-column concentration obtained from the quantitation report.
DF = Dilution factor, for manually prepared dilutions, not instrumental "dilutions".
Ve = Extract volume, mL
Vp = Volume purged, 5 mL is standard
W = Aliquot of sample (wet), g
%S = Sample % solid
5000 = Constant representing the final volume of the methanol extraction.

11.2.2.2.1 High-Level Samples Corrected for Total Water/Solvent Mixture (V_t):

Samples that are extracted prior to analysis in a water miscible solvent such as methanol are diluted by the total volume of the water/solvent mixture. The total mixture volume can only be calculated based on the sample moisture present as determined by the % moisture calculation.

$$\%\ \text{moisture} = \frac{\text{g of sample} - \text{g of dry sample}}{\text{g of sample}} \times 100$$

$$V_t = \frac{[\text{mL of solvent} + (\%\text{moisture} \times \text{g of sample})]}{100} \times 1000\text{mL/mL}$$

The calculated V_t value is now added to the volume of methanol in the sample (typically 5000µL), and the corrected concentration is calculated using the equation below:

$$\text{Corrected concentration (mg/Kg)} = \frac{(\text{Conc.})\,(V_t + \text{methanol vol.})\,(Vp)\,(DF)}{(W)\,(Ve)\,(\%S)}$$

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

All batch and sample specific QC criteria outlined in section 10 are evaluated by the analyst prior to approval of the data. When any QC criteria fail, the cause for the failure must be identified and corrected. This may include instrument recalibration followed by sample reanalysis, sample cleanup, or sample re-extraction. If it is determined that the failure is due to sample matrix effects, a project narrative report is written by the analyst for inclusion in the data report. If there is insufficient sample volume to perform the re-analysis for confirmation, this is also noted in the narrative and included in the client report.

13. Method Performance

13.1 Detection Limit Study (DL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the DL, LOD, and/or LOQ as outlined in Alpha SOP/1732. These studies performed by the laboratory are maintained on file for review.

13.2 Demonstration of Capability Studies

Refer to Alpha SOP/1739 for further information regarding IDC/DOC Generation.

13.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

14. Pollution Prevention and Waste Management

Refer to Alpha's Chemical Hygiene Plan and Waste Management and Disposal SOP for further pollution prevention and waste management information.

15. Referenced Documents

Volatile Petroleum Hydrocarbons (VPH)

Reference Method No.: Method for the Determination of Volatile Petroleum Hydrocarbons (VPH), Massachusetts DEP, ORS, BWSC. Revision 2.1, February 2018.

Quality Control Requirements and Performance Standards for the ***Analysis of Volatile Petroleum Hydrocarbons (VPH)*** in Support of Response Actions under the Massachusetts Contingency Plan (MCP), Section IV C, Rev 0, January, 2017

1. Scope and Application

Matrices: This method is suitable for the analysis of waters, soils, sludges, sediments, wastes and non-aqueous-phase liquids (NAPL). Water samples may be analyzed directly for volatile petroleum hydrocarbons by purge-and-trap concentration and gas chromatography. Soil/sediment samples are dispersed in methanol to dissolve the volatile organic constituents. A portion of the methanol solution is then analyzed by purge-and-trap GC.

This method is designed to measure the collective concentrations of volatile aliphatic and aromatic petroleum hydrocarbons in water and soil. Volatile aliphatic hydrocarbons are collectively quantitated within two ranges: C_5 through C_8, and C_9 through C_{12}. Volatile aromatic hydrocarbons are collectively quantitated within the C_9 to C_{10} range. These aliphatic and aromatic hydrocarbon ranges correspond to a boiling range between approximately 36ºC and 220ºC.

This method is based on a purge-and-trap, gas chromatography (GC) procedure using in-series Photoionization and Flame Ionization Detectors (PID/FID). This method should be used by, or under the supervision of, analysts experienced in the use of purge-and-trap systems and gas chromatographs. The analysts should be skilled in the interpretation of chromatograms and their use as a quantitative tool. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

This method is also able to measure the individual concentrations of the VPH Target Analytes: benzene, toluene, ethylbenzene, xylenes, naphthalene, and methyl-tert-butyl ether (MTBE). Results for these individual analytes are reported at client request.

Petroleum products suitable for evaluation by this method include gasoline, mineral spirits, and certain petroleum naphthas. This method, in and of itself, is not suitable for the evaluation of kerosene, jet fuel, heating oils, lubricating oils, and/or other petroleum products which contain a significant percentage of hydrocarbons heavier than C_{12}.

The Reporting Limits (RLs) of this method for each of the collective aliphatic and aromatic ranges are typically 5 - 10 mg/kg in soil and 100 - 150 µg/L in aqueous samples. The RLs of this method for the Target VPH Analytes are typically 0.05 to 0.25 mg/kg in soil for all compounds. In aqueous samples, the typical reporting limits are 1 to 5 µg/L for all compounds.

This method includes a data adjustment step to subtract the concentration of VPH Target Analytes from the concentration of the aliphatic range results when the individual compounds are reported (Alpha product VPH Deluxe). This step is taken by the laboratory, and both adjusted and unadjusted values are reported to the client.

Data generated using this method is reported using the format specified in the MADEP VPH method.

Like all GC procedures, this method is subject to a “false positive” bias in the reporting of Target VPH analytes, in that non-targeted hydrocarbon compounds eluting or co-eluting within a specified retention time window may be falsely identified and/or quantitated as a Target VPH analyte.

Confirmatory analysis by gas chromatography/mass spectrometry (GC/MS) analysis may be performed in cases where target analyte identification is suspect.

Regulatory Parameter List:

Parameter	CAS
C5-C8 Aliphatic Hydrocarbons	-
C9-C12 Aliphatic Hydrocarbons	-
C9-C10 Aromatic Hydrocarbons	-
Benzene	71-43-2
Toluene	108-88-3
Ethylbenzene	100-41-4
m/p-Xylenes	108-38-3/106-42-3
o-Xylene	95-47-6
Naphthalene	91-20-3
Methyl-tert-butyl ether	1634-04-4

Definitions: See Alpha Analytical Quality Manual.

♦ **Analytical Batch** is defined as a group of field samples with similar matrices, which are processed as a unit. For Quality Control purposes, if the number of samples in such a group is greater than 20, then each group of 20 samples or less is defined as a separate analytical batch.

♦ **Calibration Check Standard** is defined as a calibration standard which is analyzed daily to verify the calibration state of an instrument. The calibration check standard is prepared from the same stock solution as the initial calibration standards, and is spiked at the concentration of the Level 4 initial calibration standard.

♦ **Calibration Standards** are defined as a series of standard solutions prepared from a stock standard solution, containing known concentrations of each analyte and surrogate compound of interest.

♦ **Unadjusted C_5 through C_8 Aliphatic Hydrocarbons** are defined as all aliphatic hydrocarbon compounds, which elute on the FID chromatogram from n-pentane (C_5) to just before n-nonane (C_9).

♦ **Unadjusted C_9 through C_{12} Aliphatic Hydrocarbons** are defined as all aliphatic hydrocarbon compounds, which elute on the FID chromatogram from n-nonane (C_9) to just before naphthalene.

♦ **C_9 through C_{10} Aromatic Hydrocarbons** are defined as all aromatic hydrocarbon compounds, which elute on the PID chromatogram from just after o-xylene to just before naphthalene. Although it is an aromatic compound with 10 carbon atoms, naphthalene is excluded from this range because it is evaluated as a separate (Target) analyte.

♦ **Field Duplicates** are defined as two separate samples collected at the same time and place, under identical circumstances and managed the same throughout field and laboratory procedures. Analyses of field duplicates give a measure of the precision associated with sample collection, preservation, and storage, as well as laboratory procedures.

- **Target VPH Analytes** are defined as benzene, toluene, ethylbenzene, m-xylene, p-xylene, o-xylene, naphthalene, and methyl tert-butyl ether.

- **Adjusted C_5 through C_8 Aliphatic Hydrocarbons** are defined as all hydrocarbon compounds which elute on the FID chromatogram from n-pentane (C_5) to just before n-nonane (C_9), corrected for MTBE, Benzene, and Toluene.

- **Adjusted C_9 through C_{12} Aliphatic Hydrocarbons** are defined as all hydrocarbon compounds which elute on the FID chromatogram from n-nonane (C_9) to just before naphthalene, corrected for Ethylbenzene, m/p-Xylene, and o-Xylene.

- **Volatile Petroleum Hydrocarbons (VPH)** are defined as collective fractions of hydrocarbon compounds eluting from n-pentane to naphthalene, excluding Target VPH Analytes. VPH is comprised of C5 through C8 Aliphatic Hydrocarbons, C9 through C12 Aliphatic Hydrocarbons, and C9 through C10 Aromatic Hydrocarbons.

- **Volatile Petroleum Hydrocarbon (VPH) Component Standard** is defined as a 15-component mixture of the aliphatic and aromatic compounds listed in Table 2. The compounds comprising the VPH Component Standard are used to (a) define the individual retention times and chromatographic response factors for each of the Target VPH Analytes, (b) define and establish the windows for the collective aliphatic and aromatic hydrocarbon ranges of interest, and (c) determine average chromatographic response factors that can in turn be used to calculate the collective concentration of hydrocarbons within these ranges.

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one of the following laboratory personnel before performing the modification: Area Supervisor, Laboratory Services Manager, Laboratory Director, or Quality Assurance Officer.

A major modification to this procedure requires demonstration of performance. The identification of major method modification requiring performance demonstration is directed by the QA Officer and/or Laboratory Director on a case-by-case basis.

2. Summary of Method

Samples are analyzed using purge-and-trap sample concentration. The gas chromatograph is temperature programmed to facilitate the separation of organic compounds. Detection is achieved by a photoionization detector (PID) and flame ionization detector (FID) connected in series. Quantitation is based on comparing the PID and FID detector response of a sample to a standard comprised of aromatic and aliphatic hydrocarbons. The PID chromatogram is used to determine the individual concentrations of Target Analytes and collective concentration of aromatic hydrocarbons within the C_9 through C_{10} range. The FID chromatogram is used to determine the collective concentration of aliphatic hydrocarbons within the C_5 - C_8 and C_9 - C_{12} ranges.

2.1 Method Modifications from Reference

2.1.1 Trap

We currently use a Supelco K trap. A trap desorption efficiency study was performed using a gasoline standard. Results were acceptable within method required criteria. Results of the comparison study are kept on file by the QA department.

3. Reporting Limits

Table 1 lists our routine reporting limits.

4. Interferences

4.1 Impurities in the purge gas, organic compounds out-gassing from the plumbing ahead of the trap, and solvent vapors in the laboratory account for the majority of contamination problems. The analytical system must be free from contamination under the conditions of the analysis. Running laboratory reagent blanks as described in Section 9.1 demonstrates the system is free of contamination. The use of non-Teflon plastic tubing, non-Teflon thread sealants, or flow controllers with rubber components in the purge and trap system must be avoided.

4.2 Sample contamination occurs by diffusion of volatile organics through the septum seal into the sample during shipment and storage. Trip blanks are prepared from reagent water or methanol as appropriate, and are carried through sampling and subsequent storage and handling steps to serve as a check on such contamination.

4.3 Contamination by carry-over can occur whenever high level and low level samples are sequentially analyzed. To reduce carry-over, the sample syringe must be rinsed with reagent water between sample analyses. Each autosampler position is also monitored for positive hits and subsequent sample analyses are checked for potential carry-over. If carry-over is suspected, the sample is reanalyzed for confirmation. Whenever an unusually concentrated sample is encountered, it should be followed by an analysis of reagent water to check for cross contamination. For samples containing large amounts of water-soluble materials, suspended solids, high boiling compounds or high purgeable levels, it may be necessary to wash the purging device with a detergent solution, rinse it with reagent water, and then dry it in a 105°C oven between analyses. The trap and other parts of the system are subject to contamination; therefore, frequent bakeout and purging of the entire system may be required.

4.4 The response selectivity of a photoionization detector (PID) is used in this method to differentiate aromatic hydrocarbons from aliphatic hydrocarbons. All compounds eluting on the PID chromatogram after o-xylene are identified by the method as aromatic hydrocarbons. This will lead to an overestimation of aromatic hydrocarbons within samples, as the PID will also detect certain aliphatic compounds, particularly unsaturated compounds such as alkenes. This is a limitation of the method, and the significance and implication of the overestimation will vary from sample to sample.

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material safety data sheets is available to all personnel involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

5.1 Lab coats, safety glasses, and gloves must be worn when handling samples, standards, or solvents.

5.2 All standard preparation must be performed in the volatiles hood.

5.3 All expired standards must be placed into the waste bucket in the lab, for future disposal by the Hazardous Waste Manager. The container must be labeled properly with hazard warning labels indicating the container contents. Unopened expired standards get placed in the proper VOA lab pack area designated by the Hazardous Waste Manager.

5.4 Bottles containing flammable solvents must be stored in the flammables cabinet.

6. Sample Collection, Preservation, Shipping and Handling

A summary of sample collection, preservation and holding times is provided in Table 3.

6.1 Sample Collection and Preservation

6.1.1 Aqueous Samples

Aqueous samples are collected in triplicate, without agitation and without headspace, in contaminant-free, 40mL glass VOA vials with Teflon-lined septa screw caps. The Teflon liner must contact the sample. Samples are acidified to a pH of 2.0 or less at the time of collection. This is typically accomplished by adding 3 to 4 drops (0.1 to 0.2mL) of 1:1 HCl (1 part reagent water and 1 part concentrated HCl) to a 40mL sample vial. Samples must be cooled to 4ºC immediately after collection.

