December, 1999

EXECUTIVE SUMMARY

The former Carborundum Company's Hyde Park facility ("site") in Niagara Falls is listed on the New York State Department of Environmental Conservation's (NYSDEC) list of Inactive Hazardous Waste Disposal Sites. The site, which is classified as a Class 2 site, is identified as Site No. 932036. A Class 2 site is defined as a site that poses a significant threat to the public health or the environment and requires mitigative action.

A Remedial Investigation (RI) of the site was completed in 1996 by Duke Engineering & Services, Inc. (DE&S), a Phase II RI was completed in May 1998, and a borehole investigation was completed as part of this interim remedial measure (IRM) in September 1998. Results of the RI, Phase II RI and IRM investigation indicate that soils in five areas on the property contain volatile organic compounds (VOCs) and/or polycyclic aromatic hydrocarbons (PAHs) at concentrations that exceed NYSDEC Soil Cleanup Objectives.

A work plan and a plans and specifications document for conducting soil removal as part of an IRM were submitted and approved by the NYSDEC. An IRM is a planned action(s) that can be conducted without extensive investigation and is designed to be a permanent part of the final remedy for a site. The purpose of this IRM was to excavate contaminated soils from the property in order to remove a source of contamination to groundwater. The overall objective of the IRM was to affect an improvement in groundwater quality with time following source removal.

The specific objectives of the IRM included:

- i) Refine the extent of known soil contamination to allow cost-effective and efficient removal of soils. This objective was achieved through a borehole drilling and soil sampling program to refine the extent of contamination.
- ii) Excavate contaminated soils and test to determine appropriate disposal options. This objective was achieved through a test pit program that allowed pre-characterization of soils for disposal.
- iii) Dispose of soil at appropriate facility.

The IRM field program included the installation of boreholes and collection of soil samples prior to excavation plan development to define the lateral and vertical extent of soils containing contaminants of concern (COCs) at concentrations that exceed:

- NYSDEC Soil Action Levels that are listed in the "Contained-In" Policy, and
- NYSDEC Soil Clean-up Objectives that were determined for the site based on the procedure described in NYSDEC TAGM HWR-94-4046, January 24, 1994.

During the IRM drilling program, 39 boreholes were completed within the fenced area of the facility to supplement previous soil sampling and to better define the lateral and vertical extent of soils containing COCs above NYSDEC Soil Clean-up Objectives.

Following the IRM investigation, an air dispersion model was constructed to evaluate the potential impact of excavation activities on employees currently working at the former Carborundum Company Facility, and to the general public in the vicinity of the site. The air model was used to help develop an excavation plan that would minimize potential air impacts during execution of the IRM. Concerns for potential emission or volatilization of contaminants into the air during excavation and removal of contaminated soil were evaluated by using the air model to simulate excavation conditions at the site. This simulation was constructed to mimic site weather, wind pattern, and contaminant concentrations in soil as closely as possible. The results of the air modeling indicate that emission of contaminants from the site during excavation could be significantly reduced if stockpiling of contaminated soils on site could be eliminated or reduced. In addition to air modeling, continuous air monitoring was conducted during excavation at the site to ensure that site workers and area residents were not exposed to VOCs in air or excessive dust. No significant VOC or dust concentrations were detected during the IRM that would indicate a potential for site worker or community concern.

Based on the results of the air modeling work, a test pit sampling program was conducted in April 1999. The purpose of the test pit sampling was to pre-characterize contaminated soils for disposal purposes. This pre-characterization allowed the excavation of soils directly onto trucks to be hauled off-site to an appropriate disposal facility, minimizing the need to stockpile soils on-site.

Soil excavated from the site was segregated into three categories for disposal purposes. These categories include:

1. Clean Soils - Soil with contaminant concentrations below the NYSDEC soil clean-up objectives for VOCs and/or PAHs.
2. Non-Hazardous Soils - Soil with contaminant concentrations above the clean-up objectives for VOCs and/or PAHs, but below the action level concentrations for VOCs. There are no action level concentrations for PAHs.
3. Action Level Soils - Soil with contaminant concentrations above NYSDEC action levels for VOCs.

A total of 67 test pits were spatially located within planned excavation areas at a frequency of approximately one per 800 ft² area. At least two test pits were located in each excavation subarea. Test pits were located so that they did not overlap previous sampling locations in order to identify any unknown localized zones of contamination. The results from test pit sampling determined that contaminated soils at the site could be disposed as non-hazardous waste, except for soils in three areas: Areas 2C, 2D and 5. Soils from areas 2D, part of 2C, and 5 were managed as action level soils and disposed in a RCRA Part 373 landfill. Soils from Area 2D failed Toxic Characteristic Leachate Procedure (TCLP) testing due to trichloroethene and were disposed using waste code D040. Soils from Area 5 also failed TCLP testing due to lead and were disposed using waste code D008. Soils from part of Area 2C exceeded action levels for vinyl chloride and trichloroethene. Soils from this area were disposed using waste codes U043 and U228.

A photoionization detector (PID) was used to screen soils for VOCs as they were excavated. Based on PID readings, field observations, and test pit sampling results, soils were segregated for use as clean backfill, disposal as non-hazardous waste in Modern Corporation's RCRA Part 360

landfill, or disposal as action level soil in CWM Chemical Services' RCRA Part 373 landfill. Non-hazardous soils were loaded directly onto trucks for off-site disposal. Potentially clean soils were stockpiled and sampled to confirm that they could be used as clean backfill. Potential action level soils were stockpiled on-site and sampled to confirm that they could be properly disposed at CWM's facility. A total of 35,606 tons, or approximately 23,700 yd³ of soil was excavated and removed from the site between May and August 1999.

Once it was believed that soils containing COC concentrations above NYSDEC Soil Clean-up Objectives were removed from each area, DE&S field personnel conducted verification sampling of the floor and walls of the excavation. Verification samples document the condition of soils left on-site on the walls and floors of the excavations. Verification samples were collected based on the following sampling rationale:

- Samples were collected in areas suspected to have the highest COC concentrations based on visual or olfactory evidence of contamination, or on PID readings; or,
- If no evidence of contamination was observed, samples were collected from material types believed to be most heavily impacted based on site conditions or grain size, etc.

Some verification samples contain COC's above cleanup objectives. This is due to site conditions that prevented the removal of all contaminated soils from the site in some areas. Areas where contaminated soils remain on-site include: Areas 1A/1C, 1D-extension/2C and 2A.

Several verification samples collected from the north wall of areas 1A/1C exceeded the clean-up objective for trichloroethene and/or PAHs. These samples do not represent contaminated soil remaining on-site because the north wall of areas 1A and 1C extended to the north property boundary.

Approximately 700 yd³ of non-hazardous soil containing VOCs remains on-site below 20ft in depth in areas 1D-extension/2C. Verification sampling results also indicate that one verification sample contains vinyl chloride above the action level in area 1D-extension on the floor below the former location of the solvent storage area at 24 ft depth. An estimated 40 yd³ of action level soil remains on-site at this location. Additional excavation in these locations was not possible because of significant concern for reduced slope stability near the liquid nitrogen above-ground storage tank (AST).

Verification sampling results indicate that non-hazardous soil remains in area 2A in four locations: at the east wall corresponding to the property boundary from 0 to 16 ft in three samples, on the west wall near the hydrogen gas cylinders from 10 to 16 ft in one sample, on the floor in the north-east corner in one sample at 24 ft, and the floor in the west end in six samples at 18 to 24 ft.

Excavating further east was not conducted because the excavation extended to the east property boundary. An estimated 800 ft² of non-hazardous soil remains between 0-16 ft in depth on the east property boundary. Excavating further west was not possible due to the proximity of the hydrogen gas cylinders. An estimated 60 yd³ of non-hazardous soil remains between 10-16 ft in depth on the west wall. Excavating deeper than 24 ft in the north-east corner was not possible

because of significant concern for reduced slope stability. An estimated 80 yd³ of non-hazardous soil remains below 24 ft in this area. Excavating deeper than 18 to 24 ft on the floor in the west end was not possible due to the presence of loose sands, silts, gravels and boulders in this area that caused a significant concern for slope stability; the proximity of the hydrogen gas cylinders and the liquid nitrogen AST; and significant groundwater seepage that compounded slope stability issues. The estimated volume of non-hazardous soils remaining on the floor below 18ft depth in the west end of area 2A is 1,100 yd³.

Verification sampling results also indicate that action level soil remains in area 2A on the east wall in one sample. An estimated 150 ft² of action level soil remains between 10-16 ft depth in this area. Excavating further east was not conducted because the verification sample was collected at the east property boundary.

A total of 35,606 tons, or approximately 23,700 yd³ of soil were excavated and removed from the site. An estimated total of 1980 yd³ remains on-site at depths below 10 feet. The volume of soil remaining represents approximately 8% of the total volume of identified contaminated soil. Over 90% of contaminated soils have been removed from the property, including over 2000 tons of action level soil. Given the removal of most of the contaminated soil, the IRM objective of improving groundwater quality with time should be attained.

1. INTRODUCTION

The former Carborundum Company's Hyde Park facility ("site") in Niagara Falls is listed on the New York State Department of Environmental Conservation's (NYSDEC) list of Inactive Hazardous Waste Disposal Sites. The site, which is classified as a Class 2 site, is identified as Site No. 932036. A Class 2 site is defined as a site that poses a significant threat to the public health or the environment and requires mitigative action. Figure 1 provides a site location map.

A Remedial Investigation (RI) of the site was completed in 1996 by Duke Engineering & Services, Inc. (DE&S), a Phase II RI was completed in May 1998, and a borehole investigation was completed as part of this interim remedial measure (IRM) in September 1998. Results of the RI, Phase II RI and IRM investigation indicate that soils in five areas on the property contain volatile organic compounds (VOCs) and/or polycyclic aromatic hydrocarbons (PAHs) at concentrations that exceed NYSDEC Soil Cleanup Objectives.

A work plan and a plans and specifications document for conducting soil removal as part of an IRM were submitted and approved by the NYSDEC. Removal of contaminated soils was executed as a permanent part of the remedial solution for the site.

This document provides details on the execution and results of the IRM. The remainder of this section describes the purpose and objectives of the IRM program, the NYSDEC "Contained-In" Policy that was invoked during site cleanup, and provides a summary of the results of the IRM soil boring investigation completed at the site in September 1998. Section 2 provides details on the methodology and procedures used during the completion of the IRM. Section 3 provides the results of soil excavation and disposal. Section 4 provides results on soil conditions at the site following the IRM. Section 5 describes site restoration.

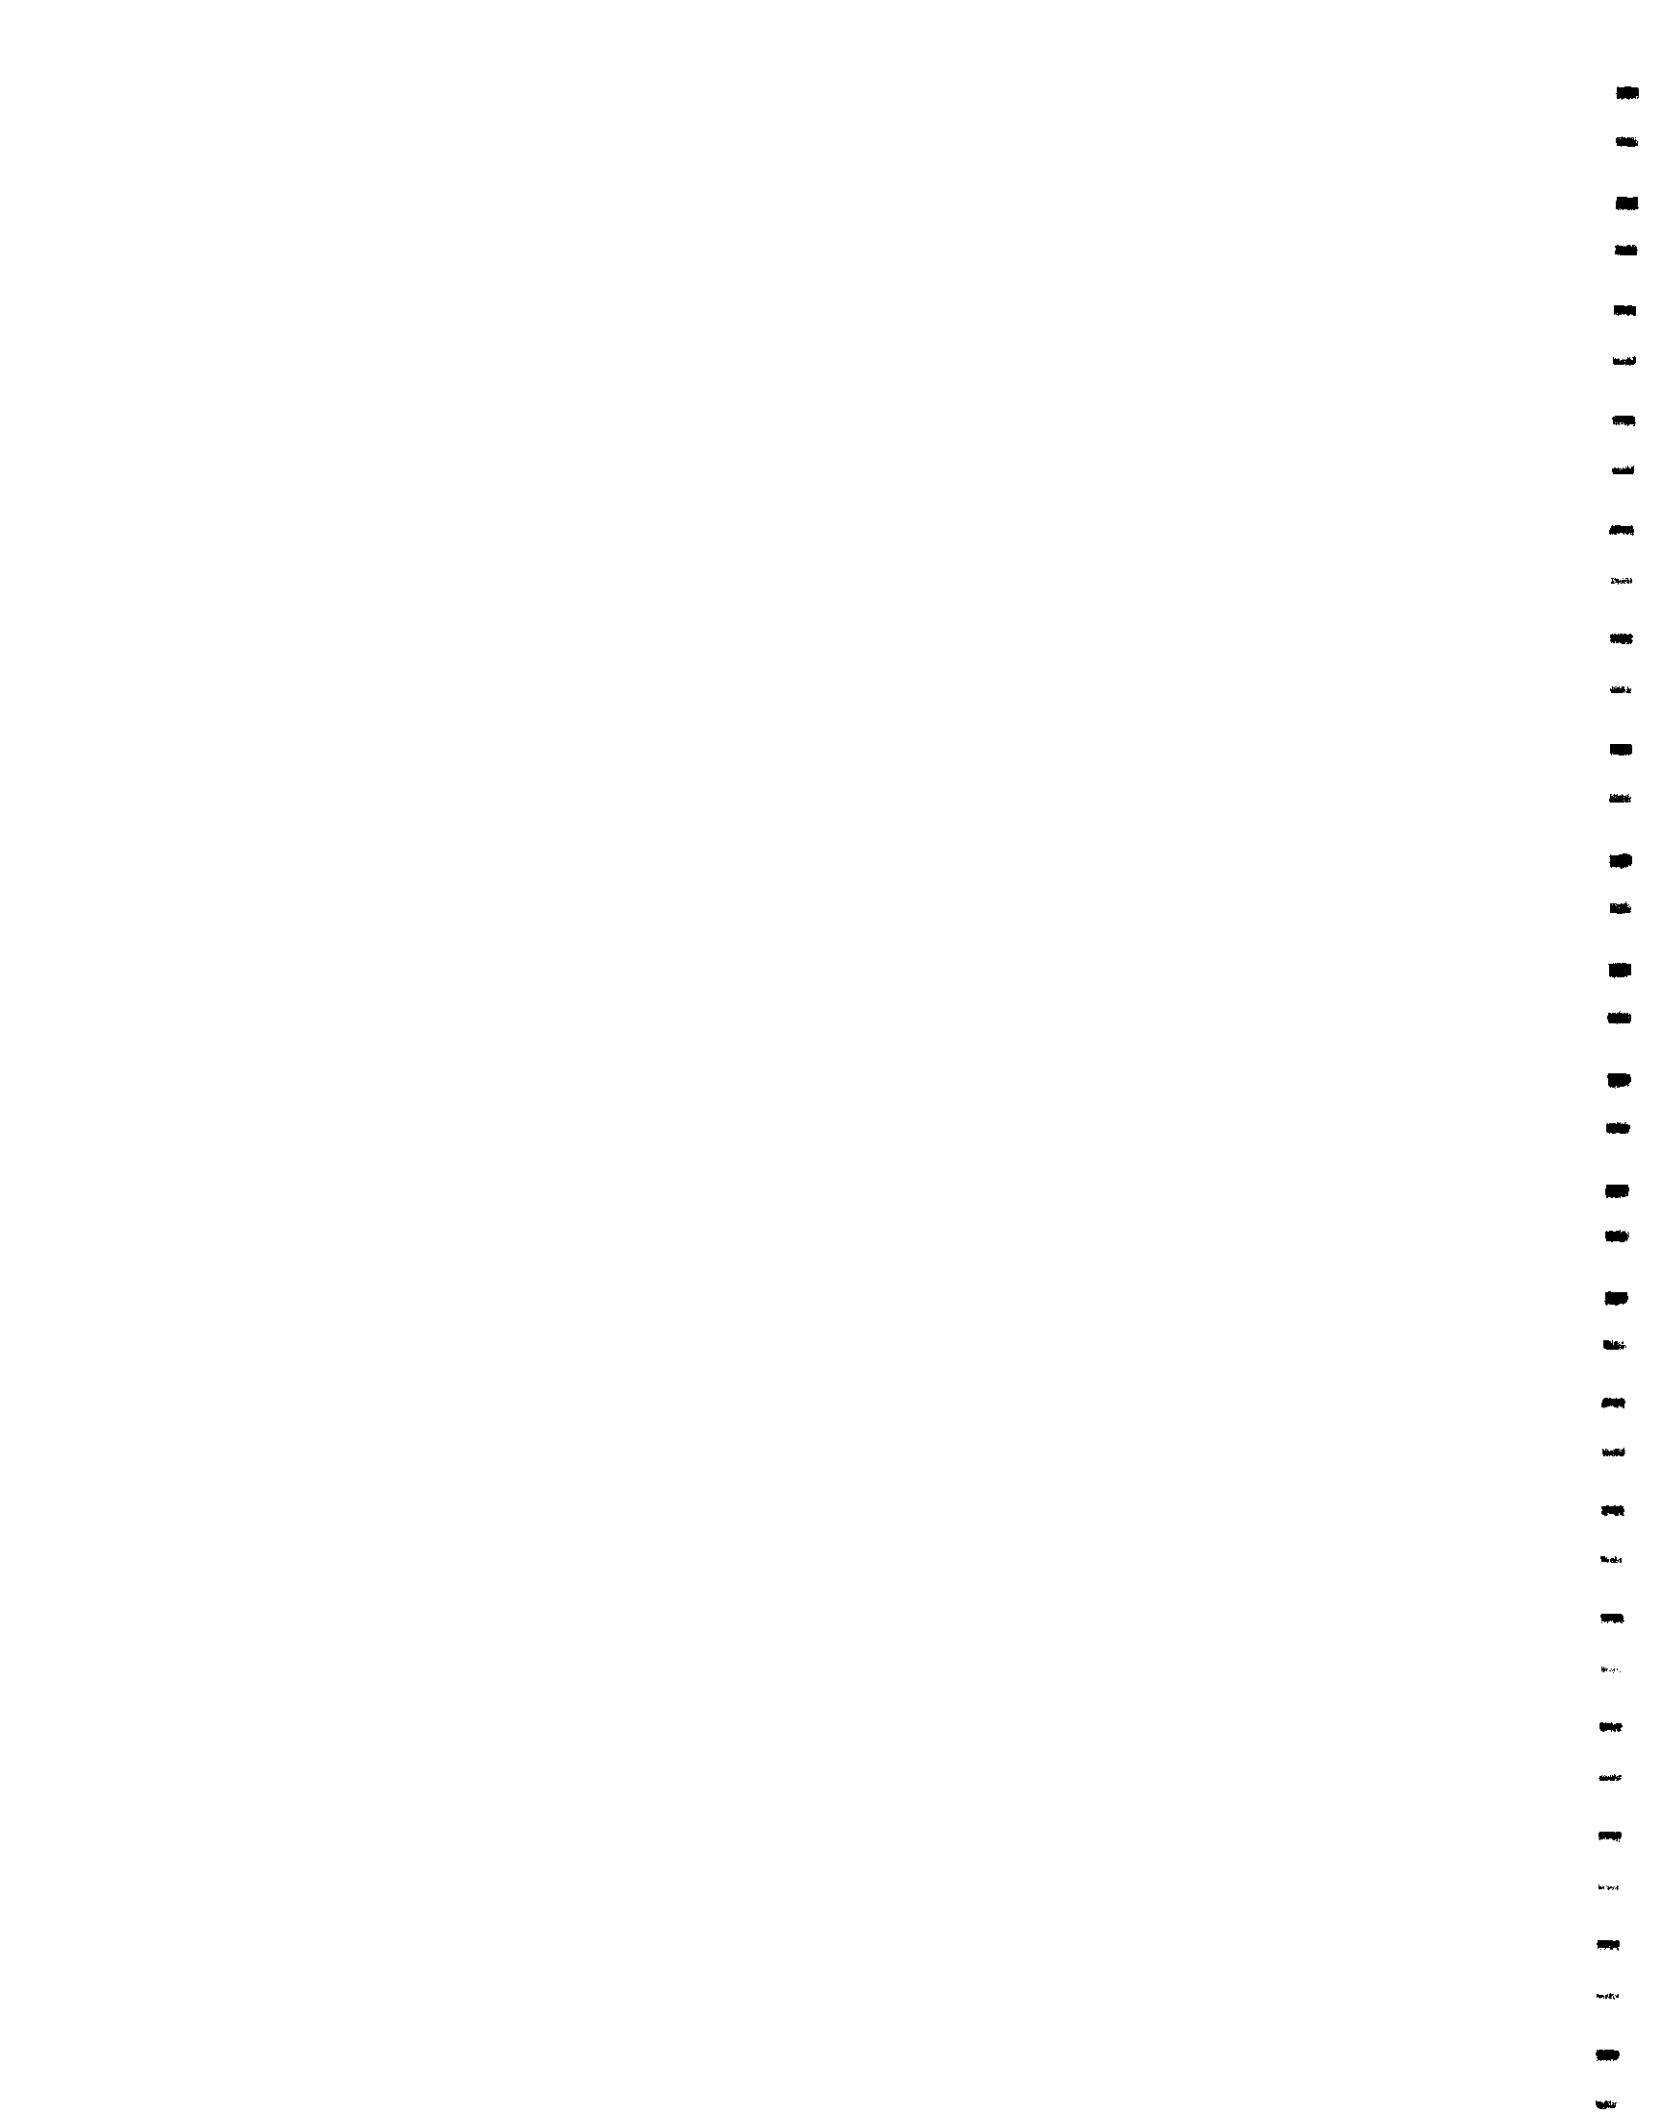

1.1. PURPOSE AND OBJECTIVES OF THE IRM PROGRAM

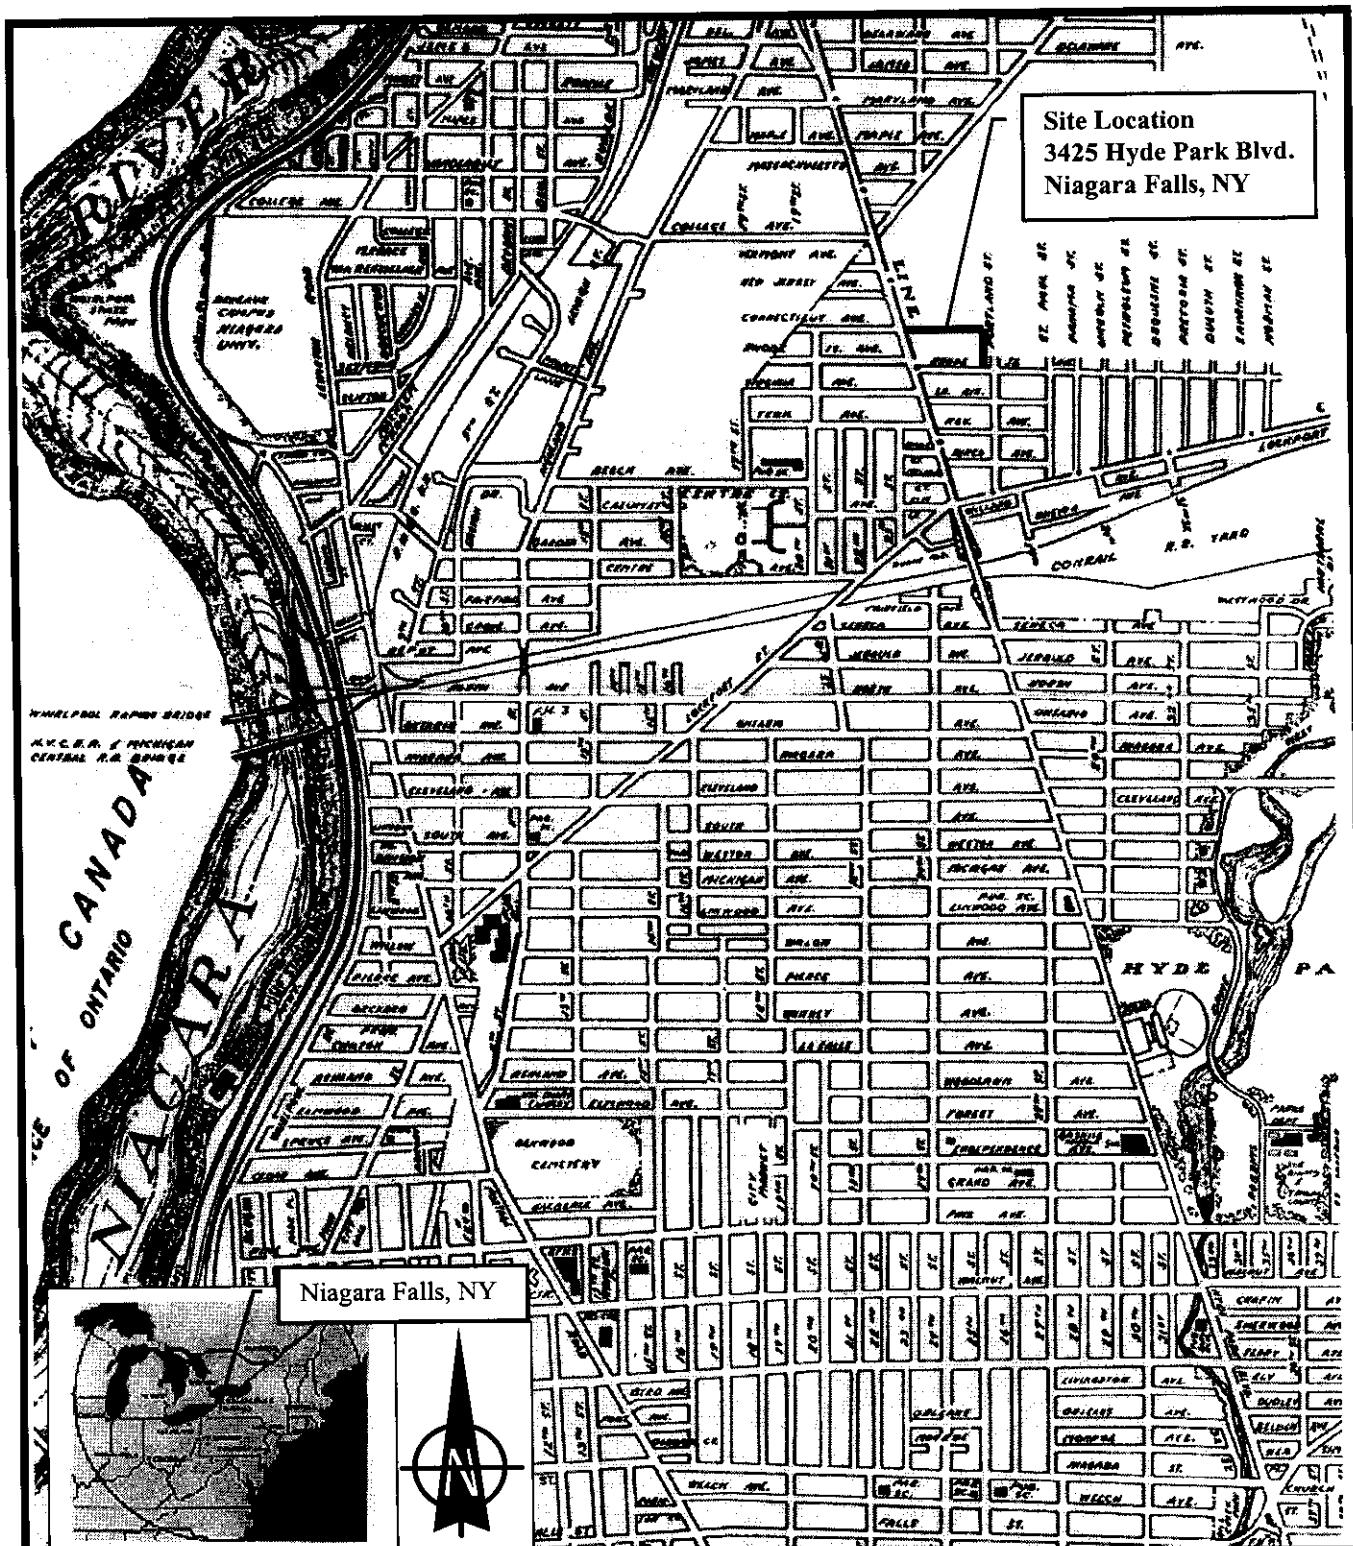

An IRM is a planned action(s) that can be conducted without extensive investigation and is designed to be a permanent part of the final remedy for a site. The purpose of this IRM was to remove contaminated soils from the property in order to remove a source of contamination to groundwater. The overall objective of the IRM was to affect an improvement in groundwater quality with time following source removal.

