Environmental Restoration Record of Decision Provan Ford Site Newburgh, Orange County, New York Site Number B00127-3

March 2005

New York State Department of Environmental Conservation
GEORGE E. PATAKI, *Governor*DENISE M. SHEEHAN, *Acting Commissioner*

DECLARATION STATEMENT ENVIRONMENTAL RESTORATION RECORD OF DECISION

Provan Ford Environmental Restoration Site Newburgh, Orange County, New York Site No. B00127-3

Statement of Purpose and Basis

The Record of Decision (ROD) presents the selected remedy for the Provan Ford Site, an environmental restoration site. The selected remedial program was chosen in accordance with the New York State Environmental Conservation Law and is not inconsistent with the National Oil and Hazardous Substances Pollution Contingency Plan of March 8, 1990 (40CFR300), as amended.

This decision is based on the Administrative Record of the New York State Department of Environmental Conservation (NYSDEC) for the Provan Ford environmental restoration site, and the public's input to the Proposed Remedial Action Plan (PRAP) presented by the NYSDEC. A listing of the documents included as a part of the Administrative Record is included in Appendix B of the ROD.

Assessment of the Site

Actual or threatened releases of hazardous substances and petroleum products from this site, if not addressed by implementing the response action selected in this ROD, presents a current or potential significant threat to public health and/or the environment.

Description of Selected Remedy

Based on the results of the Site Investigation/Remedial Alternatives Report (SI/RAR) for the Provan Ford site and the criteria identified for evaluation of alternatives, the NYSDEC has selected soil excavation and groundwater treatment by *in situ* chemical oxidation. The components of the remedy are as follows:

- A remedial design program to provide the details necessary to implement the remedial program.
- A pre-design investigation to determine the extent of off-site groundwater and vapor contamination.
- Demolition of the former Provan Ford operations building and wash rack.

- Excavation of subsurface soils impacted with VOCs or light non-aqueous phase liquid (LNAPL).
- LNAPL recovery from open excavation areas.
- Off-site treatment/disposal of excavated soil and LNAPL to an appropriate, NYSDEC approved disposal facility.
- Removal, cleaning and off-site disposal of the 8,000 gallon underground storage tank (UST) present under the wash rack area.
- Backfill excavated areas with clean fill.
- Treatment of on-site groundwater using *in situ* chemical oxidation.
- Covering all vegetated areas with clean soil and all non-vegetated areas with either concrete or a paving system.
- Development of a site management plan to address residual contamination and any use restrictions.
- Annual certification of the institutional and engineering controls.
- Imposition of an environmental easement.
- Operation of the remedial components until achievement of remedial objectives or technical impracticability.
- Institution of a long term monitoring program.

New York State Department of Health Acceptance

The New York State Department of Health (NYSDOH) concurs that the remedy selected for this site is protective of human health.

Declaration

The selected remedy is protective of human health and the environment, complies with State and Federal requirements that are legally applicable or relevant and appropriate to the remedial action to the extent practicable, and is cost effective.

Environmental Restoration RECORD OF DECISION

Provan Ford Site Newburgh, Orange County, New York Site No.B00127-3 March 2005

SECTION 1: SUMMARY OF THE RECORD OF DECISION

The New York State Department of Environmental Conservation (NYSDEC), in consultation with the New York State Department of Health (NYSDOH), has selected a remedy for the Provan Ford Site. The presence of hazardous substances has created threats to human health and/or the environment that are addressed by this remedy.

The 1996 Clean Water/ Clean Air Bond Act provides funding to municipalities for the investigation and cleanup of brownfields. Under the Environmental Restoration (Brownfields) Program, the state provides grants to municipalities to reimburse up to 90 percent of eligible costs for site investigation and remediation activities. Once remediated the property can then be reused.

As more fully described in Sections 3 and 5 of this document, the washing, service and maintenance of tanker trucks have resulted in the disposal of hazardous substances, including volatile organic compounds (VOCs), semi-volatile organic compounds (SVOCs), and petroleum wastes. These hazardous substances have contaminated the soil, groundwater and soil vapor at the site, and have resulted in:

- a threat to human health associated with potential exposure to contaminated soil, groundwater and soil vapor.
- an environmental threat associated with the impacts of contaminants to the groundwater.

To eliminate or mitigate these threats, the NYSDEC has selected the following remedy to allow for commercial, industrial or restricted residential use of the site:

- A remedial design program to provide the details necessary to implement the remedial program.
- A pre-design investigation to determine the extent of off-site groundwater and vapor contamination.
- Demolition of the former Provan Ford operations building and wash rack.

- Excavation of subsurface soils impacted with VOCs or light non-aqueous phase liquid (LNAPL).
- LNAPL recovery from open excavation areas.
- Off-site treatment/disposal of excavated soil and LNAPL to an appropriate, NYSDEC approved disposal facility.
- Removal, cleaning and off-site disposal of the 8,000 gallon underground storage tank (UST) present under the wash rack area.
- Backfill excavated areas with clean fill.
- Treatment of on-site groundwater using *in situ* chemical oxidation.
- Covering all vegetated areas with clean soil and all non-vegetated areas with either concrete or a paving system.
- Development of a site management plan to address residual contamination and any use restrictions.
- Annual certification of the institutional and engineering controls.
- Imposition of an environmental easement.
- Operation of the remedial components until achievement of remedial objectives or technical impracticability.
- Institution of a long term monitoring program.

The selected remedy, discussed in detail in Section 8, is intended to attain the remediation goals identified for this site in Section 6. The remedy must conform with officially promulgated standards and criteria that are directly applicable, or that are relevant and appropriate. The selection of a remedy must also take into consideration guidance, as appropriate. Standards, criteria and guidance are hereafter called SCGs.

SECTION 2: SITE LOCATION AND DESCRIPTION

The Provan Ford Site is located at 146-172 Mill Street in the City of Newburgh, Orange County, as shown on Figures 1 and 2. The site is situated on approximately 3.5 acres and contains the former Provan Ford operations building. The building construction is slab-on-grade and concrete block with a footprint of approximately 18,000 square feet, used primarily for garage and storage space. The remainder of the site is mostly paved asphalt, with some gravel covered areas and an earthen covered area on the northwest end. A truck wash area, consisting of two concrete pads and large steel truck wash rack, used for washing tank trucks, is located immediately west of the building. The surrounding area is mixed residential and commercial. Ridgewood Corp. borders the site on

the south. Gary's Truck & Trailer Repair and a residential area are located to the southeast. Quassaick Creek is located approximately 700 feet to the south and the Hudson River is located approximately 4000 feet east of the site.

SECTION 3: SITE HISTORY

3.1: Operational/Disposal History

The property was initially developed in the 1940s as a commercial facility and expanded in the 1950s. Provan Ford is the original occupant and had operated at the site for over 50 years as a large truck dealership/repair facility and a petroleum/industrial tanker cleaning facility. Housekeeping practices diminished in later years with the occurrence of various incidents involving discharges of petroleum and other liquid substances to the ground, floor drains, and City sewer. The on-site drainage system was connected to the City's combined sewer system which ultimately discharged to the Hudson River. On-site oil-water separators were also not properly maintained. The facility has past violations of the City's pretreatment ordinance for oil and grease and discharge of potentially flammable products to the City's sewer collection system. Large explosions and fires were reputedly attributed to discharges from the site. An adjacent structure was destroyed by fire after a series of explosions within the City's sewer system. The NYSDEC responded to several spill related incidences at the facility. These included on-site spills, chemical odors reported by adjacent businesses, and fumes in City sewers.

Provan vacated the property in 1998 as the result of tax foreclosure. On June 29,1999, the City of Newburgh took ownership. Gary's Heavy Truck Repair occupied the property from March 1998 to March 2000. The site is currently vacant.