The laboratory must determine the pH of all water samples. The pH measurement may be performed on leftover sample. If the pH of any sample is above 2, it must be noted on a narrative report for inclusion in the client report.

6.1.2 Soil Samples

Soil samples are collected in duplicate contaminant free 40mL VOC vials with Teflon-lined septa screwcaps. Soil samples are collected in a manner that minimizes sample handling and agitation. The use of specially designed airtight collection samplers is recommended. All sediment must be removed from the glass threads of the vial to ensure an adequate seal. Samples must be cooled to 4ºC immediately after collection.

Methanol preservation of soil samples is mandatory. Methanol (purge-and-trap grade) must be added to the sample vial before or immediately after sample collection. In lieu of the in-field preservation of samples with methanol, soil samples may be collected in specially designed, airtight sampling devices, provided that the samples are extruded and preserved in methanol with 48 hours of collection.

6.1.2.1 The desired ratio of methanol-to-soil is 1mL methanol / 1 gram soil, ± 25%. The exact weight of the soil sample and volume of methanol must be known or ascertained by the laboratory when calculating and reporting soil concentration data.

In all cases, the soil sample in the vial must be completely covered by the methanol.

6.1.2.2 An additional sample of the soil must also be obtained (without methanol) to be used for the determination of soil moisture content to allow for the calculation of the dry weight results, and to calculate the methanol dilution effect. (See Section 11.3)

6.2 Sample Shipping

A reagent water trip blank accompanies each batch of water samples.

A methanol trip blank accompanies each batch of soil samples.

6.3 Sample Handling

A chain of custody form must accompany all sampling vials and must document the date and time of sample collection and, where appropriate, the volume of methanol added. Observations of vial leakage must be so noted on the laboratory/data report sheet. Any sample received by the laboratory that is not packed in ice or cooled to 4ºC must be so noted on the sample delivery group form.

Aqueous samples must be analyzed within 14 days of collection, soil samples within 28 days of collection.

7. Equipment and Supplies

7.1 Glassware

7.1.1 VOC Vials: 40mL VOC vials with Teflon/silicone septa for soils or waters

7.1.2 Class "A" Volumetric Flasks: 10mL, 50mL, 100mL, and 1,000mL with a ground-glass stopper.

7.1.3 Pasteur Pipets: Disposable.

7.2 Analytical Balance: A top-loading balance capable of weighing to the nearest 0.01g is used for weighing soil samples and taring prepared soil VOA vials containing the methanol.

7.3 Gas Chromatograph:

7.3.1 Gas Chromatograph, Hewlett Packard 6890 (or equivalent): An analytical system complete with temperature programmable gas chromatograph and purge-and-trap concentrator. The data station must be capable of storing and reintegrating chromatographic data and must be capable of determining peak areas using a forced baseline projection.

7.3.2 Chromatographic Column: Restek RTx-502.2, 105M x 0.53mm I.D., 3.0-micron film thickness. Alternative columns may be used as long as the method performance criteria can be met.

7.3.3 Detectors: A Photoionization Detector (PID) is used in series with a Flame Ionization Detector (FID); the PID is first in the series.

7.3.4 **Purge and Trap System:** The purge-and-trap system consists of two separate pieces of equipment: a purging device (autosampler) (EST Centurion or equivalent) coupled to the desorber (concentrator) (EST Encon or equivalent).

7.3.5 Purge/carrier gas = Helium, analytical grade, (99.999%) or Nitrogen analytical grade (99.999%).

7.3.6 The purging device is configured with 5 mL sample purge tubes, and the helium purge gas is introduced at the bottom of the water column as finely divided bubbles

7.3.7 The trap used in the desorber is typically a Supelco "K" trap. Different traps may be used if equivalent performance is demonstrated.

7.3.8 The desorber is capable of rapidly heating the trap to 260°C. The trap is not heated above manufacturer's specifications

7.4 Data System: A computer system is interfaced to the GC for collection of data. Chemstation software is used for data acquisition, and Enviroquant software is used for data reduction and processing.

7.5 Syringes: 5mL, 10mL, and 25mL gas-tight syringe.

7.6 Microsyringes: 1µL, 5µL, 10µL, 25µL, 100µL, 250µL, 500µL, and 1,000µL.

7.7 Spatula: Stainless steel.

7.8 Ottawa sand: SiO2.

8. Reagents and Standards

8.1 Organic-free reagent water: Tap water passed through activated carbon. All references to "reagent water" in this SOP refer to water prepared in this manner.

8.2 Methanol: Purge and Trap grade or equivalent, demonstrated to be free of volatile analytes. Store in flammables cabinet, away from other solvents.

8.3 Stock Standards: All stock standard solutions are purchased from commercial vendors as ampulated certified solutions. When an ampulated stock solution is opened, it is transferred to a labeled amber screw cap vial. The expiration date of the stock solution is either the vendor specified expiration date or 1 month from the date the ampule was opened, whichever is sooner. Store at -10°C to -20°C, protected from light.

8.3.1 **Primary VPH Stock Standard:** (Absolute Standards, Cat # 93624) or equivalent

Component	Concentrations, µg/mL
Pentane	50
2-Methyl pentane	50
Methyl-t-butyl-ether	50
2,2,4-Trimethylpentane	50
Benzene	50
Toluene	50

Nonane	50
Decane	50
Ethylbenzene	50
m-Xylene	50
p-Xylene	50
o-Xylene	50
1,2,4-Trimethylbenzene	50
n-Butylcyclohexane	50
Naphthalene	50
2,5-Dibromotoluene (surrogate)	50

8.3.2 Surrogate Stock Standard: 2,5-Dibromotoluene, 10,000µg/mL; Restek Cat # 30453 or equivalent.

8.3.3 Water LCS/LFB Standard: Contains the same compounds as Section 8.3.1 at a concentration of 50µg/mL, Ultra Scientific Cat # SMA-111-1 or equivalent, obtained from a second primary source.

8.3.4 Soil LCS/MS Stock Standard: VPH Matrix Spike Surrogate (revised), 500ug/mL each compound, Absolute Standard Cat# 93625 or equivalent, obtained from a second primary source.

8.3.5 Liquid MS Stock Standard: VPH Matrix Spike Surrogate (revised), 50ug/mL each compound, Restek Cat# 30605 or equivalent, obtained from a second primary source.

8.4 Intermediate Standards: Intermediate standards are prepared volumetrically by diluting the appropriate stock standard(s) with methanol. Intermediate standards expire one month from the date of preparation, or on the earliest expiration date of any of the stock solutions used to prepare the intermediate standard. Store with limited headspace at -10°C to -20°C.

8.4.1 Surrogate standard solutions: Into a 20mL ground glass stoppered volumetric flask, add 1mL of the stock listed in Section 8.3.2. Bring to volume with methanol. The concentration of the intermediate solution is 500µg/mL. The standard is then transferred into labeled 40mL amber VOA screw cap vials and stored in the volatiles freezer at -10° C to -20°C. Record all preparation information, including preparation date, expiration date, preparer's initials, and methanol lot number in the volatiles standard prep logbook.

8.4.2 VPH Water Surrogate: Take 100µl of the intermediate standard prepared in section 8.4.1, add to 900 ul of methanol. The concentration of this solution is 50µl/ml. The standard is stored in a mininert and stored in the volatiles freezer at -10° C to -20°C. Record all preparation information, including preparation date, expiration date, preparer's initials, and methanol lot number in the volatiles standard prep logbook.

8.5 Initial Aqueous Calibration Standards: Initial calibration standards are prepared at the six concentrations listed in Table 2 by adding the amounts of the stock standard (from Section 8.3.1) for levels one and two listed below to a 100mL volumetric flask filled with organic-free water. Mix aqueous standards by inverting the flask three times. Discard the solution contained in the neck of the flask, and fill a 40ml amber sample vial from the standard solution contained in the expanded area of the flask. For levels three to six repeat process by adding the amounts of the stock standard listed into a 50ml volumetric flask. Aqueous standards are not stable and should be discarded after one hour.

Calibration Level	Amount of Primary VPH Stock (µL)
1	2
2	10
3	20
4	50
5	100
6	200

8.6 Initial Soil/Solid Calibration Standards: Initial calibration standards are prepared at the six concentrations listed in Table 2 by adding the amounts of the stock standard (from Section 8.3.1) for levels one and two listed below to a 100mL volumetric flask filled with organic-free water. Mix aqueous standards by inverting the flask three times. Discard the solution contained in the neck of the flask, fill a 5ml syringe with the calibration standard and add to a non-preserved 40ml amber vial. For levels three to six spike listed amounts from the table below into a 5ml syringe filled with organic free water. Add contents of syringe to a non-preserved 40ml amber vial.

1	2
2	10
3	2
4	5
5	10
6	20

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

9.1 Blank(s)

Analyze a method blank once per analytical batch prior to sample analysis to demonstrate that the system is free of contaminants. The method blank for water samples is 5ml of water with 5µl of VPH Water surrogate (8.4.2) added. The method blank for soil is created by weighing 15g of Ottawa sand into 15ml of methanol, and spiking with 75µl surrogate (8.4.1). A 100µl aliquot of this is taken and added to 4.9ml reagent water to create a method blank for soil samples.

The method blank must not contain any target analytes at or above the compound reporting limits. Samples may not be run until a passing blank is analyzed.

9.2 Laboratory Control Sample (LCS) or Laboratory Fortified Blank (LFB)

An LCS is analyzed with each batch of 20 or less field samples.

The LCS for soil samples consists of weighing 15g of Ottawa sand, adding it to 15ml methanol and spiking with 75µl Soil LCS/MS Stock Standard (8.3.4). A 100µl aliquot of this is taken and added to 4.9ml reagent water.

The LCS for aqueous samples consists of a 5.0mL aliquot of reagent water spiked with 5µL of the LCS stock standard (Section 8.3.3).

The recovery of individual target compounds and hydrocarbon ranges must be between 70% and 130%. If any recovery criteria are not met, the cause of the failure (i.e. degraded standard or instrument problems) must be determined and corrected prior to sample analysis.

- If the recoveries are low and outside of the acceptance limits, reanalyze the LCS and associated samples.
    - If still outside of the acceptance limits recalibrate.
- If the recoveries are high and outside of the acceptance limits and the affected compound was detected in the associated samples, reanalyze the LCS and the associated samples.
    - If recoveries are still outside of the acceptance limits recalibrate.
- If the recoveries are high and sample results were nondetect, data can be reported without qualification; however, the high recoveries should be noted in the laboratory narrative.

9.2.1 Laboratory Fortified Blank Duplicate or Laboratory Control Sample Duplicate (LFBD or LCSD)

A LCSD is analyzed with each batch of 20 or less field samples.

The LCSD for soil samples consists weighing 15g of Ottawa sand, adding it to 15ml methanol and spiking with 75µl Soil LCS/MS Stock Standard (8.3.4). A 100µl aliquot of this is taken and added to 4.9ml reagent water.

The LCSD for aqueous samples consists of a 5.0mL aliquot of reagent water spiked with 5µL of the LCS stock standard (Section 8.3.3).

The recovery of individual target compounds and hydrocarbon ranges must be between 70% and 130%. The RPD for the LCS/LCSD pair must be less than or equal to 25%

9.3 Initial Calibration Verification (ICV)

Refer to Section 10.3.5.

9.4 Continuing Calibration Verification (CCV)

Refer to Section 10.4.

9.5 Matrix Spike (MS) / Matrix Spike Duplicate (MSD)

A Matrix Spike and/or Matrix Spike Duplicate pair is performed at the client's request.

For a liquid sample being purged as a soil/solid, the MS/MSD consists of a 5mL aliquot of a field sample, spiked with 5µL the MS stock standard (Section 8.3.5) or LCS standard (Section 8.3.3).

For a solid sample, the MS/MSD sample vial (a separate VOA sample vial preserved with Methanol) is spiked with 75µL of the MS stock standard (Section 8.3.4) and 100µL aliquot of the Methanol is added to 4.9mL of water and purged.

For a liquid sample the MS/MSD consists of a 43ml aliquot of a field sample, spiked with 43µL the MS stock standard (Section 8.3.5).

The recovery of individual target compounds and hydrocarbon ranges in the MS/MSD, corrected for the concentrations found in the neat sample, must be between 70% and 130% and the %RPD must be <50%. If the recovery criteria are not met but are met in the LCS, the failure may be attributed to sample matrix effects and must be noted on a narrative sheet for inclusion in the client report.

9.6 Laboratory Duplicate

A duplicate sample is analyzed with each batch of 20 or less field samples at the client's request. A duplicate is a split sample, taken from the same sample container and analyzed separately under the same conditions. The %RSDs of the sample and duplicate results are calculated, and must not exceed 50%.

- If RPD exceeds 50% and the results are > 5X the RL, sample analysis must be repeated.
- If an analyte is detected in one of the runs, but not in the other, then analysis must be repeated.
- If an analyte is detected in one analysis at < 5x the RL and not detected in the duplicate analysis, the RPD is not calculable and the analysis does not have to be repeated.

9.7 Method-specific Quality Control Samples

9.7.1 Surrogates

All samples and associated QC samples are spiked with the surrogate spiking solution (Section 8.4.1). The surrogate recoveries must be between 70% and 130%. If any surrogates fail the recovery criteria, the sample should be re-analyzed to determine if the failure is due to sample matrix effects. If matrix effect is confirmed, this must be noted on a narrative sheet for inclusion in the client report.

