Buffalo, NY 14203-2999

Dear Ms. Sosa and Mr. Sadowski:

Re: **Five Year Site Remedial Performance Report – 2012 - 2016**
Hyde Park Remedial Program
Bedrock and Overburden Monitoring Programs

In accordance with the July 2006 "Performance Monitoring Plan (PMP)," the following is the Five-Year Site Remedial Performance Report (Five-Year Report) for the period January 1, 2012 through December 31, 2016 for the Hyde Park Landfill Site (Site) located in the Town of Niagara, New York.

As per Section 2.6 of the PMP, "*The Five-Year report will present a review of the Site conditions and a statistical evaluation of the analytical data collected over the preceding five years. The sampling parameters, frequency, and locations will be reassessed. The need to sample the Inner piezometers (piezometer within or near the current or historical NAPL Plume boundaries) will be reviewed. The Five-Year Report will recommend any appropriate modifications to the PMP for the following five years".*

Site Conditions

Operations and monitoring at the Site are conducted in both the overburden and bedrock. There are three active remediation systems installed in the overburden:

- The Source Control (SC) System
- The Existing Barrier Collection System (EBCS) installed in 1978
- The Overburden Barrier Collection System (OBCS) installed in 1992

The overburden monitoring consists of groundwater level monitoring, non-aqueous phase liquid (NAPL) presence monitoring, and groundwater quality monitoring.

There are two active remediation systems in the Lockport bedrock:

- The NAPL Plume Containment System
- The Aqueous Phase Liquid (APL) Containment System

The containment systems are comprised of a combination of monitoring wells and purge wells. The bedrock monitoring programs consists of water level monitoring, NAPL presence monitoring, and groundwater quality monitoring. Fifth-year monitoring of the Bloody Run Creek monitoring wells is also conducted as part of the bedrock monitoring.

Community Monitoring is conducted at the Site, and includes:

- The Gorge Face Seep Inspection

- APL Flux Monitoring
- Community Well Monitoring

The "Annual Site Remedial Performance Evaluation Report" for the period of January 1, 2016 to December 31, 2016 was submitted by GSH on April 28, 2017, and contains the most current Site overburden and bedrock hydraulic and groundwater quality monitoring data. A review of the 2016 data demonstrates that:

1. The overburden monitoring systems are operating properly with overburden containment being achieved.
2. The bedrock monitoring systems are operating properly, and containment is being maintained in each of the flow zones.

Tables 1 through 3 present the Five-Year groundwater sampling data collected in 2016, as per Section 7.0 of the PMP. These tables are also presented in the "Annual Site Remedial Performance Evaluation Report".

In July 2011, the New York State Department of Environmental Conservation (NYSDEC) reclassified the Site on the Registry of Inactive Hazardous Waste Disposal Sites (Registry) to a Class 4 site, indicating that it no longer presents a significant threat to public health and/or the environment for the following reasons (quoted from the NYSDEC "Public Notice - State Superfund Program, Hooker-Hyde Park Landfill" dated July 12, 2011):

1. The Site is a 15-acre parcel that was used for the disposal of chlorinated organic chemicals. Subsequent capping and other remedial activities have increased the footprint of the landfill to nearly 20 acres.
2. A series of remedies to address source area contamination, surface soil contamination, overburden and bedrock groundwater contamination, and a contaminated creek have addressed exposure concerns.
3. A deed restriction is on file, and the site management activities, including community groundwater monitoring and daily site inspections, are ongoing.

In August 2016, the United States Environmental Protection Agency issued their "Fifth Five-Year Review Report" and concluded that "the remedy is functioning as intended by the Site's decision documents. There have been no changes in the physical conditions of the Site that would affect the protectiveness of the remedy. The hydraulic containment stipulated in the RRT has been achieved. EPA issued a dioxin RfD in 2012. The dioxin RfD does not affect the protectiveness of the remedy because there is limited to no access or exposure to the sediment at the mouth of the Bloody Run where dioxin has been historically detected. There have been no other changes in the toxicity factors for the contaminants of concern and there has been no change to the standardized risk assessment methodology that could affect the protectiveness of the remedy."