3.2: Remedial History

In June of 1998 the United State Environmental Protection Agency (USEPA) sampled over 50 drums of liquid wastes identified at the site as part of a potential removal action. Some of the drums were leaking and previously spilled over. A NYSDEC contractor secured and staged the drums on-site and cleaned up the spilled material, stockpiling the impacted soil on-site. The contractor also pumped liquids out of an oil-water separator, overflowing waste oil tank and leaking free standing tanks and disposed of the liquids at an off-site treatment facility.

An initial investigation was conducted by First Environment on the behalf of the City of Newburgh in October 1999. Work included the collection and analysis of soil and soil boring samples and installation and analysis of seven groundwater piezometers. This investigation provided a baseline for soil and groundwater quality at the site. During this investigation approximately 60 tons of previously stockpiled soil was characterized and transported to an off-site disposal facility. In addition, nine of the drums staged on site were leaking and were over packed. The results of the initial investigation are contained in the Site Investigation/Remedial Alternatives Report Work Plan, dated July 2000.

SECTION 4: ENFORCEMENT STATUS

Potentially Responsible Parties (PRPs) are those who may be legally liable for contamination at a site. This may include past owners and operators, waste generators, and haulers.

Since no viable PRPs have been identified, there are currently no ongoing enforcement actions. However, legal action may be initiated at a future date by the state to recover state response costs should PRPs be identified. The City of Newburgh will assist the state in its efforts by providing all information to the state which identifies PRPs. The City will also not enter into any agreement regarding response costs without the approval of the NYSDEC.

SECTION 5: SITE CONTAMINATION

The City of Newburgh has recently completed a site investigation/remedial alternatives report (SI/RAR) to determine the nature and extent of any contamination by hazardous substances at this environmental restoration site.

5.1: Summary of the Site Investigation

The purpose of the SI was to define the nature and extent of any contamination resulting from previous activities at the site. The SI was conducted between August 2000 and June 2004. The field activities and findings of the investigation are described in the SI report.

The following activities were conducted during the SI:

- Research of historical information;
- Collection of 20 subsurface soil locations and 2 background locations;
- Collection of 31 discrete soil samples using a direct push technique;
- Collection of 37 subsurface post-excavation soil samples from tank excavations;
- Installation of 17 soil borings and 17 monitoring wells for analysis of soils and groundwater as well as physical properties of soil and hydrogeologic conditions;
- Sampling of 20 new and existing monitoring wells and piezometers;
- A survey of public and private water supply wells in the area around the site; and
- Collection of 21 soil vapor samples. Collection of 2 indoor air samples. Collection of 1 outdoor air sample.

To determine whether the soil and groundwater contain contamination at levels of concern, data from the investigation were compared to the following SCGs:

- Groundwater, drinking water, and surface water SCGs are based on NYSDEC "Ambient Water Quality Standards and Guidance Values" and Part 5 of the New York State Sanitary Code.
- Soil SCGs are based on the NYSDEC "Technical and Administrative Guidance Memorandum (TAGM) 4046; Determination of Soil Cleanup Objectives and Cleanup Levels".

Based on the SI results, in comparison to the SCGs and potential public health and environmental exposure routes, certain media and areas of the site require remediation. These are summarized below. More complete information can be found in the SI report.

5.1.1: Site Geology and Hydrogeology

The site is underlain by up to seven feet of fill consisting of sand, silt, and gravel with traces of building debris. Below the fill are alternating layers of sand and silt with discontinuous clay or silt layers identified at several locations. Bedrock was encountered at depths of approximately 47 to 50 feet. The bedrock consists of graywacke, a course grained sandstone with poorly sorted pieces of shale.

Groundwater occurs at the site at depths ranging from 6 to 15 feet below grade, depending on location and seasonal variations. Both the overburden and bedrock groundwater flow to the southeast. A very slight downward vertical gradient was observed between the shallow and intermediate wells, while an upward gradient was observed at all locations between bedrock and intermediate wells.

5.1.2: Nature of Contamination

As described in the SI report, many soil, groundwater and soil gas samples were collected to characterize the nature and extent of contamination. As summarized in Table 1, the main categories of contaminants that exceed their SCGs are volatile organic compounds (VOCs), semivolatile organic compounds (SVOCs), and inorganics (metals).

The VOCs of concern are petroleum related compounds including benzene, toluene, ethylbenzene and xylenes (BTEX) and chlorinated solvents including 1,1,1-trichloroethane (TCA), trichloroethene (TCE), tetrachloroethene (PCE) and their breakdown products. SVOCs identified on site consist of a number of polycyclic aromatic hydrocarbons (PAHs). While metals were found slightly above SCGs, they are naturally occurring and most likely attributable to local soil background conditions.

5.1.3: Extent of Contamination

This section describes the findings of the investigation for all environmental media that were investigated.

Chemical concentrations are reported in parts per billion (ppb) for water, parts per million (ppm) for soil and micrograms per cubic meter ($\mu g/m^3$) for air samples. For comparison purposes, where applicable, SCGs are provided for each medium.

Table 1 summarizes the degree of contamination for the contaminants of concern in soil, groundwater, and soil vapor and compares the data with the SCGs for the site. The following are the media which were investigated and a summary of the findings of the investigation.

Waste Materials

Contaminant source areas are associated with the former UST areas and the wash rack area. Free product or light non-aqueous phase liquid (LNAPL) was observed in the vicinity of all USTs and under the building slab. The LNAPL on-site is generally petroleum based, but may contain dissolved chlorinated solvents. In the former 5,000 gallon USTs area, LNAPL was observed during the tank removals and in monitoring well MW-3. LNAPL was also identified under the building slab in MW-9, and was tentatively identified as diesel oil. LNAPL thickness in this well was measured at a maximum of 3.7 feet. The source of this contamination may be the wash rack area behind the building. Three piezometers were installed under the building slab (PZ-8, PZ-9 and PZ-10) to determine the extent of the LNAPL observed in MW-9, but only a sheen was observed in these piezometers. LNAPL was also identified downgradient of the building in PZ-3 and MW-7. The LNAPL in MW-7 was tentatively identified as No. 2 fuel oil and may be related to the former fuel oil spill near PZ-3.

Subsurface Soil

Shallow soil samples were collected from 0 to 6 inches and 6 to 12 inches below pavement/gravel and analyzed for SVOCs and metals. Samples were collected around the building and UST areas. Most locations exceeded SCGs for various SVOCs and metals. Carcinogenic PAHs were the primary SVOCs detected above SCGs. Heavy metals included chromium, lead, nickel and zinc, but are not necessarily site related. SVOC and metal concentrations increased slightly in the 6 to 12 inch samples.

Deep soil samples were collected from depths ranging from 5 to 16 feet below grade. The primary contaminants of concern are VOCs. Samples were collected from UST excavations, soil borings, and monitoring well borings. Total VOC detections range from non-detect to 3,042 ppm, well above the SCG of 10 ppm. The approximate extent of the VOC contamination is shown on Figure 3. BTEX compounds were identified adjacent to or underlying each of the former USTs and underlying the wash rack area. Chlorinated VOCs were identified underlying the two 5,000 gallon waste oil USTs, but also at lower concentrations adjacent to the trench drain for the wash rack. In general, concentrations are highest approximately 8 to 10 feet below grade, extending down to 14 to 16 feet below grade, which roughly corresponds to the seasonal fluctuation of the water table.

Groundwater

Twenty on-site wells and piezometers were sampled during the site investigation. The majority of these are screened at the water table, but four wells are screened 25-30 feet below these and four

wells are installed into bedrock. Concentration contours for total chlorinated compounds and total BTEX are shown on Figures 4 and 5, respectively.