Exceptions are as follows:

1. When a large amount of target or non-target material is present that co-elutes with the surrogate compound, resulting in a false high recovery. When this is evident by examination of the chromatogram, re-analysis is not required. Note the cause of the high recovery on a narrative sheet for inclusion in the client report.
2. Percent moisture of a soil/sediment sample is >25% and surrogate recovery is 10% or more.
3. The surrogate recovery is high and the sample is non-detect for all target analytes and hydrocarbon ranges.

9.7.2 Additional Instrumental Quality Control

The n-pentane (C_5) and MTBE peaks must be adequately resolved from any solvent front that may be present on the FID and PID chromatograms, respectively. This is achievable using the recommended trap and purge and trap procedures. Coelution of the m- and p- xylene isomers is permissible.

9.8 Method Sequence

The sequence of analysis is as follows:

- Calibration Standards (initial) or mid-range Calibration Check Standard (daily check of initial calibration) (REQUIRED)
- Laboratory Fortified Blank or Laboratory Control Sample (REQUIRED)
- Laboratory Fortified Blank Duplicate or Laboratory Control Sample Duplicate (REQUIRED)
- Laboratory Method Blank (REQUIRED)
- Samples (up to 20 samples)
- Duplicate sample (As requested by Client)
- Laboratory Fortified Matrix/duplicate (As requested by Client)
- Closing mid-range Calibration Check Standard after 20 samples or at the end of the batch. This standard may also be used as the opening standard for a batch. (REQUIRED)

10. Procedure

10.1 Equipment Set-up

10.1.1 Instrument Set-up Conditions

Typical instrument operating conditions are listed below. Alternate conditions are allowed, as long as method performance criteria can be met.

10.1.1.1 GC Conditions

Injection port temperature:	250ºC
Column head pressure:	20psi
Carrier gas:	Helium
Carrier gas flow:	12.5mL/min.
Temperature 1:	45 °C
Hold time 1:	2 minutes
Ramp 1:	3 ºC / minute
Temperature 2:	100 °C
Hold Time 2:	0 minute
Ramp 2:	8 °C / minute
Temperature 3:	160 °C
Hold Time 3:	0 minutes
Ramp 3	20 ºC/ minute
Temperature 4:	230 ºC
Hold Time 4:	11.6 minutes

10.1.1.2 Detector Conditions

The carrier gas flow is augmented with an additional 24mL of helium flow before entering the photoionization detector. This make-up gas is necessary to ensure optimal response from both detectors.

FID detector

Detector temperature: 250 °C
Air flow: 350 mL/minute
Hydrogen flow: 30 mL/minute

PID detector

Detector temp: 250 °C
PID lamp: 10.2 eV
Makeup gas flow: 17.5 mL/minute

10.1.1.3 Purge and Trap Conditions

Purge Time: 11 minutes
Dry purge: 4 minutes
Desorb Preheat: 225 °C
Desorb temp: 230 °C
Desorb Time: 6 minutes

Bake temp: 260 °C
Bake time: 15 minutes

10.2 Equipment Operation and Sample Processing

The same GC, Purge and Trap, and detector conditions used for the initial calibration must be employed for sample analysis. After verification of system performance by analysis of the continuing calibration standard (Section 10.4), a method blank (Section 9.1) and samples are analyzed and processed as described below.

10.2.1 Retrieve sample VOA vials from the sample bank refrigerator just prior to loading onto the Purge and Trap. Soil samples preserved with methanol and QC samples must have Surrogate Standard Solution (Section 8.4.1) added to the sample and methanol and should be vortexed to extract the volatile components into the methanol and mix the surrogate throughout the sample. Let sample settle prior to taking methanol aliquot. Add the spike volume below;

- 75uL for the 15mL Methanol vial.
- 50uL for the 10mL Methanol vial.
- 25uL for the 5mL Methanol vial.

10.2.2 For soil samples, fill the syringe with 4.9mL of reagent water. Add the appropriate amount of the methanol (typically 100µL) to the syringe containing the reagent water.

10.2.3 Samples may be analyzed continuously for up to 24 hours from the analysis start time of the continuing calibration standard.

10.2.4 Identification of an individual analyte occurs when a peak from a sample falls within the daily retention time window (Section 10.3.6). The concentration of an identified target compound is calculated using the Enviroquant data processing software. The Target

methods have been configured to utilize the quantitation formulae found in Alpha's Quality Manual.

Proper quantitation requires the appropriate selection of a baseline from which the peak area can be determined. For the integration of individual Target Analytes and surrogate compounds, a valley-to-valley approach should typically be used, though this approach may be modified on a case-by-case basis by an experienced analyst. See the Manual Integration SOP for integration guidelines.

If the response for any individual analyte exceeds the calibration range of the system, the sample must be rerun on dilution. Whenever possible, dilutions should be made to keep the concentration of the compound in the middle of the calibration curve.

10.2.5 Aliphatic and aromatic ranges of interest are determined by the collective integration of all peaks that elute between the specified range "marker" compounds (Table 4). When quantifying on a peak area basis, collective peak area integration for the fractional ranges must be from baseline (i.e. must include the unresolved complex mixture "hump" areas). This will often require the analyst to perform a manual integration. See the Manual Integration SOP for integration guidelines.

For non-target analytes eluting in the aliphatic or aromatic fractions, the upper linear range of the system is defined by peak height measurement, based upon the maximum peak height documented for an aliphatic or aromatic standard within the fraction that is shown to be within the linear range of the detector.

10.3 Initial Calibration

10.3.1 Prepare a minimum of 5 calibration standards as per Section 8.5 or 8.6.

10.3.2 Establish the GC operating conditions by loading the appropriate GC method. Typical instrument conditions are listed in Section 10.1.1.1. The same operating conditions are used for calibration and sample analyses. Create the analytical sequence using the Chemstation data acquisition software.

10.3.3 Relative Response Factors

The external standard calibration technique is used.

10.3.3.1 Individual Analytes

In each calibration standard, calculate the calibration factors and the relative standard deviation (RSD) of the calibration factors for all aromatic compounds using the Enviroquant data processing software. The calculations are performed automatically, using the formulae listed in Alpha's Quality Manual.

10.3.3.2 Hydrocarbon Ranges

A collective calibration factor must also be established for each hydrocarbon range. Calculate the collective Calibration Factors (CF) for C_5-C_8 Aliphatic Hydrocarbons and C_9-C_{12} Aliphatic Hydrocarbons using the FID chromatogram. Calculate the collective CF for the C_9-C_{10} Aromatic Hydrocarbons using the PID chromatogram. The VPH marker compounds that determine the various ranges are listed in Table 4. The compounds that are included in each of the 3 ranges are listed below:

C_5-C_8 Aliphatic Hydrocarbons:

n-Pentane, 2-Methylpentane, and 2,2,4-Trimethylpentane

C_9-C_{12} Aliphatic Hydrocarbons:

n-Nonane, n-Decane and n-butylcyclohexane

C_9-C_{10} Aromatic Hydrocarbons:

1,2,4-Trimethylbenzene.

10.3.4 Initial Calibration Criteria

If the RSD for an individual analyte is $\leq$ 20% and $\leq$ 25% for hydrocarbon ranges, then the response for this compound is considered linear over the range and the mean calibration factor can be used to quantitate sample results. If the RSD criterion is not met for an analyte, linearity through the origin cannot be assumed. The calibration may be repeated for any compounds that fail, or a separate calibration curve may be generated for this compound and used for sample quantitation.

In order for the linear regression model to be used for quantitative purposes, r (correlation coefficient) must be ≥0.99. In addition, the resulting calibration curve from the linear regression must be verified by using Percent Relative Error (%RE). For linear fit compounds, the %RE must be calculated for the standard at or near the midpoint and at the lowest level of the initial calibration. The %RE between the calculated and expected concentration of an analyte must be ≤ 30%, otherwise recalibration maybe necessary. If recalculated concentrations from the lowest calibration standard are outside the 70-130% recovery range, raise the RL to the concentration of the next highest calibration standard that exhibits acceptable recoveries when recalculated using the final calibration curve.

NOTE: Use of non-linear calibration is not allowed and is considered a significant modification.

10.3.5 ICV

After the calibration an ICV needs to be analyzed with a $\pm$30% recovery. The ICV must be prepared from a separate source standard than used for initial and continuing calibrations. The calibration standard must be analyzed immediately following the initial calibration. The ICV should be prepared at a mid-range calibration curve concentration.

Percent recoveries must be between 70-130%. Recalibrate if >10% of all analytes are outside of criteria.

10.3.6 Retention Time Windows

The retention time windows used for identification of the individual analytes are ± 0.05 RRT (Relative Retention Time) units, based on the most recent standard run. It has been determined that these limits work well, being wide enough to eliminate false-negatives while being tight enough to eliminate false-positive results. Analyst experience also weighs heavily in the determination of positive hits. If uncertainty still exists, confirmation by GC/MS is required.

VPH retention time (Rt) windows of the aliphatic ranges are defined as beginning 0.1 minutes before the Rt of the beginning marker compound and ending 0.1 before the Rt of the ending marker compound, except for C_9, which is both a beginning and ending marker compound for two different ranges.

The C_5 – C_8 Aliphatic Hydrocarbon range ends immediately (0.01 min) before the elution of the n-nonane peak.

The C_9 – C_{12} Aliphatic Hydrocarbon range begins 0.01 min. before the elution of n-nonane.

Therefore, there is no overlap of the two ranges and the n-nonane peak is only included in the C_9 – C_{12} Aliphatic Hydrocarbon range.

The VPH retention time (Rt) window for the C_9-C_{10} Aromatic Hydrocarbons is defined as beginning 0.1 minutes after the Rt of the beginning marker compound and ending 0.1 before the Rt of the ending marker compound.

VPH marker compounds and windows are summarized in Table 4.

10.4 Continuing Calibration

Verify calibration daily, after every 20 samples or less, and at the end of the analytical sequence by analyzing a continuing calibration standard. The concentration of the continuing calibration standard is the same as the Level 4 standard from the initial calibration (Section 8.5 or 8.6). The %D of each response factor must be ≤20% for target VPH analytes and the surrogate, and ≤25% for hydrocarbon ranges except for n-nonane, which must be ≤30%.

10.4.1 If these criteria are not met, inspect the analytical system to determine the cause of the drift and perform necessary maintenance before verifying calibration and proceeding with sample analyses.

10.4.2 If routine maintenance does not return the instrument performance to meet the %D criteria when compared to the last initial calibration curve, then a new initial calibration must be performed.

10.4.3 Closing Mid-range Calibration Verification

Following a batch of twenty or less samples, another CCV (Section 10.4) is analyzed. If this CCV achieves the acceptance criteria specified in Section 10.4, the sample results are considered valid. If this standard fails acceptance criteria, the samples and QC samples analyzed since the last acceptable CCV must be reanalyzed.

This QC sample may also be used as the opening CCV Standard for the next analytical batch if batches are processed continuously.

10.5 Preventive Maintenance

If the response of the PID detector decreases significantly, perform a cleaning of the PID lamp per the manufacturer's instructions. If the response is still low, the PID lamp should be replaced with a new one (PID lamp life is typically 90 - 180 days).

Additional maintenance should be performed to maintain GC system performance. This includes periodic replacement of injector septa, replacement of injector liner(s), and clipping several inches off of the injector end of the capillary column. The trap used in the Purge and Trap equipment will also need periodic replacement, when system performance degrades.

11. Data Evaluation, Calculations and Reporting

11.1 Data Manipulations

By definition, the collective concentrations of aliphatic and aromatic fractions of interest **exclude** the individual concentrations of VPH Target Analytes. Accordingly, a series of

data manipulation steps are necessary to adjust the collective range concentrations to eliminate "double counting" of analytes.

This necessary data manipulation step is taken by Alpha for inclusion on the client report. Subtract the individual concentrations of the Target analytes from the collective concentration of Unadjusted Aliphatic Hydrocarbon ranges. This calculation is performed automatically by Alpha's LIMS system according to the steps listed below.

11.1.1 Subtract the collective concentration of $C_9 – C_{10}$ Aromatic Hydrocarbons from the collective concentration of $C_9 – C_{12}$ Aliphatic Hydrocarbons. If this value is less than the Reporting Limit, report "Not Detected".

11.1.2 Subtract the individual concentrations of the VPH Target Analytes from the appropriate aliphatic range (i.e. $C_5 – C_8$, or $C_9 – C_{12}$ Aliphatic Hydrocarbons) in which they elute. If the individual concentrations of Target Analytes have not been quantitated, report the values as Unadjusted $C_5 – C_8$ Aliphatic Hydrocarbons and Unadjusted $C_9 – C_{12}$ Aliphatic Hydrocarbons, and indicate "Not Determined" for Adjusted $C_5 – C_8$ Aliphatic Hydrocarbons and Adjusted C9 – C_{12} Aliphatic Hydrocarbons.

The extent of data manipulations taken by the laboratory must be noted on the data reporting form.

11.2 Data Reporting Format

The purpose Alpha's reporting format is to provide data users with a succinct and complete summary of pertinent information and data, a clear indication of whether significant modifications were made to the VPH Method, and a clear affirmation on whether the QA/QC procedures and standards specified in this method were followed and achieved. While it is permissible to alter the form and presentation of the data, all of the information must be provided in a clear, concise, and succinct manner.

11.3 LIMS Data Corrections

Please note that the Laboratory Information Management System (LIMS) automatically adjusts soil sample results to account for the % Total Solids of the sample (as determined per Alpha SOP/07-38) and the methanol preservation dilution effect.