Statistical Evaluation

A statistical evaluation of the data from 2012 through 2016 was performed, and the results of this evaluation are presented in Attachment 1 "Statistical Evaluation of the Groundwater Monitoring Data – 5-Year Evaluation (2012-2016) Report".

The statistical evaluations (trend test and cluster analysis) conducted on the available monitoring data from 2012 through 2016 of the Lockport Bedrock APL plume containment system, NAPL plume containment system, and Bloody Run Creek monitoring system concluded the following:

1. The APL Plume Containment System had regular detections of organic acid and volatile organic compound (VOC) parameters, indicating continued presence and need for containment of these chemicals. Semi-volatile organic compounds (SVOCs) were infrequently detected (detected in 6 percent of the samples).

2. The NAPL Plume Containment System had regular detections of organic acid, VOC, and SVOC parameters. This would support that the System is successful in capturing impacted groundwater.
3. The Bloody Run Creek Monitoring System results indicate that chlorendic acid, cis-1,2-dichloroethylene, and carbon disulfide remained present at detectable concentrations but SVOCs were not present.
4. Temporal trend analysis of Site Organic Indicators (SOI) concentrations over time revealed nine data sets with decreasing trends and thirteen data sets with increasing trends. These data sets were for either chlorendic acid or VOCs in the Lockport Bedrock APL System (various flow zones).
5. The vast majority of SOI data sets either had no apparent concentration trends over time (141 data sets) or had too few detected results (1008 data sets) to perform a trend test.
6. The cluster analysis results indicate that for most of the APL Flow Zones, at least two wells appear to have very similar chemistry and may represent redundant monitoring effort. If appropriate based on the spatial layout of these wells, it may be worthwhile considering to consider removing some redundant wells from the monitoring program.
7. The cluster analysis results also indicate that there is redundancy in VOC SOIs in a number of APL flow zones and in the Bloody Run Creek System (presumably due mainly to lack of detections of VOCs). Although this is a potential redundant monitoring effort for certain VOCs, there is limited value in removing redundant VOCs from the parameter list since analysis for other VOCs would still be appropriate.
8. Due to low frequencies or no detections of SVOC parameters in the APL Plume Containment and Bloody Run Creek Monitoring Systems, respectively, it is appropriate to consider eliminate SVOCs from future monitoring.

At this time, it is recommended that SVOCs be removed from future monitoring for the APL Containment System and Bloody Run Creek Monitoring System. The next Five-Year Report is due on April 30, 2021.

If you have any questions, please feel free to contact me at 231-670-6809 or by email at joseph_branch@oxy.com.

Very truly yours,

mg/L - Milligrams per liter
µg/L - Micrograms per liter
J - Estimated concentration
NA - Not available
U - Not detected at the associated reporting limit
R - Data Rejected
Value exceeds associated screening level

Subject: **Statistical Evaluation of the Groundwater Monitoring Data**
5-Year Evaluation (2012-2016) Report
Hyde Park Landfill Site
Town of Niagara, New York

1. Introduction

This memorandum presents a statistical evaluation of the chemistry data generated from groundwater quality monitoring efforts over the past five years (2012-2016) at the Hyde Park Landfill Site (Site), located in the Town of Niagara, New York. This memorandum is part of the second 5-Year Report for the Site, and focuses on evaluating sampling parameters, frequencies and locations.

In order to assess the performance of the Site's groundwater monitoring program regarding sampling parameters, frequency and locations, a series of statistical tests were carried out. The following groups of tests/assessments were carried out:

i) The tabulation of summary statistics, including sampling frequencies, detection frequencies, the range of observations obtained, etc., was carried out for all parameters on a per-well basis.

ii) Statistical trend tests of parameter concentration vs. time were carried out on a per-well, per-parameter basis.

iii) Considering a group of nine site organic indicator parameters and sulfate, wells within each flow zone group were subjected to a hierarchical cluster analysis. This procedure was used to identify wells and/or parameters that exhibit similar concentration patterns, which identifies areas in the monitoring program where efforts may be duplicated (e.g., multiple wells monitoring similar groundwater).