1.2. SCOPE OF WORK

The specific objectives of the IRM included:

- i) Refine the extent of known soil contamination to allow cost-effective and efficient removal of soils.
- ii) Excavate contaminated soils and test to determine appropriate disposal options and,
- iii) Dispose of soil at appropriate facility.

1.3. NYSDEC "CONTAINED-IN" POLICY

The NYSDEC Division of Hazardous Substances Regulation, Bureau of Technical Support has developed a guidance document for managing listed hazardous waste. The document, Technical Administrative Guidance Memorandum #3028 dated November 30, 1992, is entitled "Contained-In" Criteria for Environmental Media (NYSDEC TAGM #3028). This contained-in policy applies to soil, sediment and groundwater contaminated by listed hazardous waste and removed pursuant to a corrective action plan. The policy states that environmental media containing hazardous constituents from listed hazardous waste can be managed as non-hazardous waste if the media contain hazardous constituent concentrations that are at or below Soil Action Level concentrations. This policy was used to manage excavated soils contaminated with VOCs at the site. Soil clean-up objectives and action level concentrations for VOCs are provided in Table 1. Soil clean-up objectives for PAHs are provided in Table 2. Soil clean-up objectives were calculated based on a technical memorandum titled "Determination of Soil Cleanup Objectives and Cleanup Levels" (NYSDEC TAGM #4046, January 24, 1994, revised March 1998). Soil cleanup objective calculations can be found in Appendix A.

Table 1. NYSDEC Soil Clean-Up Objectives and Action Level Concentrations for VOCs.

Contaminants of Concern	Clean-up Objective ($\mu\text{g}/\text{kg}$)	Action Level ($\mu\text{g}/\text{kg}$)
Trichloroethene	880	64,000
1,2-Dichloroethene (total)	410	2.8×10^6
Acetone	200	8×10^6
Vinyl Chloride	200	360
Xylenes (total)	1,680	2×10^8
Ethylbenzene	7,700	8×10^6
Toluene	2,100	20×10^6
Methylene Chloride	150	93,000

Table 2. NYSDEC Soil Clean-Up Objectives for PAHs.

Contaminants of Concern	Clean-up Objective ($\mu\text{g}/\text{kg}$)
Acenaphthylene	57,600
Anthracene	50,000
Benzo(a)anthracene	3,860
Benzo(a)pyrene	15,400
Benzo(b)fluoranthene	1,500
Benzo(k)fluoranthene	1,500
Chrysene	560
Dibenz(a,h)anthracene	14
Fluoranthene	50,000
Fluorene	50,000
Indeno(1,2,3-cd)pyrene	4,480
Naphthalene	18,200
Phenanthrene	50,000
Pyrene	50,000

2. METHODOLOGY

2.1. SUMMARY OF RESULTS OF IRM INVESTIGATION

The IRM investigation field program included the installation of boreholes and collection of soil samples prior to excavation plan development to define the lateral and vertical extent of soils containing contaminants of concern (COCs) at concentrations that exceed:

- NYSDEC Soil Action Levels that are listed in the "Contained-In" Policy, and
- NYSDEC Soil Clean-up Objectives that were determined for the site based on the procedure described in NYSDEC TAGM HWR-94-4046, January 24, 1994.

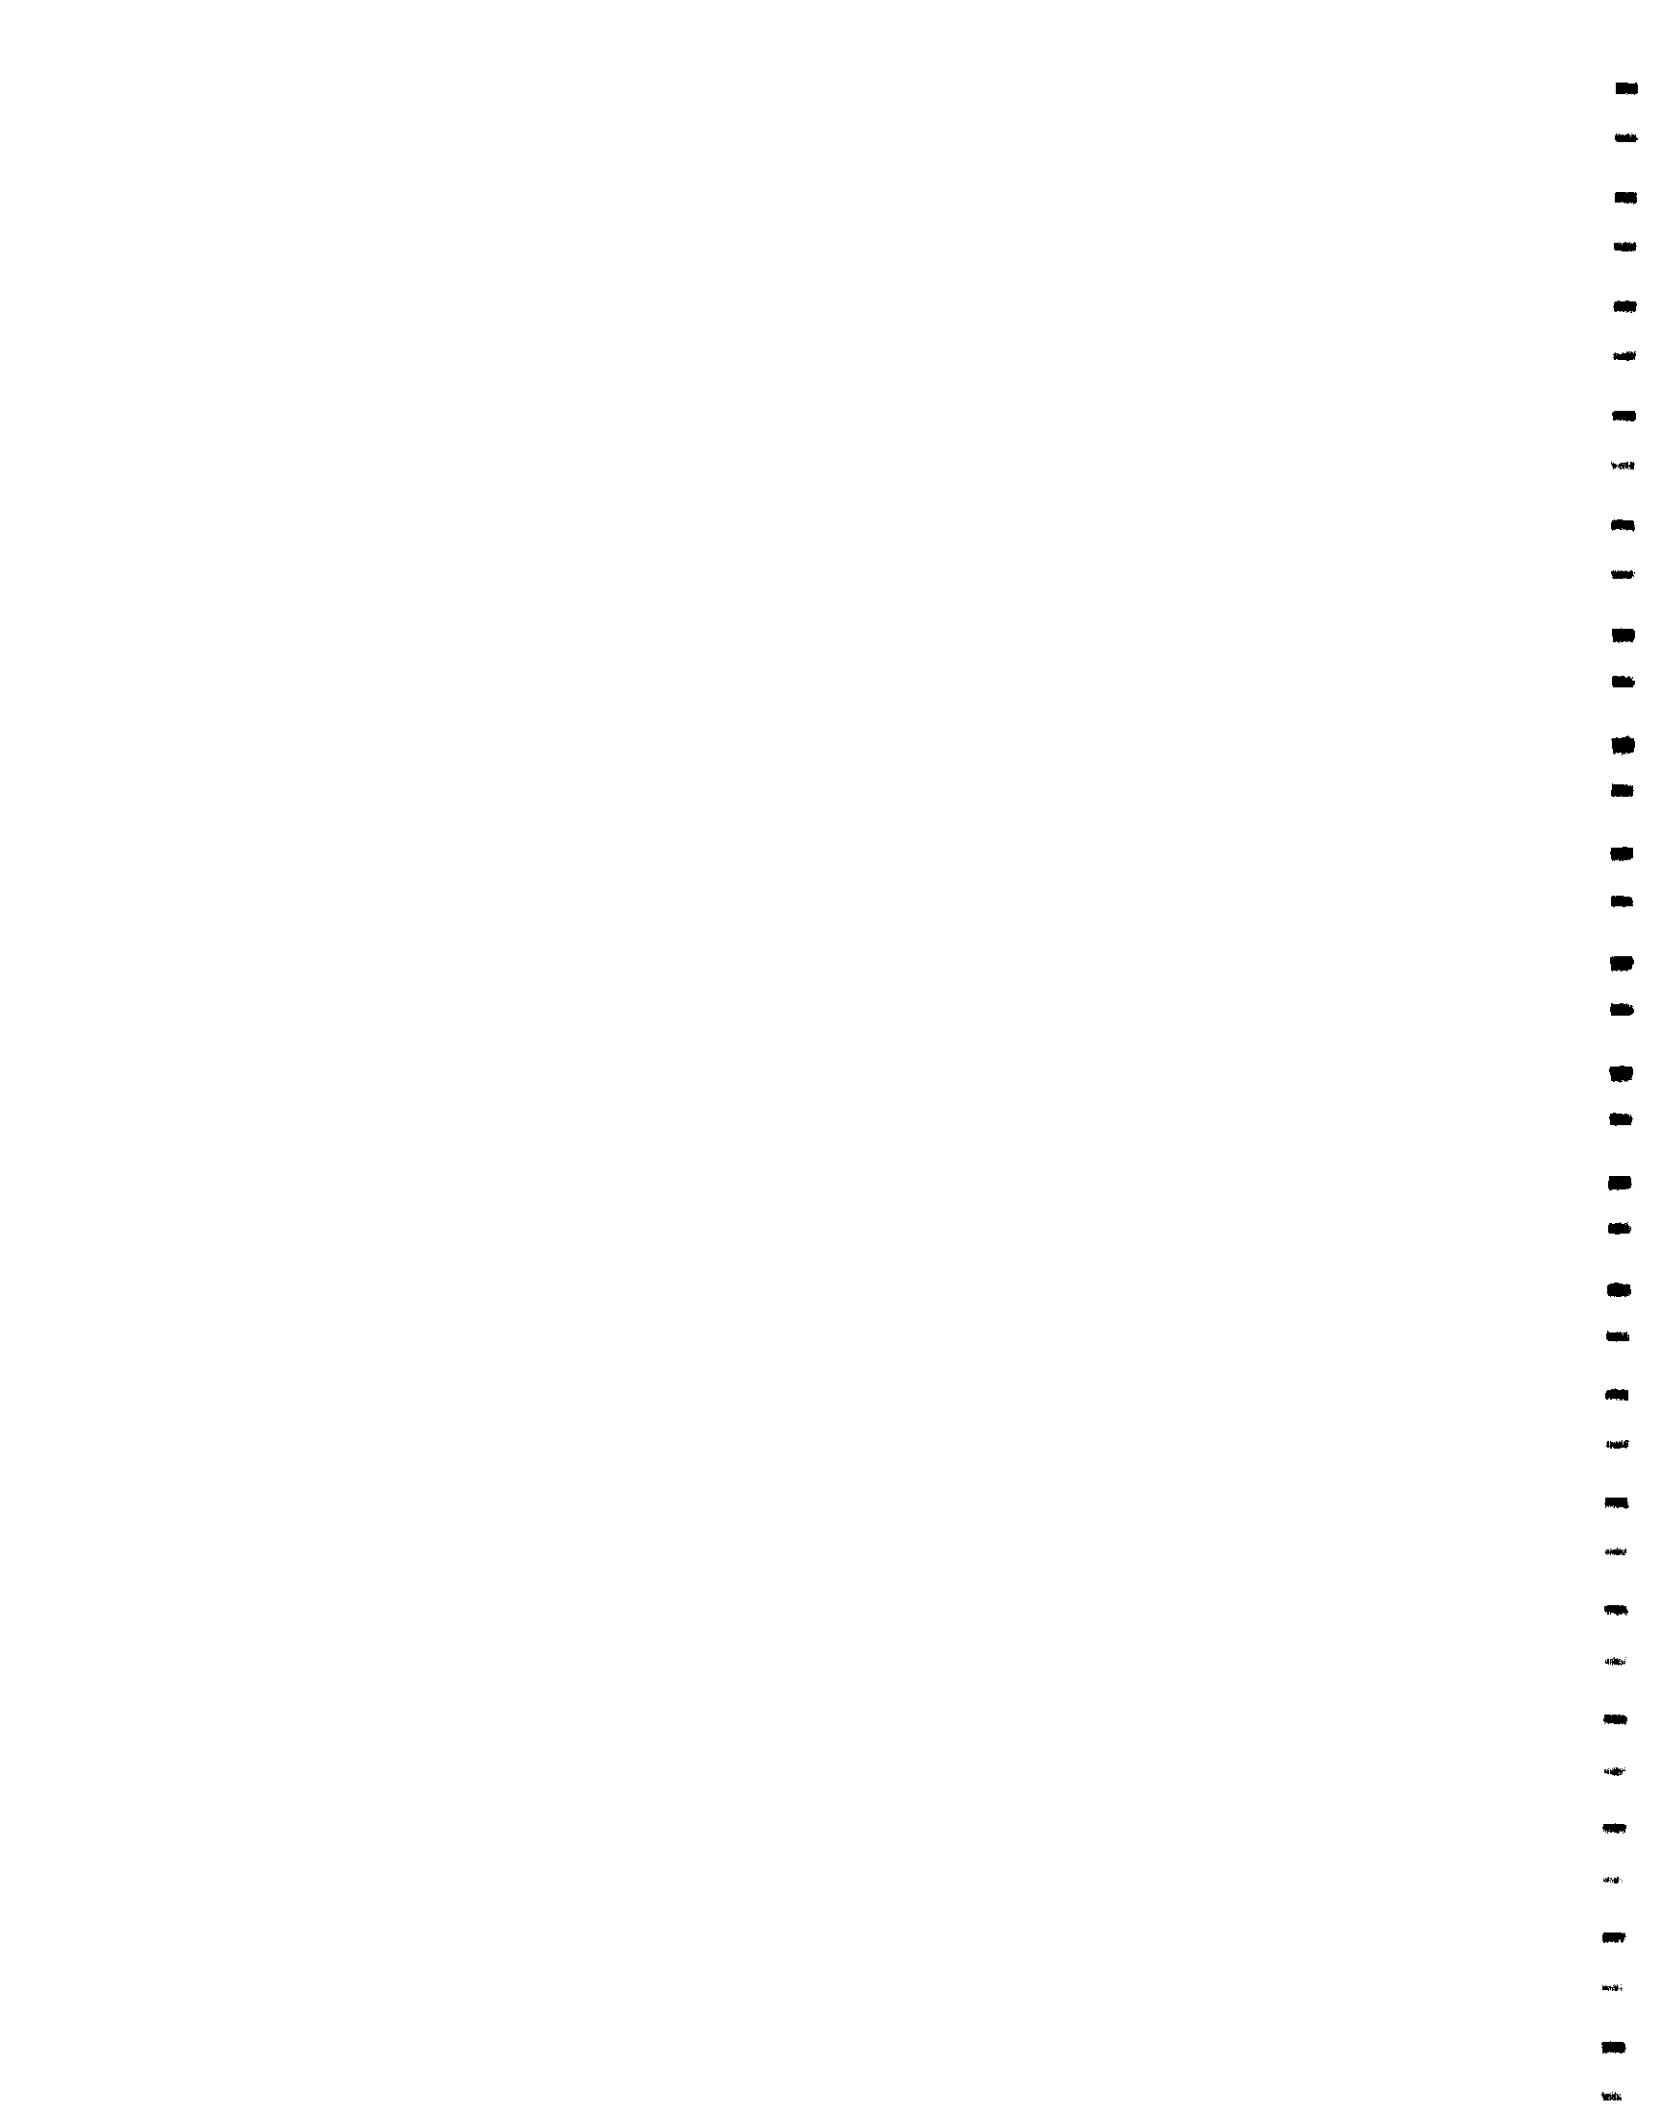

The installation of boreholes and collection of soil samples was conducted from September 14 to 17, 1998.

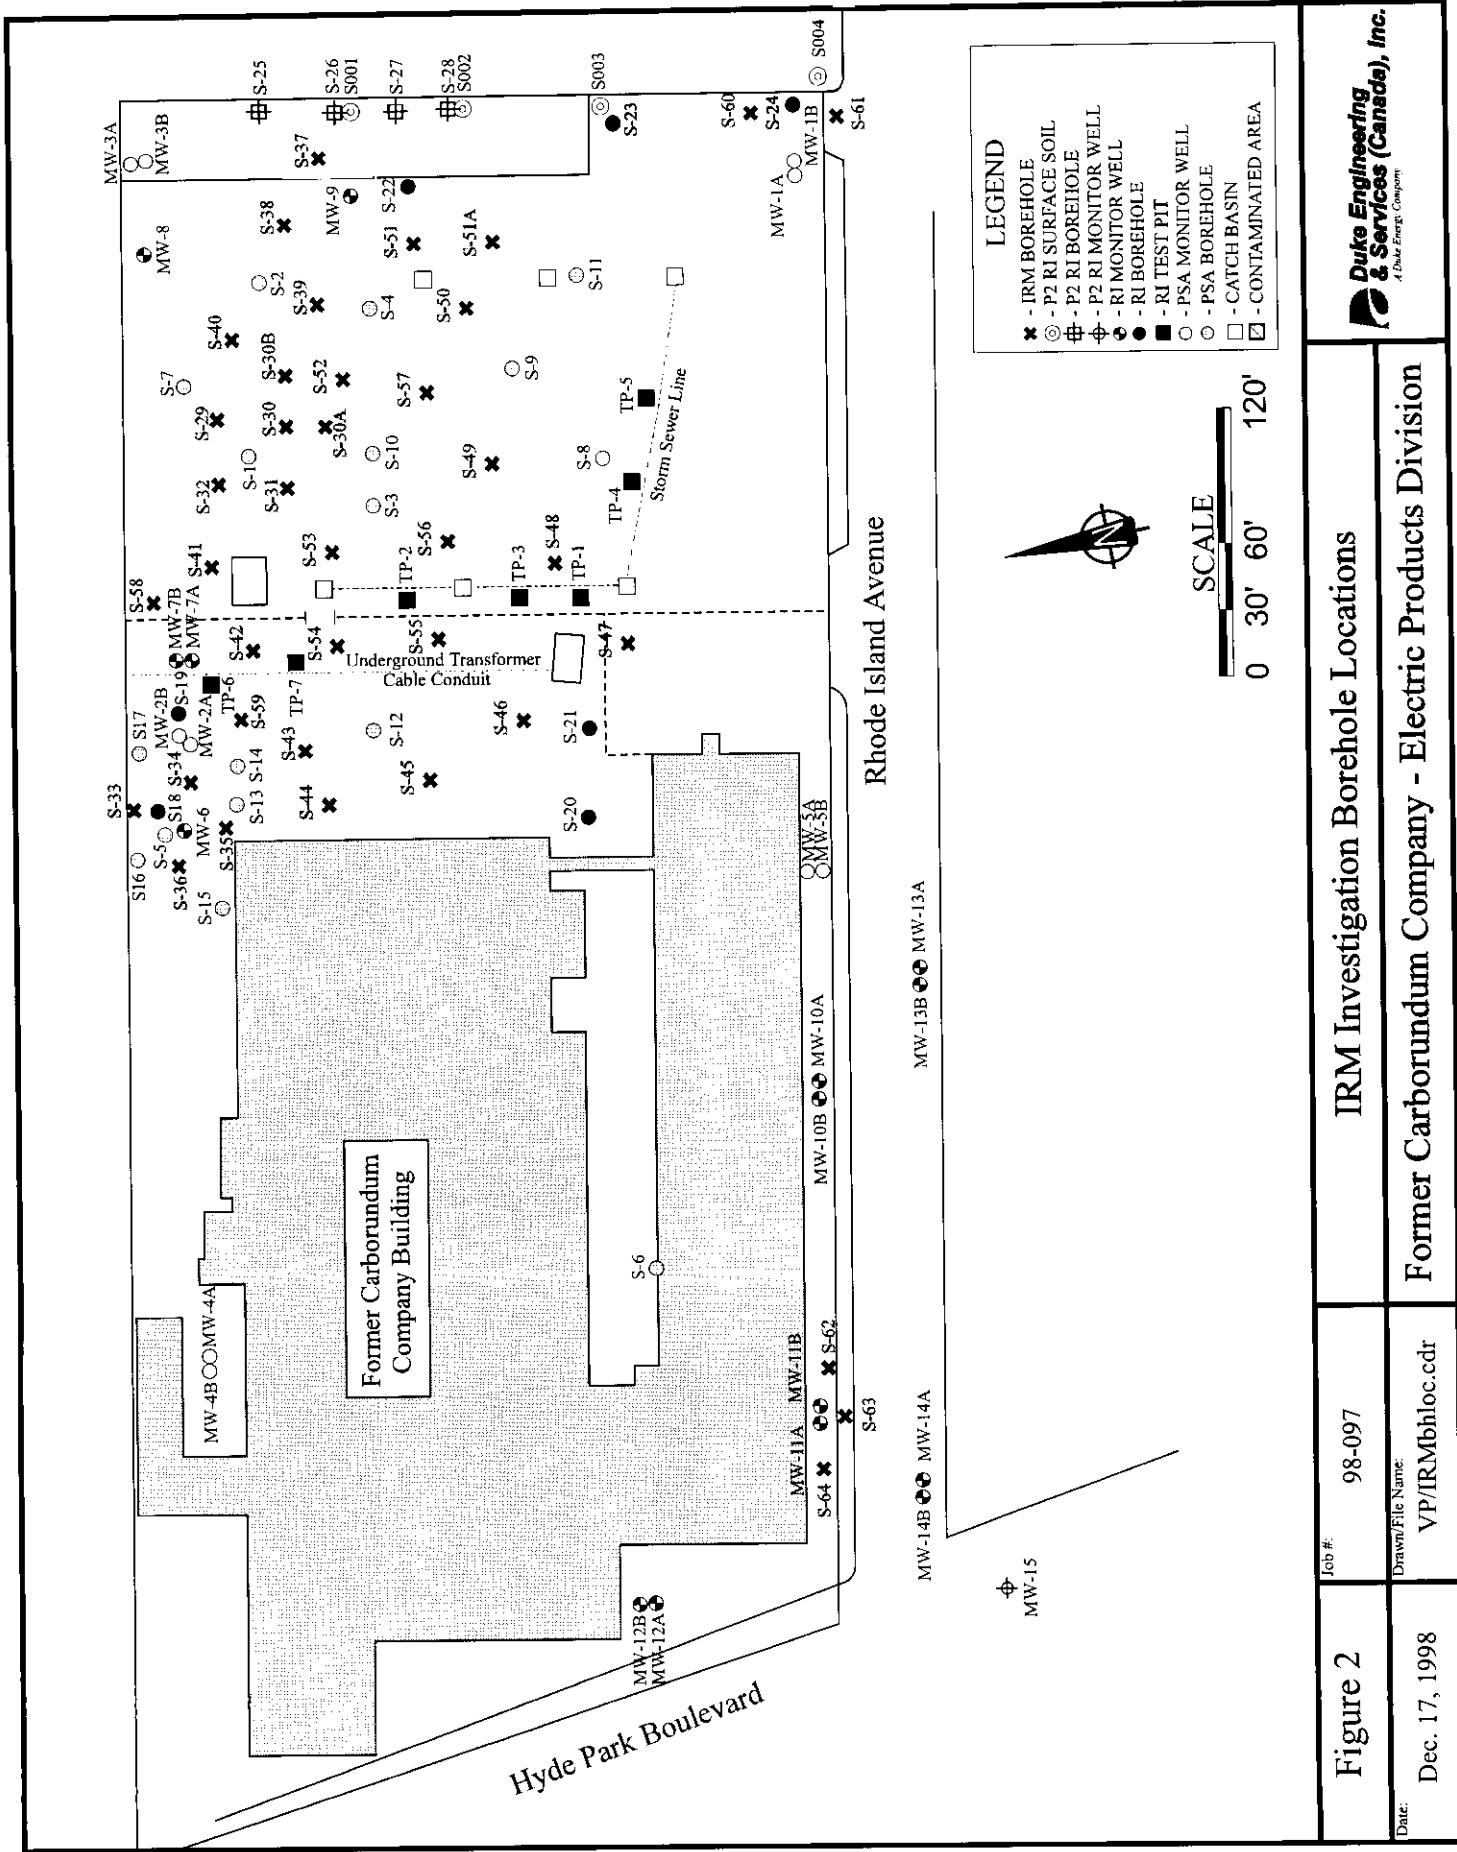

During the IRM drilling program, 39 boreholes located within the fenced area of the facility were completed to supplement previous soil sampling and to better define the lateral and vertical extent of soils containing COCs above NYSDEC Soil Clean-up Objectives. Borehole and soil sample locations are provided in Figure 2 and are numbered S-29 to S-64 (including S-30A, S-30B and S-51A).

A summary of exceedances in VOC and PAH analytical results from the PSA, RI, Phase II RI, and IRM investigation follows as Table 3 and Table 4. Based on these results, the areas and volumes of contaminated soils on-site were estimated. A table of analytical results for all soil samples collected during the PSA, RI, Phase II RI, and IRM investigation is provided in the Plans and Specifications Document for the Execution of the IRM Work Plan (DE&S, 1999).

Figure 3 identifies areas targeted for excavation, based on results of soil samples collected during the PSA, RI, Phase II RI, and IRM investigation. Excavation was divided into five general areas, identified on Figure 3 and described in Section 3. Figure 4 depicts excavation areas in the eastern portion of the site in greater detail and provides approximate depths of excavation, and estimated volumes of contaminated soil.

For more details, refer to the Plans and Specifications Document for the Execution of the IRM Work Plan.

- J indicates estimated value.
UJ indicates that the analyte was not detected above the sample quantitation limit and the reported quantitation limit is an estimated quantity.

Indicates that concentration exceeds recommended soil cleanup objective

2.2. AIR DISPERSION MODELING

An air dispersion model was constructed to evaluate the potential impact of excavation activities on employees currently working at the former Carborundum Company Facility, and to the general public in the vicinity of the site. In addition, the air model was used to help develop a work plan to minimize potential air impacts during execution of the IRM. Concerns for potential emission or volatilization of contaminants into the air during excavation and removal of contaminated soil were evaluated by using the air model to simulate excavation conditions at the site. This simulation was constructed to mimic site weather, wind pattern, and contaminant concentrations in soil as closely as possible. Details on air modeling are provided in Appendix B.

The results of the air modeling indicate that emission of contaminants from the site during excavation could be significantly reduced if stockpiling of contaminated soils on site could be eliminated or reduced. This would eliminate the emission of vapors from stockpiled soil.

Based on the air modeling work, a pre-characterization test pit sampling program was proposed. This pre-characterization of soils would allow the excavation and direct loading of soils into trucks for off-site disposal.

2.3. PRE-CHARACTERIZATION TEST PIT SAMPLING

A test pit sampling program was conducted in April 1999. The purpose of the test pit sampling was to pre-characterize soils for disposal purposes. This pre-characterization allowed the excavation of soils directly on to trucks to be hauled off-site to an appropriate disposal facility. Results of the test pit sampling were documented in a letter entitled "*Test Pit Sampling Results, Former Carborundum Globar Facility, Site #932036, Town of Niagara, NY*" dated May 4, 1999 addressed to Modern Corporation and submitted to the NYSDEC.

The remainder of this section presents the methodology used in the test pit sampling program, results of the sampling, and the approach to excavation and disposal of contaminated soils from the site.

2.3.1 Rationale and Methodology

A total of 67 test pits were installed on April 16, 19, and 20 in locations indicated on Figure 5. Test pits were spatially located within planned excavation areas at a frequency of approximately one per 800 ft² area. At least two test pits were located in each subarea. Test pits were located so that they did not overlap previous sampling locations in order to identify any unknown localized zones of contamination.