12. Contingencies for Handling Out-of-Control or Unacceptable Data

Holding time exceedance, improper preservation and observed sample headspace are noted on a project narrative report by the analyst for inclusion in the data report.

Perform instrument maintenance as described throughout this SOP as needed when instrument calibration criteria are not met. Record all maintenance in the instrument maintenance logbook.

All batch and sample specific QC criteria outlined in Section 10 are evaluated by the analyst prior to approval of the data. When any QC criteria fail, the cause for the failure must be identified and corrected. This may include instrument recalibration followed by sample reanalysis or sample re-extraction. If it is determined that the failure is due to sample matrix effects, a project narrative report is written by the analyst for inclusion in the data report. If there is insufficient sample volume to perform the re-analysis for confirmation, this is also noted in the narrative and included in the client report.

13. Method Performance

The laboratory follows the procedure found in the MADEP "Method for the Determination of Volatile Petroleum Hydrocarbons (VPH), Revision 2.1, February 2018" to determine the MDL on an annual basis. The method detection limits determined by the laboratory are on file for review.

Method performance data is on file in the laboratory QC department. Method performance data for the laboratory is compared to the MADEP VPH method criteria.

13.1 Method Detection Limit Study (MDL) / Limit of Detection Study (LOD)

The laboratory follows the procedure to determine the MDL, and LOD as outlined in Alpha SOP/08-05. These studies performed by the laboratory are maintained on file for review.

13.2 Demonstration of Capability Studies

Refer to Alpha SOP/08-12 for further information regarding IDC/DOC Generation.

13.2.1 Initial (IDOC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

13.3 Initial Demonstration of Accuracy (IDA)

Prepare and analyze seven (7) replicate Laboratory Control Samples (LCSs) fortified at a concentration of 50% of the highest calibration curve standard (100µg/L for waters and 5mg/Kg for soils/sediments). An LCS must be prepared and treated exactly as a typical field sample submitted for analysis, including exposure to all glassware, equipment, solvents and reagents. An LCS for water analyses is prepared by adding 5µL of LCS spiking solution (Section 8.3.3) in purge-and-trap grade Methanol to 5mL of organic-free water (ASTM Type I reagent grade). An LCS for soil/sediment analyses is prepared by adding 5µL of LCS spiking solution (Section 8.3.3) in purge-and-trap grade Methanol to 5 mL of organic-free water (ASTM Type I reagent grade) to obtain an equivalent concentration of 50% of the highest calibration curve standard (5mg/Kg). In addition a matrix specific method blank must be prepared and analyzed. Calculate the mean measured concentration (C_{mean}) of the replicate LCSs for VPH Target Analytes and ranges as follows:

Equation D: Calculation of C_{mean}

$$C_{mean} = \frac{(C_1 + C_2 + C_3 + ...C_n)}{n}$$

Where:

C_{mean} = Mean recovered concentration of the replicate analysis

$C_1 + C_2 + C_3 + ...C_n$ = Recovered concentrations of the replicate 1.2...n

$n = 7$

The value derived for C_{mean} must be within ± 30% of the true value or between 70µg/L and 130µg/L for waters and 3.5mg/Kg and 6.5mg/Kg for solids.

13.4 Initial Demonstration of Precision (IDP)

Using the results calculated from Section 13.3, calculate the percent relative standard deviation (%RSD) of the seven (7) replicate analyses, as indicated in the Equation E below. The %RSD must be less than or equal to 25% for both waters and solids. Higher %RSDs are allowed for n-Nonane, if included in the collective calibration standard for the C_9 through C_{12} aliphatic range. Such allowable non-conformances must be documented.

Equation E: Calculation of %RSD

$$\%RSD = \frac{S_{n-1}}{C_{mean}} \times 100$$

Where:

S_{n-1} = Sample standard deviation (n-1) of the replicate analyses

C_{mean} = mean recovered concentration of the replicate analyses

14. Pollution Prevention and Waste Management

Refer to Alpha's Chemical Hygiene Plan and Waste Management and Disposal SOP for further pollution prevention and waste management information.

VPH MARKER COMPOUNDS

Hydrocarbon Range	Beginning Marker	Ending Marker
C_5-C_8 Aliphatic Hydrocarbons (FID)	0.1 min. before n-Pentane	0.01 min. before n-Nonane
C_9-C_{12} Aliphatic Hydrocarbons (FID)	0.01 min. before n-Nonane	0.1 min. before Naphthalene *
C_9-C_{10} Aromatic Hydrocarbons (PID)	0.1 min. after o-Xylene	0.1 min. before Naphthalene

* The retention time for Dodecane (C_{12}) is approximately 2 minutes less than the retention time for naphthalene, using the column and chromatographic conditions recommended for this method. For simplicity, naphthalene is used as the ending marker for the C_9-C_{12} Aliphatic Hydrocarbon range.

ENV-SOP-WEST-0040 Extractable Petroleum Hydrocarbons (MA-EPH) 2.1

Reference: Method for the Determination of Extractable Petroleum Hydrocarbons (EPH), Massachusetts DEP, BWSC. MADEP-EPH-19-1, Revision 2.1 December 2019.

Quality Control Requirements and Performance Standards for the ***Analysis of Extractable Petroleum Hydrocarbons (EPH)*** in Support of Response Actions under the Massachusetts Contingency Plan (MCP), Section IV B, Rev 1, July 1, 2010

1. Scope and Application

Matrices: This method is suitable for the analysis of waters, soils, sediments, wastes, sludges and non-aqueous phase liquids (NAPL).

Definitions: Refer to Alpha Analytical Quality Manual.

This method is used to measure the collective concentrations of extractable aliphatic and aromatic petroleum hydrocarbons in water and soil. Extractable aliphatic hydrocarbons are collectively quantitated within two ranges: C_9 through C_{18}, and C_{19} through C_{36}. Extractable aromatic hydrocarbons are collectively quantitated within the C_{11} – C_{22} range. These extractable aliphatic and aromatic hydrocarbon ranges correspond to a boiling point range between approximately 150 °C and 265 °C.

This method is based on a solvent extraction, silica gel solid-phase extraction/fractionation process (SPE), and gas chromatography (GC) analysis using a flame ionization detector (FID). This procedure is used by, or under the supervision of, analysts experienced in extractable organics analysis. Analysts must be skilled in the interpretation of gas chromatograms and their use as a quantitative tool. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

This method is also able to measure the individual concentrations of Target Polynuclear Aromatic Hydrocarbons (PAH) Analytes, including Diesel PAH Analytes, in water and soil. Results for these individual analytes are reported at client request. The Method Detection Limits for some of these PAH compounds in water are greater than the notification and/or cleanup standards specified in the Massachusetts Contingency Plan for sites located in drinking water resource areas. In cases where it is necessary to demonstrate compliance with these standards, the use of a GC/MS method in the SIM mode may be necessary.

The fractionation step described in this method may be eliminated to allow for the determination of a Total Petroleum Hydrocarbon (TPH) value, and/or obtain qualitative “fingerprinting” information. While TPH provides little information on the chemistry, toxicity, or environmental fate of petroleum mixtures, it may be a cost-effective screening tool in cases where relatively low concentrations of contamination are suspected.

Petroleum products suitable for evaluation by this method include kerosene, fuel oil #2, fuel oil #4, fuel oil #6, diesel fuel, jet fuel, and certain lubricating oils. This method, in and of itself, is not suitable for the evaluation of gasoline, mineral spirits, petroleum naphthas, or other petroleum products that contain a significant percentage of hydrocarbons lighter than C_9. This method, in and of itself, is also not suitable for the evaluation of petroleum products that contain a significant percentage of hydrocarbons heavier than C_{36}.

This method includes a data adjustment step to subtract the concentration of Target PAH Analytes from the concentration of C_{11} through C_{22} Aromatic Hydrocarbons. This step is taken by the laboratory, and both adjusted and unadjusted values are reported to the client.

Data generated using this method is reported using the required format.

Like all GC procedures, this method is subject to a "false positive" bias in the reporting of Target PAH Analytes, in that non-targeted hydrocarbon compounds eluting or co-eluting within a specified retention time window may be falsely identified and/or quantified as a Target or Diesel PAH Analyte. In addition, this method is subject to a "false negative" bias in the reporting of Target PAH Analytes, in that the ability to identify Target PAH Analytes at low concentrations may be inhibited if a large unresolved complex mixture is present. While cleanup procedures specified in this method to segregate aliphatic and aromatic fractions will serve to mitigate this concern, confirmatory analysis by gas chromatography/mass spectrometry (GC/MS) analysis may be performed in cases where a target PAH analyte identification is suspect.

The data report packages present the documentation of any method modification related to the samples tested. Depending upon the nature of the modification and the extent of intended use, the laboratory may be required to demonstrate that the modifications will produce equivalent results for the matrix. Approval of all method modifications is by one or more of the following laboratory personnel before performing the modification: Area Supervisor, Department Supervisor, Laboratory Director, or Quality Assurance Officer.

This method is restricted to use by or under the supervision of analysts experienced in the operation of the GC/FID and in the interpretation of GC/FID data. Each analyst must demonstrate the ability to generate acceptable results with this method by performing an initial demonstration of capability.

Parameter	CAS
C9-C18 Aliphatic Hydrocarbons	-
C19-C36 Aliphatic Hydrocarbons	-
C11-C22 Aromatic Hydrocarbons	-

Benzo(g,h,i)perylene	191-24-2

2. Summary of Method

Samples submitted for EPH analysis are extracted with methylene chloride, dried over sodium sulfate, solvent exchanged into hexane, and concentrated in a Kuderna-Danish apparatus. Sample cleanup and separation into aliphatic and aromatic fractions is conducted using commercially available silica gel cartridges. The two extracts produced are then re-concentrated to final volumes of 1mL each (i.e., an aliphatic extract and an aromatic extract). The extracts are then separately analyzed by a capillary column gas chromatograph equipped with a flame ionization detector.

Average calibration factors are determined using an aliphatic hydrocarbon standard mixture and are used to calculate the collective concentrations of C_9 through C_{18} and C_{19} through C_{36} aliphatic hydrocarbons. An average calibration factor is determined using a PAH standard mixture and is used to calculate the collective C_{11} through C_{22} aromatic hydrocarbon concentration. Calibration factors determined for individual components of the PAH standard mixture are also used to calculate individual concentrations of Target PAH Analytes

2.1 Method Modifications from Reference

None.

3. Reporting Limits

The Reporting Limits (RLs) of this method for each of the collective aliphatic and aromatic fractional ranges are typically 6.67 mg/kg in soil and 100µg/L in water. The RLs of this method for the Target PAH Analytes is typically 0.33 mg/kg in soil and 10µg/L in water. Table 1 lists our routine reporting limits.

4. Interferences

4.1 High purity reagents are used to minimize interference problems.

4.2 Only high purity gases are used in the GC system to eliminate this source of possible contamination. The air and hydrogen (carrier gas – 99.999%, and detector make-up gas) are certified by the gas supplier.

4.3 Preventive instrument maintenance is performed routinely, and whenever highly contaminated extracts are analyzed that could result in chromatographic interferences or result in degradation of system performance. Section 10.5 details the maintenance steps.

4.4 Glassware must be scrupulously cleaned. This procedure is detailed in the extraction SOPs. Store dry glassware in a clean environment.

4.5 The leaching of plasticizers and other compounds have been observed from commercially available silica gel cartridges used to fractionate EPH sample extracts. This possible source of contamination is continuously monitored and documented by analysis of Laboratory Method Blanks.

4.6 Contamination by carry-over can occur whenever high-concentration and low-concentration samples are sequentially analyzed. Whenever an unusually concentrated sample is encountered, it must be followed by the analysis of a solvent blank to check for possible carry-over. If this is not done and the sample analyzed immediately following the high-concentration sample is free from contamination, then it may be assumed that carry-over is not an issue. However, if this sample did detect analytes which were present in the unusually concentrated sample, reanalysis is required for all samples analyzed after this highly concentrated sample which detected similar analytes.

4.7 Matrix interferences may be caused by contaminants that are co-extracted from the sample. The extent of matrix interference will vary considerably from one source to another depending upon the nature and diversity of the site being sampled. The silica gel SPE cleanup procedure is used to overcome many of these interferences, but some samples may require additional cleanup approaches that are beyond the scope of this method.

4.8 Certain organic contaminants mixed with petroleum product releases, including chlorinated hydrocarbons, phenols, and phthalate esters, will be quantitated as Extractable and Total Petroleum Hydrocarbons. If necessary and/or desirable, additional sample cleanup and/or analytical procedures may be employed to minimize or document the presence of such compounds.

4.9 Because of their weak polar nature, naphthalene and substituted naphthalene's are readily fractionated into the aliphatic extract if excessive amounts of hexane are used to elute the silica gel cartridge/column. Because these compounds constitute a significant percentage of the water-soluble fraction of fuel oils, this occurrence is especially problematic in the analysis of water samples. For this reason, the method requires the evaluation of the aliphatic fraction for the presence of naphthalene and 2-methylnaphthalene in the LCS/LCSD pair on a per batch basis. The fractionation surrogate, 2-Bromonaphthalene, is used to monitor sample-specific fractionation efficiency.

5. Health and Safety

The toxicity or carcinogenicity of each reagent and standard used in this method is not fully established; however, each chemical compound should be treated as a potential health hazard. From this viewpoint, exposure to these chemicals must be reduced to the lowest possible level by whatever means available. A reference file of material safety data sheets is available to all personnel

involved in the chemical analysis. Additional references to laboratory safety are available in the Chemical Hygiene Plan.