The present evaluation focused on groundwater samples collected from Bedrock Monitoring Program wells, specifically those in the Lockport Bedrock APL plume containment system, the NAPL plume containment system and the Bloody Run Creek monitoring program.

2. Statistical Tests

The statistical tests used during this evaluation are described below.

GHD
651 Colby Drive Waterloo Ontario N2V 1C2 Canada
T 519 884 0510 **F** 519 884 0525 **W** www.ghd.com

2.1 Parameter Summary Statistics by Well

In order to assess current conditions in the Site regarding sampling parameters, frequency and locations, a general account of number of parameters analysed and detected by well and number of wells where each parameter was analysed and detected was carried out. The various summary statistics produced were generated via spreadsheet calculations of the original data.

2.2 Trend Tests

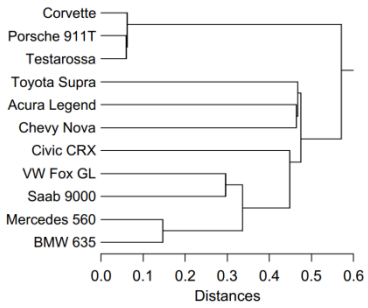
In order to look for evidence of changes (increases or decreases) in parameter concentrations over time, statistical trend tests were performed on a per parameter, per well basis. Statistical procedures for evaluating trends are discussed in United States Environmental Protection Agency (USEPA) and United States Geological Survey (USGS) guidance documents (USEPA, 2006, 2009; USGS, 2002).

The selected statistical procedure for trend evaluation was the Mann-Kendall trend test. This test is a recommended general trend test procedure for detection of *monotonic* (single-direction) trends. It does not make any distributional assumptions (e.g., does not require data to be normally or lognormally distributed) or assumptions of trend shape (e.g., does not require a linear or exponential trend), and is well suited for evaluating environmental data. This procedure is non-parametric (rank-based) and is relatively unaffected by individual outlying observations. The use of the Mann-Kendall test is therefore appropriate for evaluating temporal trends in chemical concentrations in groundwater at the Site. However, the Mann-Kendall test loses sensitivity with increasing presence of non-detect results (e.g., above 50 percent non-detects in a given data set), and is not recommended for such data (e.g., see Table 13.3 of USGS, 2002). The Mann-Kendall test was therefore used to evaluate data sets containing up to 50 percent non-detects. Additionally, data sets having fewer than four observations were deemed unsuitable for trend evaluation (i.e., having too few data to run the Mann-Kendall test with a reasonable expectation/power of detecting any underlying trends) and were not subjected to statistical testing.

Mann-Kendall testing was carried out using a proprietary validated spreadsheet add-in.

2.3 Cluster Analysis

Cluster analysis is a multivariate statistical procedure used to determine natural groupings in data. This analysis uses a correlation matrix, which is a symmetrical table of correlation coefficients for each variable (e.g., well or parameter in this case) with all other variables (Sokal and Rohlf, 1997). Cluster analysis, as performed in the present evaluation, sequentially “joins” together observations (in this case, groundwater samples) such that more similar observations are joined first, and less similar observation are joined last. By looking at patterns in the “tree” produced in the cluster analysis output, different branches may be identified that represent groupings. For example, in the following example output (taken from the SYSTAT software manual), cars with more similar performance characteristics fall into different logical groups based on clustering of the input data (acceleration, stopping distance, etc.).



Cluster analyses were performed for each flow zone group of wells considering the last five years of monitoring data for each of nine site organic indicators (see Section 3 below for a list) and sulfate. Since cluster analysis does require that the data used are normally distributed (or at least reasonably symmetrically distributed), the concentration data used were log-transformed prior to the analysis, reflecting the observed log-distribution of data sets with sufficient detected values to test. Any non-detects were assigned a value equal to one-half of the most-common detection limit, to avoid variation in detection limits unduly influencing the results. Cluster analysis was carried out using SYSTAT version 10, a commercial statistics package.

3. Scope of Data

The Bedrock Monitoring Program consists of groundwater monitoring in two systems: the Lockport bedrock and the Bloody Run Creek monitoring systems, which are described below.