A soil sample was collected from each test pit. This soil sample was a composite over the vertical extent of contamination. No known clean soils were included in test pit samples. Soil samples from each test pit were composited with those from other test pits as necessary so that each soil sample submitted for laboratory analysis represented approximately 1000 yd³ of soil. A minimum of one composite soil sample was submitted from each subarea.

Table 5 provides a breakdown of test pits, composite soil samples, and analyses for each subarea. Samples were analyzed using the Toxic Characteristic Leachate Procedure (TCLP) for compounds on the toxicity characteristic list from NYCRR Part 371, Section 371.3(e), ignitability, corrosivity, and reactivity at a frequency of approximately one per 2,000 yd³ of soil. All of the soil samples submitted for TCLP testing were split and submitted for total VOCs analysis as well. Additional testing was conducted in areas of potentially clean backfill, in areas where vinyl chloride concentrations were not well defined, and in areas where high photo ionization detector (PID) readings or field observations indicated that contamination may be present. Table 6 provides a breakdown of additional sampling that was conducted. Results of the sampling program are presented below. Laboratory analytical reports are provided in Appendix C.

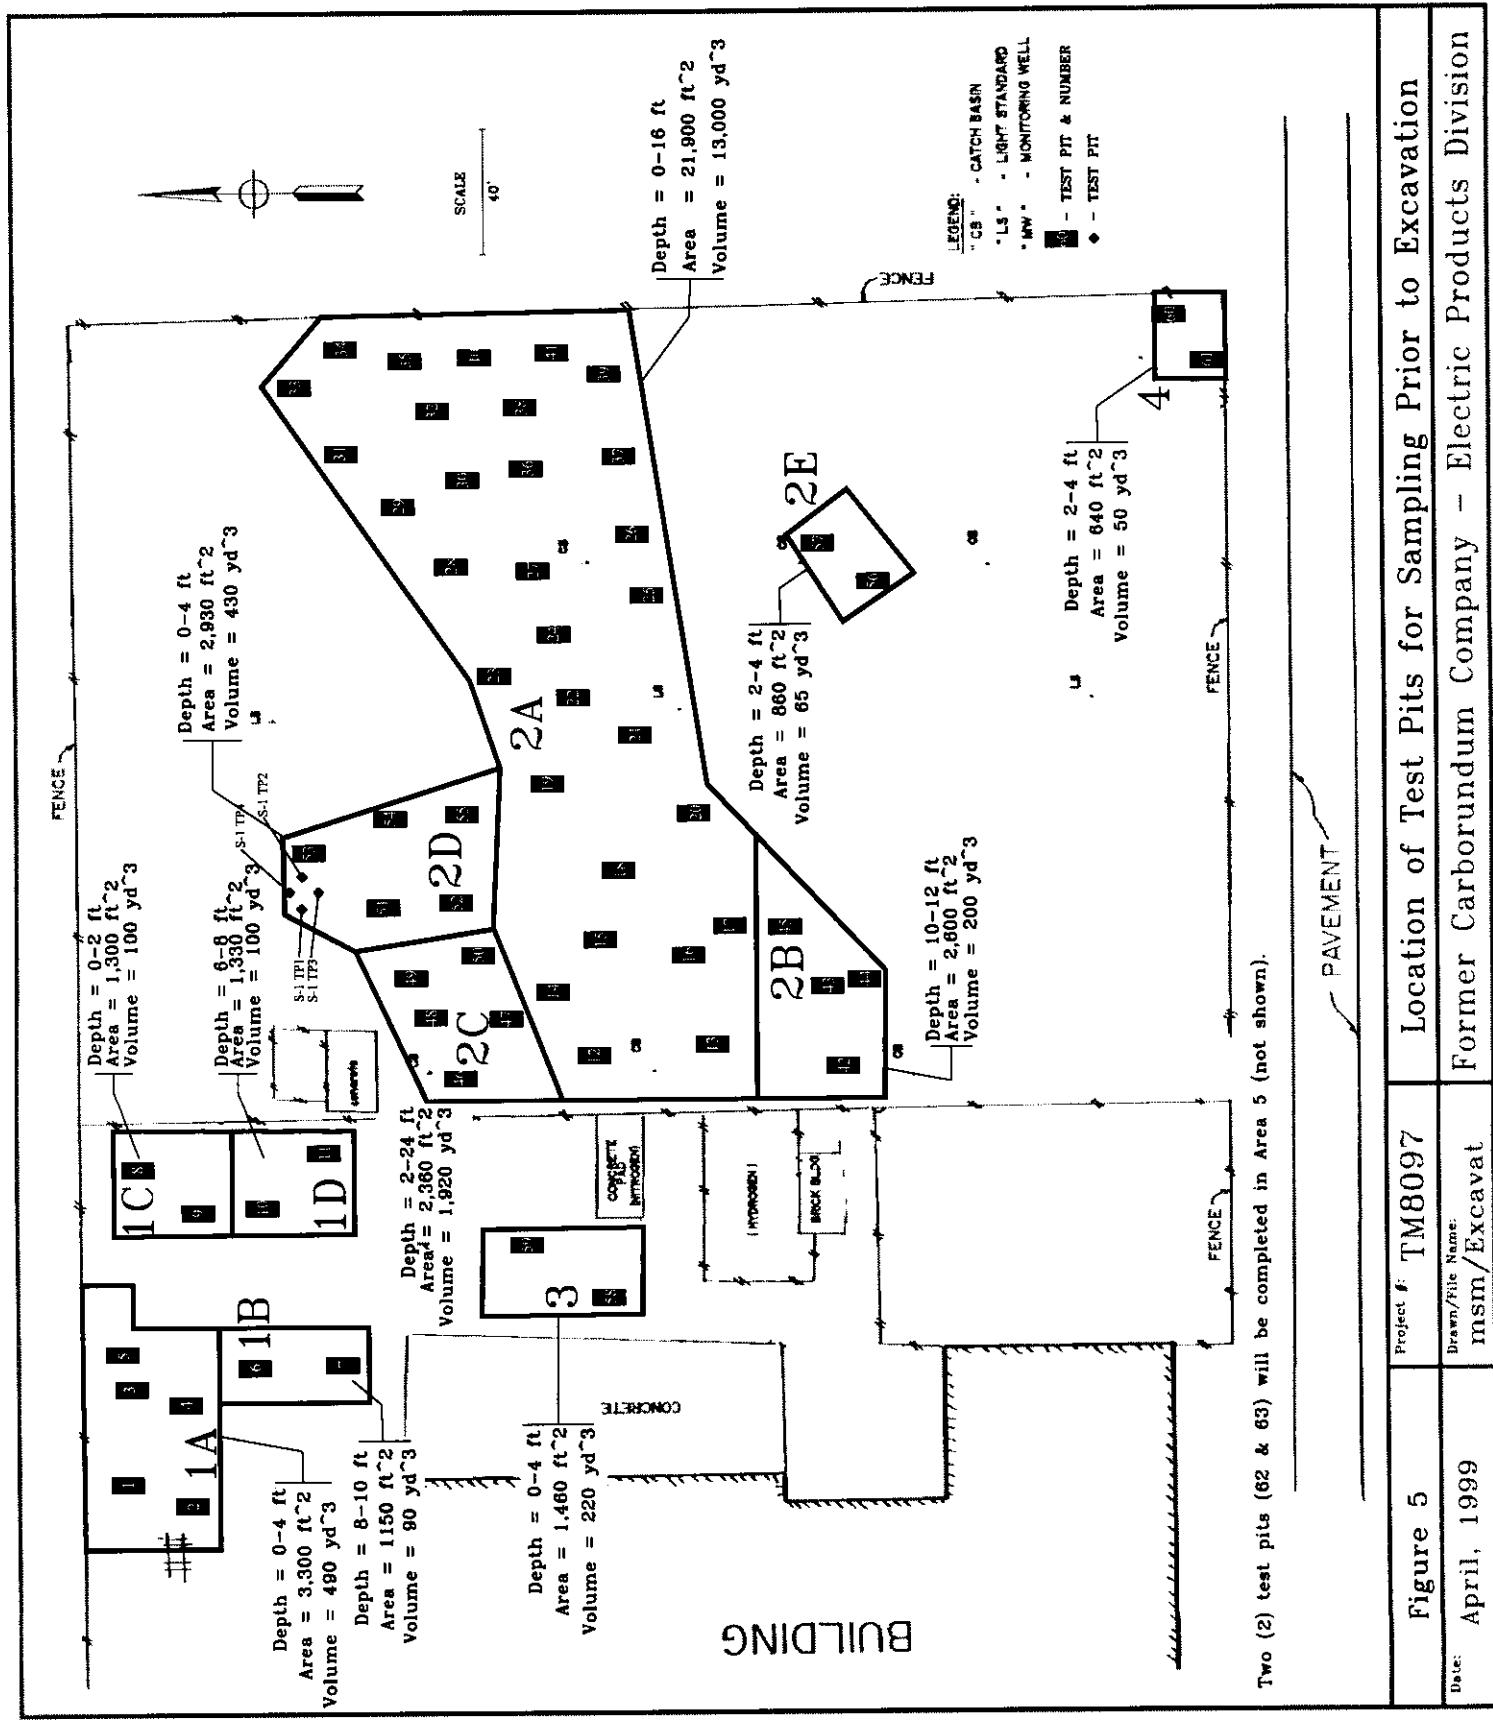

Table 5. Sampling Plan to Pre-characterize Non-hazardous Soils for Disposal

Area	Depth of Contamination	Number of Test Pits	Number of Composite Samples	Volume Represented	Tonnage* Represented	Analyses Required**

	0 to 2 ft	TP63	PCTP-S046	Vinyl Chloride	Alleviate dilution problem encountered during previous sampling

TP = test pit. PCTP = pre-characterization test pit sample.

2.3.2 Characterization of Soils for Disposal

TCLP and VOCs results are presented in Table 7 and Table 8, respectively. Two samples contained concentrations that exceeded the maximum concentration listed in NYCRR Part 371. These two samples were collected from Area 2D from a depth of 0 to 4 feet below ground surface and from Area 5 from 0 to 2 feet. The composite soil sample from Area 2D contained trichloroethene in leachate at a concentration of 860 µg/L, which exceeds the maximum NYCRR Part 371 concentration of 500 µg/L. Soils from Area 2D were therefore identified for disposal in a RCRA Part 373 landfill.

The sample collected from Area 5 contained lead in leachate at a concentration of 9,420 µg/L, which exceeds the maximum NYCRR Part 371 concentration of 5,000 µg/L. Soils from Area 5 were therefore identified for disposal in a RCRA Part 373 landfill.

Soils characterized by the remaining samples were considered non-hazardous and identified for disposal in a RCRA Part 360 landfill.

¹ Shaded areas indicate that concentration exceeds the maximum concentration² - units are $\mu\text{g/L}$ unless otherwise noted² - No detection's for herbicides, pesticides, semi-volatiles, PAHs nor COCs other than trichloroethene were detected³ - from NYCR Part 371 Identification of Hazardous Waste⁴ - no units

B - The reported value is less than the Contract Required Detection Limit (CRDL), but greater than the Instrument Detection Limit (IDL).

E - Indicates an estimated value because of the presence of interference.

F - degrees Fahrenheit

J - Indicates an estimated value.

N - Spike sample recovery not within control limits.

NA - not analyzed

U - Indicates that the analyte/compound was not detected above the detection limit indicated.

W - Post digestion spike for furnace AA analysis is out of control limits (85-115%), while sample absorbance is less than 50% of spike absorbance.

2.3.3 Pre-Characterization of Clean Overburden

Composite samples were collected in areas where clean soils were believed to be overlying contaminated soils in areas 1B, 1D, 2B, and 4. These composite samples (samples *PCTP-S004*, *PCTP-S009*, *PCTP-S030*, *PCTP-S031*, *PCTP-S037* and *PCTP-S042*) were submitted for total VOCs analysis in order to determine if the overburden soil is acceptable for use as clean backfill on the site. Clean overburden samples were collected at a frequency of 1 per 200 tons and with a minimum of two test pits per composite sample. Results of these samples are presented in Table 9. Concentrations of VOCs in all the clean overburden samples were well below the NYSDEC soil cleanup objectives. Therefore, overburden soil from Areas 1B, 1D, and 2B was identified as clean backfill.

Table 9. VOC Analytical Results from Pre-characterization of Clean Overburden.

B – Indicates that the analyte was found in both the sample and its associated laboratory blank.

J – Indicates an estimated value.

NS – Not sampled because only gravel was present from 0-2 ft in TP60 and TP61.

U – Indicates that the compound was not detected above the detection limit indicated.

2.3.4 Sampling for Vinyl Chloride

High concentrations of contaminants in soil samples collected during the PSA and RI from areas 1A, 1B, 2E, 3 and 5 resulted in dilution of the samples during laboratory analysis. Because of this dilution, detection limits reported for vinyl chloride were above the soil clean-up objective and/or action level. In an effort to clarify whether vinyl chloride was actually a concern in these areas, two soil samples were collected from each of areas 1A, 1B, 2E, 3 and 5 during test pit sampling. These ten soil samples (*PCTP-S002, PCTP-S003, PCTP-S006, PCTP-S034, PCTP-S035, PCTP-S039, PCTP-S040, PCTP-S045* and *PCTP-S046*) were analyzed for vinyl chloride only to alleviate the dilution problem and determine appropriate disposal options for affected soils. Vinyl chloride concentrations in all ten samples were non-detectable. The detection limits ranged between 140 and 180 µg/kg, which are below the soil clean up objective and soil action level for vinyl chloride. These results allowed soils to be identified for disposal in a RCRA Part 360 landfill.

The analytical results for samples from test pits 56 and 57 in Area 2E indicated that this area could be significantly reduced in size. The results presented in Table 10 indicate that the average concentrations of contaminants in the soil to be excavated do not exceed soil action levels or 10 times the Land Disposal Restriction (LDR) concentrations. These soils were therefore identified for disposal in a RCRA Part 360 landfill. Areas 2D and 5 were not included in Table 10 because soils from these areas exceed NYCRR Part 371 maximum concentrations and therefore will be disposed in a RCRA Part 373 landfill.

2.3.5 Discrete Sampling for VOCs

Additional sampling included discrete soil sampling for total VOCs analysis. Discrete samples were collected when obvious locations of staining, odor and/or elevated PID readings were noted (samples *PCTP-S047* and *PCTP-S052*). Samples were also collected in Area 2B, where DE&S field personnel determined that discrete samples might allow a reduction in excavation area (*PCTP-S048* and *PCTP-S049*). Discrete samples were also collected in Area 2C around borehole S-53 where action level soils have been identified (*PCTP-S050* to *PCTP-S054*). The laboratory analytical results for discrete soil samples are presented in Table 11. The concentrations in Table 11 are included in the calculation of average contaminant concentrations presented in Table 10.

Results of discrete sampling indicated that the southernmost boundary of Area 2B could be adjusted slightly to the north because samples collected from the zone of contamination in test pits 42 and 44 did not contain concentrations of VOCs above NYSDEC soil cleanup objectives.

Table 10 - Summary of Average Total Contaminant concentrations in Soil, Action Level Concentrations, and Concentrations that are Ten Times the LDR

- Shaded areas denote COC exceedance of the Cleanup Objective
870 - Shaded areas denote COC exceedance of the Soil Action Level

¹ - Recommended Soil Cleanup Objectives calculated based on 1.4% TOC in soil (NYSDEC TAGM HWR-94-4046, January 24, 1994).
² - Soil Action Level (NYSDEC TAGM #3028, November 30, 1992).

D - Indicates all compounds identified in an analysis at a secondary dilution factor.

J - Indicates an estimated value.

U - Indicates that the compound was not detected above the detection limit indicated.

2.3.6 Correlation of Analytical and Screening Results

Analytical results for VOCs in TCLP leachate and for VOCs in soil were compared for sixteen soil samples. Figure 6 shows the correlation between VOC concentrations in leachate vs. VOC concentrations in soil for trichloroethene (TCE). This tentative relationship indicates that as trichloroethene concentrations increase in soil, they also increase in leachate. No unusually high concentrations of trichloroethene were detected in leachate where trichloroethene was not also detected at high concentrations in soil.

All soil samples collected during test pit sampling were screened with a PID to allow an assessment of the correlation of VOC analytical results and PID field screening results as shown in Figure 7. Figure 7 indicates a generally linear trend on the logarithmic graph between total VOCs in soil and headspace gas PID results; however the relationship is not highly accurate. Soil samples with total VOC concentrations of between 1,000 and 1,500 µg/Kg exhibit PID readings as low as 8 ppm or as high as 800 ppm. Additional graphs and PID results for each sample are provided in Appendix E.

The PID was used as a screening tool along with field observations to segregate potentially clean soils from the soils that exceeded cleanup objectives or action levels as excavation was conducted. Soils that exhibited a PID reading of less than 10 ppm generally did not contain total VOCs above 1,000 ppm. Graphs for trichloroethene and vinyl chloride in Appendix E show that soils exhibiting a PID reading of less than 10 ppm generally did not contain trichloroethene or vinyl chloride above their respective cleanup objectives. This information was used to develop a rule of thumb for soil screening and segregation during excavation. Soil that did not exhibit staining, odors or other signs of contamination and that exhibited a response of less than 10 ppm on the PID during excavation was segregated, stockpiled, and sampled to determine if it could be used as clean backfill. Similarly, soils that exhibited a response of greater than 500 ppm on the PID were segregated, stockpiled and sampled to ensure that they did not contain VOCs above action level concentrations. The action level for vinyl chloride of 360 µg/Kg is less than 500 ppm; however, vinyl chloride is a breakdown product of trichloroethene, and as such does not occur on the site as a pure product. Vinyl chloride is only a fraction of the total VOC concentration found in on-site soils. For this reason, a PID screening limit of 500 ppm was considered sufficient to identify potential action level concentrations of vinyl chloride in soil.

2.3.7 Approach to Excavation and Disposal

The results from test pit sampling determined that soils at the site can be disposed as non-hazardous waste, except for soils in Areas 2C, 2D and 5. Soils from areas 2D, part of 2C, and 5 were managed as action level soils and disposed in a RCRA Part 373 landfill. Soils from Area 2D failed TCLP testing due to trichloroethene and were disposed using waste code D040. Soils from Area 5 failed TCLP testing due to lead and were disposed using waste code D008. Soils from part of Area 2C exceeded action levels for vinyl chloride and trichloroethene. Soils from this area were disposed using waste codes U043 and U228.

Discrete sampling in Area 2B and test pit results in Area 2E allowed a slight reduction in the size of these areas. All of Area 2D was considered action level soils, as well as part of Area 2C and all of Area 5. Figure 8 depicts the modified excavation areas and action level soil areas based on the data obtained from test pit sampling. Table 12 provides an updated breakdown of soil excavation areas and volumes

TOTALS			17,950		1,410		16,540		

¹ NOTE: Approximately 80 yd³ of soil in Area 2c contains VOCs above action levels.
The total approximate volume of action level soils on the site is 540 yd³.

2.4. ON-SITE SCREENING AND SEGREGATION OF SOILS

During the execution of the IRM soil excavation program, the results from the pre-characterization test pit sampling program were combined with on-site soil screening to ensure appropriate soil disposal. Soils were inspected by DE&S personnel for staining and screened for VOCs using the PID as they were excavated. Soil that demonstrated PID readings greater than 500 ppm was stockpiled and sampled for VOCs analysis to determine the appropriate disposal option. Soil that had PID readings less than 500 ppm and greater than 10 ppm was disposed in a RCRA Part 360 landfill as non-hazardous material. Soil that had PID readings less than 10 ppm was stockpiled for VOCs analysis as potentially clean backfill. Soil was stockpiled on and covered by plastic sheeting while on site to minimize dust and volatilization.

Soil excavated from the site was segregated into three categories for disposal purposes. These categories include:

1. Clean Soils - Soil with contaminant concentrations below the NYSDEC soil clean-up objectives for VOCs and/or PAHs.
2. Non-Hazardous Soils - Soil with contaminant concentrations above the clean-up objectives for VOCs and/or PAHs, but below the action level concentrations for VOCs. There are no action level concentrations for PAHs.
3. Action Level Soils - Soil with contaminant concentrations above NYSDEC action levels for VOCs.

2.5. SOIL DISPOSAL AND HAULING

Action level soils excavated from the site were disposed at CWM Chemical Services, a RCRA Part 373 registered landfill. Non-hazardous soils were disposed at MODERN landfill, a RCRA Part 360 municipal waste landfill. Both landfills are located in Model City, New York. Trucks hauling to CWM were lined and covered with plastic. Trucks hauling to MODERN were covered with tarps. To increase IRM work efficiency, double hauling was conducted when feasible. This involved trucks hauling non-hazardous soil to MODERN landfill returning to the site with clean fill. Trucks were decontaminated at MODERN landfill with clean water. The cleaning procedure was spot checked by DE&S field staff and two rinsate samples (*RINSATE-1* and *RINSATE-2*) were collected during the IRM. The laboratory analytical results for the rinsate samples are attached in Appendix F. The route used by the trucks went through the Niagara Vest Inc. property located to the north of the site. The route was accessed from Hyde Park Boulevard. Written permission to use the property was provided by Niagara Vest Inc. and a letter is attached in Appendix G.

2.6. AIR MONITORING

Continuous work area and community air monitoring was conducted by DE&S personnel on-site during excavation activities according to the Health and Safety Plan in the Plans and Specifications Document.

Three air monitoring stations were set up daily, if possible; two downwind of excavation activities and one upwind. Wind direction was determined using a wind sock. In general, wind direction was not consistent throughout the day, nor from day to day during the IRM. Each station included one dust monitor (MIE Personal Dataram Monitor) and one PID monitor (RAE MultiRAE O₂-LEL-H₂S-CO-PID Detector). The monitors had datalogging capabilities and recorded dust or total VOCs concentrations, short-term exposure limits (STEL) and the maximum and minimum one minute averages. There were no VOCs concerns and in general, no dust concerns identified during monitoring. Some exceedances were noted for dust in the data; however, because of the small working space, air monitoring stations often had to be placed closer than 25 feet from the work area or directly beside truck routes. This sometimes affected the one minute average and STEL dust readings. High dust readings however were not continuously or consistently encountered. During wet weather, the air monitoring stations were dismantled because the instruments could be damaged and because dust and VOCs in air concerns are minimized when excavations and truck routes are wet.

Air monitoring data is summarized in tables that are attached in Appendix H. Complete data logs are available upon request for inspection.

Contaminant concentrations in the workers' breathing zone were monitored throughout each day using a PID. Readings did not exceed 5 ppm and therefore, air purifying respirators were not required for personnel working on the site.

2.7. WELL ABANDONMENT AND RESTORATION

Groundwater monitoring well MW-9 was located in the north-east portion of excavation area 2A. Prior to excavating in this area, the monitoring well was abandoned on May 28, 1999 by Earth Dimensions, Inc. of Elma, New York. Abandonment was performed in accordance with NYSDEC monitoring well decommissioning procedures (NYSDEC, October 1996). The well was drilled out to 43.5 ft BGS with 6 inch hollow stem augers and grouted from the bottom using a tremmie pipe.

Monitoring wells MW-6, MW7A-7B and MW11A-11B were in the center of excavations 1A/1C and 5 but they were not damaged. The concrete well protectors were replaced and the concrete pads around the wells were replaced. The stickup height of MW-6 was lowered following excavation because the final grade in area 1A was lower than pre-work conditions. Area 1A contained the railroad spur, which was raised above the surrounding area; however, at the request of Kanthal-Globar, the railroad spur was not replaced and the area was graded level with the lower surrounding grade.

2.8. EXCAVATION WATER DISPOSAL

Groundwater and purge water encountered in the IRM excavations was pumped into 20,000 gallon tanks for settling prior to diversion to a sanitary sewer access on Rhode Island Avenue. The City of Niagara Falls, with permission from the Town of Niagara, issued DE&S a permit for water disposal. Initially, 1,500 gallons per day was permitted for discharge to the sanitary sewer for treatment at the City of Niagara Falls wastewater

treatment plant. The permitted volume was increased to 20,000 gallons per day as the project progressed and more water was encountered. The total volume of wastewater discharged to the sanitary sewer was 307,600 gallons. DE&S was required by the City of Niagara Falls to sample the discharge water and report the results monthly. The samples were collected from the storage tanks and/or excavations into a clean glass jar and transferred immediately into laboratory prepared bottles. The permits and monthly reports are attached in Appendix I. A summary table of analytical results for discharge samples and mass discharged to the sewer is provided in Table 13.

2.9. VERIFICATION SAMPLING AND QUALITY ASSURANCE/QUALITY CONTROL

Once it was believed that soils containing COC concentrations above NYSDEC Soil Clean-up Objectives were removed from each area, DE&S field personnel conducted verification sampling of the floor and walls of the excavation. Discrete grab samples were collected by using a corner of the backhoe bucket and scraping a vertical section of the excavation over a distance of approximately two feet. DE&S collected the grab sample from the bucket and transferred it to a clean sample container. Verification samples were collected based on the following sampling rationale:

- Samples were collected in areas suspected to have the highest COC concentrations based on visual or olfactory evidence of contamination, or on PID readings; or,
- If no evidence of contamination was observed, samples were collected from material types believed to be most heavily impacted based on site conditions or grain size, etc.

Each soil sample was collected in two self-sealing plastic bags: one bag was sealed with maximum headspace and allowed to reach ambient temperature for headspace gas measurement with a PID, and one bag was sealed with minimum headspace and stored on ice for possible selection for laboratory analysis. Headspace gas readings for VOCs were measured using the PGM-50 Multi Gas Monitor manufactured by RAE Systems Inc. Headspace gas concentrations were measured by inserting the instrument probe in the plastic bag and simultaneously manipulating the sample. The results of headspace screen were used to determine whether samples should be submitted to the laboratory, or if additional excavation should be conducted.

NYSDEC personnel collected selected split soil samples for analysis to provide an independent evaluation of soil sampling results. DE&S collected duplicate samples at a frequency of approximately one for every fifteen samples to check the precision of the analytical laboratory and sampling procedures, for QA/QC purposes. When filling duplicates or splits, the verification sample jar and the duplicate/split sample jar were filled simultaneously to maximize homogeneity between samples. Sample jars were filled leaving the smallest amount of headspace possible. Samples were identified with the area name and numbered sequentially. A trip blank was submitted for VOCs analysis with each shipment of VOC samples.

B - Parameter found in laboratory daily blank

D - Sample was diluted and detection limit was higher

Results of verification samples were used to determine whether additional excavation was required, or if excavations could be closed and backfilled. Verification samples that indicated the need for additional excavation became interim samples, as verification samples should represent the condition of soils left on-site. Samples were segregated into interim and verification samples as follows:

- Interim samples are those samples that were collected as verification samples, but laboratory analytical results indicated exceedances of the clean-up objectives or action levels, triggering further excavation and sampling.
- Verification samples are samples that represent the final conditions of the excavations and thus characterize the soil remaining on site.

Samples were analyzed by Severn Trent Laboratories (STL), a New York State certified analytical laboratory. Analytical reports were provided in accordance with ASP Category B deliverables. Data validation was completed by CRA Services. Sample data was validated at a rate of 35%.

2.10. DATA VALIDATION

Validation of the data was completed for both field and laboratory aspects of the sampling program. Data validation consisted of:

- Assessment of the field sampling protocols and Quality Assurance/Quality Control (QA/QC) procedures, and
- Assessment of the laboratory analytical methodology and QA/QC procedures.