All personnel handling environmental samples known to contain or to have been in contact with municipal waste must follow safety practices for handling known disease causative agents.

5.1 Lab coats, safety glasses, and gloves must be worn when handling samples, extracts, standards, or solvents.

5.2 All solvent and extract transfers must be handled in the vented bench area in the GC laboratory.

5.3 All stock standards, working standards, and vialed sample extracts must be placed into the waste bucket in the lab, for future disposal by the Hazardous Waste Manager. The container must be labeled properly with hazard warning labels indicating the container contents.

5.4 Bottles containing flammable solvents must be stored in the flammable's cabinet.

6. Sample Collection, Preservation, Shipping and Handling

6.1 Sample Collection

Aqueous samples are collected in two 1L amber glass jars with teflon-lined lids. Solid samples are collected in 250mL wide-mouth amber glass jars with teflon-lined lids. All containers are purchased pre-cleaned and certified from commercial vendors.

6.2 Sample Preservation

Both aqueous and solid samples are then preserved by packing in coolers with ice or ice packs, to maintain a temperature of 4 ±2 ° C. Additionally, aqueous samples are preserved at the time of sampling by the addition of approximately 5mLs of 1:1 HCl. The sample pH must be less than 2.0 after addition of the acid. Upon receipt at the laboratory, the samples are transferred into sample storage refrigerators to maintain at a temperature of 4 ±2 ° C.

6.3 Sample Shipping

No specific requirements.

6.4 Sample Handling

Aqueous and soil/sediment samples must be extracted within 14 days of sample collection and be analyzed within 40 days of the extraction date. Additionally, if the sample must be frozen it needs to be within 24hours after collection and then it can be extracted up to 14 days after thawing.

7. Equipment and Supplies

7.1 **Gas Chromatograph, Agilent 6890A and 7890A:** An analytical system complete with gas chromatograph configured for split-splitless injection and all required accessories including autosampler syringes, analytical columns, gases, and flame ionization detectors (FID). The systems used for this analysis are configured with dual injectors/dual columns for

7.2 **GC Column:** is listed below. Alternative columns may be used as long as the method performance criteria can be met.

RTx-5MS: Cat. #12624 from Restek or equivalent; 30m, 0.32mm, 0.25µm

7.3 **Microsyringes:** 10µL, 100µL, 250µL, 500µL and 1000µL

7.4 **Volumetric Flasks:** 10mL and 25mL, used for standard preparation.

7.5 Precision liner: Cat. #AGO-4680 from Phenomenex or equivalent

7.6 Siltek FID jet: Cat. #21683, #20673 from Restek or equivalent

8. Reagents and Standards

Reagent grade or pesticide grade chemicals are used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. Other grades may be used, provided it is first ascertained that the reagent is of sufficient high purity to permit its use without lessening the accuracy of the determination.

NOTE: Store the standard solutions (stock, composite, calibration, internal, and surrogate) at 4 ±2 ºC in Teflon(R)-sealed containers in the dark.

8.1 Reagents

8.1.1 Reagent Water: All reagent water is from Alpha's DI treatment system and is demonstrated to be free of interferences or contaminants.

8.1.2 Solvents: Hexane, Methylene Chloride (DCM), and Acetone; pesticide grade or better. Store away from other solvents.

8.2 Stock Standard Solutions: All stock standard solutions are purchased from commercial vendors as ampulated certified solutions. They can be replaced with different standards as long as they contain all target analytes. Stock solutions are stored per manufacturer's recommendations.

8.3 Intermediate/Working Standard Solutions

Intermediate and working standards expire 6 months from the date of preparation or on the earliest expiration date of any of the stock solutions used to prepare it. Standards are stored in the refrigerator. Standard preparation information including the analyst's initials, preparation date, expiration date and standard identifier are recorded.

8.3.1 Calibration Standards

The Aliphatic calibration standards are prepared volumetrically by diluting the appropriate stock standard(s) with hexane. The Aromatic calibration standards are prepared volumetrically by diluting the appropriate stock standard(s) with methylene chloride. Calibrations are performed at the 6 concentration levels listed in Table 2. The list of typical ampulated calibration standards:

- **ALIPHATIC WORKING STANDARD at 200µg/mL:**
  - 1-Chlorooctadecane Solution, Ultra, #IST-470-1 at 2000µg/mL
  - Fractionation Surrogate Spike Mix, Accustandard, #DRH-MA-FSS-50X at 2000µg/mL
  - Naphthalene, Accustandard, #M-502-40-10X at 2000µg/mL
  - 2-Methylnaphthalene, Accustandard, #APP-9-133-20X at 2000µg/mL
  - MA-EPH n-Hydrocarbon Standard, Absolute, #93459 at 2000µg/mL
- **AROMATIC WORKING STANDARD at 200µg/mL:**
  - Fractionation Surrogate Spike Mix, Accustandard, #DRH-MA-FSS-50X at 2000µg/mL

- O-Terphenyl Standard, Accustandard, #DRH-006-SS at 1000µg/mL
- Aromatic Hydrocarbon Standard, Ultra, #SMA-300-1 at 1000µg/mL

8.3.2 Second Source (ICV):

The Aliphatic and Aromatic ICV standards are prepared volumetrically by diluting the appropriate stock standard(s) with hexane and ethylene chloride accordingly. The list of typical ampulated calibration standards:

- **ALIPHATIC ICV STANDARDS at 10ug/mL**:
  - Proposed DEP(MA)-Aliphatic Hydrocarbons, Accustandard, #DRH-007S at 1000µg/mL
  - Naphthalene, Absolute, #90298 at 2000µg/mL
  - 2-Methylnaphthalene, Absolute, #90798 at 2000µg/mL
  - 1-Chlorooctadecane, Restek, #31098 at 10000µg/mL
  - MA-Fractionation Surrogate Spike Mix, Restek, #31480 at 4000µg/ml
- **AROMATIC ICV STANDARDS at 10ug/mL:**
  - Proposed DEP(MA)-PAH Mix, Accustandard, #DRH-006S at 1000ug/mL
  - MA Fractionation Surrogate Spike Mix, Restek, #31480 at 4000µg/mL
  - O-Terphenyl, Restek, #31097 at 10000µg/mL

8.3.3 Surrogate Spiking Solution

The extraction surrogates are 1-chloro-octadecane (COD) and Ortho-Terphenyl (OTP).The surrogate spiking solution is prepared by adding 10mL of MA-EPH Surrogate Spike (Absolute, Cat. #51075 at 2000µg/mL) to a 500mL volumetric flask and bringing to volume with acetone. The final concentration of the spiking solution is **40µg/mL**.

8.3.4 LCS/MS Spiking Solution

This solution is used for preparing Laboratory Control Samples (LCS) and Matrix Spikes (MS), if requested. The solution is prepared by adding 10mL of the MA-EPH Aromatic Hydrocarbons (Absolute, Cat. #50003, at 2000µg/mL, consists of the 17 PAH compounds listed in Table 1) and 10mL of the MA-EPH n-Hydrocarbon Standard (Absolute, Cat. #93459 at 2000µg/mL, consists of the 14 normal alkanes listed in Table 2) to a 200mL volumetric flask and bringing to volume with pentane. The final concentration of the spiking solution is **100µg/mL**. This solution must always be brought to room temperature prior to use.

8.3.5 Fractionation Surrogate Spiking Solution

The fractionation surrogates are 2-Fluorobiphenyl and 2-Bromonaphthalene. This solution is added to all extracted samples and QC samples prior to sample cleanup and fractionation using the silica gel cartridges. This serves as an important check on the ability of the fractionation to accurately separate the aliphatic from the aromatic compounds. The solution is prepared by adding 10mL of the MA Fractionation Surrogate Spike Mix (Restek, Cat. #31480 at 4000µg/mL) and volumetric dilution to 1000mL with hexane. The final concentration of the surrogate solution is **40µg/mL**.

8.3.6 Fractionation Check Solution

This solution is used to monitor the fractionation efficiency of the silica gel cartridge, and to establish the optimum volume of hexane needed to sufficiently elute aliphatic

hydrocarbons from the cartridge without eluting the aromatic hydrocarbons prior to the methylene chloride elution. Fractionation checks are performed whenever a new lot of silica gel cartridges is received, prior to using them for actual samples.

The solution is prepared by adding 1mL of the Aromatic Hydrocarbon Standard (Ultra, Cat. #SMA-300-1 at 1000µg/mL), 1mL of the Aliphatic Hydrocarbon Standard (Ultra, Cat. #SMA-310-1 at 1000µg/mL) and 1mL of Surrogate Spiking Solution (Ultra, Cat. #ISM-580-1 at 2000µg/mL) to a 50mL volumetric flask, bringing to volume with hexane. The final concentration of the solution is **40µg/mL** for Surrogates and **20µg/mL** for aliphatic and aromatic compounds.

8.4 Hydrogen gas: From Alpha generator.

8.5 Zero Air: From Alpha generator

9. Quality Control

The laboratory must maintain records to document the quality of data that is generated. Ongoing data quality checks are compared with established performance criteria to determine if the results of analyses meet the performance characteristics of the method.

9.1 Blank(s)

Extraction blanks are performed with each extraction batch of 20 or less samples, according to the extraction SOPs.

The extraction blank must not contain any of the individual target analytes or hydrocarbon ranges above the reporting limits. If any reportable analytes are detected in the blank, the entire extraction batch is suspect.

- If concentration of contaminant in sample is <10x concentration in blank all samples associated with this blank must be re-extracted and re-analyzed. If re-extraction cannot be performed due to insufficient sample volume CS must be notified immediately.
- No corrective action is required if concentration of contaminant in sample is >10x concentration in blank or if contaminant is not detected in sample.

The surrogate recoveries must also be within the acceptance criteria listed in Section 9.7.1. If surrogate acceptance criteria are exceeded, the extraction batch must be evaluated to determine if re-extraction or re-analysis is necessary.

- If any of the surrogates in the blank are high, but blank is undetected for all target analytes, no corrective action is required.
- If any of the surrogates in the blank are low, but associated samples are undetected for all target analytes with passing surrogates, no corrective action is required.

If any of the surrogates in the blank are low and associated samples have positive hits, re-fractionation and/or re-extraction of the appropriate extracts is required.

9.2 Laboratory Control Sample (LCS)

An LCS/LCSD pair is extracted with each analytical batch of 20 samples or less. The LCS/LCSD consists of an aliquot of a clean (control) matrix similar to the sample matrix and of the same weight or volume. The LCS/LCSD standards must be from a different source than that used for the initial calibration. The LCS/LCSD pair is spiked with aliphatic and aromatic compounds.

The recovery of **alkanes, PAHs and all 3 ranges** must be between **40%-140%** except for **nonane** which must be between **30-140%**.

- If >10% of compounds are above the acceptance criteria (>140%), re-extraction is not required if affected compounds were not detected in associated samples.
- If any recovery criteria are not met, the extract may be re-fractionated to see if the recoveries improve. If the criteria are still not met, the entire batch must be re-extracted. If this is not possible, due to insufficient sample volume or holding time exceedances, the analyst must submit the failure on a narrative sheet for inclusion in the client report.
- The Analytical Batch Precision is determined from the Relative Percent Difference (RPD) of the concentrations (not recoveries) of LCS/LCSD pair. The **RPD** for alkanes and individual Target PAH analytes, aliphatic and aromatic hydrocarbon range concentrations must be **≤ 25 for waters and soils**.

Breakthrough of naphthalene and 2-methylnaphthalene in the aliphatic fraction is calculated. If the breakthrough is **>5%**, all associated samples and QC samples must be re-fractionated.

9.3 Initial Calibration Verification (ICV)

See Section 10.2

9.4 Continuing Calibration Verification (CCV)

See Section 10.4

9.5 Matrix Spike

A Matrix Spike and/or a Matrix Spike/Matrix Spike Duplicate pair are performed at client's request. The MS/MSD is an aliquot of actual sample spiked with the aliphatic and aromatic compounds. The recoveries in the **MS/MSD**, corrected for the concentrations found in the parent sample, must be between **40% and 140%.** If the recovery criteria are not met, but are met in the LCS, the failure may be attributed to sample matrix effects and must be noted on a narrative sheet for inclusion in the client report. If an MS/MSD is performed, the **%RPD** must be **less than 50%** for alkanes and PAHs for results >5x the reporting limit.

9.6 Laboratory Duplicate

Upon Client request, a laboratory duplicate is extracted with each analytical batch of 20 samples or less. The duplicate is a sample aliquot split from the same container as the sample and is extracted and analyzed separately following the same procedures. The RPDs for any hits in the samples, for hydrocarbon ranges or individual analytes (if reported) must be less than 50% when the results are greater than 5x the Reporting Limit. If the RPD criteria are not met, and all other QC criteria are met for the sample and it's duplicate, inspect the sample for possible non-homogeneity. If this is the suspected cause of the high RPD result(s) note this on a narrative sheet for inclusion in the client report. Otherwise, re-extraction of the sample and duplicate, and possibly the entire extraction batch, may be required. If RPD is greater than 50 and both results are >5x the RL you must repeat the analysis. If a Target PAH or Range is detected in one analysis at >5x the RL and not in the duplicate analysis, you must repeat the analysis.

9.7 Method-specific Quality Control Samples

9.7.1 Surrogate

All extracted samples and associated QC are spiked with two extraction surrogates **COD** and **OTP**. Sample extracts are also spiked with the fractionation surrogates **2-bromonaphthalene and 2-fluorobiphenyl** prior to cleanup and fractionation

using the silica gel cartridges. All surrogate recoveries must be between **40% and 140%**. If any surrogates fail the recovery criteria, samples may be re-fractionated and re-analyzed. If the surrogate limits are still not met, the affected samples must be re-extracted to confirm that the failure was due to sample matrix. If matrix effect is confirmed, this must be noted on a narrative sheet for inclusion in the client report; both sets of data are reported.