A. The Lockport Bedrock Monitoring System:

There are two active remediation systems in the Lockport bedrock:

i) The APL Plume Containment System: 59 piezometers sampled and analyzed for VOCs, SVOCs, Organic Acids, and Sulfate. Included in the system are piezometers located beyond the limits of the NAPL plume boundaries, which are designated as Outer piezometers. Only piezometers yielding sufficient water are included in the sampling program. The piezometers are distributed along eleven bedding-parallel groundwater flow zones. Monitoring of these locations generally consists of annual analysis of VOCs, SVOCs and sulfate, along with quarterly analysis of organic acids.

ii) The NAPL Plume Containment System: 17 purge wells sampled and analyzed for VOCs, SVOCs, Organic Acids, and Sulfate. These wells were sampled once during the five-year evaluation period, in 2016.

B. The Bloody Run Creek Monitoring System:

Four monitoring wells are monitored along the Bloody Run Creek. Samples collected are analyzed for VOCs, SVOCs, and Organic Acids. Sampling at these wells occurred once during the five-year evaluation period, in 2016.

From the full target compound list of chemicals sampled (VOCs, SVOCs, and Organic Acids), nine Site Organic Indicators (SOIs) are identified in the Site's Performance Monitoring Plan, based on comparisons of the Site data to screening levels. The basis for identifying the SOIs was that these parameters exceeded a screening level in more than one Outer piezometer. The nine SOIs are:

Site Organic Indicator (SOI)	Comment
Chlorendic Acid	Site-related organic acid
Benzene	Common petroleum hydrocarbon
1,1,2,2-Tetrachloroethane (1,1,2,2-PCA)	Common industrial solvent
Tetrachloroethene (PCE)	Common industrial solvent
Trichloroethene (TCE)	Common industrial solvent
cis-1,2-Dichloroethene (cis-1,2-DCE)	Degradation product of PCE and TCE
Vinyl chloride	Degradation product of PCE and TCE
bis(2-Ethylhexyl)phthalate (BEHP)	Common laboratory contaminant
Methylene chloride	Common laboratory contaminant

An additional inorganic parameter included in the monitoring program, and considered in the statistical analyses, is sulfate. The Site's Performance Monitoring Plan indicates that sulfate concentrations are an important component of the monitoring program, providing information on relative age of the groundwater.

Groundwater samples collected during the last five years (2012-2016) at different sampling frequencies were used for this evaluation. Considering the three types of statistical evaluations performed, the following parameters were considered:

i) Statistical summaries were produced for the entire list of acids, VOCs, SVOCs and sulfate in all wells included in the Lockport Bedrock and Bloody Run Creek Monitoring Systems.

ii) For the trend tests, the nine SOIs and sulfate were considered for all wells in the Lockport Bedrock System. In general, other organic parameters were not detected in groundwater samples collected over the past 5 years (2012-2016), preventing any meaningful assessment of temporal trends. Trends were not assessed for wells in the Bloody Run Creek Monitoring System, as only one sampling event occurred in the past 5 years.

iii) Similarly, the cluster analyses considered only the nine SOIs and sulfate. Cluster analyses were performed for the NAPL purge wells and wells in eight bedrock flow zone groups where monitoring is carried out. A modified cluster analysis (individual trees, not a matrix) was conducted using monitoring data from the Bloody Run Creek wells, due to only a single sampling event and low detection frequencies for monitored parameters.

4. Results

The results from the statistical tests are summarized below.

4.1 Statistical Data Summary

The data sets considered, along with the summary statistics produced, are listed in Table 1. A total of 7126 data sets (approximately 90 chemicals analyzed at least once in the past five years in groundwater samples from the 80 wells) were evaluated. Of these 7126 data sets, only 1129 (16 percent) include at least one detected concentration during the past 5 years. A breakdown by monitoring system is shown in the following table.