The highest VOC concentrations in the groundwater were detected in the wash rack area in PZ-7. Chlorinated VOCs totaled 68,170 ppb and BTEX totaled 3,290 ppb. Levels decreased in the intermediate well, MW-10I, to 523 ppb total chlorinated VOCs and 15 ppb BTEX. VOC concentrations were also high near the two former 5000 gallon USTs. Chlorinated VOCs totaled 50,300 ppb in MW-3 decreasing to 2,120 ppb in MW-3I. BTEX compounds were also detected up to 1,900 ppb in MW-3, but not in the intermediate well. The two chlorinated VOC plumes sink and converge in the southeast corner of the site as the intermediate wells were primarily impacted in the downgradient wells. 2,660 ppb total chlorinated VOCs were detected in the furthest downgradient well, MW-11I, indicating that the plume likely extends off site. The BTEX plume, however, does not appear to extend off site as no BTEX was detected in this well. BTEX contamination is also present in the vicinity of the former 8000 gallon gasoline UST and 10,000/20,000 gallon UST areas. BTEX was detected up to 42,000 ppb in MW-5 and 45,700 ppb in MW-7. No chlorinated VOCs were detected in these wells during the latest sampling round (October 2003).

VOCs were not detected in any of the bedrock monitoring wells indicating the contamination is confined to the overburden aquifer.

Soil Vapor/Air

Soil vapor samples were collected in the southeast portion of the site near the property boundary to determine if VOCs were potentially migrating off-site through the soil vapor. Sample locations and results are shown on Figure 6. Initially 21 samples were collected in 2001 and analyzed for BTEX compounds and total VOCs. Additional soil vapor testing was conducted in 2003 to evaluate if the site could be impacting the adjacent Ridgewood plumbing supply building. Concentrations were generally low near the property boundary, except for sample SG-4A with total VOCs detected at an estimated 1,987 μ g/m³. Two air samples were collected within the Ridgewood warehouse and one outside (ambient air) sample was collected using *Summa* canisters. Several VOCs were detected in the indoor air samples including benzene (up to 214 μ g/m³) and cis 1,2-DCE (at 20 μ g/m³), the only chlorinated VOC detected. At this time, it is unclear whether the detection of these chemicals in the indoor air at Ridgewood Plumbing is a result of vapor intrusion or a result of the presence of commercial plumbing products stored on-site. Additional investigation and/or mitigation will be completed as part of the pre-design investigation as specified in this ROD.

5.2: Interim Remedial Measures

An interim remedial measure (IRM) is conducted at a site when a source of contamination or exposure pathway can be effectively addressed before completion of the SI/RAR. The following IRMs were conducted as part of this investigation during November 2000 (the drum removal) and June and July 2001 (all other IRMs):

Characterization and disposal of 78 drums previously identified on site. Nine of the drums
were characterized and disposed as hazardous waste, with the remainder disposed as nonhazardous waste.

- Removal and off-site disposal of a 10,000 gallon gasoline UST and adjacent 20,000 gallon diesel UST. Both tanks had leaked and adjacent soil was excavated to remove visible petroleum contaminated soil surrounding the tanks. The excavation was completed to a maximum depth of 14 feet and approximately 10 feet beyond the limits of the USTs in all directions. The excavated soil was disposed of off site.
- Removal and off-site disposal of a 4,000 gallon gasoline UST, associated piping and gasoline dispensers. The UST had several holes and heavily contaminated soil surrounding the tank was excavated to a depth of 9.5 feet and disposed of off site.
- Removal and off-site disposal of two 5,000 gallon waste oil USTs. Product was observed in the excavation and grossly contaminated soil was removed to a depth of 11 feet and disposed of off site.
- Removal and off-site disposal of a 550 gallon heating oil UST. The tank had several holes
 and contaminated soil associated with the tank was excavated to a depth of 5.5 feet and
 disposed of off site.
- Pumping and off-site disposal of the contents of an 8,000 gallon fuel oil UST. This tank is
 partly below the groundwater table and currently empty; therefore, it appears to be sound.
 The wash rack is constructed above this tank which is currently preventing the removal of
 this UST.
- Cleaning and removal of the interior oil-water separator.
- Cleaning and removal of storm drains and approximately 190 feet of piping leading to the exterior oil-water separator. The oil-water separator was also cleaned and, although disconnected from service, remains on site for potential future use.
- Cleaning of floor drains within the building. After cleaning, the floor drains were sealed with concrete.

5.3: Summary of Human Exposure Pathways:

This section describes the types of human exposures that may present added health risks to persons at or around the site. A more detailed discussion of the human exposure pathways can be found in Appendix 6 of the SI/RA report.

An exposure pathway describes the means by which an individual may be exposed to contaminants originating from a site. An exposure pathway has five elements: [1] a contaminant source, [2] contaminant release and transport mechanisms, [3] a point of exposure, [4] a route of exposure, and [5] a receptor population.

The source of contamination is the location where contaminants were released to the environment (any waste disposal area or point of discharge). Contaminant release and transport mechanisms carry contaminants from the source to a point where people may be exposed. The exposure point

is a location where actual or potential human contact with a contaminated medium may occur. The route of exposure is the manner in which a contaminant actually enters or contacts the body (e.g., ingestion, inhalation, or direct contact). The receptor population is the people who are, or may be, exposed to contaminants at a point of exposure.

An exposure pathway is complete when all five elements of an exposure pathway exist. An exposure pathway is considered a potential pathway when one or more of the elements currently does not exist, but could in the future.

Pathways which are known to or potentially exist at the site include:

Soil

- Direct contact with surface soil contaminated with volatile organic compounds (VOCs), and semi-volatile organic compounds (SVOCs) are potential exposure pathways for trespassers. However, exposure of trespassers to contaminated soil is not expected since most of the site is paved or covered with gravel. Additionally, those areas that are not paved are covered with brush thereby limiting access to unpaved areas.
- During excavation work, construction workers could come in to direct contact with contaminated sub-surface soil, potentially resulting in dermal exposures or exposure through the inhalation of soil particles.

Groundwater

• Ingestion of contaminated groundwater is a potential pathway at this site. However, the facility and the surrounding neighborhood are supplied with public water. Therefore, ingestion of contaminated groundwater is not expected.

Ambient (Outdoor) Air

• Inhalation of VOCs and particulates is a potential exposure pathway for nearby businesses and residences during excavation and demolition activities. However, a Community Air Monitoring Plan implemented during demolition and intrusive activities would minimize inhalation exposures.

Indoor Air

- Inhalation of volatile organic compounds in indoor air that are a result of vapor intrusion is a potential exposure pathway at this site. However, the on-site building is currently vacant.
- Inhalation of volatile organic compounds in indoor air that are a result of vapor intrusion is a potential exposure pathway at nearby off-site properties. This exposure pathway will be further investigated in the future.

5.4: Summary of Environmental Impacts

This section summarizes the existing and potential future environmental impacts presented by the site. Environmental impacts include existing and potential future exposure pathways to fish and wildlife receptors, as well as damage to natural resources such as aquifers and wetlands.

No current pathways for environmental exposure have been identified for this site. The nearest creek is 700 feet south of the site and is not receiving drainage from the site. The exterior oil-water separator previously discharged to the City storm sewer which released into the Hudson River, but has been cleaned and disconnected from service. Site contamination has impacted the groundwater resource in the overburden aquifer. While this aquifer is not used as drinking water in vicinity of the site, it is considered a resource.

SECTION 6: SUMMARY OF THE REMEDIATION GOALS AND THE PROPOSED USE OF THE SITE

Goals for the remedial program have been established through the remedy selection process stated in 6 NYCRR Part 375-1.10. At a minimum, the remedy selected must eliminate or mitigate all significant threats to public health and/or the environment presented by the hazardous substances disposed at the site through the proper application of scientific and engineering principles.