The only exception to this is when large amounts of extracted material co-elute with any of the surrogate compounds, resulting in false high recoveries. When this is evident by examination of the sample chromatogram, re-extraction or re-fractionation is not required. Note the cause for the high recovery on a narrative sheet for inclusion in the client report.

9.8 Method Sequence

The typical daily analytical sequence is:

- Calibration Check Standard
- Laboratory Method Blank
- Laboratory Control Sample
- Laboratory Control Sample Duplicate
- 20 or less samples
- Duplicate sample (as requested)
- Laboratory Fortified Matrix/duplicate (as requested)
- Calibration Check Standard

10. Procedure

10.1 Equipment Set-up

10.1.1 Sample Extraction

Aqueous samples are extracted at acid pH (less than pH 2) with methylene chloride using a separatory funnel (Method 3510C). See extraction SOP for details.

Solid samples are extracted with methylene chloride using Soxhlet extraction (Method 3540C) or microwave extraction (Method 3546) procedures. See appropriate extraction SOP for details.

10.1.2 Extract Fractionation

Silica gel fractionation is used for sample cleanup and separation into aliphatic and aromatic extracts. Silica gel cartridges are purchased from commercial vendors and tested prior to use. See appropriate extraction SOP for details.

10.1.3 GC Conditions:

A dual-injector/dual-column/dual-detector approach involves the use of the columns listed in section 7.2. This allows for the simultaneous analysis of both fractions. Typical GC conditions are listed below but may be altered as long as method performance criteria are met.

Temperature1: 35 ºC
Time1: 1.14 minutes
Ramp1: 14.05ºC/minute
Final Temperature: 320ºC
Time2: 4 minutes
Total Time: 22.99 minutes
Temperature3: 230ºC

Injector Temperature: 285ºC
FID Temperature: 350ºC
Carrier gas: Hydrogen
Carrier pressure program:
9.89 psi initial
79cm/sec 20.6psi final
Detector Air: 300mL/minute
Detector Hydrogen: 30mL/minute
Injection Volume: 1 µL

10.2 Retention Time Windows

10.2.1 Prior to running an Initial Calibration on the instruments and when a new column has been installed you must compare the retention time windows.

10.2.2 Make 3 separate injections over a 72-hour period of Aliphatic and Aromatic standards to give the windows a broader window.

10.2.3 Record all retention times for each compound and range data points for Aliphatic and Aromatic sides on a spreadsheet to get the standard deviation and three times the standard deviation.

10.2.4 Save the retention time spreadsheet with the instrument for ten years.

10.3 Initial Calibration

10.3.1 Prepare calibration standards using the procedures in Section 8.3.1 at the concentrations listed in Table 2. At the minimum 5 standards must be used or 6 if non-linear regression will be used.

10.3.2 Establish the GC operating conditions by loading the appropriate GC method. Typical instrument conditions are listed in section 10.1.3. The same operating conditions are used for calibrations and sample analyses. Create the analytical sequence using the Agilent Chemstation data acquisition software. Record the calibration standard, unique lot number (EPH#) and analyst's initials in the analytical sequence list.

10.3.3 A 1µL injection volume of each calibration standard is typically used. Other injection volumes may be employed, provided that the analyst can demonstrate adequate sensitivity for the compounds of interest. The same injection volume must be used for calibration standards, samples and QC samples.

10.3.4 Calibration Factors

The external standard calibration technique is employed in this method. Calibration factors are determined for the individual PAH target compounds, the aromatic hydrocarbon range, and the two aliphatic hydrocarbon ranges as described below.

10.3.4.1 Individual PAH Target Compounds: In each standard, calculate the calibration factor for each analyte, the mean calibration factor, and the relative standard deviation (RSD) of the calibration factors. The calculations are performed automatically, using the formula listed in Alpha's Quality Manual and the CF equation below:

Calibration factor: Target PAH Analytes:

$$\textit{Calibration Factor (CF)} = \frac{\text{area of peak}}{\text{concentration injected (ng/µL)}}$$

10.3.4.2 Hydrocarbon Ranges: In each standard, calculate the calibration factor for each range, the mean calibration factor, and the relative standard deviation (RSD) of the calibration factors. The calculations are performed automatically, using the formulae listed in Alpha's Quality Manual.

Range Calibration Factor: Hydrocarbon Ranges:

$$\textit{Range CF} = \frac{\text{Area of Summation of Range Components}}{\text{Total concentration injected (ng/µL)}}$$

10.3.5 Initial Calibration Acceptance Criteria

If the **RSD for an analyte or range is < 25%,** then the response of the instrument for this compound is considered linear over the range and the mean calibration factor can be used to quantitate sample results.

If the **RSD for any analyte or range is > 25%**, then linearity through the origin cannot be assumed. An alternative calculation may be done by the use of linearity as long as the correlation coefficient (r) is **>0.99**. If both of these quantitation methods fail criteria for any compound in the initial calibration, then the system must be reevaluated, and a new calibration curve must be analyzed.

Percent Relative Error (%RE): For linear and quadratic fit compounds, the %RE must be calculated for the standard at or near the midpoint and at the lowest level of the initial calibration. The %RE between the calculated and expected concentration of an analyte must be ≤ 30%, otherwise recalibration is necessary.

10.3.6 Initial Calibration Verification

The initial calibration is verified using a standard source different than that used for the initial calibration. This standard is analyzed immediately after each initial calibration. Percent recoveries must be between **80-120%** for each target analyte.

10.3.6.1 EPH retention time (Rt) windows are defined as beginning 0.1 minutes before the elution of the beginning marker compound and ending 0.1 minutes after the elution of the ending marker compound, except for n-C_{19}, which is both a beginning and ending marker compound for two different ranges.

The C_9 – C_{18} Aliphatic Hydrocarbon range ends immediately (0.1minutes) before the elution of the n-C_{19} peak. The C_{19} – C_{36} Aliphatic Hydrocarbon range begins 0.1 before the elution of the n-C_{19} peak; therefore, there is no overlap of the two ranges and the n-C_{19} peak is only included in the C_{19} – C_{36} Aliphatic Hydrocarbon range.

EPH marker compounds and windows are summarized in Table 4.

10.4 Equipment Operation and Sample Processing

10.4.4 Additional Instrument QC

10.4.1.1 All four surrogate compounds must be adequately resolved from any individual analytes in the aliphatic and aromatic standards.

10.4.1.2 The n-nonane peak must be adequately resolved from the solvent peak.

10.4.1.3 All individual compound peaks in the aliphatic standard must be adequately resolved to baseline. In the aromatic standard, baseline separation must be seen for Phenanthrene and Anthracene. Benzo(a)anthracene, Chrysene, Benzo(b)fluoranthene, Benzo(k)fluoranthene, Dibenzo(a,h)anthracene, and Indeno(1,2,3-cd)pyrene will not demonstrate baseline separation, and may be reported as an un-resolved mixture, unless adequate resolution is obtained. (Adequate resolution is assumed to be achieved if the height of the valley between the two peaks is less than 25% of the average height of the two peaks.)

10.4.1.4The response ratio of C_{28} to C_{20} must be at least 0.85, to demonstrate that the system is not exhibiting mass discrimination. The response ratio for all CCVs is recorded in the instrument sequence log.

10.4.1.5Surrogates 1-Chloro-Octadecane and o-Terphenyl must be adequately resolved from any individual components in the aliphatic and aromatic hydrocarbon standards.

10.4.1.6Peaks for Naphthalene and n-dodecane in the aliphatic hydrocarbon fraction must be adequately resolved to allow for an accurate determination of the naphthalene concentration in the LCS/LCSD pair.

10.4.2 Sample Analysis

10.4.2.1 The same GC operating conditions used for the initial calibration must be employed for sample analyses, including sample injection volume (Section 10.1.3).

10.4.2.2 Samples are analyzed in a set referred to as an analytical sequence. The sequence begins with a mid-level calibration standard, followed by QC samples and sample extractsand ends with a mid-level calibration standard. An instrument solvent blank(s) can be loaded in the sequence after samples that appear to have a high concentration of petroleum hydrocarbons to prevent carryover into following samples. If any samples appear to have carryover in them from the previous sample, they are rerun. Instrument solvent blanks cannot be loaded before any instrument QC such as calibration standards. Inject 1µL sample extract using the solvent flush technique. The sample and calibration standard injection volume must be equal.

10.4.2.3 Establish daily retention time windows for each analyte of interest. Use the absolute retention time for each analyte as the midpoint of the window for that day. The daily retention time window equals the midpoint ± 3 times the standard deviation determined in Section 10.2.6.1. Alternatively, the default value of 0.1 minutes may be used for daily retention time window.

10.4.2.4 Tentative identification of an analyte occurs when a peak from a sample extract falls within the daily retention time window. Confirmation on a second GC column or by GC/MS analysis may be necessary.

10.4.2.5 Validation of GC system qualitative performance must be accomplished by the analysis of midlevel standards within the analysis sequence. If any of the standards fall outside their daily retention time window, the system is out of control. In such cases, the cause of the problem must be determined and corrected. All samples analyzed after the last passing CCV must be reanalyzed.

10.4.2.6 Aliphatic and aromatic ranges of interest are determined by the collective integration of all peaks eluting between specified range “marker”

compounds. The markers are the start time of the eluting peak and the stop time of the eluting peak.

10.4.2.7 When quantifying the aliphatic and aromatic ranges the integration must be from baseline (i.e., must include the unresolved complex mixture, or “hump”, areas). For the integration of individual Target Analytes and surrogate compounds, a valley-to-valley approach should typically be used, though this approach may be modified on a case-by-case basis by an experienced analyst.

10.4.2.8 Baseline correction using a system solvent blank is only permissible for the calculation of aliphatic and aromatic hydrocarbon range concentrations in accordance with the method. However, this correction is not routinely performed by Alpha.

10.4.2.9 If the Target PAH Analytes are to be quantitated using this method and the response for an individual analyte exceeds the linear range of the system, dilute the extract with methylene chloride and reanalyze. Extracts must be diluted so that all peaks are on scale. Overlapping peaks are not always evident when peaks are off scale. Computer reproduction of chromatograms, manipulated to ensure that all peaks are on scale over a 100-fold range, is acceptable if linearity is demonstrated prior to the analysis of samples.

10.4.3.0 For non-target analytes eluting in the aliphatic, aromatic or TPH fractions, the upper linear range of the system must be defined by peak height measurement, based upon the maximum peak height documented for an aliphatic or aromatic standard within the fraction that is shown to be within the linear range of the detector.

Under circumstances that a sample dilution is required because either the concentration of one or more of the target analytes exceeds the concentration of the respective calibration standard, or any non-target peak eluting with any aliphatic or aromatic range exceeds the peak height documented for the highest range-specific calibration standard, the RL for each target analyte and/or range must be adjusted in direct proportion to the dilution factor.

10.4.3.1 When performing dilutions for target analytes over the curve, the target analyte with the highest concentration is diluted to be with 60-80% of the highest calibration standard, so that the RLs will not be unnecessarily raised for analytes not needing dilutions. If there is a diluted and an undiluted run of the same sample the lowest dilution must be sent for TARGETS and the hydrocarbon range.

10.4.4 Data Transmission

When reporting multiple sets of data for a particular QC element or Sample, the “Arolist” file must be sent to the LIMS last in order to ensure that the C11-C22 Aromatic Adjusted Range is calculated correctly.

10.5 Continuing Calibration

10.5.1 The initial calibration curve is verified on each working day prior to the analysis of samples by the injection of the midpoint Calibration Standard. Continuing calibrations are also run throughout the analytical sequence, typically after every 20 samples or every 24 hours (whichever is more frequent) and at the end of analytical sequence. The percent difference (**%D**) for all aliphatic and aromatic analytes must be **less than or equal to**

25% except for **n-nonane**, which must be **<30.** In closing CCAL: up to four (4) compounds may exhibit a %D or % drift >25 but <40.

10.5.2 The Retention Times of each analyte are updated every time a CC is injected.

10.5.3 If the %D criteria cannot be met, inspect the gas chromatographic system to determine the cause and perform whatever maintenance is necessary before verifying calibration and proceeding with sample analysis.

10.5.4 If after maintenance the system still fails the calibration verification criteria, a new initial calibration curve must be analyzed.

10.6 Preventive Maintenance

10.6.1 Preventive Maintenance

Routine preventive maintenance must be performed to maintain GC system performance. This includes periodic replacement of injector septa, replacement of injector liner(s), and clipping several inches off the injector end of the capillary column.

10.6.2 Additional Maintenance

Additional maintenance may be required if system performance degrades. Autosampler syringes and syringe needles must be periodically inspected, especially if erratic response or peak discrimination is seen. If the maintenance steps listed above do not improve system performance, it may be necessary to replace the GC column(s).

11. Data Evaluation, Calculations and Reporting

The concentration reported for a particular hydrocarbon range or individual target analyte in an extract is calculated using the Enviroquant data processing software. The Enviroquant methods have been configured to utilize the quantitation formulas found in Alpha's Quality Manual. Proper quantitation requires the appropriate selection of a baseline from which the peak area or height can be determined. See the Manual Integration SOP for integration guidelines.