	Lockport Bedrock Monitoring System		*Bloody Run Creek Monitoring System*
	APL Plume Containment System	*NAPL Plume Containment System*	
Number of data sets	5304	1474	348
Number with detects	584	528	17
Percentage with detects	11%	36%	5%

Of the 90 parameters included in monitoring, 24 were not detected in any wells over the past five years. Another 27 parameters were rarely detected (i.e., in fewer than 10 wells), and 34 parameters were infrequently detected (in more than 10, but fewer than half of the monitoring wells). There were five parameters that were detected relatively frequently, in more than 50 percent of the wells included in the monitoring program. These included:

Sulfate (80 of 80 wells sampled)	*cis*-1,2-DCE (47 of 80 wells)	Carbon disulfide (50 of 80 wells)
Chlorendic acid (49 of 80 wells)	Toluene (48 of 80 wells)	

The breakdown of percentage of detected parameters by groups (acids, SVOCs and VOCs) and by monitoring system is:

- APL Plume Containment System (59 piezometers):
  - Acids were detected in 62 percent of samples collected from the piezometers. The most frequently detected acid was chlorendic acid (342 detections in 564 samples).
  - SVOCs were detected in 6 percent of the samples collected from the piezometers. The most frequently detected SVOCs were BEHP (12 detections in 244 samples), 2,4-dimethylphenol (10 detections in 244 samples) and phenol (9 detections in 244 samples).
  - VOCs were detected in 34 percent of the samples collected from the piezometers. The most frequently detected VOCs were: cis-1,2-DCE (95 detections in 244 samples), toluene (84 detections in 244 samples), benzene (78 detections in 244 samples), carbon disulfide (77 detections in 244 samples) and chlorobenzene (74 detections in 244 samples).

- NAPL Plume Containment System (17 wells):
  - Acids were detected in 100 percent of the samples collected from the wells. The most frequently detected acid was chlorendic acid (in 16 wells; all except PW-4U). The other four acids monitored (benzoic acid, 2-chlorobenzoic acid, 3-chlorobenzoic acid and 4-chlorobenzoic acid) were each detected in 12 NAPL puge wells.
  - SVOCs were detected in 83 percent of the samples collected from the wells. The most frequently detected SVOCs were phenol (detected in 12 wells), hexachlorobutadiene (detected in 9 wells), hexachlorobenzene (detected in 8 wells), hexachloroethane (detected in 7 wells) and 2,4-dichlorophenol (detected in 7 wells).
  - VOCs were detected in 100 percent of the samples collected from the wells. There is a large group of 23 VOC parameters that were detected in 13-17 of the 17 wells (i.e., VOCs are frequently detected in NAPL purge wells).
- Blood Run Creek Monitoring System (4 wells):
  - Acids: only chlorendic acid was detected in 3 of the 4 wells
  - SVOCs were not detected in any of the 4 samples collected.
  - VOCs were detected in all 4 samples collected (1 per well). The most frequent detected VOCs were: cis-1,2-DCE (detected in 3 wells) and carbon disulfide (detected in 2 wells).

4.2 Trend Tests

Table 2 presents the results for the Mann-Kendall trend tests performed on the SOIs data and for sulfate. Of the 1171 data sets evaluated, 1008 were not suitable for trend analysis due to insufficient detected data (i.e., fewer than 50 percent detected observations). Out of the remaining 163 data sets tested, 141 had no statistically significant trend, nine had statistically significantly (above 95 percent confidence) decreasing trends, and thirteen had increasing trends in parameter concentrations over time between 2012-2016. The data sets with statistically significant trends are summarized below.

Well	*Monitoring Program*	*Parameter*	*Trend Test Conclusion*
AGW-1M-07	LB - APL (flow zone 7)	chlorendic acid	Decreasing
AGW-1M-09	LB – APL (flow zone 9)	chlorendic acid	Increasing
D1M-09	LB – APL (flow zone 9)	benzene	Decreasing
D1U-04	LB - APL (flow zone 4)	chlorendic acid	Decreasing
D2U-04	LB - APL (flow zone 4)	sulfate	Increasing
F2L-11	LB - APL (flow zone 11)	benzene	Increasing
F2M-09	LB – APL (flow zone 9)	chlorendic acid	Increasing
F2U-02	LB - APL (flow zone 2)	chlorendic acid	Increasing
G6-02	LB - APL (flow zone 2)	cis-1,2-DCE	Decreasing
G6-04	LB - APL (flow zone 4)	chlorendic acid	Increasing