The proposed future use for the Provan Ford Site is commercial, industrial or restricted residential.

The remediation goals for this site are to eliminate or reduce to the extent practicable:

- the presence of LNAPL as a source of soil, groundwater and soil vapor contamination;
- exposures of persons at or around the site to VOCs in soil, soil vapor and groundwater;
- the release of contaminants from soil into groundwater that may create exceedances of groundwater quality standards; and
- the release of contaminants from subsurface soil and groundwater into indoor air through soil vapor; and
- off-site migration of groundwater that does not attain groundwater quality standards.

Further, the remediation goals for the site include attaining to the extent practicable:

- ambient groundwater quality standards and
- SCGs for subsurface soil.

SECTION 7: SUMMARY OF THE EVALUATION OF ALTERNATIVES

The selected remedy must be protective of human health and the environment, be cost-effective, comply with other statutory requirements. Potential remedial alternatives for the Provan Ford Site were identified, screened and evaluated in the RA report which is available at the document repositories established for this site.

All of the remedial alternatives evaluated (except no further action) include the demolition of the on-site building and wash rack and excavation of heavily impacted soil and LNAPL with off-site treatment and disposal. Demolition of the building will allow efficient removal of the area of LNAPL which originates under the wash rack and extends under the building. Excavation is considered the only practical means for removal of LNAPL from soil and the groundwater interface.

All of the action alternatives also include measures to mitigate any vapor intrusion impacts in adjacent off-site buildings, which may be identified during the remedial design, or future on-site buildings during site redevelopment.

A summary of the remedial alternatives that were considered for this site are discussed below. The present worth represents the amount of money invested in the current year that would be sufficient to cover all present and future costs associated with the alternative. This enables the costs of remedial alternatives to be compared on a common basis. As a convention, a time frame of 30 years is used to evaluate present worth costs for alternatives with an indefinite duration. This does not imply that operation, maintenance, or monitoring would cease after 30 years if remediation goals are not achieved.

7.1: <u>Description of Remedial Alternatives</u>

The following potential remedies were considered to address the contaminated soil, groundwater, and soil gas at the site.

Alternative 1: No Further Action

Present Worth:	\$323,000
Capital Cost:	\$0
Annual OM&M:	
(Years 1-30):	. \$21,000

The No Further Action alternative recognizes remediation of the site conducted under previously completed IRMs. To evaluate the effectiveness of the remediation completed under the IRM, only continued monitoring is necessary. This alternative would leave the site in its present condition and would not provide any additional protection to human health or the environment.

Alternative 2: Soil Excavation\SVE, Groundwater Air Sparging, Site Cover

Present Worth:	 \$1,510,000
Capital Cost:	 \$1,320,000

Annual OM&M:	
(Years 1-5):	\$36,000
(Years 6-7):	\$21,000

This alternative would involve excavation to remove heavily impacted soils and LNAPL from source areas with transport off site for treatment/disposal, and a combination of soil vapor extraction (SVE)/air sparging to treat the remaining VOC-impacted soil to SCGs and contaminated groundwater to groundwater standards. An estimated 4,600 cubic yards of soil would be excavated from the wash rack and former UST areas (ranging from depths of approximately 5 to 16 feet below grade). The building and wash rack would be demolished to allow access to contamination under those areas and the 8,000 gallon UST under the wash rack would be excavated, cleaned and disposed of off site. Excavated areas would be backfilled with clean fill.

Remaining soil, in excess of SCGs, would be treated by SVE and the groundwater contamination would be treated by air sparging. SVE is an *in situ* process where VOCs present in unsaturated soil are removed by physically applying a vacuum to the subsurface. The vacuum creates air movement and VOCs are drawn through a vapor treatment system. Air sparging involves the injection of air into the groundwater through a series of injection wells to strip VOCs out the groundwater. The air injected would be collected by the SVE wells and treated through that system.

This alternative would include a site cover to limit contact with residual SVOC-contaminated soil and would include measures to mitigate any vapor intrusion impacts in adjacent off-site buildings identified during the remedial design. In addition, a site management plan would be developed stipulating development and usage restrictions. It is estimated that this alternative could be designed in 6 months, implemented in four to six weeks and would meet remediation goals within 3 to 5 years. A pilot test would be required to determine the effectiveness of this technology under site conditions.

Alternative 3: Soil Excavation, In Situ Groundwater Chemical Oxidation, Site Cover

Present Worth:	\$1,580,000
Capital Cost:	\$1,430,000
Annual OM&M:	
(Years 1-2):	\$61,000
(Years 3-4):	\$21,000

This alternative would involve excavation to remove LNAPL and all VOC-impacted soil in excess of SCGs from source areas with transport off site for treatment/disposal, and groundwater treatment with *in situ* chemical oxidation. *In situ* chemical oxidation would involve the subsurface introduction of oxidizing agents, such as potassium permanganate, to degrade organic constituents in groundwater to innocuous substances such as carbon dioxide, water and inorganic chloride. The groundwater would be treated by delivering the oxidant into the aquifer by a network of vertical injection wells. Injection wells would be located near source areas and the southeast corner of the site to treat groundwater on site and a short distance off site.

An estimated 5,800 cubic yards of soil would be excavated under this alternative consisting of soil from the wash rack and UST areas, similar to Alternative 2, but including all VOC-impacted soil to SCGs. As in Alternative 2, the building and wash rack would be demolished to allow access to contamination under those areas and the 8,000 gallon UST under the wash rack would be excavated, cleaned and disposed of off site. Excavated areas would be backfilled with clean fill.

Similar to Alternative 2, this alternative would also include a site cover to limit contact with residual SVOC-contaminated soil and would include measures to mitigate any vapor intrusion impacts in adjacent off-site buildings identified during the remedial design. In addition, a site management plan would be developed stipulating development and usage restrictions. It is estimated that this alternative could be designed in 6 months, with implementation over a one to two year period to meet remedial objectives. A pilot test would be required to determine the effectiveness of *in situ* chemical oxidation under site specific conditions and contaminants present.

Alternative 4: Soil Excavation, Groundwater Extraction and Treatment, Site Cover

Present Worth:	\$2,820,000
<i>Capital Cost:</i>	\$1,640,000
Annual OM&M:	
(Years 1-10):	
(Years 11-12):	

This alternative would involve excavation to remove LNAPL and VOC-impacted soil in excess of SCGs from source areas with transport off site for treatment/disposal, and groundwater extraction and treatment. The soil excavation would consist of the same methods, areas and volumes described under Alternative 3. Groundwater treatment, however, would consist of the installation of extraction wells in source areas and the southeast corner of the site. Groundwater would be extracted through these wells and treated on site through activated carbon units or an air stripper with discharge to surface water or re-injection.

Similar to Alternatives 2 and 3, this alternative would also include a site cover to limit contact with residual SVOC-impacted soil and would include measures to mitigate any vapor intrusion impacts in adjacent off-site buildings identified during the remedial design. In addition, a site management plan would be developed stipulating development and usage restrictions. It is estimated that this alternative could be designed in 6 months with a duration of operation of 10 years.

Alternative 5: Soil Excavation and *In Situ* Groundwater Chemical Oxidation

<i>Present Worth:</i>	0,000
Capital Cost:	0,000
Annual OM&M:	
(Years 1-2):	1,000
(Years 3-4):	

This alternative would be similar to Alternative 3 except that it would involve additional soil excavation to reduce levels of SVOCs below SCGs rather than the use of a site cover. For cost

estimating purposes it is assumed that two feet of soil would require excavation over the entire site, however, verification sampling would confirm actual excavation limits. The excavated soil would be characterized and it is assumed that disposal would be to an off-site disposal facility as non-hazardous waste. Excavated areas would be backfilled with clean fill. Since all wastes would be eliminated from the site, a site cover and institutional controls would not be necessary. It is estimated that this alternative could be designed in 6 months, with implementation over a one to two year period to meet remedial objectives

7.2 Evaluation of Remedial Alternatives

The criteria to which potential remedial alternatives are compared are defined in 6 NYCRR Part 375, which governs the remediation of environmental restoration projects in New York State. A detailed discussion of the evaluation criteria and comparative analysis is included in the RA report.