2.10.1 Field Sampling QA/QC

To ensure that representative samples were collected in the field and were delivered to the laboratory without degradation or contamination of the sample, the following field QA/QC measures were taken:

- Stainless steel sampling equipment including sampling spatulas or trowels were rinsed in detergent solution and distilled water after each sample.
- Samples collected directly from the excavator bucket were collected from soil that had not come in contact with the bucket itself in an effort to prevent cross-contamination.
- Field staff used new latex gloves for each sample.
- Soil samples were immediately screened for organic vapors using a PID, and were transferred to clean glass jars.
- Samples were delivered to the laboratory in sealed, iced coolers under chain-of-custody within 48 hours of sampling.

During sampling, duplicate samples and travel blanks were collected to assess analytical precision and to identify potential sample contamination during sampling or transportation. The additional samples, all analyzed for VOCs, included the following:

- Duplicate soil samples were collected at a rate of at least 15%. A total of 38 duplicate samples were collected from a total of 224 interim or verification soil samples.
- Travel/trip blanks were shipped to the laboratory at a rate of 1 per sample shipment that contained samples for VOCs analysis. A total of 31 trip blanks were submitted to the laboratory.

Relative percent differences (RPDs) between sets of duplicate samples were calculated as follows:

$$RPD = \frac{X_1 - X_2}{\bar{X}} \times 100$$

where X_1 = concentration of first duplicate

X_2 = concentration of second duplicate

\bar{X} = mean concentration

Duplicate samples showed fair correlation, with RPDs of less than 156% between analytes for all parameters. The average of all RPDs ranged between 16% and 67%. The overall sample quality is considered to be acceptable. RPDs of greater than 100% are likely due to inhomogeneities in the soil. RPDs of all field duplicate samples are provided in Table 14.

All travel blank samples were analyzed for VOCs. VOCs were not detected in the blank samples.

2.10.2 Laboratory QA/QC

STL provided ASP Category B deliverables for all requested analyses. Soil samples were analyzed for VOCs using EPA SW-846 Method 8260, as specified in the IRM Work Plan. The results showed that all samples were analyzed within the required holding time. Internal laboratory QA/QC procedures were sufficient to meet the criteria outlined in the method.

Approximately 35% of collected data were validated by CRA Services of Niagara Falls, New York. Their report is provided in Appendix J. Only a portion of collected data was validated because results have already been used on a fast turnaround-time basis to make field decisions. All verification samples that contain concentrations of COCs above NYSDEC Soil Clean-Up Objectives were validated. Data validation shows that QA/QC was generally acceptable.

2.11. SURVEYING EXCAVATION VOLUMES

The volume of each excavation area was surveyed by Niagara Boundary and Mapping Services of Lewiston, New York. Survey data was used to document excavation size and determine the volume of backfill needed for each excavation. The volume of areas that were required to be backfilled immediately were estimated by DE&S field personnel and MODERN's field supervisor.

2.12. SITE RESTORATION

2.12.1 Imported Backfill

Imported backfill consisted of clean, self-compacting fill classified as silt or clay (SM, SC, or CL) by the Unified Soil Classification System (USCS). Crushed stone backfill was also used as a surface treatment in excavated areas. Imported backfill came from four approved sources: 827 Lake Road, 1500 James Avenue, Bridle Path residential development and MODERN landfill clean soil stockpile at Harold and Pletcher Roads. DE&S collected one composite sample from each source. Each composite sample represented 20 truckloads, or approximately 500 tons. Backfill samples were submitted for TAL/TCL analysis. None of the backfill samples contained contaminant concentrations above regulatory guidelines. The acceptance letters and laboratory reports for imported backfill sources are provided in Appendix K.

Backfill was placed by a bulldozer and compacted in approximately 1 foot lifts using a sheep's foot roller. Some lifts were thicker in very deep excavations due to water seepage problems. Stone was placed by a bulldozer and compacted with a smooth drum roller.

Soil backfill was placed up to 2 ft BGS, above which approximately 6 inches of asphalt and stone that was stripped from excavated areas and stockpiled on the site was placed and compacted. Then one foot of imported stone was placed as a base for surface treatment. Surface treatment in paved areas included the placement of three inches of

gravel and then three inches of asphalt. Surface treatment in unpaved areas included installation of six inches of gravel.

2.12.2 On-Site Backfill

In addition to imported fill, on-site soils and soil stockpiles determined to be clean following analytical testing were used as backfill on site. Analytical data from the on-site clean soil stockpiles are provided in Appendix L.

2.12.3 Stone and Asphalt Backfill

Surface stone and asphalt removed from the excavation areas prior to excavation was stockpiled on site for use as asphalt base during site restoration.

2.12.4 Grading Area 1A

As per discussions with KANTHAL-GLOBAR, area 1A was not restored to previous grade. Previous grade was approximately two feet above surrounding areas because of an abandoned railway spur. The railway spur was removed and the area was graded level with surrounding areas.

2.12.5 Fencing

Fencing along the north property boundary and north-south fencing located north of the liquid nitrogen AST was repaired.

2.12.6 Utilities

Utilities were restored to pre-work conditions by MODERN and it's subcontractors. Light standards and electrical wiring were replaced. Concrete piping for the parking lot drainage to storm sewers was replaced with PVC piping. Concrete catch basins were reused, however one concrete catch basin was damaged during excavation work and had to be replaced with a new concrete catch basin.

2.12.7 Paving

All excavation areas previously paved were repaved as well as some small unexcavated areas damaged while moving equipment.

3. IRM SOIL EXCAVATION RESULTS

This section describes the removal of contaminated soil from the site and the condition of soils remaining on-site following excavation. Table 15 summarizes the total volumes, tonnage and lateral areas of excavation. Figure 9, Figure 10 and Figure 11 show the estimated areas, the actual excavated areas and comparison of the estimated and actual excavated areas. Sampling results and excavations are described in the following sections. Each area is discussed separately, except where areas were merged during excavation such as in Area 1A that extended into Area 1C, creating one excavated area. Photographs are provided in Appendix M. Laboratory analytical reports are provided in Appendix N. Total tonnage reports from MODERN landfill and CWM landfill are provided in Appendix O and Appendix P, respectively.

3.1. AREAS 1A AND 1C

Area 1A was identified as an area contaminated with PAHs and VOCs from 0 to 4 ft BGS. Area 1C was identified as an area contaminated with VOCs from 0 to 2 ft BGS. Soil excavated from these areas was non-hazardous and disposed at MODERN landfill. Excavation of areas 1A and 1C was conducted between May 17 and July 12, 1999.

A total of 13 interim samples, 27 verification samples and 3 duplicate samples were collected and submitted to STL for PAHs and/or VOCs analysis. Table 16 is the sample control log for areas 1A and 1C. Interim sampling results indicated that soils from the west and east walls of area 1A contained total PAH concentrations above the clean-up objective requiring further excavation. Excavation of the west wall of area 1A extended 195 ft along an abandoned railway spur. Excavation of the east wall of area 1A extended into area 1C. Interim sampling results from area 1C indicated that the north end of the floor of 1C contained acetone above the clean-up objective; therefore, additional excavation was performed.

One verification sample collected from the north wall of areas 1A and 1C exceeded the clean-up objective for trichloroethene of 19,000 µg/Kg. Further excavation to the north was not conducted because the north wall of areas 1A and 1C also represents the north property boundary. A summary of verification sampling VOC results is provided in Table 17.

Due to the discovery of PAHs in Area 1A, DE&S and the NYSDEC established a PAH clean-up objective of 25 ppm (25,000 µg/Kg) total PAHs for soil in areas 1A and 1C. This objective was established on June 16, 1999 because clean-up objectives for some individual PAH compounds are quite low and difficult to achieve given the widespread occurrence of PAHs in industrialized areas. Given the historical, current and future use of the property as an industrial site, the likelihood of human exposure to contaminated soil through ingestion and other routes of exposure considered for health-based criteria is very low. Therefore, the 25,000 µg/Kg total PAHs clean-up objective was considered protective of human health and the environment, and reasonably achievable at an industrial facility.

Seven verification samples (*IAVS005, -010, -078, -137, -138, -208, -209*) collected from the north wall exceeded the total PAH clean-up objective with concentrations that ranged between 28,000 and 457,000 µg/Kg total PAHs. Plastic sheeting was placed along the north wall to help prevent potential recontamination of clean backfill. These samples do not represent contaminated soil remaining on-site because the north wall of the excavation extended to the north property boundary.

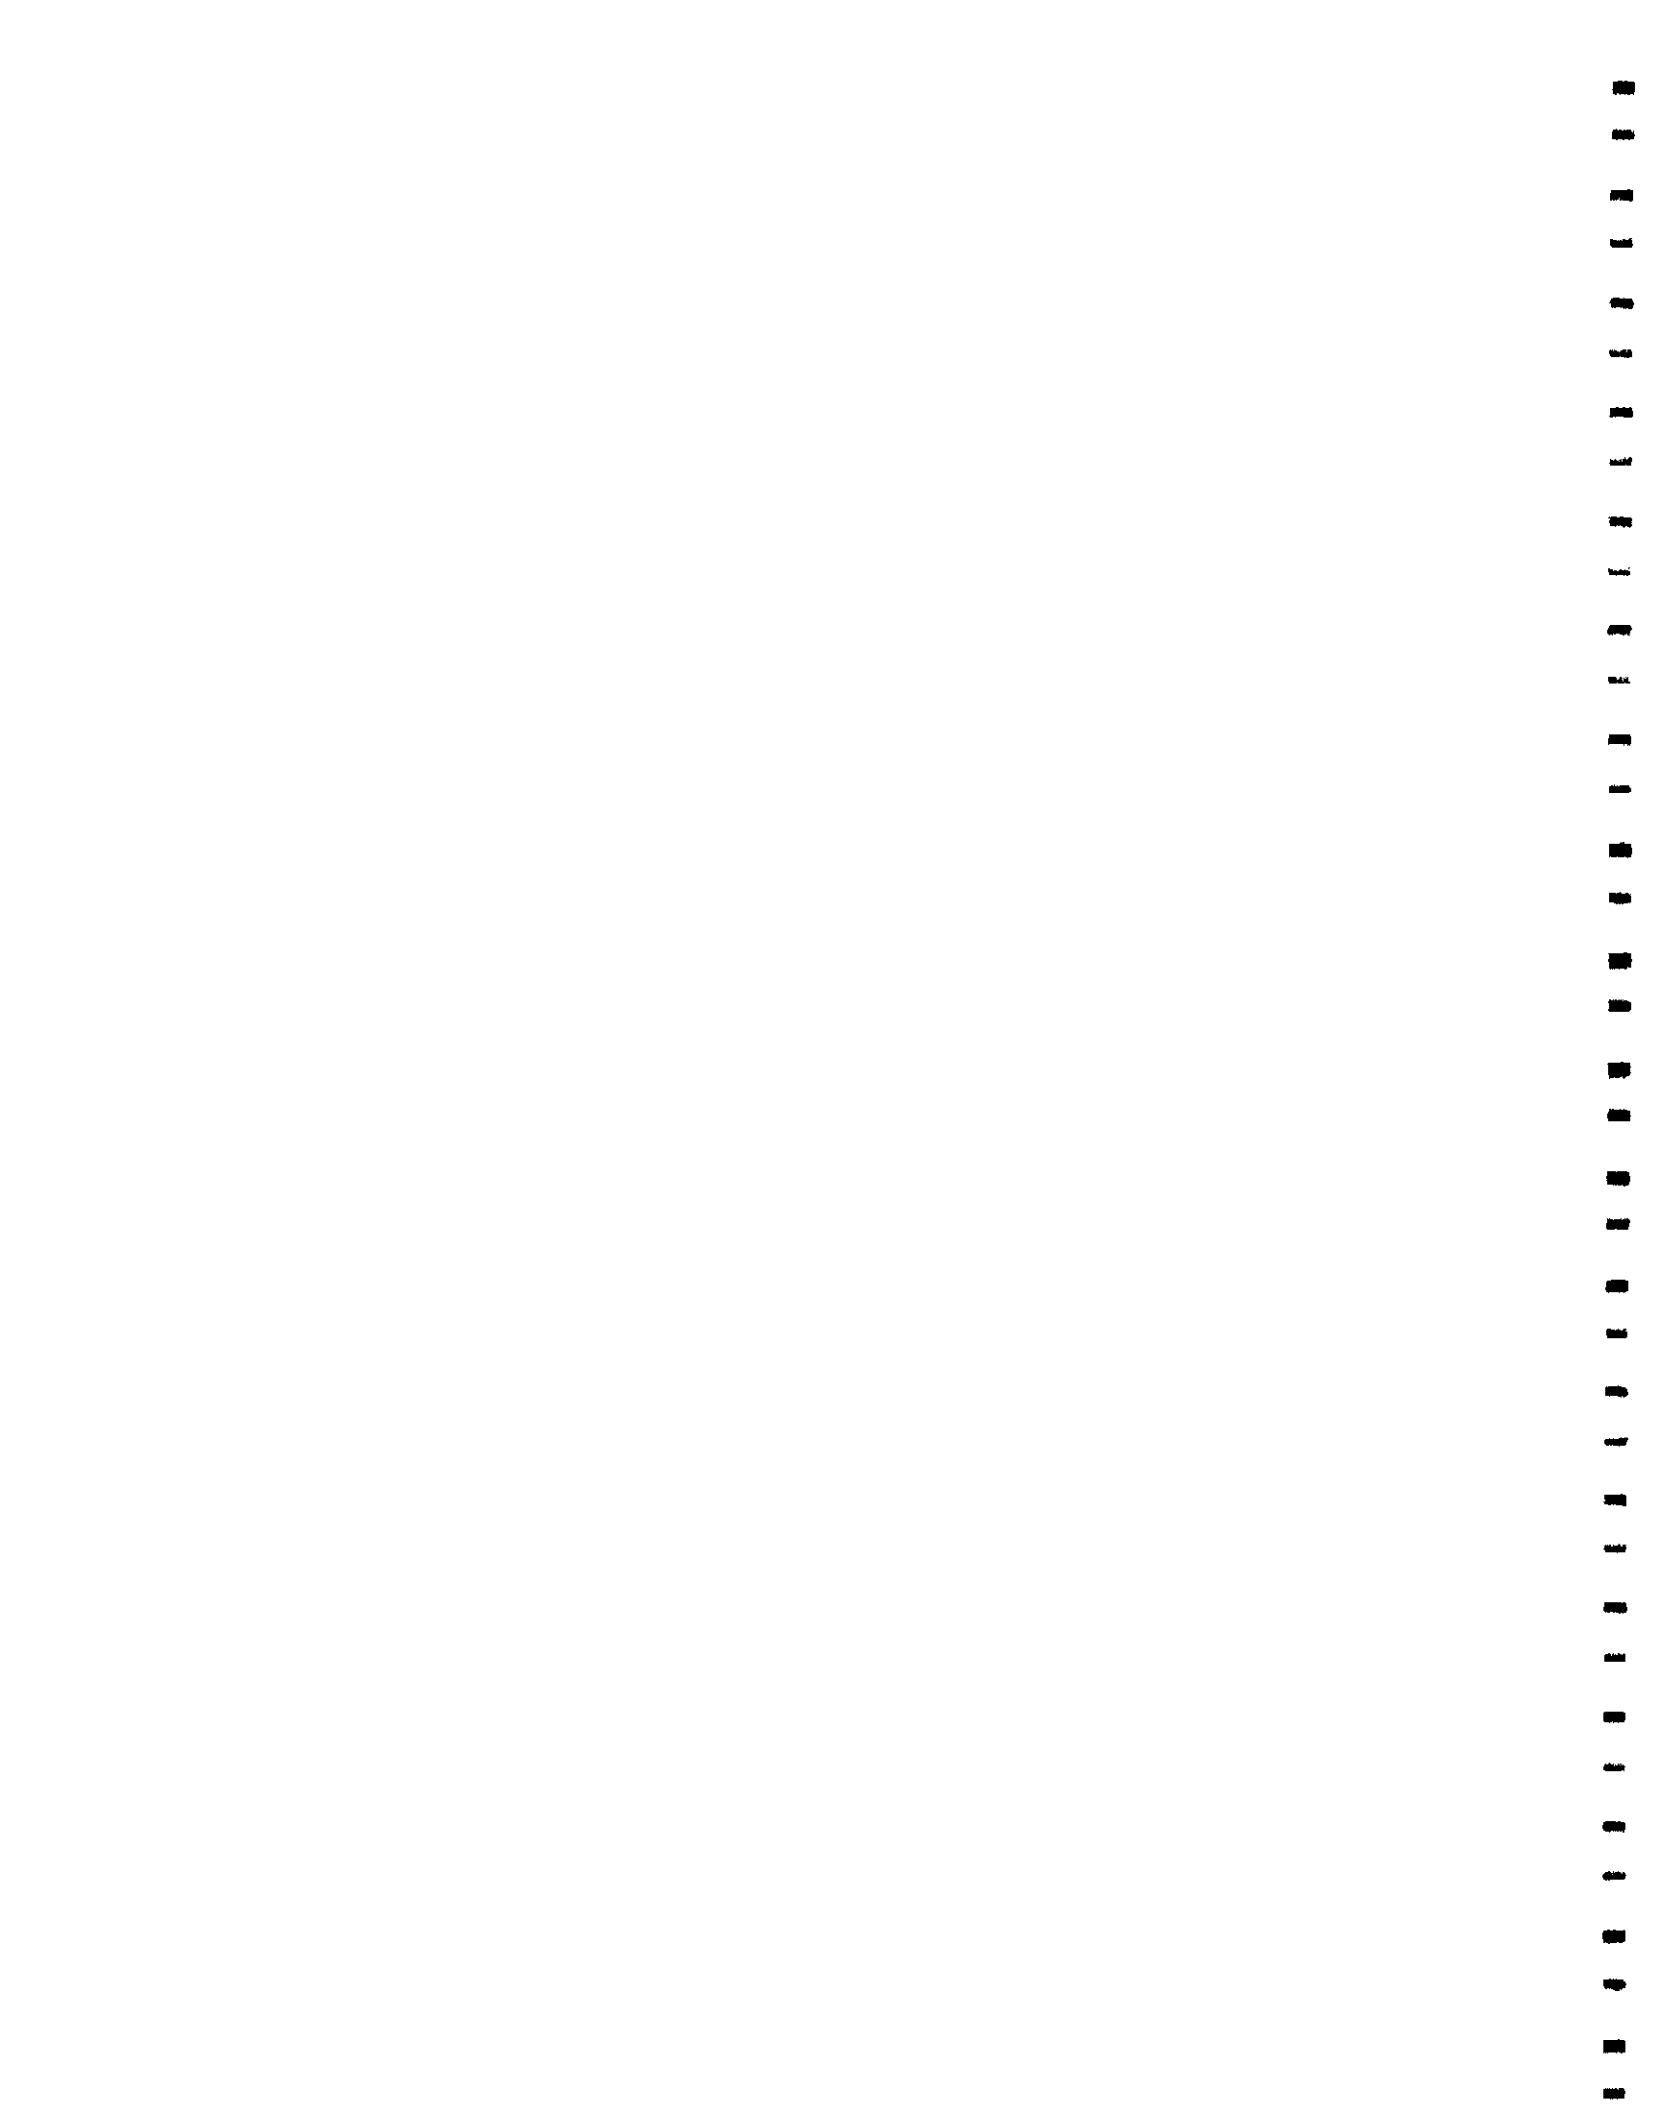

Verification sample *IAVS079* collected from the east wall did not exceed the total PAH clean-up objective; however, the NYSDEC split sample A615-11 did. Upon further examination it has been determined that there was likely an error during labeling, and the split sample was actually split from a different sample. This cannot be confirmed; however, the split sample is suspect. Due to this uncertainty the split sample A615-11 was discarded. Verification samples collected from the remaining excavation surfaces did not exceed the total PAH clean-up objective. A summary of verification sampling PAH results is provided in Table 18.

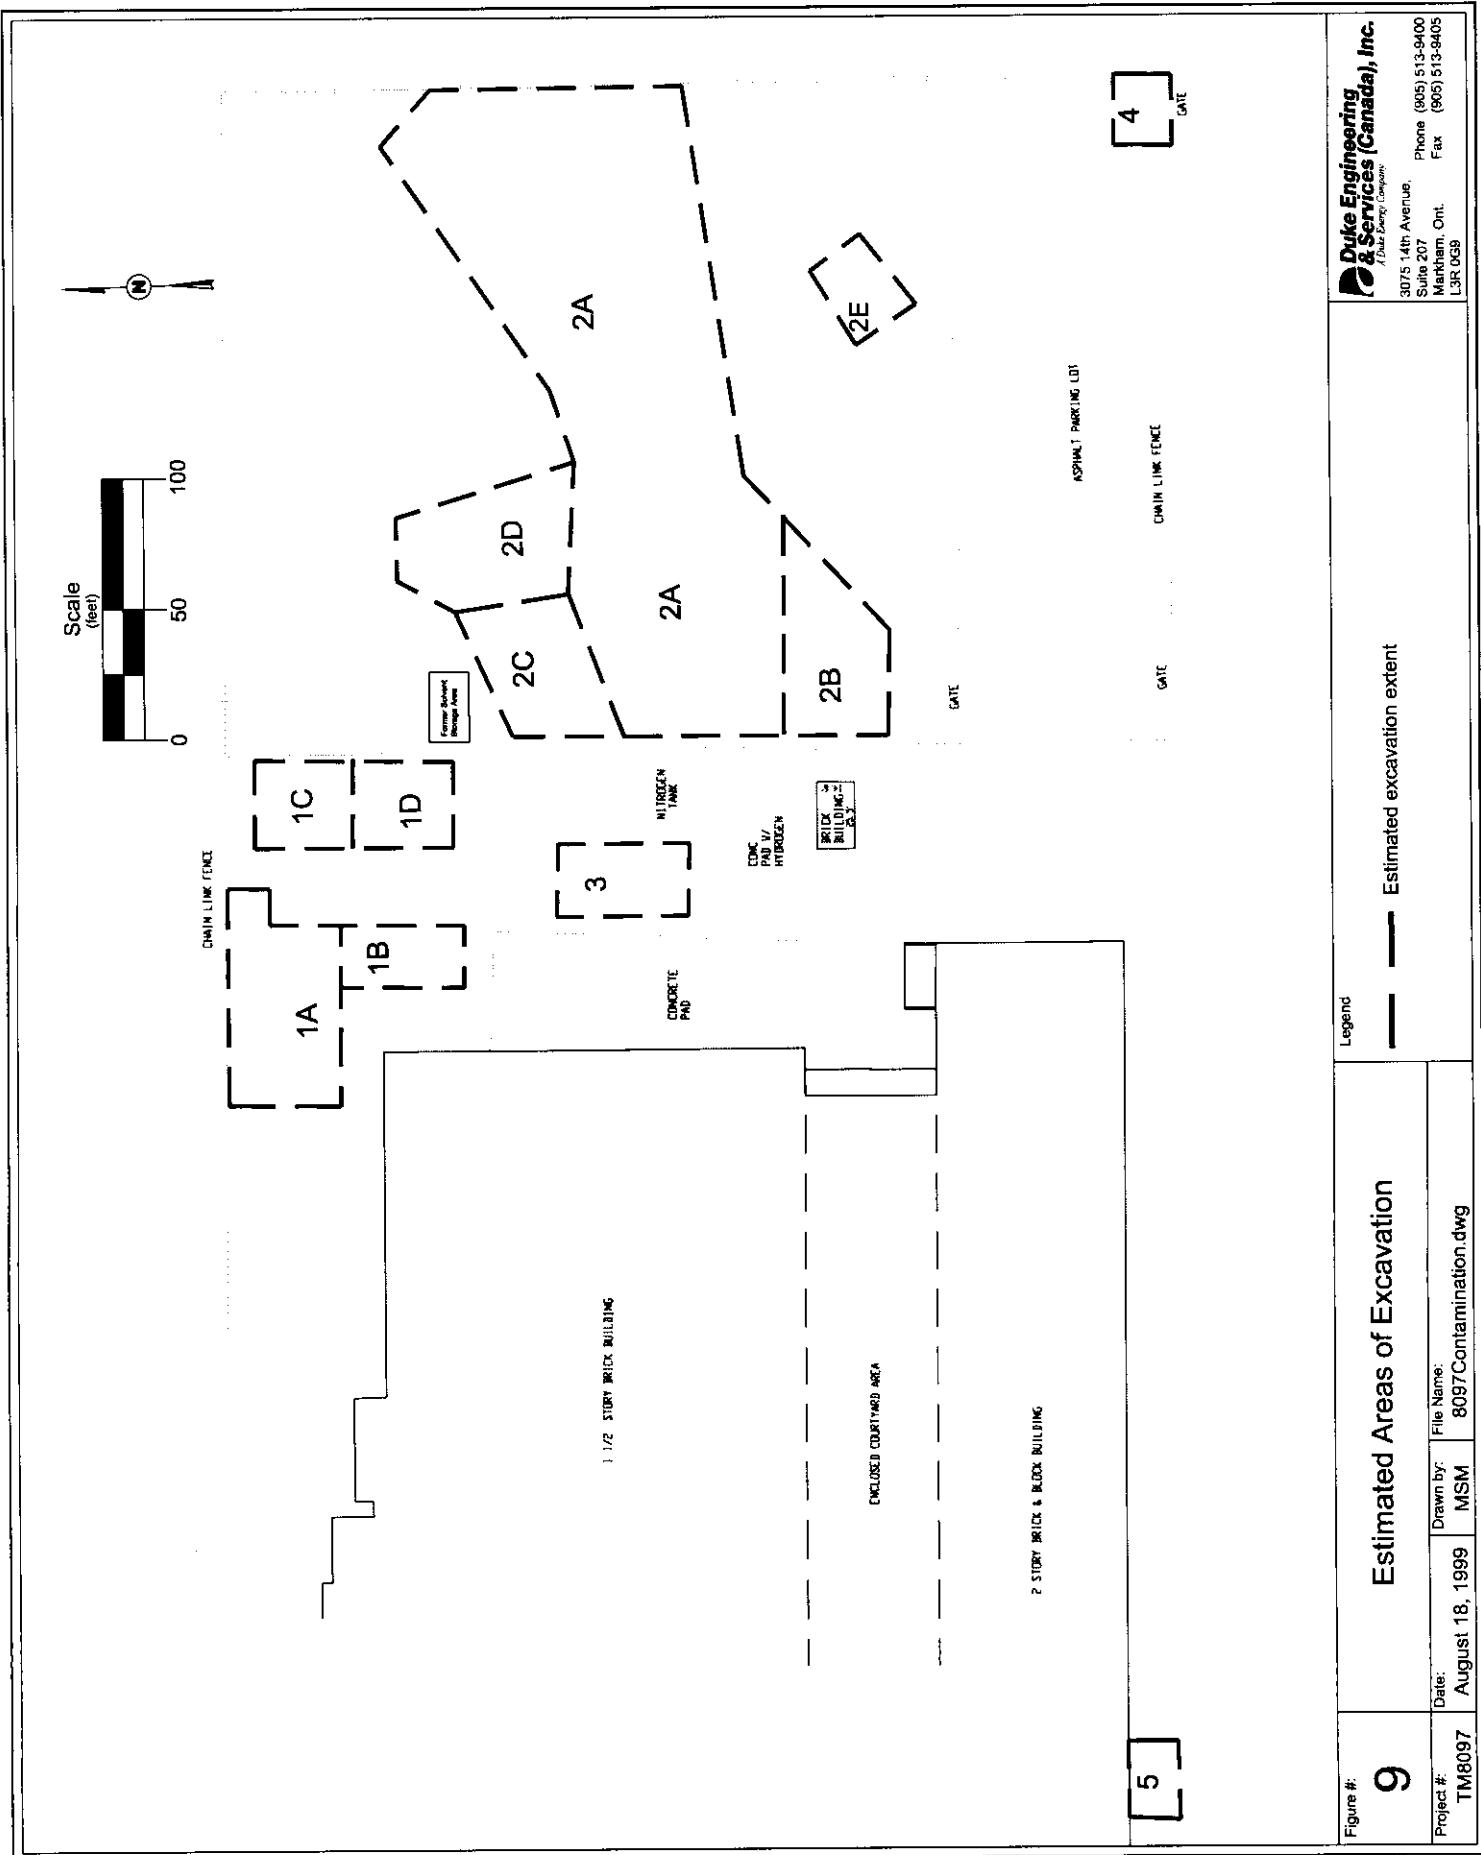

A total of 2,058 tons or 1,515 yd³ of non-hazardous material was hauled from areas 1A and 1C. Figure 12 and Figure 13 show the locations of verification samples and the extents of excavation. The final depth of excavation in areas 1A and 1C ranged from 2 to 4 ft BGS.