11.1 Hydrocarbon Ranges

11.1.1 Aliphatic Fraction

11.1.1.1 Determine the total area count for all peaks start time eluting 0.1 minutes before n-C_9 and 0.1 minutes before the start time elution of n-C_{19}. It is not necessary to identify or quantitate individual aliphatic compounds within this range. The area due to the aliphatic extraction surrogate (COD) must not be included in this area.

11.1.1.2 Determine the total area count for all peaks start time eluting at 0.1 minutes before n-C_{19} and 0.1 minutes stop time after the elution of n-C_{36}. It is not necessary to identify or quantitate individual aliphatic compounds within this range.

11.1.1.3 Using the average calibration factor from the initial calibration, or linear regression analysis (if used), calculate the collective concentrations of C_9 through C_{18} Aliphatic Hydrocarbons, C_{19} through C_{36} Aliphatic Hydrocarbons, and individual concentrations of the sample surrogate, COD.

11.1.2 Aromatic Fraction

11.1.2.1 Determine the total area count for all peaks start time eluting 0.1 minutes before naphthalene and 0.1 minutes stop time after

benzo(g,h,i)perylene. The area due to the aromatic extraction surrogate (OTP) and the fractionation surrogates (2-Fluorobiphenyl and 2-Bromonaphthalene) must not be included in this area.

11.1.2.2 Using the average calibration factor from the initial calibration, or linear regression analysis (if used), calculate the concentrations of Unadjusted C_{11} through C_{22} Aromatic Hydrocarbons, the sample surrogate standard (OTP), and the fractionation surrogates.

11.2 Individual Aromatic Target Analytes

Determine the area for each of the individual PAH analytes found in the aromatic fraction. Using the average calibration factor from the initial calibration, or linear regression analysis (if used), calculate the concentrations of the individual analytes.

11.3 Data Manipulations

11.3.1 The collective concentration of the aromatic fraction (and/or TPH) **excludes** the individual concentrations of the Target PAH Analytes. Accordingly, a data manipulation step is necessary to adjust the collective range concentration calculated in Sections 11.1.1 and 11.1.2, to eliminate 'double counting' of analytes.

This necessary data manipulation step is taken by Alpha for inclusion on the client report. Subtract the individual concentrations of the Target or Diesel PAH Analytes from the collective concentration of Unadjusted C_{11} through C_{22} Aromatic Hydrocarbons and/or Unadjusted TPH. This calculation is performed automatically by Alpha's LIMS system.

Soil samples are reported on a dry-weight basis, utilizing formulae found in Alpha's Quality Manual. This calculation is performed automatically by Alpha's LIMS system.

The extent of data manipulations taken by the laboratory must be noted on the data reporting form. Refer to the MCP EPH WSC-CAM Section 3 and Table IV B-4 for reporting requirements for MCP.

11.3.2 Contamination of SPE Cartridges

11.3.2.1 Range integration areas may be affected by peaks identified during the injection of a Laboratory Method Blank and determined to be attributable to the leaching of plasticizers or other contaminants from silica gel SPE cartridges. In general, this contamination affects the C_{11} – C_{22} Aromatics. **Blank correction is not permissible.**

11.3.2.2 The laboratory must report the presence of this contamination in the associated range. Optionally, the laboratory may perform GC/MS analysis of the laboratory method blank extract to demonstrate that the contaminant in question is not a C_{11} – C_{22} aromatic compound. Analysis of only the method blank is acceptable as long as the associated samples exhibit the same contaminant peak at the same retention time. If demonstrated not to be a C_{11} – C_{22} aromatic compound, the contaminant does not need to be included in the calculation of the hydrocarbon range concentration. The laboratory must provide a discussion

in the case narrative if this approach is used (MADEP-EPH-19-1, section 11.2.6).

12. Contingencies for Handling Out-of-Control Data or Unacceptable Data

Holding time exceedances, improper preservation and observed sample headspace are noted on the nonconformance report form.

Perform instrument maintenance as described throughout this SOP as needed when instrument calibration criteria are not met. Record all maintenance in the instrument maintenance logbook.

All batch and sample specific QC criteria outlined in Section 9 are evaluated by the analyst prior to approval of the data. When any QC criteria fail, the cause for the failure must be identified and corrected. This may include instrument recalibration followed by sample reanalysis or sample re-extraction. If it is determined that the failure is due to sample matrix effects, a project narrative report is written by the analyst for inclusion in the data report. If there is insufficient sample volume to perform the re-analysis for confirmation, this is also noted in the narrative and included in the client report.

13. Method Performance

13.1 Detection Limit Study (DL) / Limit of Detection Study (LOD) / Limit of Quantitation (LOQ)

The laboratory follows the procedure to determine the DL, LOD, and/or LOQ as outlined in Alpha SOP ID 1732. These studies performed by the laboratory are maintained on file for review.

13.1.1 Additional MAEPH Criteria

Analyze over three days a minimum of seven replicates of reagent water and/or clean sand blanks that have been fortified with all analytes or interest. Spiking concentrations are typically 10µg/L for water, and 0.17mg/kg for soil.

13.1.1.1 Water MDLs are determined by extracting a minimum of 7 replicates of 1L reagent water blanks spiked with OTP, COD and each analyte of interest.

13.1.1.2 Soil/sediment MDLs are determined by extracting a minimum of 7 replicates of 15g sand blanks spiked with OTP, COD, and each analyte of interest.

13.1.1.3 The mean accuracy of Nonane (C9), expressed as a percentage of the true value, must be between 30% and 140%. For other analytes, excluding C36, the mean accuracy must be between 40% and 140%. For each analyte, the %RSD must be less than or equal to 25%.

13.2 Demonstration of Capability Studies

Refer to Alpha SOP ID 1739 for further information regarding IDC/DOC Generation.

13.2.1 Initial (IDC)

The analyst must make an initial, one-time, demonstration of the ability to generate acceptable accuracy and precision with this method, prior to the processing of any samples.

13.2.2 Continuing (DOC)

The analyst must make a continuing, annual, demonstration of the ability to generate acceptable accuracy and precision with this method.

13.2.3 Additional MAEPH Criteria

13.2.3.1 Accuracy and Precision

13.2.3.1.1 Extract each replicate according to the extraction SOP and analyze each replicate according to the procedures described in Section 10.3.2.

13.2.3.1.2 Calculate the measured concentrations of each analyte in all replicates, the mean accuracy (as percentage of true value) for each analyte, and the precision (as %RSD) of the measurements for each analyte.

13.2.3.1.3 For each analyte, excluding n-C_{36}, the mean accuracy, expressed as a percentage of the true value, must be within ± 40% of the true value for both aqueous and soil matrices. Poorer recoveries may be experienced for the n-C_{36} standard. For each analyte, the %RSD must be ± 25% for both aqueous and soil matrices. A higher %RSD is allowed for nonane if it is included in the collective calibration standard for the C_9 – C_{18} aliphatic range. Such allowable non-conformances must be documented.

13.2.3.2 Fractionation Efficiency

13.2.3.2.1 To demonstrate the initial capability of properly fractionating aliphatic and aromatic hydrocarbons in a sample, the analyst must first prepare and analyze the Fractionation Check Solution specified in Section 8.3.5.

13.2.3.2.2 To demonstrate the initial capability of properly fractionating aliphatic and aromatic hydrocarbons at least four (4) replicate FCCs must be extracted, fractionated per the appropriate extraction SOP, and analyzed. The mean % Recovery of the subject fractionation surrogates is determined.

13.2.3.2.3 For each analyte within the Fractionation Check Solution, excluding n-nonane, the % mean accuracy for four (4) replicate samples, expressed as a percentage of the mean true value, must be between 40% - 140%. Lower recoveries are permissible for n-nonane. If recovery of n-nonane is < 30%, the source of the problem must be found, and the fractionation check repeated.

13.2.3.3 Subsequent to the initial demonstration of laboratory capability, a Fractionation Check Solution is analyzed for each new lot of silica gel cartridges.

14. Pollution Prevention and Waste Management

Refer to Alpha's Chemical Hygiene Plan and Hazardous Waste Management and Disposal SOP for further pollution prevention and waste management information.

Issued April 01, 2024

CERTIFICATE OF APPROVAL FOR LABORATORY SERVICE

Issued in accordance with and pursuant to section 502 Public Health Law of New York State

MR. JOHN TRIMBLE
ALPHA ANALYTICAL
320 FORBES BOULEVARD
MANSFIELD, MA 02048

NY Lab Id No: 11627

is hereby APPROVED as an Environmental Laboratory in conformance with the National Environmental Laboratory Accreditation Conference Standards (2016) for the category ENVIRONMENTAL ANALYSES NON POTABLE WATER
All approved analytes are listed below:

Perfluorinated Alkyl Acids

Perfluorobutanoic Acid (PFBA)	EPA 1633 (Draft)
Perfluorododecanoic Acid (PFDOA)	EPA 1633 (Draft)
Perfluoroheptanesulfonic Acid (PFHPS	EPA 1633 (Draft)
Perfluoroheptanoic Acid (PFHPA)	EPA 1633 (Draft)
Perfluorohexanesulfonic Acid (PFHXS	EPA 1633 (Draft)
Perfluorohexanoic Acid (PFHXA)	EPA 1633 (Draft)
Perfluorononanoic Acid (PFNA)	EPA 1633 (Draft)
Perfluorooctanesulfonic Acid (PFOS)	EPA 1633 (Draft)
Perfluorooctanoic Acid (PFOA)	EPA 1633 (Draft)
Perfluoropentanesulfonic Acid (PFPES	EPA 1633 (Draft)
Perfluoropentanoic Acid (PFPEA)	EPA 1633 (Draft)
Perfluorotetradecanoic Acid (PFTA)	EPA 1633 (Draft)
Perfluoroundecanoic Acid (PFUNA)	EPA 1633 (Draft)
PFEESA	EPA 1633 (Draft)

Petroleum Hydrocarbons

Diesel Range Organics	EPA 8015D

Phthalate Esters

Benzyl butyl phthalate	EPA 8270E
Bis(2-ethylhexyl) phthalate	EPA 8270E
Diethyl phthalate	EPA 8270E
Dimethyl phthalate	EPA 8270E
Di-n-butyl phthalate	EPA 8270E
Di-n-octyl phthalate	EPA 8270E

Polychlorinated Biphenyls

Aroclor 1016 (PCB-1016)	EPA 8082A
Aroclor 1221 (PCB-1221)	EPA 8082A

Serial No.: 68852

Property of the New York State Department of Health. Certificates are valid only at the address shown and must be conspicuously posted by the laboratory. Continued accreditation depends on the laboratory's successful ongoing participation in the Program. Consumers may verify a laboratory's accreditation status online at https://apps.health.ny.gov/pubdoh/applinks/wc/elappublicweb/, by phone (518) 485-5570 or by email to elap@health.ny.gov.

All approved analytes are listed below:

Polychlorinated Biphenyls

Aroclor 1232 (PCB-1232)	EPA 8082A
Aroclor 1242 (PCB-1242)	EPA 8082A
Aroclor 1248 (PCB-1248)	EPA 8082A
Aroclor 1254 (PCB-1254)	EPA 8082A
Aroclor 1260 (PCB-1260)	EPA 8082A
Aroclor 1262 (PCB-1262)	EPA 8082A
Aroclor 1268 (PCB-1268)	EPA 8082A

Polynuclear Aromatics

Acenaphthene	EPA 8270E
Acenaphthylene	EPA 8270E
Anthracene	EPA 8270E
Benzo(a)anthracene	EPA 8270E
Benzo(a)pyrene	EPA 8270E
Benzo(b)fluoranthene	EPA 8270E
Benzo(g,h,i)perylene	EPA 8270E
Benzo(k)fluoranthene	EPA 8270E
Chrysene	EPA 8270E
Dibenzo(a,h)anthracene	EPA 8270E
Fluoranthene	EPA 8270E
Fluorene	EPA 8270E
Indeno(1,2,3-cd)pyrene	EPA 8270E
Naphthalene	EPA 8270E
Phenanthrene	EPA 8270E
Pyrene	EPA 8270E

Priority Pollutant Phenols

2,3,4,6 Tetrachlorophenol	EPA 8270E

Serial No.: 68852

All approved analytes are listed below:

Priority Pollutant Phenols

2,4,5-Trichlorophenol	EPA 8270E
2,4,6-Trichlorophenol	EPA 8270E
2,4-Dichlorophenol	EPA 8270E
2,4-Dimethylphenol	EPA 8270E
2,4-Dinitrophenol	EPA 8270E
2-Chlorophenol	EPA 8270E
2-Methyl-4,6-dinitrophenol	EPA 8270E
2-Methylphenol	EPA 8270E
2-Nitrophenol	EPA 8270E
3-Methylphenol	EPA 8270E
4-Chloro-3-methylphenol	EPA 8270E
4-Methylphenol	EPA 8270E
4-Nitrophenol	EPA 8270E
Pentachlorophenol	EPA 8270E
Phenol	EPA 8270E

Semi-Volatile Organics

1,1'-Biphenyl	EPA 8270E
1,2-Dichlorobenzene, Semi-volatile	EPA 8270E
1,3-Dichlorobenzene, Semi-volatile	EPA 8270E
1,4-Dichlorobenzene, Semi-volatile	EPA 8270E
2-Methylnaphthalene	EPA 8270E
Acetophenone	EPA 8270E
Benzaldehyde	EPA 8270E
Benzoic Acid	EPA 8270E
Benzyl alcohol	EPA 8270E
Caprolactam	EPA 8270E
Dibenzofuran	EPA 8270E