The first two evaluation criteria are termed "threshold criteria" and must be satisfied in order for an alternative to be considered for selection.

- 1. <u>Protection of Human Health and the Environment</u>. This criterion is an overall evaluation of each alternative's ability to protect public health and the environment.
- 2. <u>Compliance with New York State Standards, Criteria, and Guidance (SCGs)</u>. Compliance with SCGs addresses whether a remedy will meet environmental laws, regulations, and other standards and criteria. In addition, this criterion includes the consideration of guidance which the NYSDEC has determined to be applicable on a case-specific basis.

The next five "primary balancing criteria" are used to compare the positive and negative aspects of each of the remedial strategies.

- 3. <u>Short-term Effectiveness</u>. The potential short-term adverse impacts of the remedial action upon the community, the workers, and the environment during the construction and/or implementation are evaluated. The length of time needed to achieve the remedial objectives is also estimated and compared against the other alternatives.
- 4. <u>Long-term Effectiveness and Permanence</u>. This criterion evaluates the long-term effectiveness of the remedial alternatives after implementation. If wastes or treated residuals remain on-site after the selected remedy has been implemented, the following items are evaluated: 1) the magnitude of the remaining risks, 2) the adequacy of the engineering and/or institutional controls intended to limit the risk, and 3) the reliability of these controls.
- 5. <u>Reduction of Toxicity, Mobility or Volume</u>. Preference is given to alternatives that permanently and significantly reduce the toxicity, mobility or volume of the wastes at the site.
- 6. <u>Implementability</u>. The technical and administrative feasibility of implementing each alternative are evaluated. Technical feasibility includes the difficulties associated with the construction of the remedy and the ability to monitor its effectiveness. For administrative feasibility, the availability

of the necessary personnel and materials is evaluated along with potential difficulties in obtaining specific operating approvals, access for construction, institutional controls, and so forth.

7. <u>Cost-Effectiveness</u>. Capital costs and operation, maintenance, and monitoring costs are estimated for each alternative and compared on a present worth basis. Although cost-effectiveness is the last balancing criterion evaluated, where two or more alternatives have met the requirements of the other criteria, it can be used as the basis for the final decision. The costs for each alternative are presented in Table 1.

This final criterion is considered a "modifying criterion" and is taken into account after evaluating those above. It is evaluated after public comments on the Proposed Remedial Action Plan have been received.

8. <u>Community Acceptance</u>. Concerns of the community regarding the SI/RA reports and the PRAP have been evaluated. The responsiveness summary (Appendix A) presents the public comments received and the manner in which the NYSDEC addressed the concerns raised. In general, the public comments received were supportive of the selected remedy.

SECTION 8: SUMMARY OF THE SELECTED REMEDY

Based on the Administrative Record (Appendix B) and the discussion presented below, the NYSDEC has selected Alternative 3, soil excavation, *in situ* groundwater chemical oxidation and a site cover as the remedy for this site. The elements of this remedy are described at the end of this section.

The selected remedy is based on the results of the SI and the evaluation of alternatives presented in the RAR.

Alternative 3 has been selected because, as described below, it satisfies the threshold criteria and provides the best balance of the primary balancing criteria described in Section 7.2. It would achieve the remediation goals for the site by removing the wastes and soil that create the most significant threat to public health and the environment, it would eliminate the source of contamination to groundwater, and it would create the conditions needed to restore groundwater quality to the extent practicable. It is also capable of treating off-site groundwater contamination a relatively short distance downgradient of the site and can be implemented in the shortest time period minimizing site disturbance during its period of treatment. Alternatives 2 and 4 would also comply with the threshold selection criteria but to a lesser degree or with lower certainty.

Because Alternatives 2, 3, 4 and 5 satisfy the threshold criteria, the five balancing criteria are particularly important in selecting a final remedy for the site.

Alternatives 2 (excavation/SVE/air sparging/site cover), 3 (excavation/ chemical oxidation/site cover), 4 (excavation/groundwater extraction and treatment/site cover), and 5 (excavation/chemical oxidation) all would have short-term impacts which can easily be controlled. The time needed to achieve the remediation goals for wastes and heavily contaminated soil would be similar for all alternatives. Achieving SCGs for the remaining, lower impacted soil, however, would be longer for

Alternative 2. Achieving groundwater goals would take longest (10 years) for Alternative 4, 3 to 5 years for Alternative 2 and 1 to 2 years for Alternatives 3 and 5.

All alternatives would be equally effective over the long-term as wastes and VOC-impacted soil would be removed, SVOC-impacted soil would be covered or removed, and on-site groundwater would be treated to standards. Alternative 5 would be slightly more effective as SVOC-contaminated soil would be removed and would not rely on maintenance of a site cover and institutional controls.

All alternatives would equally reduce the toxicity, mobility and volume of VOC-impacted soil and wastes through removal or in-situ treatment. Alternative 5 would provide further toxicity and volume reduction by removal of the additional SVOC-impacted soil. However, SVOCs have low mobility and exposure could be mitigated through maintenance of a site cover. Alternative 2 could reduce the migration of VOCs through the soil vapor possibly eliminating the need for any mitigative vapor intrusion measures for off-site buildings. All alternatives would be capable of treating on-site groundwater to standards; Alternatives 3 and 5 would also be capable of treating off-site groundwater contamination.

In terms of implementability, all alternatives would involve commonly available technologies. Each would require demolition of the building and wash rack to excavate soils under these areas. Alternative 2 would require a pilot test to determine the effectiveness of SVE under the site conditions. Soil heterogeneity could negatively impact the effectiveness of SVE at this site. Piping associated with the SVE/air sparging system could obstruct full use of the property by a future developer during the treatment period. Alternatives 3 and 5 would also require a pilot test to determine the effectiveness of chemical oxidation in treatment of the groundwater at this site, but this technology has proven effective on other sites. Alternative 4 would require compliance with discharge limits for the treated groundwater and discharge options could be limited. Alternative 5 would be more difficult to implement due to the removal of SVOC-impacted soil and could become impractical if impacted areas are more widespread than currently estimated.

The cost of the alternatives varies significantly. Alternatives 2 and 3 would be the least expensive alternatives and similar in cost. Alternative 4 would be significantly more costly than these due to the high costs associated with operation and maintenance of a groundwater treatment system. Alternative 5 would be the most costly alternative because of the extra cost for removal of the SVOC-impacted soil. Removal of the SVOC-impacted soil is not considered to be justified due to the relatively high cost to remove this soil as opposed to application of a site cover.

The estimated present worth cost to implement the remedy is \$1,580,000. The cost to construct the remedy is estimated to be \$1,430,000 and the estimated average annual operation, maintenance, and monitoring costs for 2 years is \$61,000.

The elements of the selected remedy, as presented in Figure 7, are as follows:

• A remedial design program would be implemented to provide the details necessary for the construction, operation, maintenance, and monitoring of the remedial program.