Well	Monitoring Program	Parameter	Trend Test Conclusion
G6-04	LB - APL (flow zone 4)	cis-1,2-DCE	Decreasing
G6-05	LB - APL (flow zone 5)	benzene	Increasing
G6-05	LB - APL (flow zone 5)	PCE	Increasing
G6-05	LB - APL (flow zone 5)	TCE	Increasing
G6-05	LB - APL (flow zone 5)	vinyl chloride	Increasing
G6-06	LB - APL (flow zone 6)	cis-1,2-DCE	Increasing
H2U-02	LB - APL (flow zone 2)	chlorendic acid	Decreasing
H2U-02	LB - APL (flow zone 2)	cis-1,2-DCE	Decreasing
H2U-02	LB - APL (flow zone 2)	vinyl chloride	Decreasing
H5-07	LB - APL (flow zone 7)	TCE	Decreasing
H5-09	LB – APL (flow zone 9)	chlorendic acid	Increasing
I1-07	LB – APL (flow zone 1)	chlorendic acid	Increasing

Note: LB – APL: the Lockport Bedrock Monitoring System – APL plume containment system.

4.3 Cluster Analysis

Hierarchical cluster analyses were performed grouping wells within a flow zone group considering the nine SOI parameters and sulfate. The results of the cluster analysis are shown in Figures 1-10. In these figures, the connecting lines to the right of the correlation matrices show which wells are more similar (lines connecting close to the matrix) and different (lines connecting further from the matrix) from one another. Similarly, the connecting lines at the bottom of the correlation matrices show which analytes are more similar or more different. Where wells or parameters are joined quickly together (i.e., are more similar), these may indicate overlap/duplication of monitoring efforts, and could be adjusted to optimize the monitoring program. Apparent groups with overlaps are summarized in the following table:

Well Group	Similar wells	Similar parameters
Flow Zone 1	I1-01 and H2U-01	i) Benzene and MC ii) cis-1,2-DCE and TCE iii) PCE, 1,1,2,2-PCA and VC
Flow Zone 2	F2U-04, F2U-02, J6-02, H5-02 and to a lesser extent I1-02	i) cis-1,2-DCE and TCE ii) 1,1,2,2-PCA and PCE iii) The 7 VOC SOIs
Flow Zone 4	All wells but H5-04 and G6-04	cis-1,2-DCE, TCE, VC, benzene, 1,1,2,2-PCA and PCE
Flow Zone 5	All wells but D1U-05 and G6-05	cis-1,2-DCE, TCE, 1,1,2,2-PCA, VC and benzene
Flow Zone 6	G1M-06 and F6-06	benzene, MC, 1,1,2,2-PCA and PCE
Flow Zone 7	H5-07, J6-07, I1-07 and AGW-1M-07	The 7 VOC SOIs

Well Group	Similar wells	Similar parameters
Flow Zone 9	Not as similar as other flow zones AGW-1M-09 and F2M-09	6 of the 7 VOC SOIs (excluding benzene)
Flow Zone 11	B2L-11, E6-11 and J6-11	6 of the 7 VOC SOIs (excluding benzene)
Purge Wells	i) PW-5MR and PW-6MR ii) PW-2L, PW-3L, PW-10U, PW-8U and PW-6UR iii) APW-1 and PW-1L	More dissimilar than in flow zones (1,1,2,2-PCA, PCE, MC, benzene and VC are somewhat similar)
Bloody Run Creek	BR-2 and BR-4	VC, MC, 1,1,2,2-PCA, benzene and PCE

The cluster analysis results generated considering data from the APL containment system piezometers generally show that SOI concentrations are fairly similar within the same Flow Zone. This is particularly evident for VOC SOIs, likely due to the prevalence of non-detect results for these parameters (particularly in in Flow Zones 7, 9 and 11). The monitoring results for Flow Zones 4, 5 and 7 are quite consistent across the wells monitored, indicating an apparent lack of variation in chemistry within these flow zones.