Backfilling and grading in areas 1A and 1C was completed on July 15, 1999. Backfill material was attained from 827 Lake Road.

3.2. AREA 1B

Area 1B was identified as an area contaminated with VOCs from eight to ten ft BGS. Soil excavated from this area was non-hazardous and disposed at MODERN Landfill. Soil from zero to eight feet BGS was excavated and stockpiled on-site for use as clean backfill. Area 1B was excavated on July 21, 1999.

Eight verification samples and one duplicate sample were collected on July 21, 1999 and submitted to STL for VOCs analysis. Table 19 is the sample control log for area 1B. All of the verification samples had VOC concentrations below the clean-up objectives; therefore, additional excavation was not required. A summary of verification sampling results is provided in Table 20.

A total of 255 tons or approximately 162 yd³ of non-hazardous material was excavated and disposed from area 1B. The total volume of clean and non-hazardous material excavated from area 1B was 460 yd³. Figure 14 and Figure 15 show the locations of verification samples and the estimated and actual extents of excavation in area 1B. The final depth of area 1B was ten ft BGS

Table 19 - Sample Control Log for Area 1B.

3.3. AREAS 1D, 1D-EXTENSION AND 2C

Area 1D was identified as an area contaminated with VOCs from 6 to 8 ft BGS. Excavation in area 1D revealed that contaminated soils extended toward the east beneath an on-site structure formerly used as a solvent storage area. The structure was demolished on June 21, 1999 and area 1D was extended toward the east, eventually joining area 2C. Area 2C was identified as an area contaminated with VOCs from 0 to 24 ft BGS. Action level concentrations of vinyl chloride were identified in the center of the area from 4 to 8 ft BGS. Areas 1D, 1D-extension and 2C were excavated between May 18 and July 20, 1999.

Each bucket of excavated soil was screened with the PID and observations were noted. Stained material that exhibited PID readings greater than 500 ppm was sent directly to CWM. Material that was not stained but had PID readings greater than 500 ppm total VOCs was stockpiled and sampled to determine the appropriate disposal location. Material that was not stained and had PID readings less than 500 ppm total VOCs was sent directly to MODERN's landfill as non-hazardous material.

A total of 13 interim samples, 33 verification samples and 3 duplicate samples were collected from these areas and submitted to STL for VOCs analysis. Table 21 is the sample control log for areas 1D, 1D-extension and 2C. Interim sampling results indicated that soils in area 1D from the floor in the south-east corner exceeded the clean-up objectives requiring additional excavation. Interim sampling results indicated that soils in area 1D-extension from the floor and north wall exceeded the clean-up objectives and/or the action levels requiring additional excavation. Interim sampling results indicated that soils in area 2C from the floor and the east wall exceeded the clean-up objectives requiring additional excavation.

Additional excavations were conducted in an attempt to remove remaining contaminated soil from the area. However, the proximity of the liquid Nitrogen AST limited the lateral extent of excavation toward the west. In addition, a depth of greater than 24 feet could not be reached due to the non-cohesive nature of subsurface materials and the high rate of groundwater seepage into the excavation at depth. The excavation was extended to the greatest attainable depth and lateral extent.

Verification sampling results indicate that soil containing non-hazardous concentrations of VOCs remains in areas 1D-extension and 2C on the floor at a depth of 24 ft (samples *IDVS213*, *IDVS216*, *2CVS176*[dup *2CVS177*], *2CVS179*, *2CVS182*, *2CVS183* and *2CVS189*[dup *2CVS193*]), on the east wall (samples *2CVS180* and *2DVS241*) at 20 ft and on the north wall (sample *IDVS220*) at 20 ft. Approximately 700 yd³ of non-hazardous soil remains on-site in areas 1D-extension and 2C. Additional excavation in these locations was not possible because of significant water seepage, large cobbles and reduced slope stability. No verification samples in area 1D exceeded the clean-up objectives for VOCs.

Verification sampling results also indicate that soil (sample *IDVS213*) containing vinyl chloride above the action level remains in area 1D-extension on the floor at 24 ft below

the former location of the solvent storage area. An estimated 200 ft² of action level soil remains around sample location 1DVS213. Assuming the depth of action level soil in this area is 6 ft, then approximately 40 yd³ of action level soil remains on-site. Excavating deeper in this area was also not possible as explained above.

A summary of verification sampling results is provided in Table 22.

A total of 7,111 tons or 4,041 yd³ of non-hazardous soil was excavated from areas 1D, 1D-extension and 2C. A total of 1,187.09 tons or 674 yd³ of action level soil was excavated from areas 1D, 1D-extension and 2C. Figure 16 and Figure 17 show the locations of verification samples and the estimated and actual extents of excavation in areas 1D, 1D-extension and 2C.

Backfilling of areas 1D, 1D-extension and 2C was completed on July 22, 1999. The backfill for these areas was attained from 827 Lake Road, 1500 James Avenue and Bridle Path.

3.4. AREAS 2A AND 2E

Area 2A was identified as an area contaminated with VOCs from 0 to 16 ft BGS. Area 2E was identified as an area contaminated with VOCs from 0 to 4 ft BGS. Soil excavated from these areas was non-hazardous and disposed at MODERN landfill. Excavation of areas 2A and 2E was conducted between May 19 and July 22, 1999.

A total of 18 interim samples, 74 verification samples and 4 duplicate samples were collected from the areas and submitted to STL for VOCs analysis. Table 23 is the sample control log for areas 2A and 2E. Interim sampling results indicated that soils in area 2A from the south, east and west walls and the floor in the north-east corner and in the west end exceeded the clean-up objectives and/or the action levels requiring additional excavation. Excavation of the south wall of 2A extended into area 2E.

Interim samples 2AVS113, 2AVS153 and 2C1D156 exceeded the action level for vinyl chloride. These samples were collected from 10-16 ft BGS on the west wall of 2A near the hydrogen gas cylinders, the liquid nitrogen AST and the intersection of areas 2A and 2C, respectively. Additional material was excavated from these sample locations and sent to CWM.

Verification sampling results indicate that non-hazardous soil remains in area 2A at the east wall from 0 to 16 ft (samples 2AVS042-043, 2AVS052-053 and 2AVS093-098), on the west wall near the hydrogen gas cylinders from 10 to 16 ft (sample 2AVS255), the floor in the north-east corner (sample 2AVS092) at 24 ft and the floor in the west end (samples 2AVS125, 2AVS127 and 2AVS133-136) at 18 to 24 ft. Excavating further east was not possible because the excavation extended to the east property boundary. An estimated 800 ft² of non-hazardous soil remains between 0-16 ft BGS on the east wall. Excavating further west was not possible because of the proximity of the hydrogen gas cylinders. Excavating deeper than 24 ft in the north-east corner was not possible because of significant water seepage, large cobbles and reduced slope stability. The west end of 2A was excavated to 16 feet and four interim samples (samples 2AVS101[dup 2AVS102], 2AVS106, 2AVS110 and 2AVS115) were collected. All four samples exceeded the VOC clean-up objectives. The west end of 2A was then further excavated to 18 feet. In three areas, floor samples were collected at 18 ft (samples 2AVS124, 2AVS129 and 2AVS133) and test pits were installed to 24 feet. Samples 2AVS125-127, 2AVS130-132 and 2AVS134-136 were collected from the test pits at 20, 22 and 24 feet. The verification samples indicated that the west end of area 2A remained above the clean-up objectives at 24 ft BGS in two of the three test pits. Samples 2AVS129-132 were collected from the east half of the west portion of area 2A and did not exceed the VOC clean-up objectives. The west end of area 2A was not excavated to 24 ft due to:

- i) excavation was difficult due to the presence of loose sands, silts, gravels and boulders in this area and there was a significant concern for slope stability,
- ii) the proximity of the hydrogen gas cylinders and the liquid nitrogen AST, and
- iii) significant groundwater seepage that compounded slope stability issues.

The estimated volume of non-hazardous soils remaining in area 2A is 1,100 yd³.

Verification sampling results also indicate that action level soil remains in area 2A on the east wall (sample 2AVS043). An estimated 150 ft² of action level soil remains between 10-16 ft BGS on the east wall around sample location 2AVS043. Excavating further east was not possible because the verification sample was collected at the east property boundary.

The laboratory analytical results for the verification samples are provided in Table 24.

A total of 20,680 tons or 11,074 yd³ of non-hazardous material was excavated from areas 2A and 2E. A total of 57 tons or 32 yd³ of action level soils was excavated from Area 2A. The total volume of clean, non-hazardous and action level material excavated from 2A was 13,369 yd³. Figure 18 and Figure 19 show the locations of verification samples and the estimated and actual extents of excavation in areas 2A and 2E. The final depth of excavation in area 2A ranged between 11 and 24 ft. The depth of area 2E was 11 ft.

Backfilling of areas 2A and 2E started on June 8 and was completed on July 22, 1999. The backfill for these areas was attained from 827 Lake Road and Bridle Path.

1 - The results reported are the average of the sample and duplicate.

2 - The results reported are the average of the DE&S verification sample and the NYSDEC split sample.

J - Indicates an estimated value. Compound meets identification criteria and is less than the specific detection limit but greater than zero.

B - Indicates that the analyte was found in both the sample and its associated laboratory blank. Possible/probable blank contamination.

D - Indicates compound identified in an analysis at a secondary dilution factor.

Nd - not detected

Shaded concentrations indicate an exceedance of the clean-up objective

Shaded concentrations indicate an exceedance of the action level

Shaded concentrations indicate an exceedance of the action level

3.5. AREA 2B

Area 2B was identified as an area contaminated with VOCs from 10 to 12 ft BGS. Soil excavated from this area was non-hazardous and disposed at MODERN landfill. Soil from 0 to 10 ft BGS was excavated and stockpiled on-site for use as clean backfill. Excavation of area 2B was conducted between July 7 and August 4, 1999.

Interim sampling results indicated that soils from the floor, west and south walls contained VOC contaminant concentrations above the clean-up objectives and required further excavation. A total of 12 interim samples, 14 verification samples and 3 duplicate samples were collected from area 2B and submitted to STL for VOCs analysis. Table 25 is the sample control log for area 2B. All of the verification samples had VOC concentrations below the clean-up objectives. A summary of verification sampling results is provided in Table 26. A total of 2,388 tons or approximately 1,294 yd³ of non-hazardous material was excavated from area 2B. The total volume of clean and non-hazardous material excavated from area 2B was approximately 2,074 yd³. Figure 20 and Figure 21 show the locations of verification samples and the estimated and actual extents of excavation in area 2B. The final depth of area 2B ranged between 13.5 and 16 ft BGS.

Area 2B was backfilled on August 4 and 5, 1999 with material attained from 1500 James Avenue and Harold and Pletcher Roads.

Table 25 - Sample Control Log for Area 2B.

Sample ID	Date	Description	Headspace Gas Readings (ppm)	Verify or Interim	NYSDDEC Split #	Exceeds clean-up criteria
2BVS163	July 7/99	Floor, north west corner, 13.5 ft	3.5	Verify	-	no

3.6. AREA 2D

Area 2D was identified as an area containing soils with trichloroethene and vinyl chloride concentrations above action levels; however, during the pre-characterization test pit program, a composite soil sample collected from 0 to 4 ft BGS in area 2D contained trichloroethene in leachate above the maximum NYCRR Part 371 concentration of 500 µg/L. Soil from 0 to 4 ft BGS in area 2D was therefore disposed at CWM. Remaining soils were disposed at MODERN. Area 2D was excavated between May 25 and July 19, 1999.

Interim samples were collected to identify when the excavation of action level soils was complete and verification samples were collected to identify when the excavation of clean-up objective soils was complete. A total of 4 interim samples, 8 verification samples and 2 duplicate samples were collected from area 2D and submitted to STL for VOCs analysis. Table 27 is the sample control log for area 2D. The interim samples had VOC contaminant concentrations that exceeded the clean-up objectives but not the action levels. Following removal of the action level soil, remaining soils were excavated and verification samples were collected. None of the verification samples exceeded the clean-up objectives. A summary of verification sampling results is provided in Table 28. A total of 319 tons or 140 yd³ of non-hazardous material was hauled from area 2D. A total of 847 tons or 370 yd³ of action level material was hauled from area 2D. Figure 22 and Figure 23 show the locations of verification samples and both the estimated and actual extents of excavation of area 2D. The final depth of area 2D ranged between 4 and 7 ft BGS.

Area 2D was backfilled on July 23, 1999 with material attained from Harold and Pletcher Roads.

3.7. AREA 3

Area 3 was identified as an area contaminated from 0 to 4 feet BGS with VOCs. Soil excavated from this area was non-hazardous and disposed at MODERN landfill. Area 3 was excavated between May 18 and 25, 1999.

A total of one interim sample, eight verification samples and one duplicate sample were collected and submitted to STL for VOCs analysis. Table 29 is the sample control log for area 3. The interim sample exceeded the clean-up objective for acetone requiring additional excavation of the west wall. All of the verification samples had VOC concentrations below the clean-up objectives. A summary of verification sampling results is provided in Table 30. A total of 522 tons or 246 yd³ of non-hazardous material was excavated from area 3. Figure 24 and Figure 25 show the locations of verification samples and the estimated and actual extents of excavation in area 3.

Area 3 was backfilled on June 8, 1999 with material attained from 827 Lake Road.

3.8. AREA 4

Area 4 was identified as an area contaminated from 2 to 4 feet BGS with VOCs. Material from 0 to 2 ft BGS consisted of asphalt and rock and was stockpiled on-site for later use as asphalt base. Soil excavated from 2 to 4 ft BGS in this area was non-hazardous and disposed at MODERN landfill. Area 4 was excavated on July 9, 1999.

A total of six verification samples and one duplicate sample were collected and submitted to STL for VOCs analysis. Table 31 is the sample control log for area 4. None of the verification samples exceeded the clean-up objectives for VOCs. A summary of verification sampling results is provided in Table 32. A total of 124 tons or 44 yd³ of non-hazardous soil was excavated from area 4. The total volume of clean and non-hazardous material excavated from area 4 was 83 yd³. Figure 26 and Figure 27 show the locations of verification samples and both the estimated and actual extents of excavation in area 4.

Area 4 was backfilled on July 15, 1999 with material attained from 1500 James Avenue.

3.9. AREA 5

Area 5 was identified as an area contaminated from 0 to 2 feet BGS with xylenes (total) and lead. During the pre-characterization test pit program, a composite soil sample collected from 0 to 2 ft BGS contained lead in leachate above the maximum NYCRR Part 371 concentration of 5,000 µg/L. Therefore, soil from this area was disposed at CWM. Area 5 was excavated on July 9, 1999.

Area 5 was excavated to 2.5 ft because the depth of the sand fill was 2.5 ft and the fill was underlain by native clay. A total of five verification samples and two duplicate samples were collected and submitted to STL for VOCs and total lead in soil. Table 33 is the sample control log for area 5. None of the verification samples exceeded the cleanup objectives for VOCs. Total lead concentrations for all of the verification samples were below 100 ppm, or 100,000 µg/kg, which is within the range of site background lead concentrations. A summary of verification sampling results is provided in Table 34. A total of 58 tons or 40 yd³, was excavated from area 5. Figure 28 and Figure 29 show the locations of verification samples and both the estimated and actual extents of excavation of area 5.

Area 5 was backfilled on July 9, 1999 with asphalt and stone stockpiled on-site.

Table 33 - Sample Control Log for Area 5.

4 - Duplicate for lead only.

5 - Duplicate for VOCs only.

J - Indicates an estimated value. Compound meets identification criteria and is less than the specific detection limit but greater than zero. B - Indicates that the analyte was found in both the sample and its associated laboratory blank. Possible/probable blank contamination.

D - Indicates compound identified in an analysis at a secondary dilution factor.

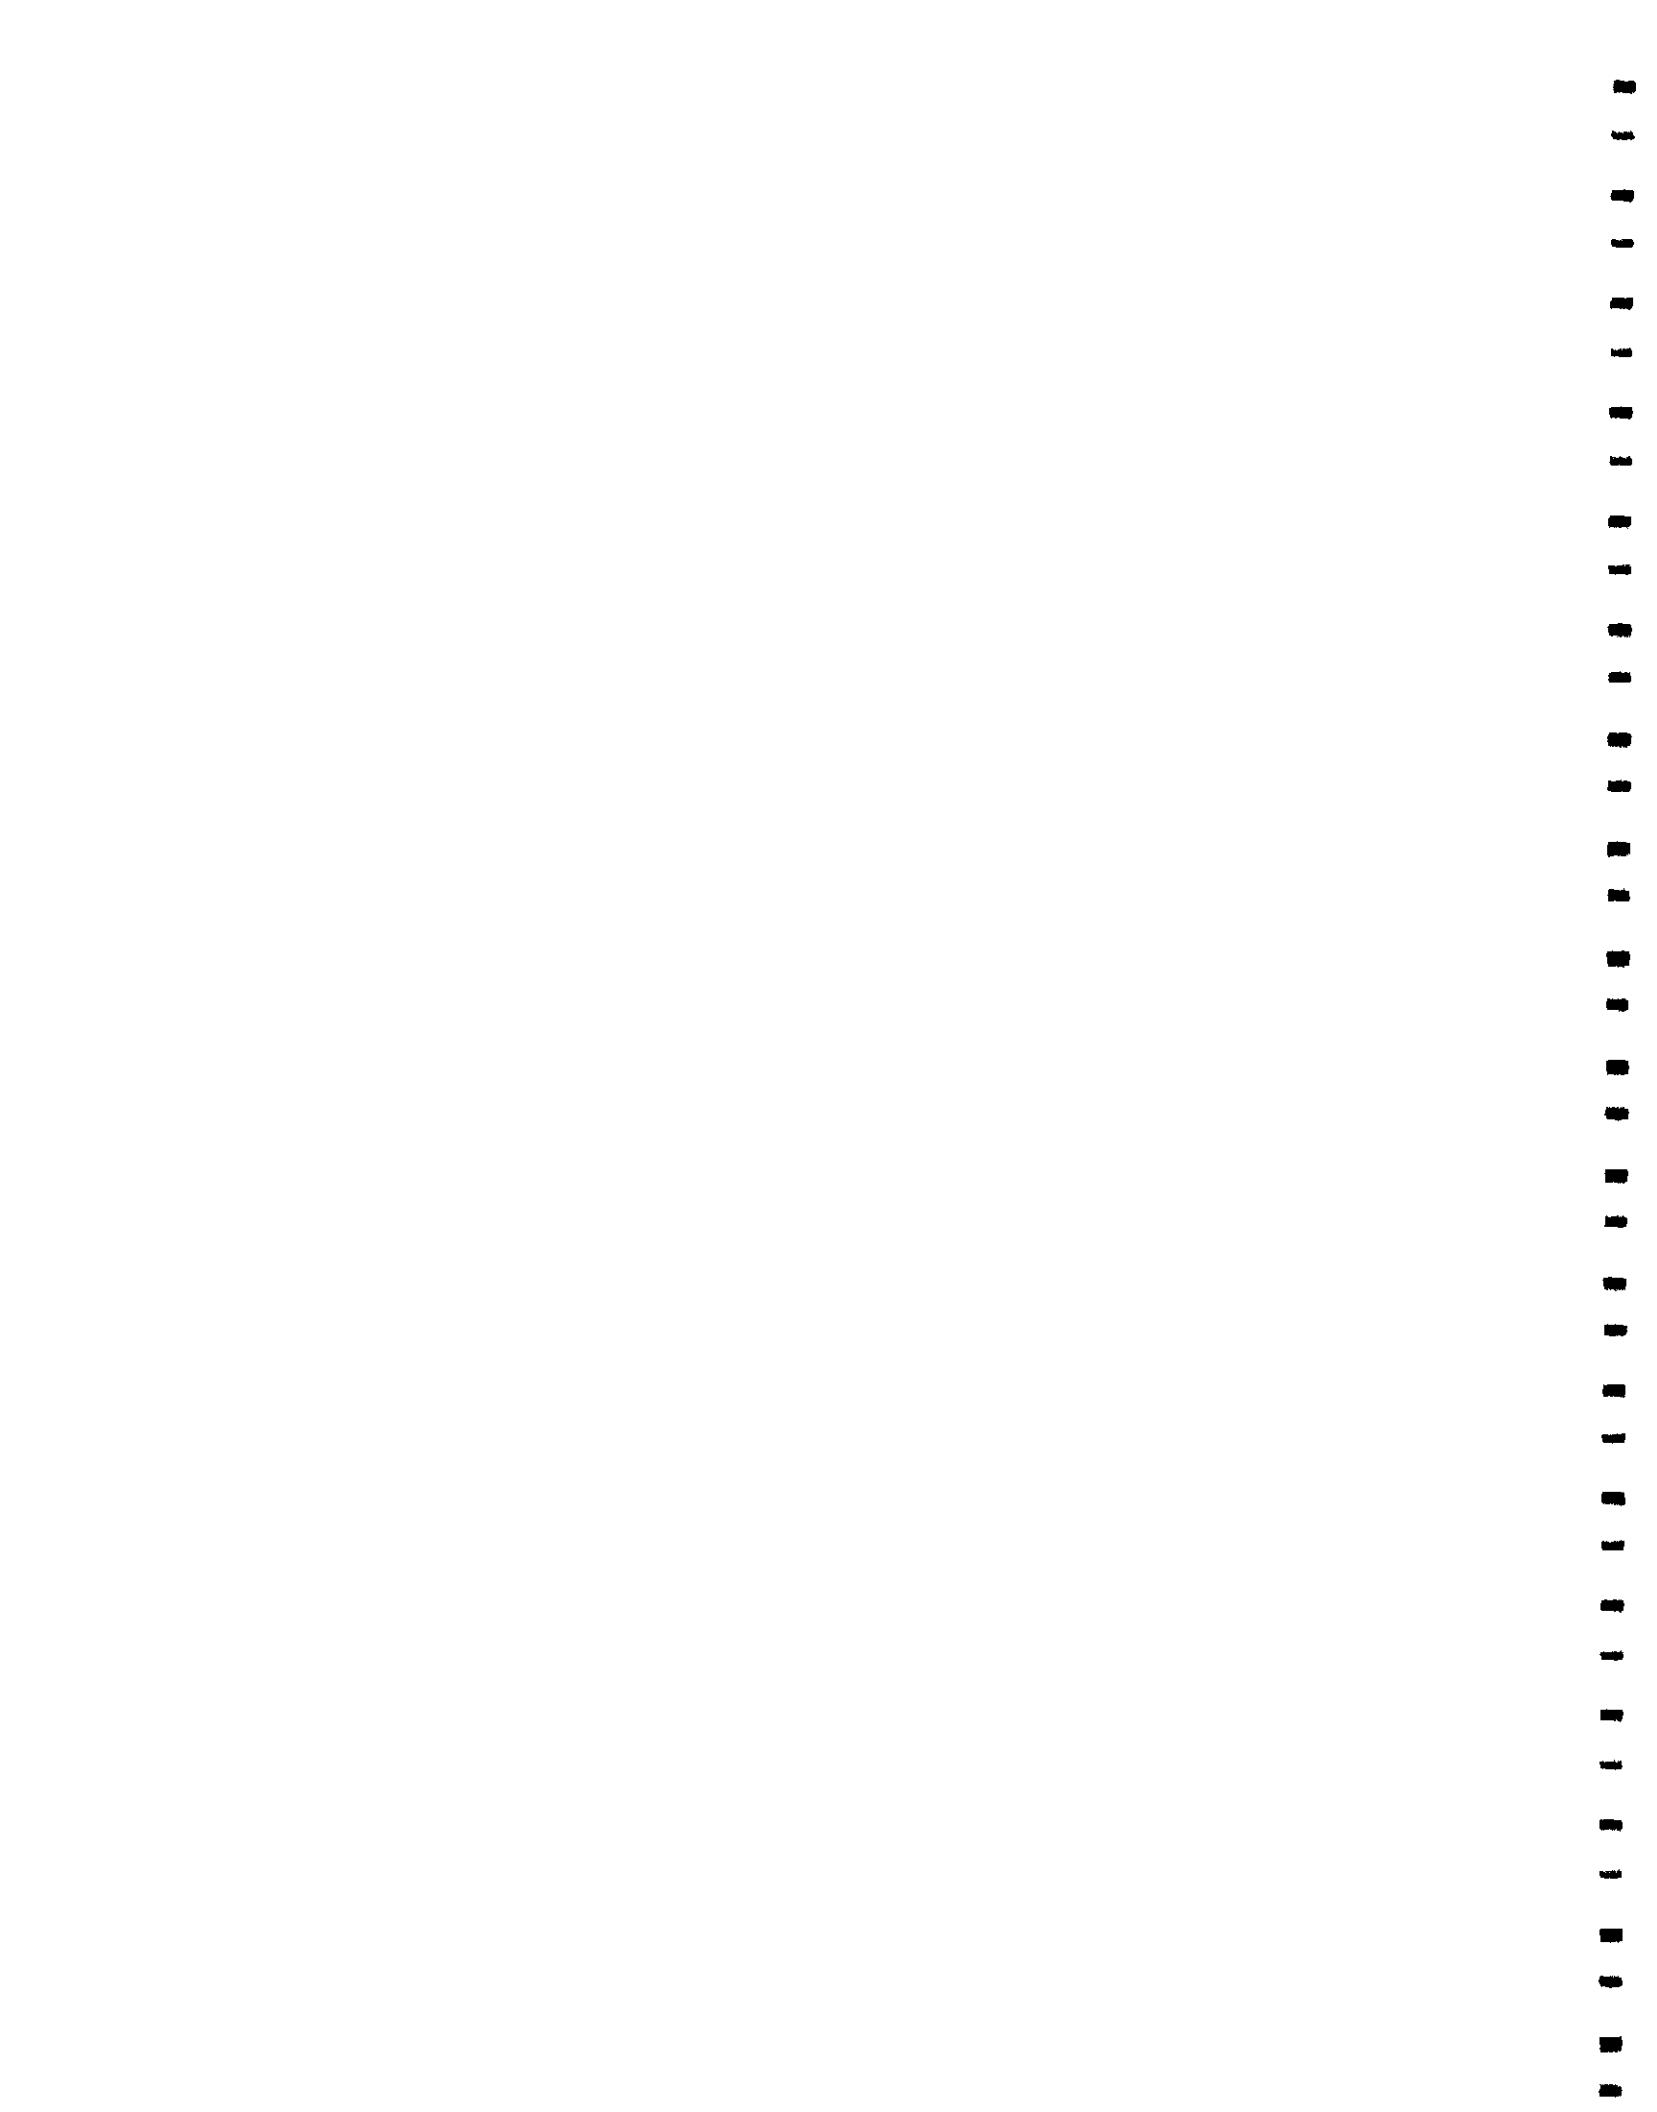

N - Spiked sample recovery not within control limits.