- A pre-design investigation to determine the extent of off-site groundwater and vapor contamination. The results of this sampling would be evaluated to determine the need for off-site remedial measures and the need for vapor mitigation measures at the off-site buildings.
- Demolition of the former Provan Ford operations building and wash rack to facilitate soil excavation and LNAPL removal from under those areas.
- Excavation of subsurface soils visibly impacted with LNAPL and/or containing VOCs in excess of SCGs to mitigate human contact and migration of contaminants into the groundwater. The approximate limits of the remedial areas are shown in Figure 7, estimated to be a total of 5,800 cubic yards of soil.
- LNAPL recovery from open excavation areas.
- Off-site treatment/disposal of excavated soil and LNAPL at an appropriate, NYSDEC approved disposal facility.
- Removal, cleaning and off-site disposal of the 8,000 gallon UST present under the wash rack area.
- Backfill excavated areas with un-impacted overlying soil or clean fill.
- Treatment of on-site groundwater to mitigate off-site migration of contaminants and to reduce VOC concentrations to groundwater standards, to the extent feasible, using *in situ* chemical oxidation.
- All vegetated areas will be covered by either a one foot (commercial or industrial use) or two foot (restricted residential use) thick cover consisting of clean soil underlain by an indicator such as orange plastic snow fence to demarcate the cover soil from the subsurface soil. The top six inches of soil would be of sufficient quality to support vegetation. Clean soil would constitute soil with no analytes in exceedance of NYSDEC TAGM 4046 soil cleanup objectives or local site background as determined by the procedure in DER 10 ("Tech Guide"). Non-vegetated areas (buildings, roadways, parking lots, etc) would be covered by a paving system or concrete at least 6 inches in thickness.
- Since the remedy results in contamination above unrestricted levels remaining at the site, a site management plan (SMP) will be developed and implemented. The SMP will include the institutional controls and engineering controls to: (a) address residual contaminated soils that may be excavated from the site during future redevelopment. The plan would require soil characterization and, where applicable, disposal/reuse in accordance with NYSDEC regulations; (b) evaluate the potential for vapor intrusion for any buildings developed on the site, including provision for mitigation of any impacts identified; (c) provide for the operation and maintenance of the components of the remedy; (d) limit the use and development of the property to commercial or industrial, if a one foot soil cover is used, or

restricted residential, if a two foot soil cover is used; and (e) identify any restrictions on groundwater use.

- The SMP will require the property owner to provide an Institutional Control/ Engineering Control (IC/EC) certification, prepared and submitted by a professional engineer or site representative acceptable to the NYSDEC annually or for a period to be approved by the NYSDEC, which would certify that the institutional controls and engineering controls put in place, are unchanged from the previous certification and nothing has occurred that would impair the ability of the control to protect public health or the environment or constitute a violation or failure to comply with any operation an maintenance or soil management plan.
- Imposition of an institutional control in form of an environmental easement that would: (a) require compliance with the approved site management plan; (b) limit the use and development of the property to commercial or industrial uses (one foot soil cover) or restricted residential (two foot soil cover); (c) restrict use of groundwater as a source of potable or process water, without necessary water quality treatment as determined by the Orange County Department of Health; and, (d) require the property owner to complete and submit to the NYSDEC IC/EC certification.
- The operation of the components of the remedy would continue until the remedial objectives have been achieved, or until the NYSDEC determines that continued operation is technically impracticable or not feasible.
- Since the remedy results in untreated hazardous substances remaining at the site, a long term monitoring program would be instituted. The monitoring would inspect the integrity of the site cover on an annual basis. If groundwater standards are not achieved, post remedial groundwater monitor program would be performed. This program would allow the effectiveness of the remediation and site cover to be monitored and would be a component of the operation, maintenance, and monitoring for the site.

SECTION 9: HIGHLIGHTS OF COMMUNITY PARTICIPATION

As part of the Provan Ford Site environmental restoration process, a number of Citizen Participation activities were undertaken to inform and educate the public about conditions at the site and the potential remedial alternatives. The following public participation activities were conducted for the site:

- Repositories for documents pertaining to the site were established.
- A public contact list, which included nearby property owners, elected officials, local media and other interested parties, was established.
- A fact sheet was sent to the public contact list announcing the start of the project and availability of the SI/RAR work plan.

- A fact sheet was sent to the public contact list summarizing the PRAP and announcing the public meeting for the PRAP.
- A public meeting was held on March 7, 2005 to present and receive comment on the PRAP.
- A responsiveness summary (Appendix A) was prepared to address the comments received during the public comment period for the PRAP.

SUBSURFACE SOIL	Contaminants of Concern	Concentration Range Detected (ppm) ^a	SCG ^b (ppm) ^a	Frequency of Exceeding SCG
	Shallow Soil (0-6 inch	nes below pavement/gravel)		
Semivolatile Organic	Benzo(a)anthracene	ND ^c -23	0.224	16/20

a ppb = parts per billion, which is equivalent to micrograms per liter, ug/L, in water; ppm = parts per million, which is equivalent to milligrams per kilogram, mg/kg, in soil; ug/m³ = micrograms per cubic meter

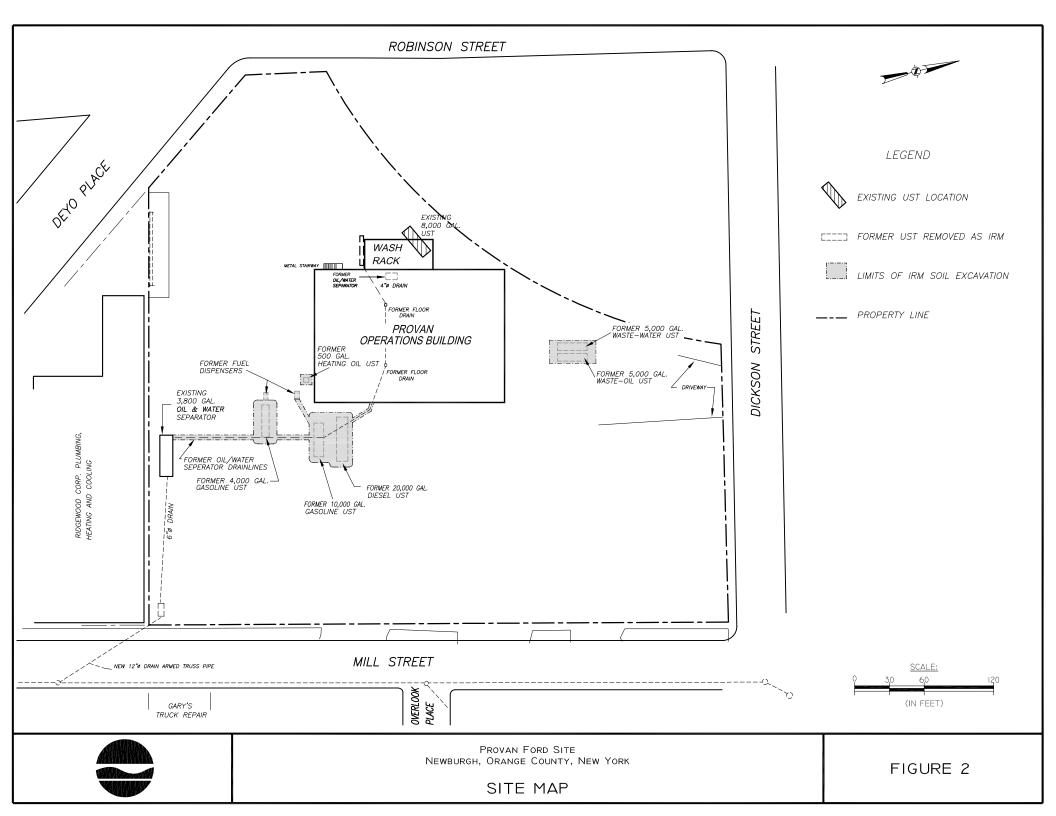

^bSCG = standards, criteria, and guidance values;