From inspection of the cluster analysis matrices (see Figures), certain wells appear to be more distinctive in terms of SOI concentrations. These include:

- Flow Zone 1 G6-01 (particularly for VC, 1,1,2,2-PCA, PCE)
- Flow Zone 2, G6-02 (VC, 1,1,2,2-PCA, PCE and TCE)
- Flow Zone 4, G6-04 (all VOC SOIs but MC)
- Flow Zone 5, G6-05 (VOC SOIs except PCE and MC)
- Flow Zone 6, H2M-06 (primarily TCE)
- Flow Zone 7, C3-07 (low chlorendic acid)
- Flow Zone 9, H2M-09 and H5-09 (low chlorendic acid)
- Flow Zone 11, G6-11 (low chlorendic acid)
- Flow Zone 11, AFW-1L-11 (low benzene)
- Within the NAPL Purge wells, there is a group of 5 wells with low VOC SOI concentrations (top of Figure 9 – APW-2, APW-1, PW-1L, PW-2M, PW-7U). There are also 4 or so wells with higher VOC concentrations (bottom of Figure 9 – PW-6MR, PW-5UR, PW-3M, PW-4U).

Variations in sulfate concentrations are generally different from other parameters for wells within the same flow zone (not for the NAPL purge wells). This is likely reflective of its high detection frequency relative to the SOIs at most wells. Chlorendic acid concentrations appear to have relatively high variability across wells in Flow Zone 2, and to a lesser degree in Flow Zone 9.

The cluster analysis for the Bloody Run Creek System was conducted using individual trees (as opposed to a matrix) due to only having one observation per well. Wells BR-2 and BR-4 appear to have the most similar SOI concentrations, while well BR-1 has the most dissimilar SOI concentrations relative to the other locations. Five of the seven VOC SOIs are tightly clustered (i.e., are not detected in samples from the Bloody Run Creek System).

5. Conclusions

Based on the statistical evaluations performed considering the monitoring data generated from 2012-2016 sampling of the Lockport Bedrock APL, NAPL purge well and Bloody Run Creek monitoring systems, the following conclusions are made:

1) In the APL Plume Containment System, regular detection of acid and VOC parameters is noted, indicating continued presence and need for containment of these chemicals. SVOCs are infrequently detected.

2) The NAPL Plume Containment System has regular detections of acid, VOC and SVOC parameters. This would support that the System is successful in capturing impacted groundwater.

3) The Bloody Run Creek Monitoring System results indicate that chlorendic acid, cis-1,2-PCE and carbon disulfide, but no SVOCs, remain present at detectable concentrations.

4) Temporal trend analysis of SOI concentrations over time revealed nine data sets with decreasing trends, and thirteen data sets with increasing trends (see list in Section 4.2 above). These data sets were for either chlorendic acid or VOCs in the Lockport Bedrock APL System (various flow zones).

5) The vast majority of SOI data sets either had no apparent concentration trends over time (141 data sets), or had too few detected results (1008 data sets) to perform a trend test.

6) The cluster analysis results indicate that for most of the APL Flow Zones, at least two wells appear to have very similar chemistry and may represent redundant monitoring effort (see Figures and list in Section 4.3 above). If appropriate based on the spatial layout of these wells, it may be worthwhile considering removing some redundant wells from the monitoring program.

7) The cluster analysis results also indicate that there is redundancy in VOC SOIs in a number of APL flow zones and in the Bloody Run Creek System (presumably due mainly to lack of detections of VOCs). Although this is a potential redundant monitoring effort, the nature of laboratory analysis is such that a VOC scan typically analyzes all VOCs at once, so there is not a strong motivation to try to remove redundancy within these VOC SOIs.

8) Due to low frequencies or no detections of SVOC parameters in the APL Plume Containment and Bloody Run Creek Monitoring Systems, it may be appropriate to consider eliminating SVOCs from future monitoring, at least for some locations and/or flow zones.

Based on these findings, continued monitoring of the three Systems and reevaluation of the monitoring data during the next 5 year review is appropriate and warranted.