Nd - not detected

Shaded concentrations indicate an exceedance of the clean-up objective

Shaded concentrations indicate an exceedance of the action level

4. CONDITION OF SOIL REMAINING ON SITE

The goal of the IRM was to remove contaminated soils from the site. A total of 35,606 tons, or approximately 23,700 yd³, of soil was excavated and removed. Site conditions prevented the removal of some contaminated soils. An estimated total of 1980 yd³ remains on-site at depths below 10 feet. The volume of soil remaining represents approximately 8% of the total volume of identified contaminated soil. The objective of the IRM was to affect an improvement in groundwater quality with time following source removal. Over 90% of contaminated soils have been removed from the property, including over 2000 tons of action level soil. It is believed that a significant proportion of the source of contamination to groundwater has been removed from the site, and the objective of the IRM will be achieved.

Areas where contaminated soils remain on-site or at the property boundaries include 1A/1C, 1D/1D-extension/2C and 2A/2E. These areas are described below and are shown on Figure 30.

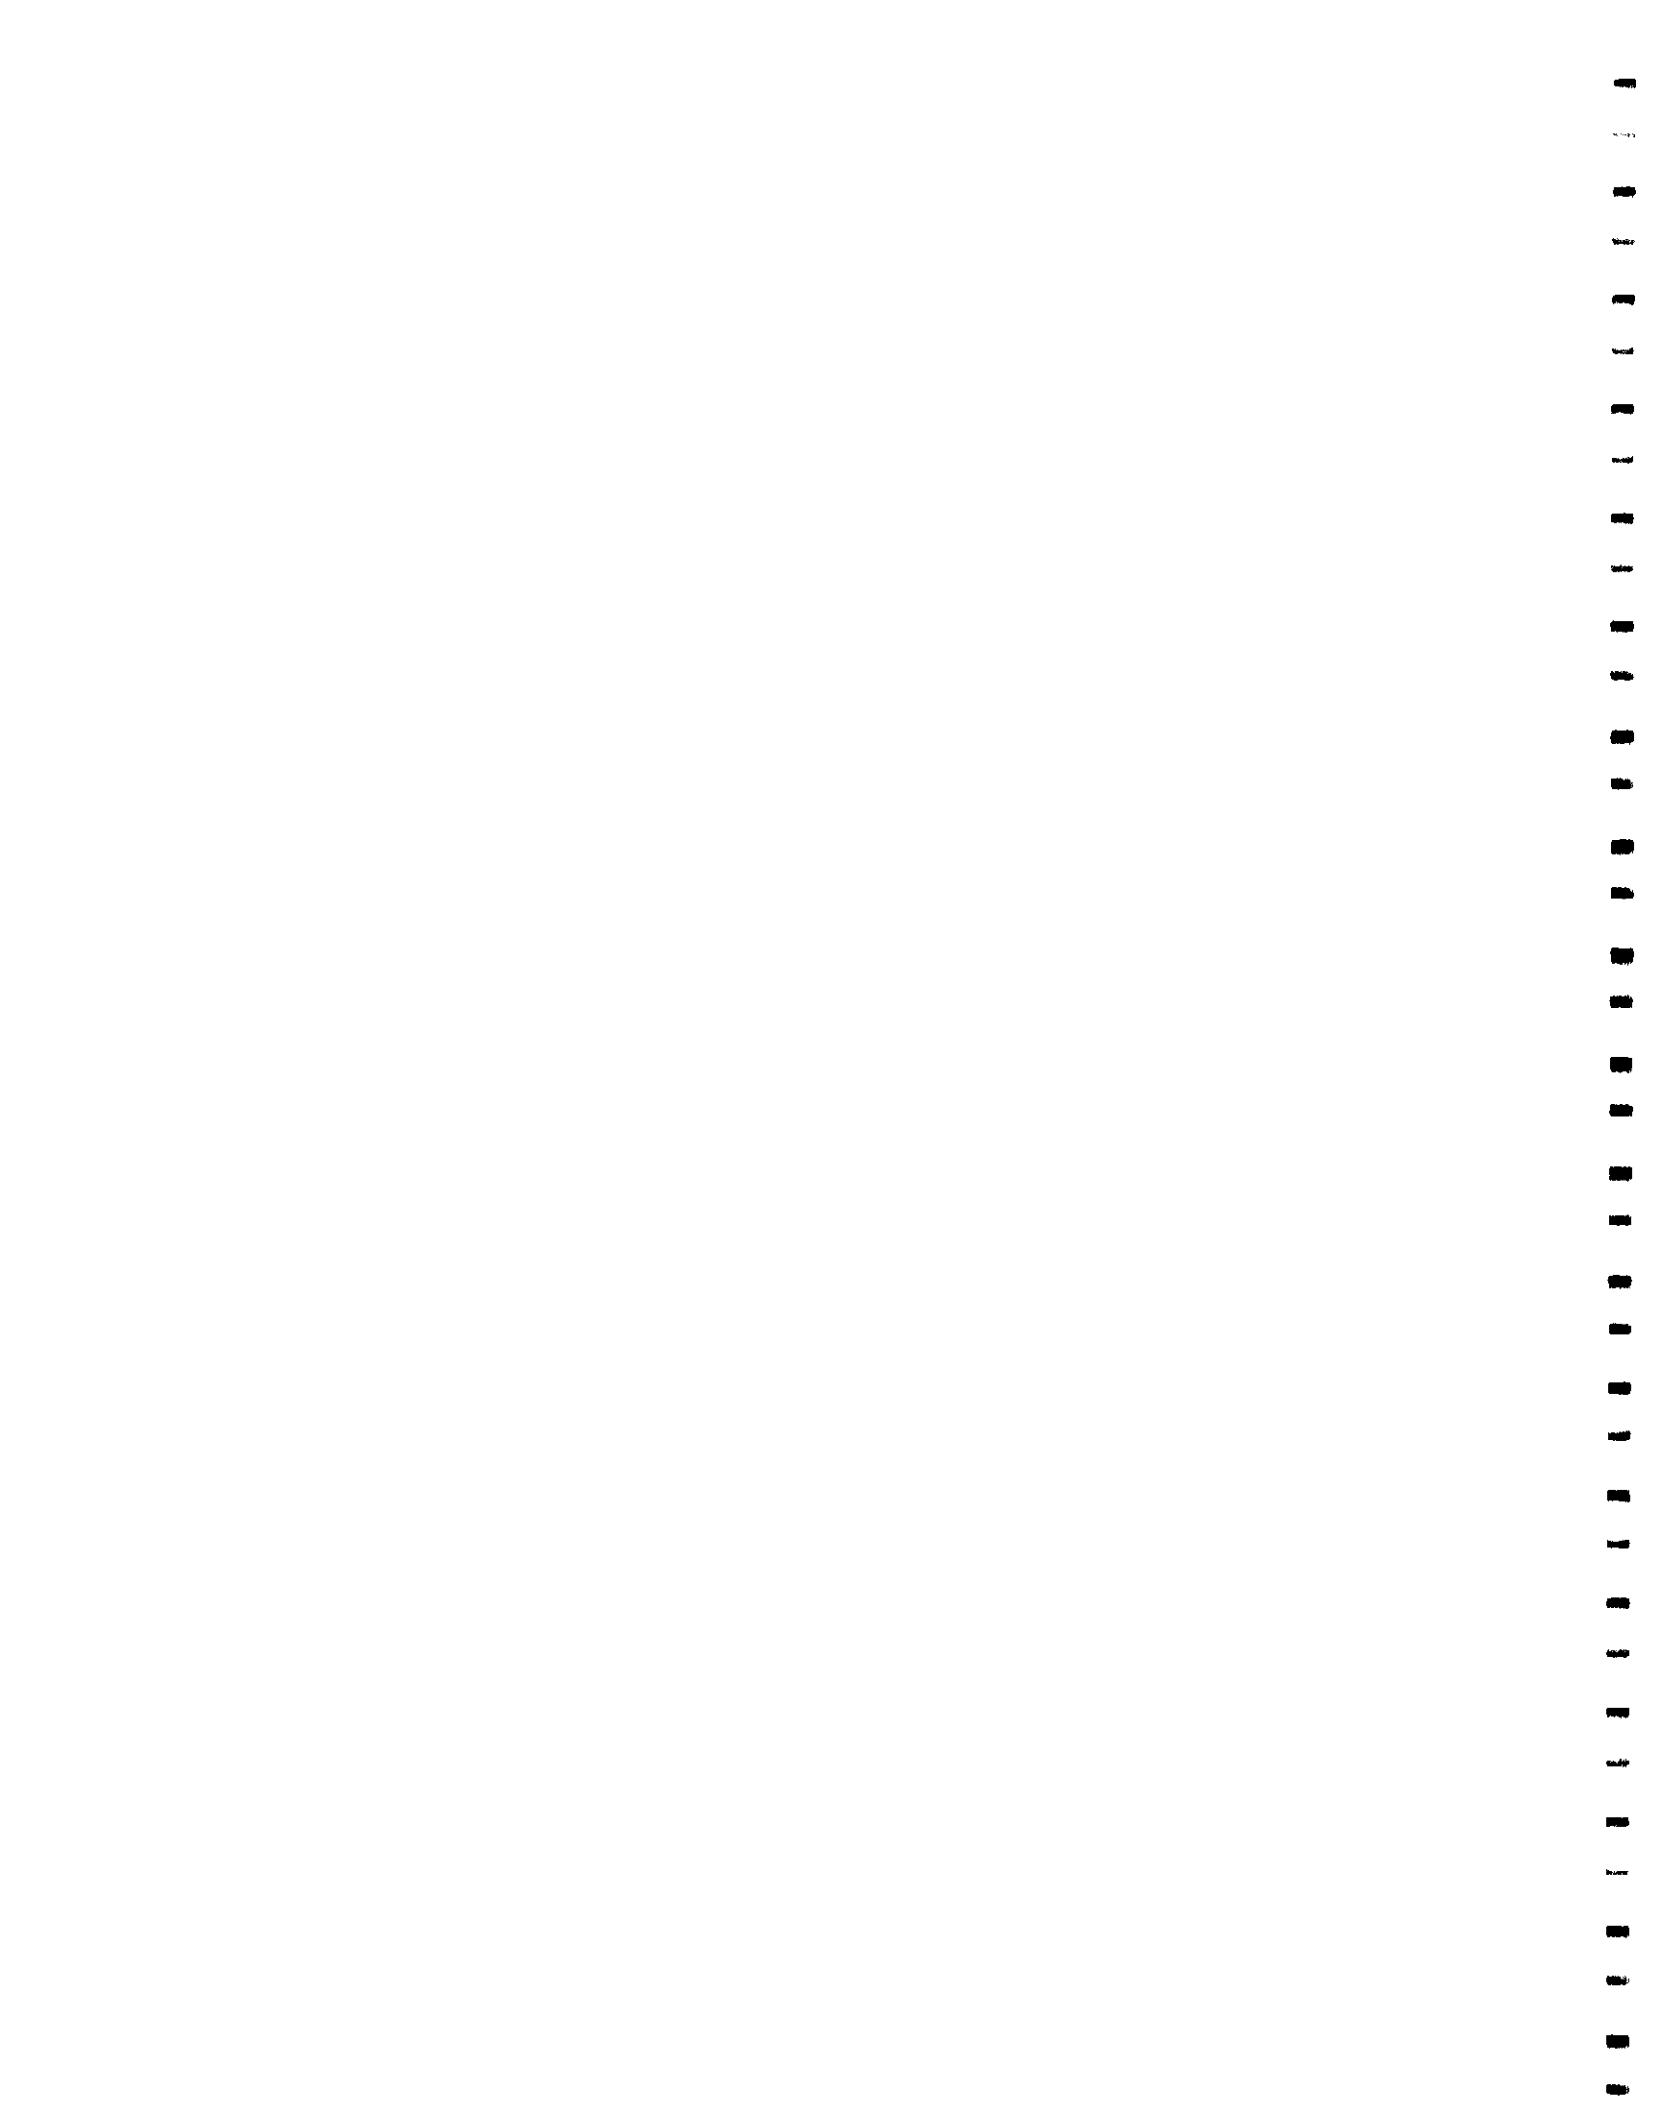

4.1. AREAS 1A AND 1C

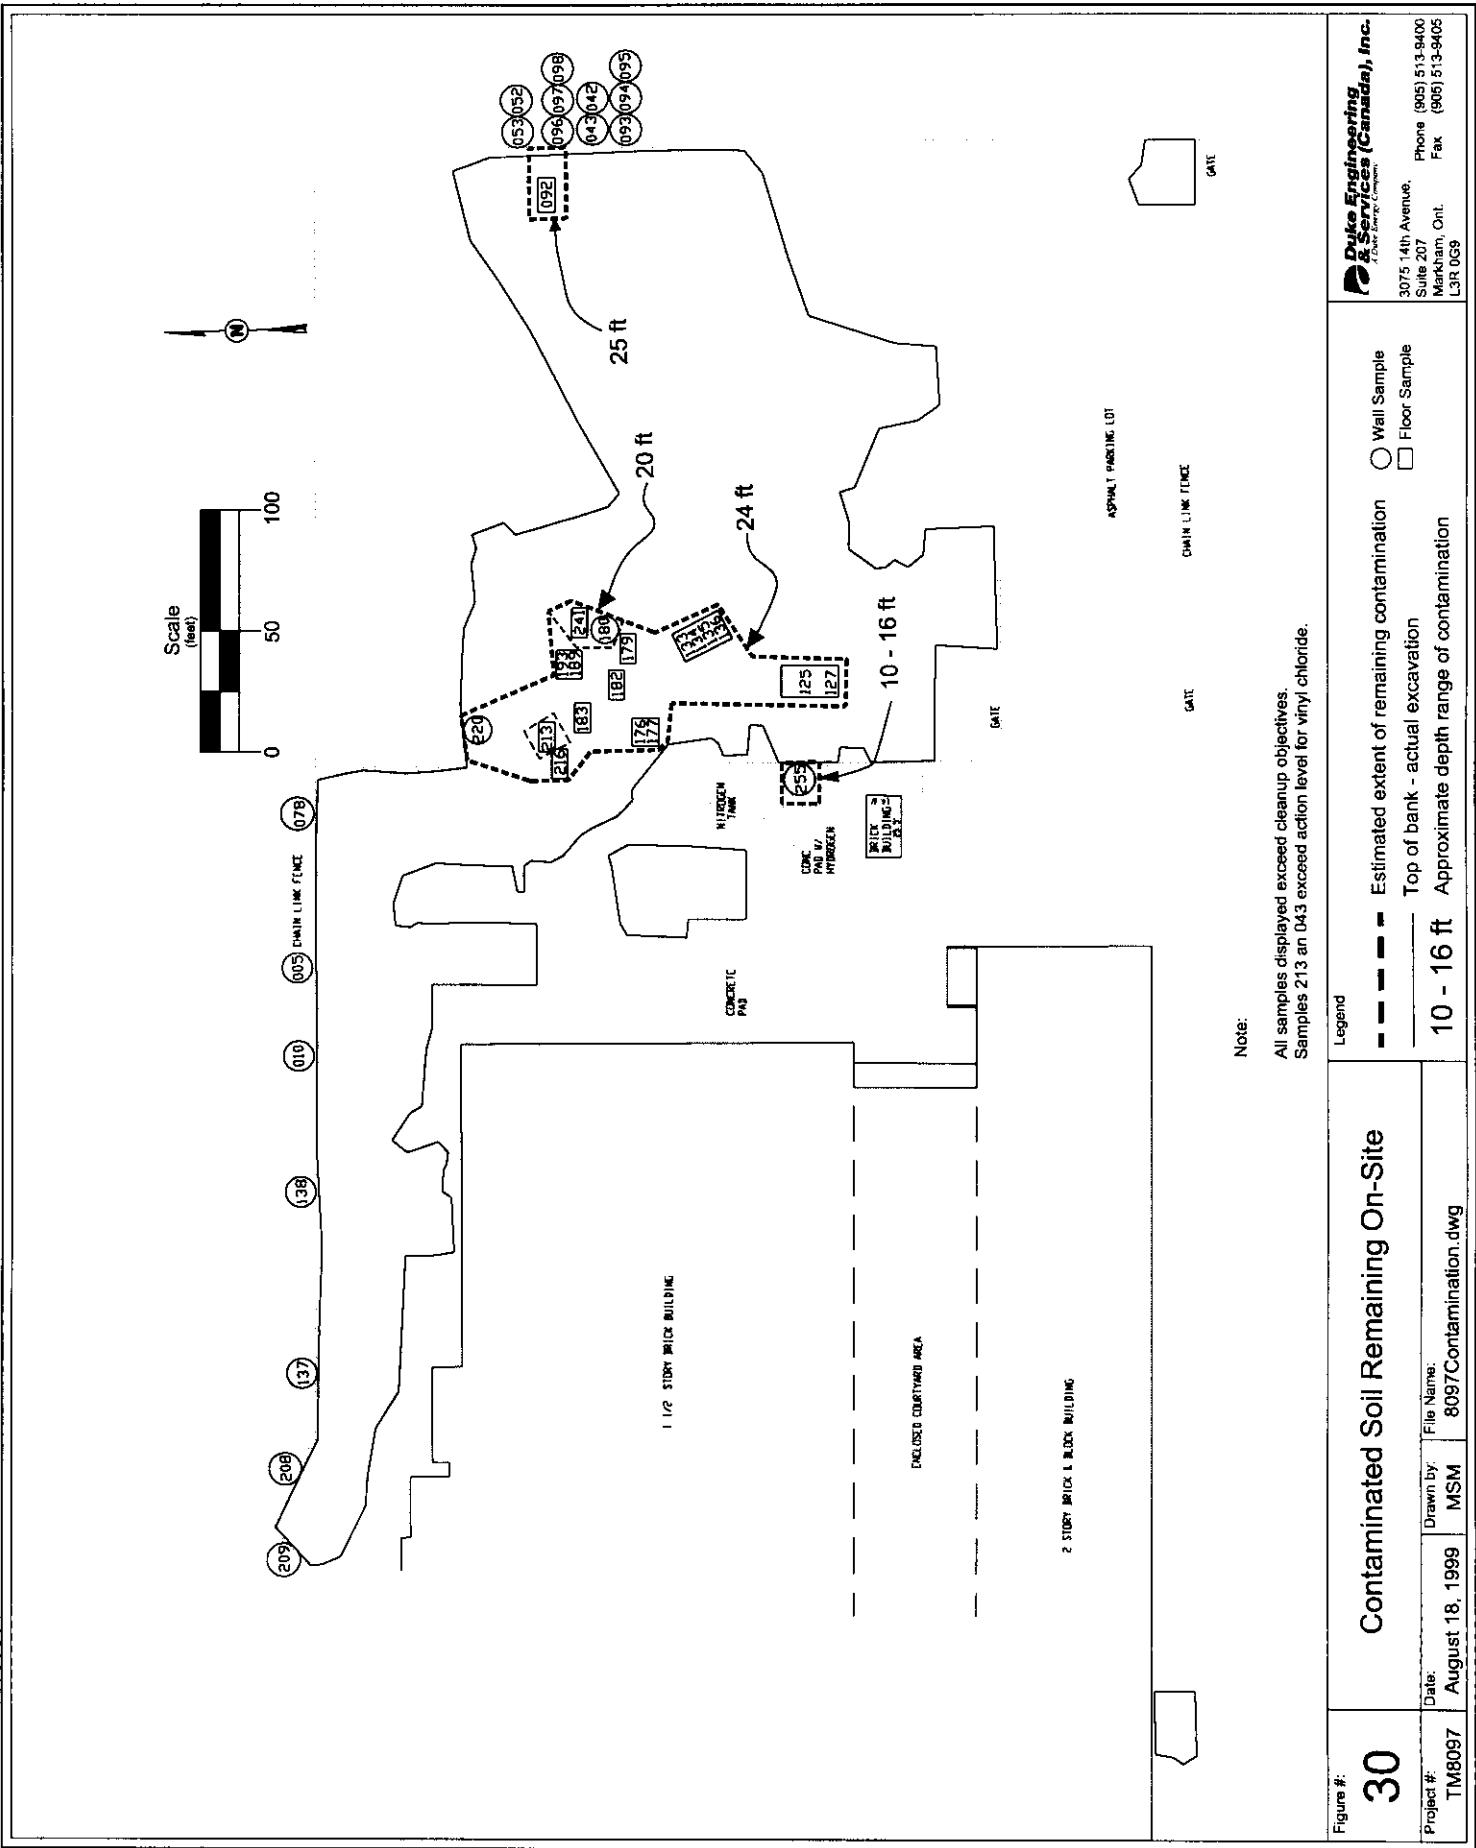

Several verification samples collected from the north wall of areas 1A and 1C exceeded the clean-up objective for trichloroethene and/or PAHs. These samples do not represent contaminated soil remaining on-site because the north wall of areas 1A and 1C extended to the north property boundary.

4.2. AREAS 1D, 1D-EXTENSION AND 2C

Verification sampling results indicate that non-hazardous soil remains on-site in areas 1D-extension and 2C on the floor at a depth of 24 ft (samples *IDVS213*, *IDVS216*, *2CVS176*[dup *2CVS177*], *2CVS179*, *2CVS182*, *2CVS183* and *2CVS189*[dup *2CVS193*]), on the east wall (sample *2CVS180*) at 20 ft and on the north wall (sample *IDVS220*) at 20 ft. Approximately 700 yd³ of non-hazardous soil remains on-site in areas 1D-extension and 2C. Additional excavation in these locations was not possible because of significant concern for reduced slope stability near the liquid nitrogen AST. No verification samples in area 1D exceeded the clean-up objectives for VOCs.

Verification sampling results also indicate that soil (sample *IDVS213*) containing vinyl chloride above the action level remains in area 1D-extension on the floor at 24 ft depth below the former location of the solvent storage area. An estimated 200 ft² of action level soil remains near sample location *IDVS213*. Assuming the depth of action level soil in this area is 6 ft, then approximately 40 yd³ of action level soil remains on-site. Excavating deeper in this area was not conducted due to slope stability concerns, as explained above.

4.3. AREAS 2A AND 2E

Verification sampling results indicate that non-hazardous soil remains in area 2A in four locations: at the east wall from 0 to 16 ft (samples 2AVS042-043, 2AVS052-053 and 2AVS093-098), on the west wall near the hydrogen gas cylinders from 10 to 16 ft (sample 2AVS255), the floor in the north-east corner (sample 2AVS092) at 24 ft and the floor in the west end (samples 2AVS125, 2AVS127 and 2AVS133-136) at 18 to 24 ft.

Excavating further east was not conducted because the excavation extended to the east property boundary. An estimated 800 ft² of non-hazardous soil remains between 0-16 ft BGS on the east wall. Excavating further west was not possible because of the proximity of the hydrogen gas cylinders. As estimated 60 yd³ of non-hazardous soil remains between 10-16 ft on the west wall.

Excavating deeper than 25 ft in the north-east corner was not possible because of significant concern for reduced slope stability. An estimated 80 yd³ of non-hazardous soil remains below 25 ft in this area.

The west end of 2A was excavated to 18 feet. In three areas, floor samples were collected at 18 ft (samples 2AVS124, 2AVS129 and 2AVS133) and test pits were installed to 24 feet to determine the depth of contamination. Samples 2AVS125-127, 2AVS130-132 and 2AVS134-136 were collected from the test pits at 20, 22 and 24 feet. Results indicated that the west end of area 2A remained above the clean-up objectives at 24 ft BGS in two of the three test pits. Samples 2AVS129-132 were collected from the east half of the west portion of area 2A and did not exceed the VOC clean-up objectives. It was decided not to excavate further because:

- i) excavation was difficult due to the presence of loose sands, silts, gravels and boulders in this area and there was a significant concern for slope stability,
- ii) the proximity of the hydrogen gas cylinders and the liquid nitrogen AST, and
- iii) significant groundwater seepage that compounded slope stability issues.

The estimated volume of non-hazardous soils remaining in the west end of area 2A is 1,100 yd³. It is believed that contamination encountered in this area extends north into the contaminated zone identified in Area ID extension/2C at a depth of 24 ft.

Verification sampling results also indicate that action level soil remains in area 2A on the east wall (sample 2AVS043). An estimated 150 ft² of action level soil remains between 10-16 ft BGS on the east wall near sample location 2AVS043. Excavating further east was not conducted because the verification sample was collected at the east property boundary.