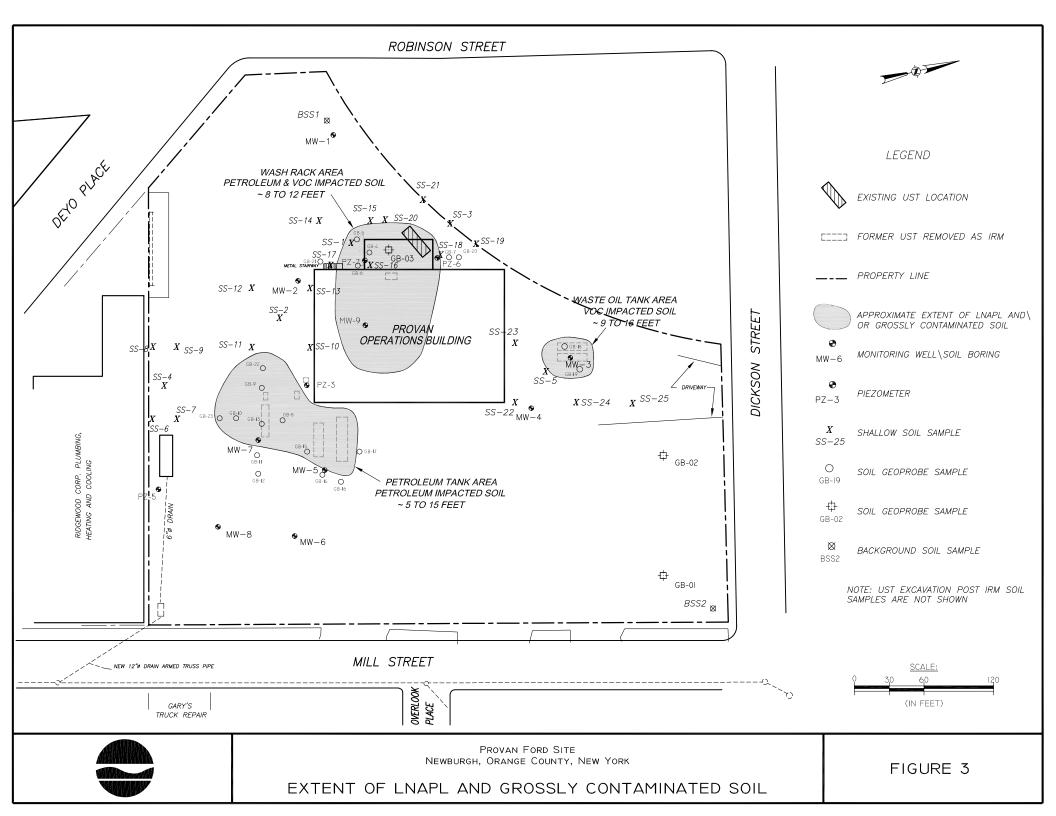

^cND = non detect.