CERTIFICATE OF APPROVAL FOR LABORATORY SERVICE

Issued in accordance with and pursuant to section 502 Public Health Law of New York State

MR. JOHN TRIMBLE
ALPHA ANALYTICAL
320 FORBES BOULEVARD
MANSFIELD, MA 02048

NY Lab Id No: 11627

is hereby APPROVED as an Environmental Laboratory in conformance with the National Environmental Laboratory Accreditation Conference Standards (2016) for the category ENVIRONMENTAL ANALYSES SOLID AND HAZARDOUS WASTE
All approved analytes are listed below:

Semi-Volatile Organics

Acetophenone	EPA 8270E
Benzaldehyde	EPA 8270E
Benzoic Acid	EPA 8270E
Benzyl alcohol	EPA 8270E
Caprolactam	EPA 8270E
Dibenzofuran	EPA 8270E

Volatile Organics

1,4-Dioxane	EPA 8270E SIM
Ethylene Glycol	EPA 8015D
Isobutyl alcohol	EPA 8015D
tert-butyl alcohol	EPA 8015D

Sample Preparation Methods

	EPA 3570
	EPA 3580A
	EPA 3050B
	EPA 3051A

Serial No.: 68853

Property of the New York State Department of Health. Certificates are valid only at the address shown and must be conspicuously posted by the laboratory. MR. MARCO SOARES
ALPHA ANALYTICAL LLC
8 WALKUP DR
WESTBOROUGH, MA 01581-1019

NY Lab Id No: 11148

is hereby APPROVED as an Environmental Laboratory in conformance with the National Environmental Laboratory Accreditation Conference Standards (2016) for the category ENVIRONMENTAL ANALYSES POTABLE WATER
All approved analytes are listed below:

Bacteriology

Coliform, Total / E. coli (Qualitative)	SM 20, 21-23 9223B (-04) (Colilert)
E. coli (Enumeration)	SM 20, 21-23 9223B (-04) (Colilert)
Heterotrophic Plate Count	SM 20, 21-23 9215B (-04)

Fuel Additives

Methyl tert-butyl ether	EPA 524.2
Naphthalene	EPA 524.2

Microextractables

1,2,3-Trichloropropane, Low Level	EPA 504.1
1,2-Dibromo-3-chloropropane, Low Le	EPA 504.1
1,2-Dibromoethane, Low Level	EPA 504.1

Miscellaneous

Odor	SM 21-23 2150 B (-97)
Organic Carbon, Dissolved	SM 21-23 5310C (-00)
Organic Carbon, Total	SM 21-23 5310C (-00)
Turbidity	SM 21-23 2130 B (-01)
	EPA 180.1 Rev. 2.0

Non-Metals

Alkalinity	SM 21-23 2320B (-97)
Chloride	EPA 300.0 Rev. 2.1
Color	SM 21-23 2120B (-01)
Cyanide	SM 20, 21-23 4500-CN E
Fluoride, Total	EPA 300.0 Rev. 2.1
	SM 21-23 4500-F C (-97)
Nitrate (as N)	EPA 353.2 Rev. 2.0
	EPA 300.0 Rev. 2.1

Expires 12:01 AM April 01, 2025
Issued April 01, 2024

CERTIFICATE OF APPROVAL FOR LABORATORY SERVICE

Issued in accordance with and pursuant to section 502 Public Health Law of New York State

MR. MARCO SOARES
ALPHA ANALYTICAL LLC
8 WALKUP DR
WESTBOROUGH, MA 01581-1019

NY Lab Id No: 11148

is hereby APPROVED as an Environmental Laboratory in conformance with the National Environmental Laboratory Accreditation Conference Standards (2016) for the category ENVIRONMENTAL ANALYSES NON POTABLE WATER
All approved analytes are listed below:

Nitroaromatics and Isophorone

1,3-Dinitrobenzene	EPA 8270E
2,4-Dinitrotoluene	EPA 625.1
	EPA 8270E
2,6-Dinitrotoluene	EPA 625.1
	EPA 8270E
Isophorone	EPA 625.1
	EPA 8270E
Nitrobenzene	EPA 625.1
	EPA 8270E

Nitrosoamines

N-Nitrosodimethylamine	EPA 625.1
	EPA 8270E
N-Nitrosodi-n-propylamine	EPA 625.1
	EPA 8270E
N-Nitrosodiphenylamine	EPA 625.1
	EPA 8270E

Nutrient

Ammonia (as N)	SM 4500-NH3 H-2011
	EPA 350.1, Rev. 2.0 (1993)
Kjeldahl Nitrogen, Total	EPA 351.1 (Rev. 1978)
	SM 4500-NH3 H-2011
Nitrate (as N)	EPA 353.2, Rev. 2.0 (1993)
	EPA 300.0, Rev. 2.1 (1993)
	SM 4500-NO3 F-2016
	EPA 9056A
Nitrate-Nitrite (as N)	EPA 353.2, Rev. 2.0 (1993)

Serial No.: 68690

Property of the New York State Department of Health. Certificates are valid only at the address shown and must be conspicuously posted by the laboratory. Continued accreditation depends on the laboratory's successful ongoing participation in the Program. Consumers may verify a laboratory's accreditation status online at https://apps.health.ny.gov/pubdoh/applinks/wc/elappublicweb/, by phone (518) 485-5570 or by email to elap@health.ny.gov.

All approved analytes are listed below:

Nutrient	
Nitrate-Nitrite (as N)	SM 4500-NO3 F-2016
Nitrite (as N)	EPA 353.2, Rev. 2.0 (1993)
	SM 4500-NO3 F-2016
	SM 4500-NO2 B-2011
Orthophosphate (as P)	SM 4500-P E-2011
Phosphorus, Total	SM 4500-P E-2011
Organophosphate Pesticides	
Atrazine	EPA 625.1
	EPA 8270E
Parathion ethyl	EPA 8270E
Thionazin	EPA 8270E
Petroleum Hydrocarbons	
Diesel Range Organics	EPA 8015D
Gasoline Range Organics	EPA 8015D
Phthalate Esters	
Benzyl butyl phthalate	EPA 625.1
	EPA 8270E
Bis(2-ethylhexyl) phthalate	EPA 625.1
	EPA 8270E
Diethyl phthalate	EPA 625.1
	EPA 8270E
Dimethyl phthalate	EPA 625.1
	EPA 8270E
Di-n-butyl phthalate	EPA 625.1
	EPA 8270E
Di-n-octyl phthalate	EPA 625.1

Issued April 01, 2024

CERTIFICATE OF APPROVAL FOR LABORATORY SERVICE

Issued in accordance with and pursuant to section 502 Public Health Law of New York State

MR. MARCO SOARES
ALPHA ANALYTICAL LLC
8 WALKUP DR
WESTBOROUGH, MA 01581-1019

NY Lab Id No: 11148

is hereby APPROVED as an Environmental Laboratory in conformance with the National Environmental Laboratory Accreditation Conference Standards (2016) for the category ENVIRONMENTAL ANALYSES SOLID AND HAZARDOUS WASTE
All approved analytes are listed below:

Chlorinated Hydrocarbon Pesticides

4,4'-DDE	EPA 8081B
4,4'-DDT	EPA 8081B
Aldrin	EPA 8081B
alpha-BHC	EPA 8081B
alpha-Chlordane	EPA 8081B
Atrazine	EPA 8270E
beta-BHC	EPA 8081B
Chlordane Total	EPA 8081B
delta-BHC	EPA 8081B
Dieldrin	EPA 8081B
Endosulfan I	EPA 8081B
Endosulfan II	EPA 8081B
Endosulfan sulfate	EPA 8081B
Endrin	EPA 8081B
Endrin aldehyde	EPA 8081B
Endrin Ketone	EPA 8081B
gamma-Chlordane	EPA 8081B
Heptachlor	EPA 8081B
Heptachlor epoxide	EPA 8081B
Lindane	EPA 8081B
Methoxychlor	EPA 8081B
Pentachloronitrobenzene	EPA 8270E
Toxaphene	EPA 8081B

Chlorinated Hydrocarbons

1,2,3-Trichlorobenzene	EPA 8260D
1,2,4,5-Tetrachlorobenzene	EPA 8270E
1,2,4-Trichlorobenzene	EPA 8270E

Serial No.: 68691

Property of the New York State Department of Health. Certificates are valid only at the address shown and must be conspicuously posted by the laboratory. Continued accreditation depends on the laboratory's successful ongoing participation in the Program. Consumers may verify a laboratory's accreditation status online at https://apps.health.ny.gov/pubdoh/applinks/wc/elappublicweb/, by phone (518) 485-5570 or by email to elap@health.ny.gov.

CERTIFICATE OF APPROVAL FOR LABORATORY SERVICE

Issued in accordance with and pursuant to section 502 Public Health Law of New York State

MR. MARCO SOARES
ALPHA ANALYTICAL LLC
8 WALKUP DR
WESTBOROUGH, MA 01581-1019

NY Lab Id No: 11148

is hereby APPROVED as an Environmental Laboratory in conformance with the National Environmental Laboratory Accreditation Conference Standards (2016) for the category ENVIRONMENTAL ANALYSES SOLID AND HAZARDOUS WASTE
All approved analytes are listed below:

Chlorinated Hydrocarbons

2-Chloronaphthalene	EPA 8270E
Hexachlorobenzene	EPA 8270E
Hexachlorobutadiene	EPA 8270E
Hexachlorocyclopentadiene	EPA 8270E
Hexachloroethane	EPA 8260D
	EPA 8270E

Chlorophenoxy Acid Pesticides

2,4,5-T	EPA 8151A
2,4,5-TP (Silvex)	EPA 8151A
2,4-D	EPA 8151A
2,4-DB	EPA 8151A
Dalapon	EPA 8151A
Dicamba	EPA 8151A
Dichloroprop	EPA 8151A
MCPA	EPA 8151A
MCPP	EPA 8151A

Haloethers

2,2'-Oxybis(1-chloropropane)	EPA 8270E
4-Bromophenylphenyl ether	EPA 8270E
4-Chlorophenylphenyl ether	EPA 8270E
Bis(2-chloroethoxy)methane	EPA 8270E
Bis(2-chloroethyl)ether	EPA 8270E

Low Level Polynuclear Aromatic Hydrocarbons

Acenaphthene Low Level	EPA 8270E SIM
Acenaphthylene Low Level	EPA 8270E SIM
Anthracene Low Level	EPA 8270E SIM

Serial No.: 68691

Property of the New York State Department of Health. Certificates are valid only at the address shown and must be conspicuously posted by the laboratory. Continued accreditation depends on the laboratory's successful ongoing participation in the Program. NY Lab Id No: 11148

is hereby APPROVED as an Environmental Laboratory in conformance with the National Environmental Laboratory Accreditation Conference Standards (2016) for the category ENVIRONMENTAL ANALYSES SOLID AND HAZARDOUS WASTE
All approved analytes are listed below:

Low Level Polynuclear Aromatic Hydrocarbons

Benzo(a)anthracene Low Level	EPA 8270E SIM
Benzo(a)pyrene Low Level	EPA 8270E SIM
Benzo(b)fluoranthene Low Level	EPA 8270E SIM
Benzo(g,h,i)perylene Low Level	EPA 8270E SIM
Benzo(k)fluoranthene Low Level	EPA 8270E SIM
Chrysene Low Level	EPA 8270E SIM
Dibenzo(a,h)anthracene Low Level	EPA 8270E SIM
Fluoranthene Low Level	EPA 8270E SIM
Fluorene Low Level	EPA 8270E SIM
Indeno(1,2,3-cd)pyrene Low Level	EPA 8270E SIM
Naphthalene Low Level	EPA 8270E SIM
Phenanthrene Low Level	EPA 8270E SIM
Pyrene Low Level	EPA 8270E SIM

Metals II

Chromium VI	EPA 7196A

Minerals

Chloride	EPA 9251
Sulfate (as SO4)	EPA 9038

Miscellaneous

Cyanide, Total	EPA 9014
	EPA 9012B
Phenols	EPA 9065
Specific Conductance	EPA 9050A

Nitroaromatics and Isophorone

2,4-Dinitrotoluene	EPA 8270E
2,6-Dinitrotoluene	EPA 8270E

Serial No.: 68691

Property of the New York State Department of Health. Certificates are valid only at the address shown and must be conspicuously posted by the laboratory. All approved analytes are listed below:

Nitroaromatics and Isophorone	
Isophorone	EPA 8270E
Nitrobenzene	EPA 8260D
	EPA 8270E
Pyridine	EPA 8270E
Nitrosoamines	
N-Nitrosodimethylamine	EPA 8270E
N-Nitrosodi-n-propylamine	EPA 8270E
N-Nitrosodiphenylamine	EPA 8270E
Organophosphate Pesticides	
Parathion ethyl	EPA 8270E
Petroleum Hydrocarbons	
Diesel Range Organics	EPA 8015D
Gasoline Range Organics	EPA 8015D
Oil and Grease Total Recoverable	EPA 9071B (Solvent:Hexane)
Phthalate Esters	
Benzyl butyl phthalate	EPA 8270E
Bis(2-ethylhexyl) phthalate	EPA 8270E
Diethyl phthalate	EPA 8270E
Dimethyl phthalate	EPA 8270E
Di-n-butyl phthalate	EPA 8270E
Di-n-octyl phthalate	EPA 8270E
Polychlorinated Biphenyls	
Aroclor 1016 (PCB-1016)	EPA 8082A
Aroclor 1016 (PCB-1016) in Oil	EPA 8082A
Aroclor 1221 (PCB-1221)	EPA 8082A

Serial No.: 68691