5. SITE RESTORATION

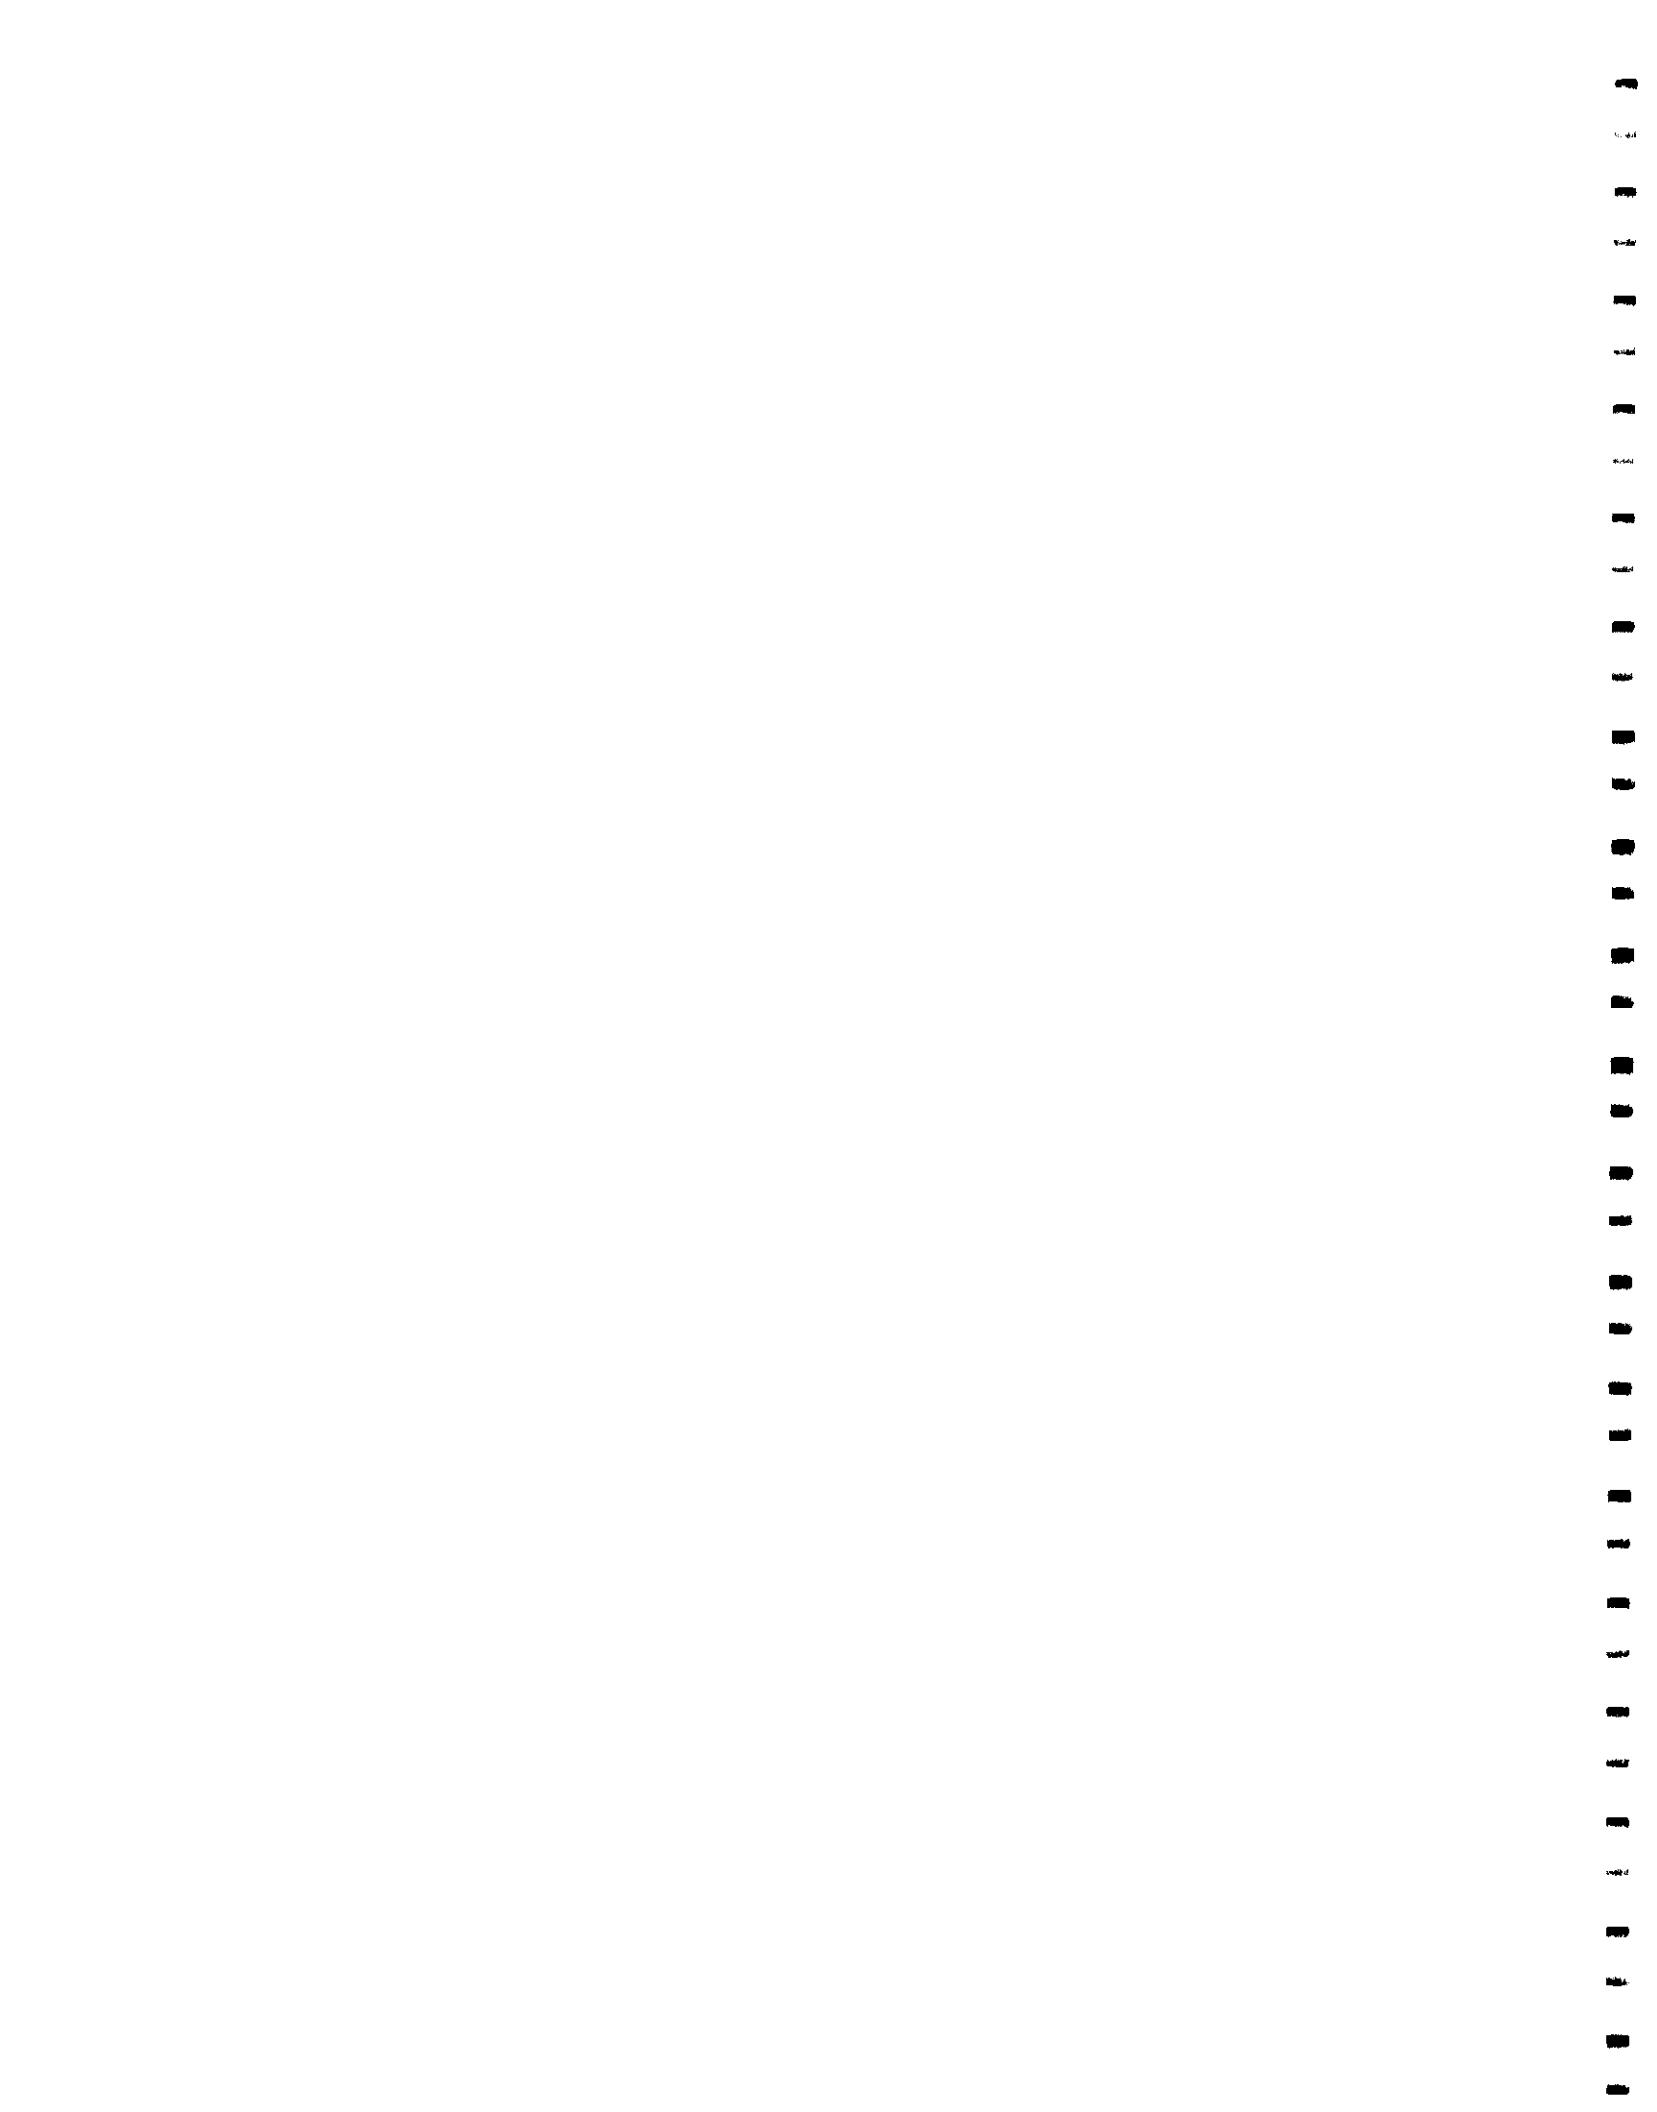

Restoration of site utilities and surfaces was completed as outlined in the plans and specifications document. A brief summary of specifications for paving and the on-site drainage system follows:

Paved areas of the site were restored by Ken Young Paving & Co. A total area of 43,028ft² was paved using two-inch binder and one-inch top on a crushed stone base to replace removed or damaged asphalt.

Underground piping for the on-site drainage system was replaced where damaged. Original piping was 12" or 18" diameter concrete. New 12" or 18" diameter high-density polyethylene (HDPE) piping meeting ASTM D3350 minimum cell classification 335420C was used to replace damaged pipe, as agreed to by Kanthal. Concrete catch basins that were removed during excavation were cleaned and replaced. One catch basin was damaged and was replaced with a new concrete catch basin designed to meet loading requirements HS 20-44. The catch basin was a 2 ft x 2 ft x 5 ft pre-cast with 6-inch walls and a heavy duty bicycle safe frame and grate.

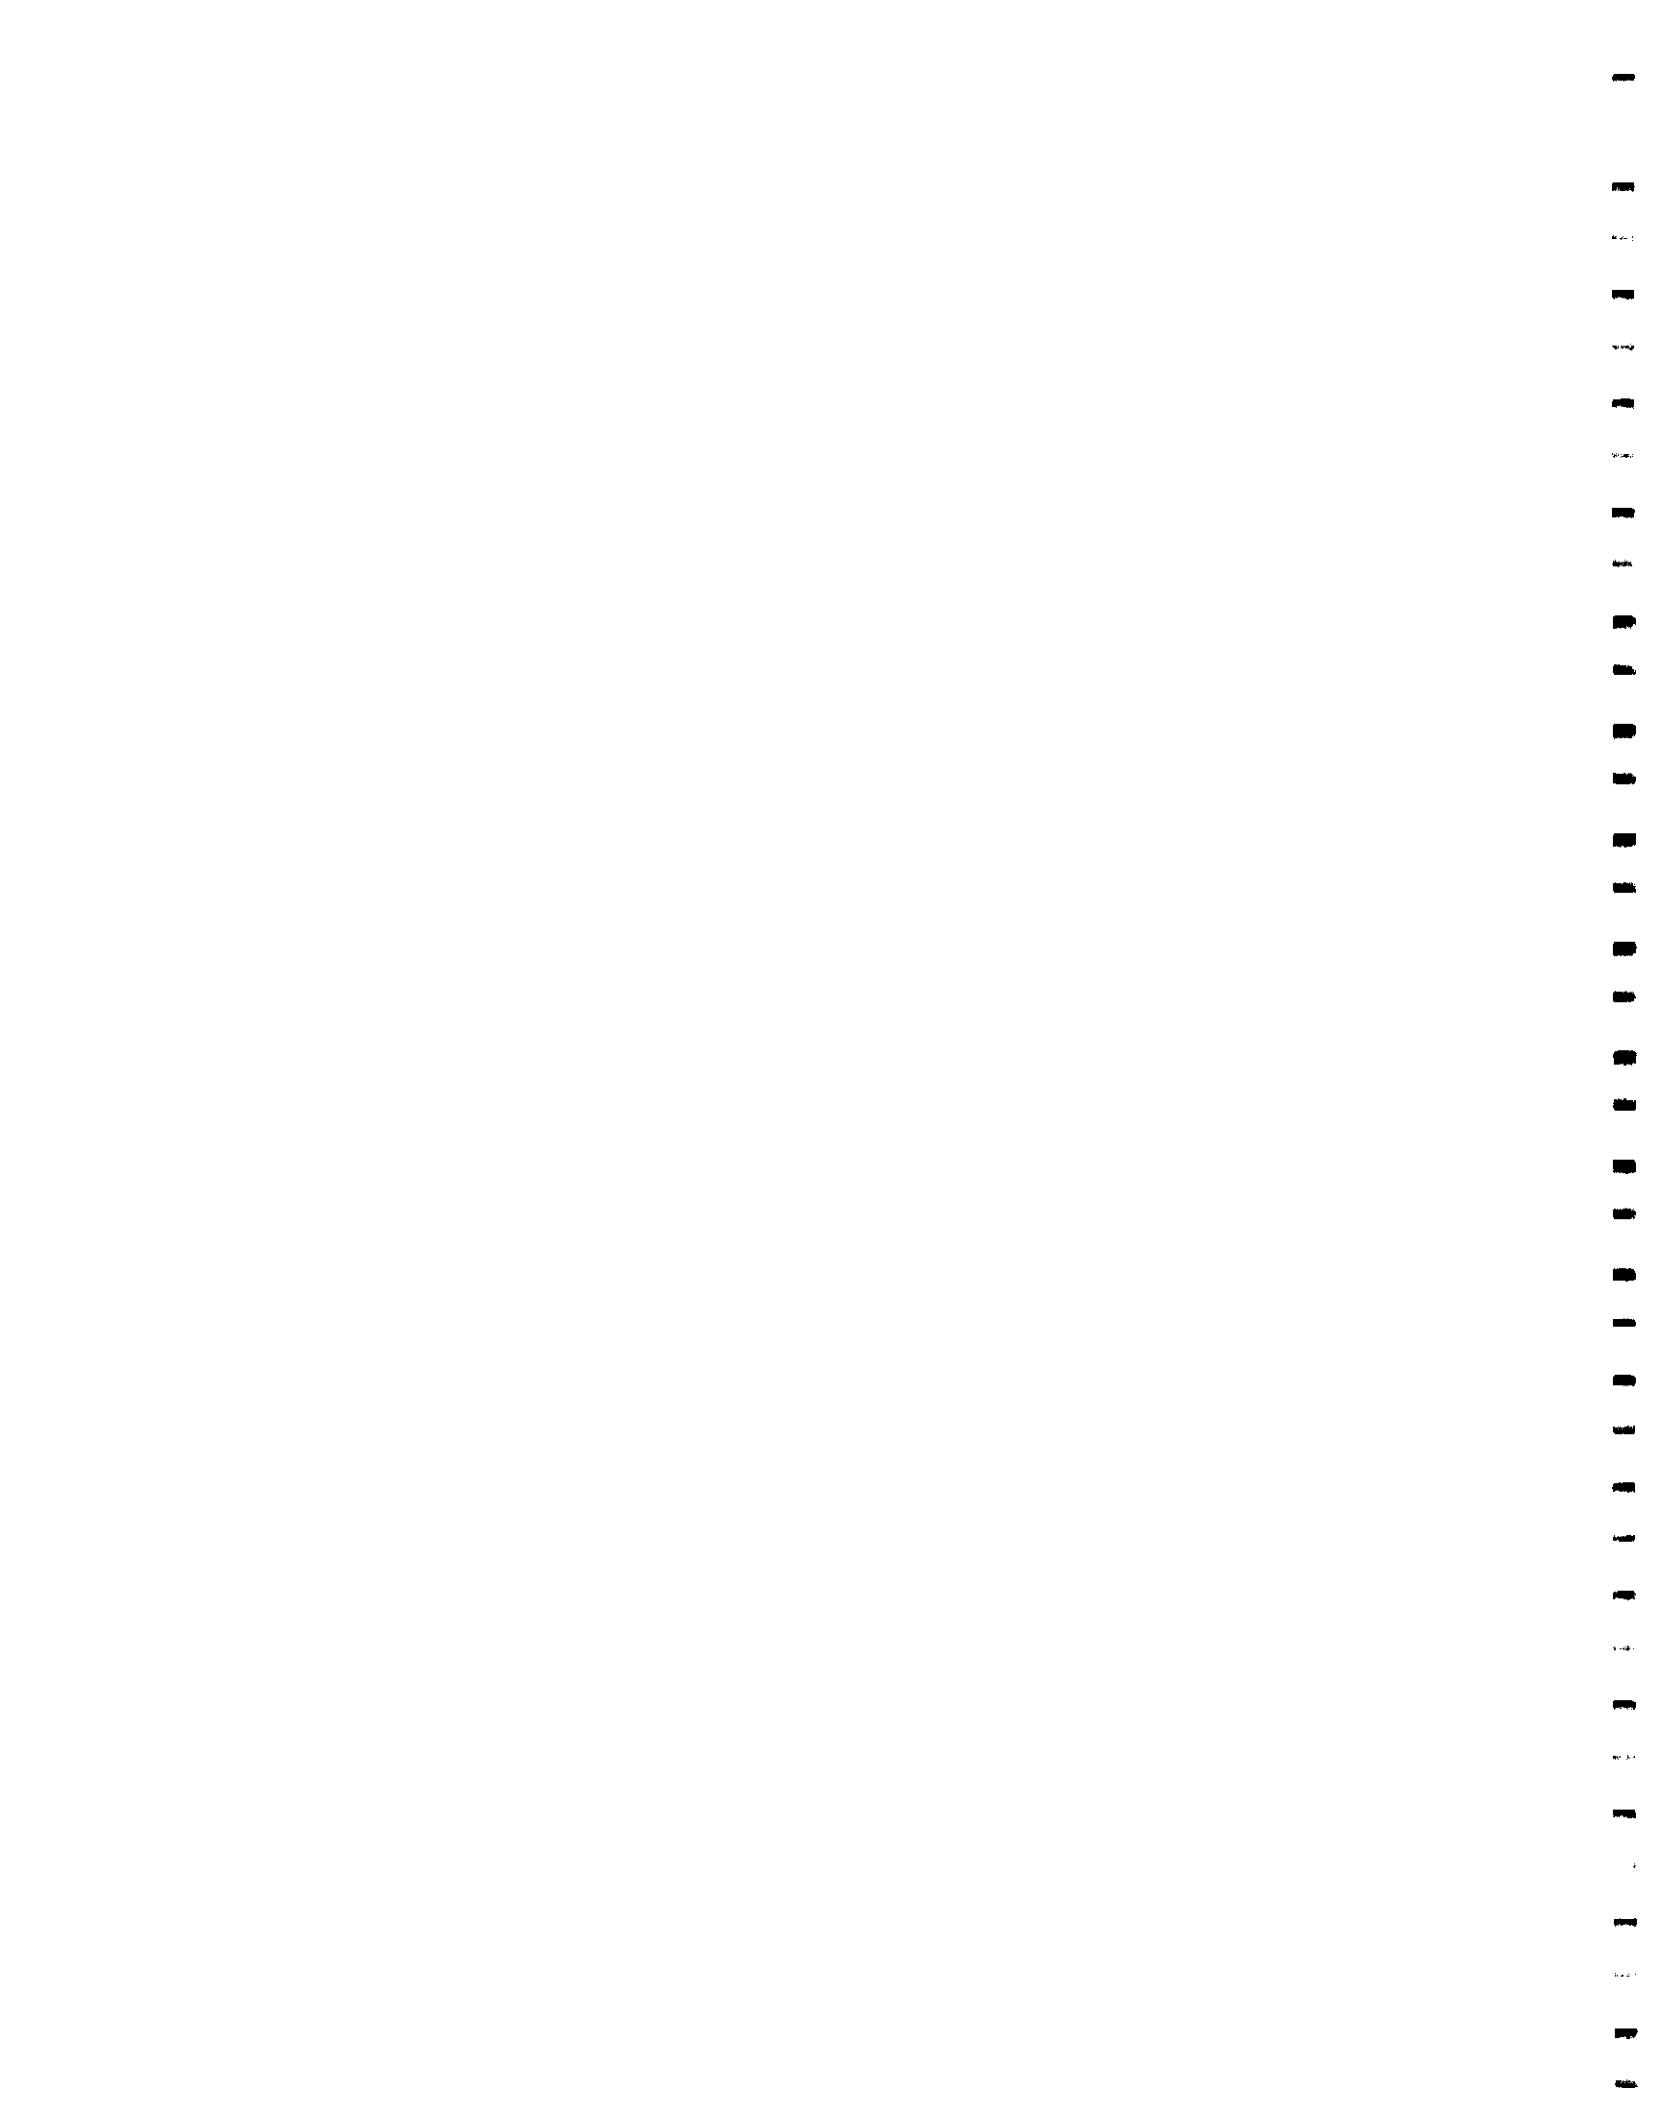

Light standards and underground electrical wiring were replaced and restored to their previous condition.

The former solvent storage structure located in the north west portion of the parking lot was demolished to allow access to soils in area 1D-extension. As agreed with Kanthal, the structure was not replaced.

Soil Cleanup Objectives Calculations

NYSDEC Soil Cleanup Objectives

Calculation of Allowable Soil Concentration

as per NYSDEC TAGM 4046 January 24, 1994, revised March 1998

DATA:

geometric mean of total organic carbon (TOC) soil sample results from RI = 1.4%

EQUATIONS:

$$f = \text{TOC\%}/100$$

$$Cs = f * Cw * Koc$$

$$\text{Soil Cleanup Objective (SCO)} = Cs * 100$$

VARIABLES:

Cs = calculated allowable soil concentration

Cw = groundwater standards in ppb from TAGM 4046

Koc = partition coefficient from TAGM 4046

SAMPLE CALCULATION FOR VINYL CHLORIDE:

$$f = 1.4\%/100 \quad 0.014$$

$$Cs = 0.014 * 0.002 * 57 \quad 0.0016$$

$$\text{SCO} = 0.0016 * 100 \quad 0.16 \text{ ppm}$$

$$160 \text{ ppb}$$

SCO was calculated for each COC. The Soil Cleanup Objective used during the IRM was the higher of the calculated SCO and the SCO from TAGM 4046. Some compounds have a maximum SCO, as indicated in TAGM 4046.

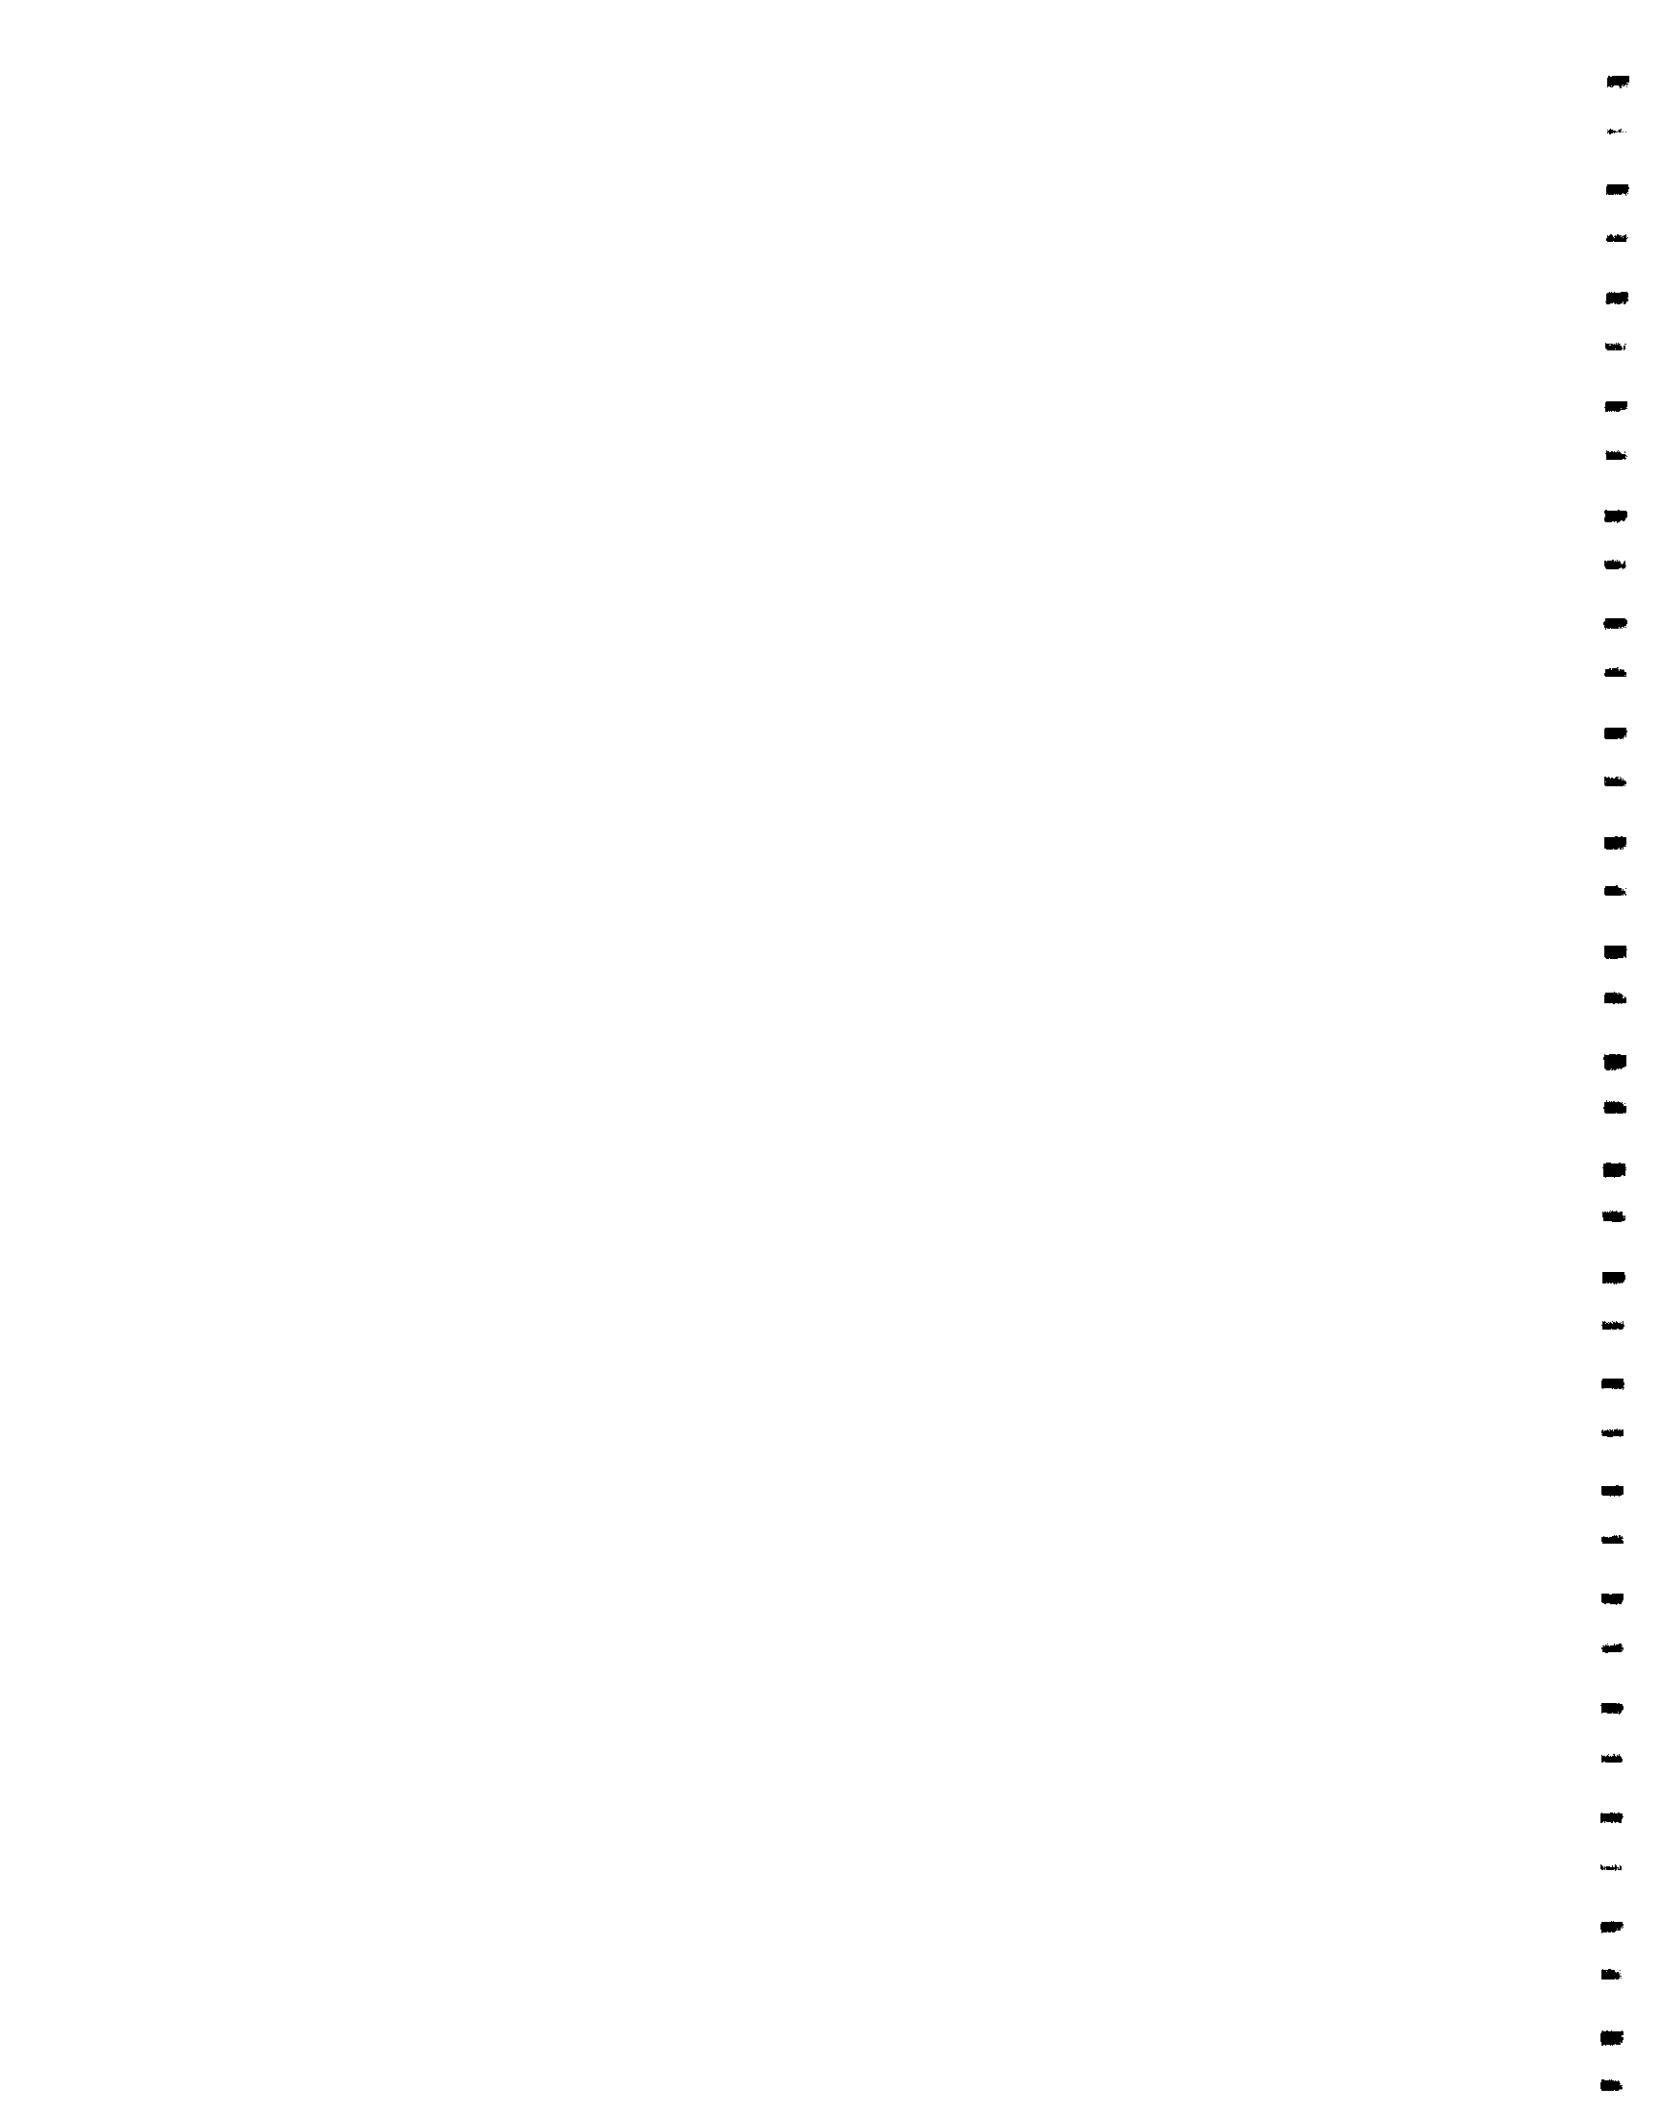

VOCs:	Cw (ppm)	Koc	Cs (ppm)	Calculated SCO(ppm)	Calculated SCO (ppb)	SCO from TAGM* (ppb)	Soil Cleanup Objective

1 Air Dispersion Modeling

An air dispersion model was constructed to qualitatively evaluate the impact of excavation activities on employees currently working at the former Carborundum Company Facility, and to the general public in the vicinity of the site. In addition, the air model was used to help develop a work plan to minimize potential air impacts during execution of the IRM. Concerns for potential emission or volatilization of contaminants into the air during excavation and removal of contaminated soil were evaluated by constructing the air model to simulate predicted conditions during excavation at the site. This simulation was constructed to mimic site weather, wind pattern, and contaminant concentrations in soil (as understood following the IRM borehole drilling and soil sampling) as closely as possible.

1.1 Model Selection

Models/methods chosen for the purpose of estimating the impact of excavation operations at the former Carborundum Company facility site are described in the sections below.

1.1.1 Emission Rates

An emission rate is the mass of a contaminant that is released per unit area, per unit time. For the purpose of dispersion modeling the emission rate required was in the units of grams per square meter per second ($\text{g}/\text{m}^2/\text{s}$)

Emission rates were calculated using the method described in the USEPA Control Technology Center “EPA-600/R-97-116” document “Air Emissions from the Treatment of Soils Contaminated with Petroleum Fuels and Other Sources” October 1997. The details of emission rate calculations and the governing equations are described in this document. Emission rates for excavation operations are not well documented/researched, however, this document summarizes available information on air emissions from the treatment of soils contaminated with volatile organic compounds.

1.1.2 Downwind Concentration

The airborne concentrations of contaminants downwind of the excavation area(s) were calculated using the USEPA air dispersion model “Industrial Source Complex, Short Term Dispersion Model Version 3 (ISCST3). The basis of the ISCST3 model is the straight line, steady state gaussian plume equation. The model estimates the downwind concentration for each hour of input meteorological data, and calculates user defined short-term average concentrations at user defined receptor locations. The details of ISCST3 and its governing equations are described in the model documentation (Users

Guide for the Industrial Source Complex (ISC) Dispersion Models: Volume I – User Instructions, Volume II – Description of Model Algorithms). Meteorological data for wind speed, direction, air temperature, stability class, Urban and Rural mixing heights, were obtained from Bee-Line Software for Buffalo, NY, for 1994 (the most recent data available at the time of the modeling).

1.2 Model Assumptions

1.2.1 Emission Rate

The emission rate calculations were made using various assumptions. Some of these assumptions are inherent to the emission rate model, others were necessary for site specific reasons.

The assumptions required by the model included:

- Several parameters such as the soil-gas to atmosphere exchange constant, equilibrium coefficient, bulk density of the soil and gas-phase mass transfer coefficient had to be assumed. Assumptions used are default parameters listed in “Air Emissions from the Treatment of Soils Contaminated with Petroleum Fuels and Other Sources” for fine-grained soils.
- Contaminant concentrations in soils are homogeneously distributed.

Other assumptions used in estimating contaminant emission rates from soil include:

- Average contaminant concentration exists throughout excavation based on all analytical results including 50% of the detection limit for contaminant concentrations below detection limit. This method was believed to most accurately reflect contaminant concentrations observed at the site.

1.2.2 Downwind Concentration

The downwind concentrations of contaminants were estimated using various assumptions. Some of these assumptions are inherent to the atmospheric dispersion model, others were necessary for site specific reasons.

The industrial source complex short-term dispersion model assumes the following:

- Air turbulence is random and the concentration distribution of the pollutant about the centerline, vertically and horizontally, has a Gaussian (normal) distribution.

- The plume is assumed to have standard deviations about the centerline of the plume (horizontal standard deviation σ_y , vertical standard deviation σ_z). These standard deviations are functions of atmospheric stability class and the downwind distance from the source.

1.3 Modeled Scenarios

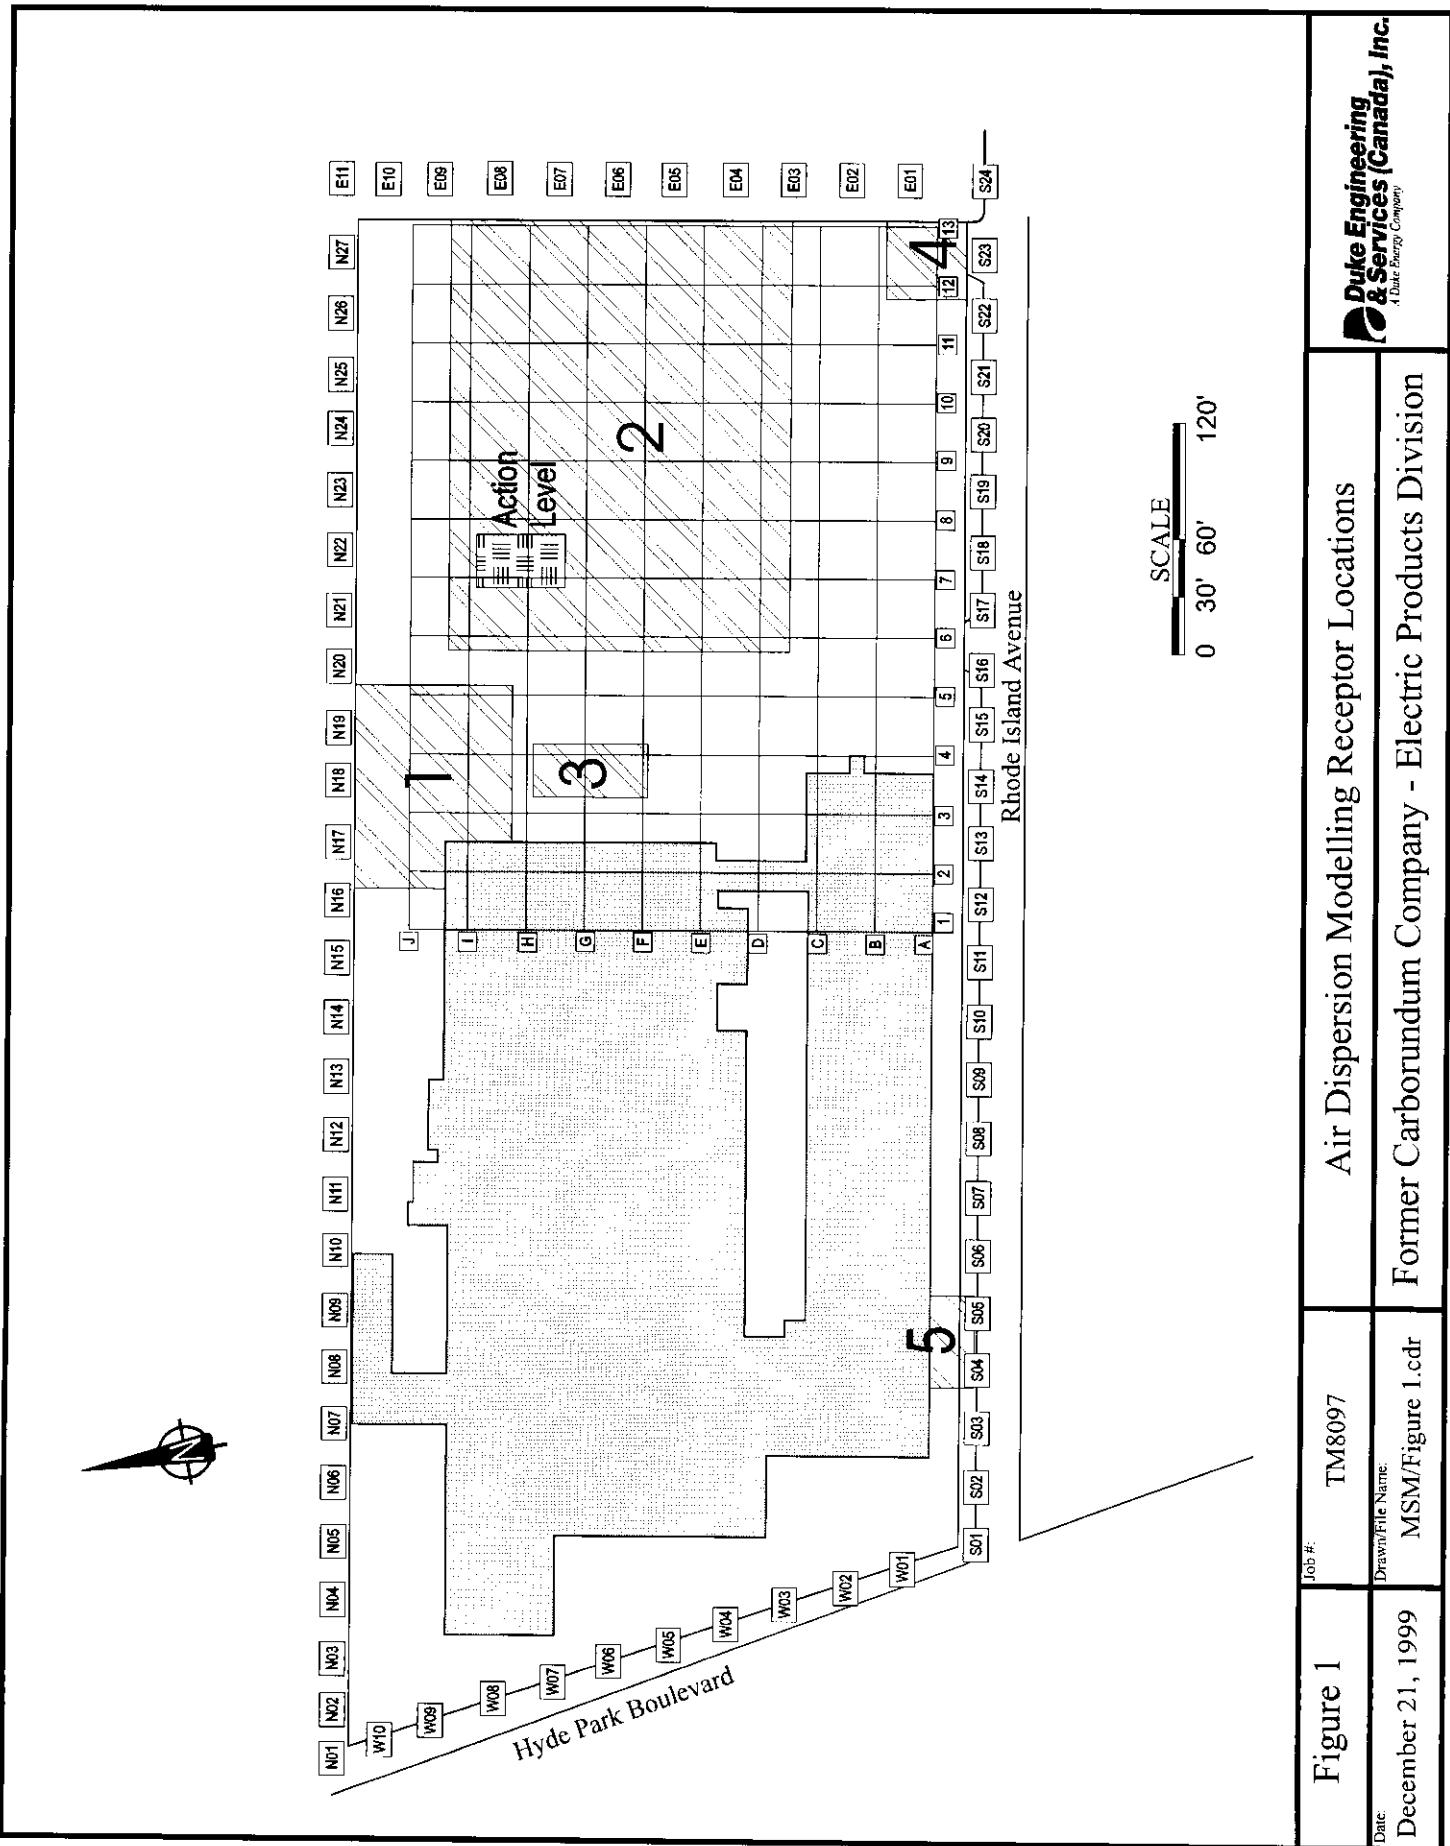

ISCST3 estimates the downwind concentration for each hour of input meteorological data at user defined receptors, and then calculates user defined short-term average concentrations these locations. The details of ISCST3 and its governing equations are described in the model documentation (Users Guide for the Industrial Source Complex (ISC) Dispersion Models: Volume I – User Instructions, Volume II – Description of Model Algorithms). Figure 1 shows the approximate location of the contaminated areas and the receptors modeled.

The 6 areas modeled for this exercise are shown on Figure 1. The area numbers correspond to those used to identify contaminated areas for the IRM. Area perimeters were adjusted for ease of model input. In the modeling scenarios described below, each receptor receives contaminants from each area individually and also from all areas at once. For example, model output for Receptor S20 allows differentiation between contaminants from individual areas 1, 2, Action Level, 3, 4 or 5 individually (simulating one area being actively excavated at a time, a reasonable assumption). Output also includes contaminants contributed from all areas to Receptor S20 (simulating all areas being actively excavated at the same time – a very conservative assumption).

The receptors modeled for this exercise include both off-site receptors and on-site receptors. Off-site receptors were modeled along the perimeter of the property and are shown on Figure 1 as North (N1-27), South(S1-24), West (W1-10) and East (E1-11). On-site receptors were modeled using a grid of receptor points, shown on Figure 1 as A1 – J13.

Downwind concentrations were calculated for six scenarios. Each scenario was calculated using: a) – a full month of meteorological data, b) – a windy day, and c) – a calm day. The scenarios modeled are described below:

1. Scenario 1 assumed that all contaminated areas were open and exposed during the model run. Emission rates were assumed to be constant for 24 hours per day. A one hour average concentration was determined for each receptor, for exposure from each of the six contaminated areas separately and also from all areas cumulatively. This scenario was the most conservative because these assumptions result in highest downwind concentrations.
2. Scenario 2 assumed that all contaminated areas were open and exposed during the model run. Emission rates were assumed to be low during non-working

hours (5pm to 7am) to simulate tarping/covering of the excavations overnight. A one hour average concentration was determined for each receptor, for exposure from each of the six contaminated areas separately and also from all areas cumulatively.

3. Scenario 3 assumed that $\frac{1}{2}$ of the contaminated areas were open and exposed during the model run. Emission rates were assumed to be low during non-working hours (5pm to 7am) to simulate tarping/covering of the excavations overnight. A one hour average concentration was determined for each receptor, for exposure from each of the six contaminated areas separately and also from all areas cumulatively.
4. Scenario 4 assumed that $\frac{1}{4}$ of the contaminated areas were open and exposed during the model run. Emission rates were assumed to be low during non-working hours (5pm to 7am) to simulate tarping/covering of the excavations overnight. A one hour average concentration was determined for each receptor, for exposure from each of the six contaminated areas separately and also from all areas cumulatively.
5. Scenario 5 assumed that 1/16 of the contaminated area labeled as Area 2 in Figure 1 was open and exposed during the model run. The location of the exposed portion of Area 2 was modeled at the southwest corner. Emission rates were assumed to be low during non-working hours (5pm to 7am) to simulate tarping/covering of the excavations overnight. A one hour average concentration was determined for each receptor, for exposure from Area 2. This model run was the least conservative because these assumptions result in the lowest downwind concentrations.
6. Scenario 6 assumed that 1/16 of the contaminated area labeled as Area 2 in Figure 1 was open and exposed during the model run. The location of the exposed portion was modeled at the east property boundary in southeast corner of Area 2. Emission rates were assumed to be low during non-working hours (5pm to 7am) to simulate tarping/covering of the excavations overnight. A one hour average concentration was determined for each receptor, for exposure from Area 2. This model run was the least conservative because these assumptions result in the lowest downwind concentrations.

Scenario 4 was used for decisions concerning allowable exposed excavation areas because it is the most reasonable scenario, given the estimated volume of soil that could be excavated per day. Site layout, surface obstructions and work area traffic requirements would not allow more than 25% of excavation areas to be open and active at one time. Scenarios assuming >25% open area were considered inappropriate. Scenario 4 was used rather than Scenarios 5 or 6 because it simulated the greatest open area and is therefore more conservative.

1.4 Model Calibration and Verification

The ISCST3 model was to be calibrated by estimating the concentrations expected during a small excavation on the north side of the former Carborundum Company Facility site and comparing the model results with actual air concentration data from the field. This information was to be used to calibrate the model for the large excavation. It was decided not to proceed with the small excavation prior to the main excavation, therefore calibration of the atmospheric dispersion model was not conducted.

1.5 Sensitivity Analysis

The emission rate calculations were determined to be most sensitive to the area of excavation. More open area resulted in greater downwind concentrations. Other parameters tested were air temperature and contaminant concentration.

Changes in temperature resulted in changes in downwind concentration due to increased or decreased emission rates. Warmer temperatures resulted in higher emission rates and therefore higher downwind concentrations. Because the model runs simulated work in February, emission rates and therefore downwind concentrations would be higher for any work done in warmer weather.

Changes in contaminant concentration also resulted in changes in downwind concentration due to increased or decreased emission rates. Higher concentration of contaminants in soils resulted in higher emission rates and therefore higher downwind concentrations.

2 Model Results

2.1 Emission Rates

Emission rates calculated using the method described in “Air Emissions from the Treatment of Soils Contaminated with Petroleum Fuels and Other Sources” for Scenario 4 are shown in Table 1. These are the emission rates used for each area in the Industrial Source Complex (ISC) Dispersion Model.

Table 1 Emission Rates for Scenario 4

Excavation Area	Average Molecular Weight (g/mole)	Calculated Emission Rate (g / (m ² * s))	Equivalent Concentration from ISC Model to 5ppm (µg/m ³)
Area 1	211.7	0.0172	48,103
Area 2	110.2	0.000629	25,040
Action	110.6	0.104	25,142
Area 3	107	0.00087	24,313
Area 4	63.7	0.000041	14,474
Area 5	100.7	0.000316	22,881
Overall	204.1	NA	46,371

The average molecular weight is a weighted average based on the individual contaminants' molecular weight and percentage contribution to the emission rate. The average molecular weight is used to convert the ISCST3 model output of µg/m³ to ppm. The average molecular weight and calculated emission rate of the area-specific contaminant mix and concentrations for each excavation area were used to determine the ISCST3 model equivalent to 5ppm, the maximum concentration allowable before action is required in the IRM health and safety plan. The last column shows the calculated equivalent concentration from the ISCST3 model to 5ppm. This allows a comparison of model output to a measurement that can be made in the field using a photoionization detector (PID).

Table 2 shows the calculation for the emission rate for Area 2 provided in Table 1. The soil concentration used for this calculation is based on the average of detected soil contaminants and 50% of the detection limit for non-detected parameters.

Table 2 Emission Rate Calculation for Area 2

2.2 Downwind Concentration

The results of dispersion modeling for Scenario 4 are summarized in Table 3. Table 3 shows each excavation area modeled, the scenario used, the maximum concentration of all contaminants ($\mu\text{g}/\text{m}^3$) at each property boundary and on-site receptor, the location of the maximum for each boundary and the calculated equivalent concentration of contaminants in parts per million (ppm). The ISCST3 model outputs results in $\mu\text{g}/\text{m}^3$ but ppm is preferred because field detection equipment measures concentrations in ppm.

Table 3 - Maximum Concentrations to Off-Site and On-Site Receptors

Area	Scenario	Maximum Concentrations to Off-Site Receptors at Property Boundaries and On-Site Receptors													
		South Property Boundary			East Property Boundary			North Property Boundary			West Property Boundary			On-Site Receptors	
		ug/m^3	ppm	Location ¹	ug/m^3	ppm	Location ¹	ug/m^3	ppm	Location ¹	ug/m^3	ppm	Location ¹	ug/m^3	ppm

3 Conclusion

The results of the dispersion modeling indicate that in order to maintain downwind concentrations of contaminants below 5ppm, the action levels for air quality monitoring described in the health and safety plan, the IRM workplan must be developed to minimize surface area of excavations and stockpiles. It is recommended that a pre-characterization test pit sampling program be conducted for each contaminated area to pre-characterize the contaminated soil and eliminate the need to stockpile excavated soils on site. It is also recommended that excavation be conducted in such a way as to minimize the amount of contaminated soil that is exposed at any given time.

The results of the air modeling indicate that emission of contaminants from the site during excavation could be significantly reduced if stockpiling of contaminated soils on site could be eliminated or reduced. This would eliminate the emission of vapors from stockpiled soil. In addition, air modeling identified the need to conduct excavation in small areas as much as possible to reduce the exposure of contaminated soils to air.

Based on the air modeling work, a pre-characterization test pit sampling program was proposed. This pre-characterization of soils would allow the excavation and direct loading of soils into trucks for off-site disposal.

Re: Vinyl Chloride Reporting Limits for Carborundum Samples

Dear Ms. Hanson:

This letter is in response to your facsimile sent to my attention on 22 April 1999 regarding the above referenced subject matter. As we discussed, several samples submitted for volatile organic analysis following SW-846 Method 8260 required methanol dilutions based on the concentrations of target analytes. These dilutions resulted in elevated reporting limits for all analytes. In response to your question regarding vinyl chloride estimated values (J) based on the dilutions, I have included an example calculation. Please note that the laboratory default value (estimated value = J) is 0.9ug/kg for vinyl chloride.

1. Estimated Reporting limit (J) for a Soil Methanol Extract

$$\frac{10\text{ml MEOH}}{5\text{g soil}} \times \frac{5\text{ml purge}}{0.1\text{ul}} \times \frac{0.9}{(\text{J CRQL})} = \frac{45}{0.86\%} = 105\text{J (ug/Kg)} \\ (\text{injection volume}) \qquad \qquad \qquad (\% \text{solids})$$

Please feel free to call me should you have any questions regarding this information.

Sincerely,

Christopher A. Ouellette
Laboratory Director