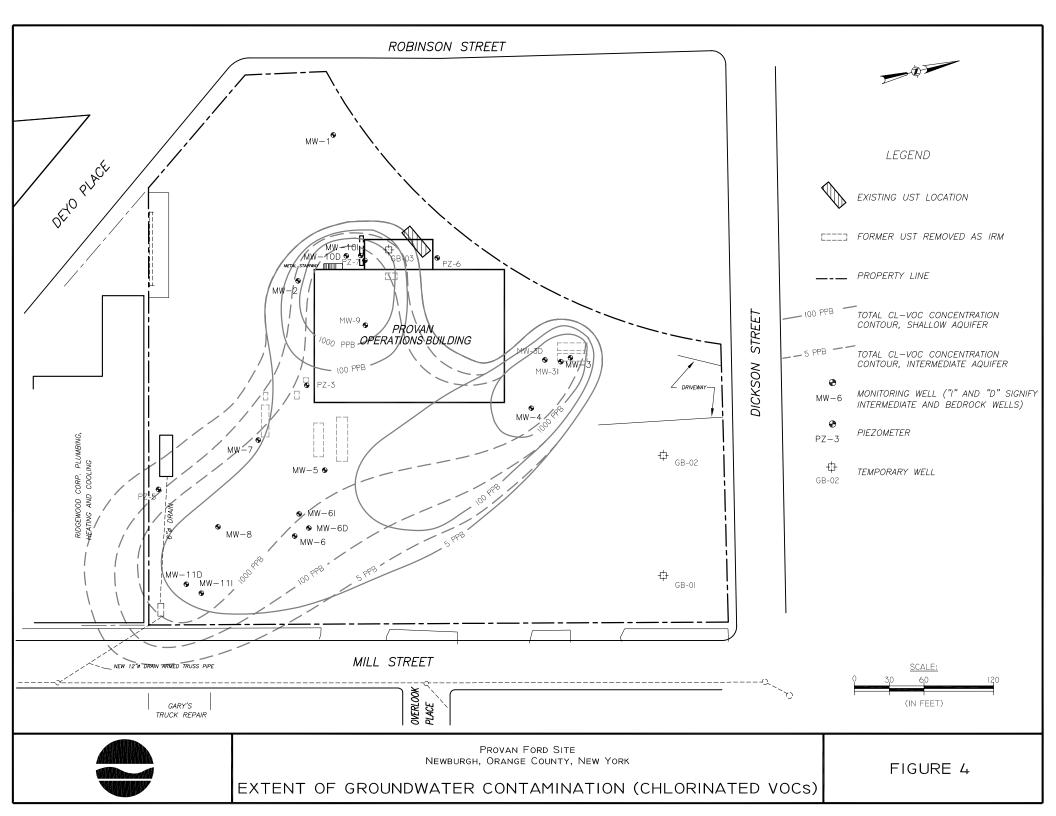

TABLE 2 Remedial Alternative Costs

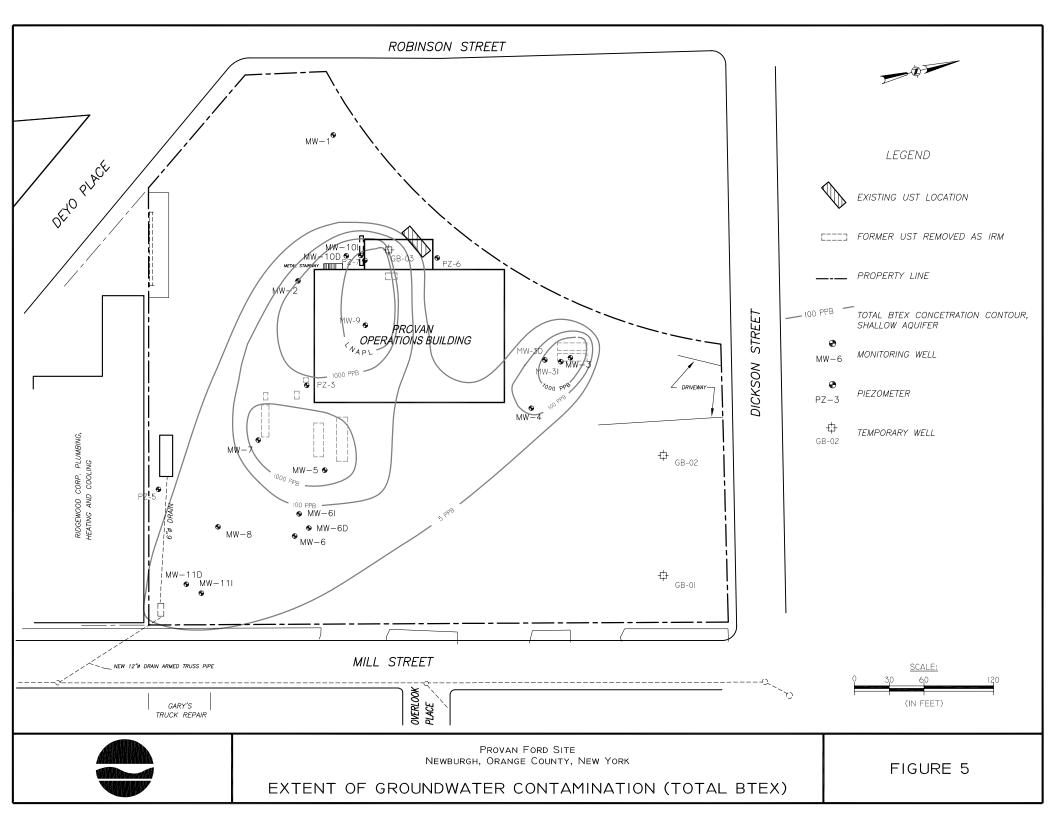

Remedial Alternative	Capital Cost	Annual OM&M	Total Present Worth
1. No Further Action	\$0	\$21,000	\$323,000
2. Soil Excavation\SVE, Groundwater Air Sparging and Site Cover	\$1,320,000	\$36,000	\$1,510,000
3. Soil Excavation, <i>In Situ</i> Groundwater Chemical Oxidation and Site Cover	\$1,430,000	\$61,000	\$1,580,000
4. Soil Excavation, Groundwater Extraction & Treatment and Site Cover	\$1,640,000	\$150,000	\$2,820,000
5. Soil Excavation, <i>In Situ</i> Groundwater Chemical Oxidation and Site Cover	\$2,790,000	\$61,000	\$2,940,000

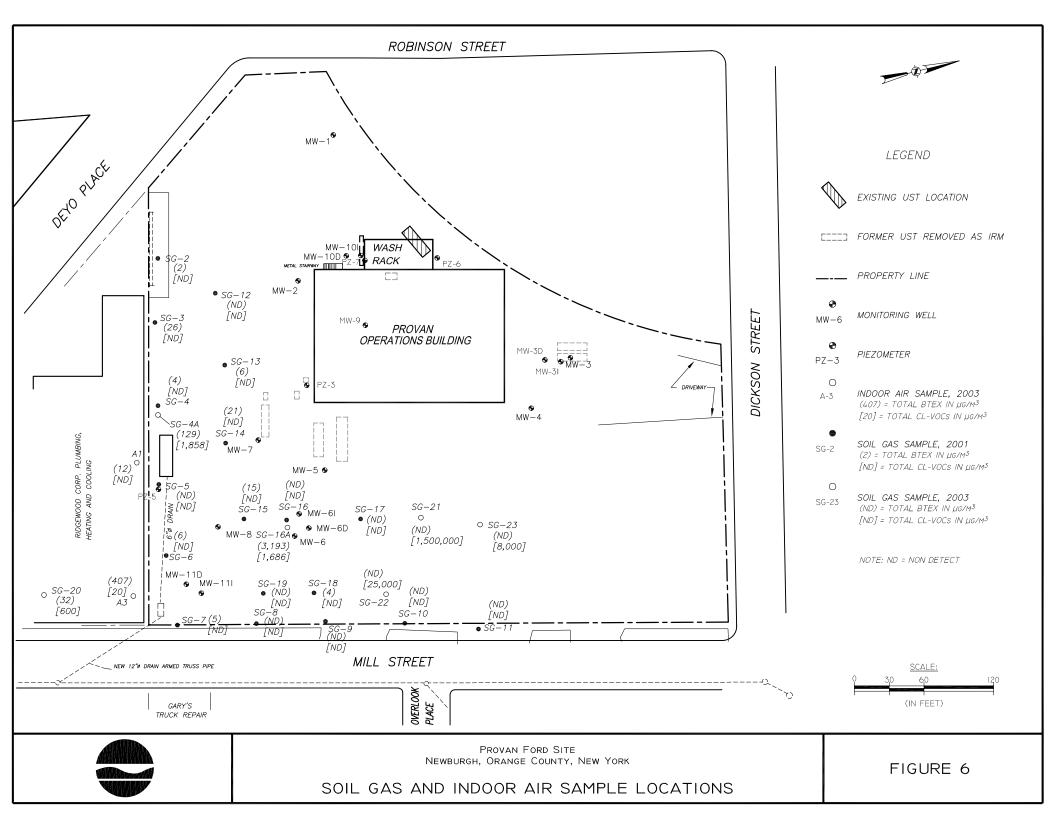

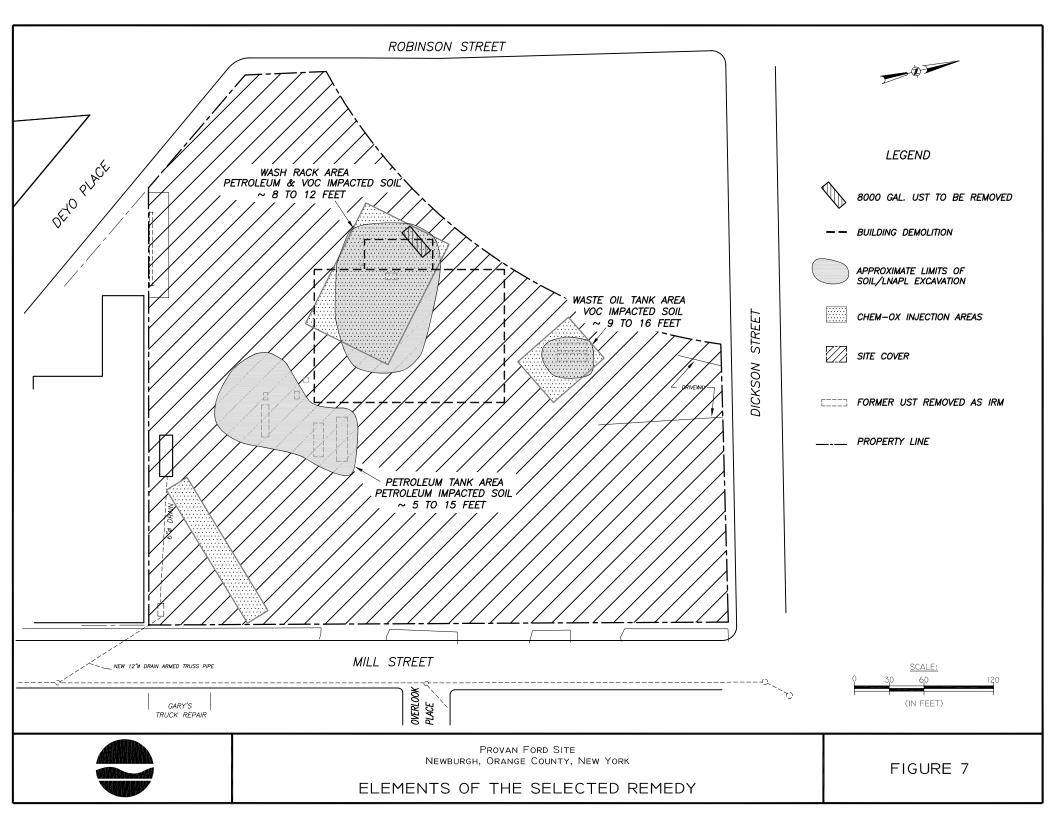

APPENDIX A

Responsiveness Summary

RESPONSIVENESS SUMMARY

Provan Ford Environmental Restoration Site Newburgh, Orange County, New York Site No. B00127-3

The Proposed Remedial Action Plan (PRAP) for the Provan Ford Site, was prepared by the New York State Department of Environmental Conservation (NYSDEC) in consultation with the New York State Department of Health (NYSDOH) and was issued to the document repositories on February 11, 2005. The PRAP outlined the remedial measure proposed for the contaminated soil, groundwater and soil vapor at the Provan Ford Site.

The release of the PRAP was announced by sending a notice to the public contact list, informing the public of the opportunity to comment on the proposed remedy.

A public meeting was held on March 7, 2005, which included a presentation of the Site Investigation (SI) and the Remedial Alternatives Report (RAR) as well as a discussion of the proposed remedy. The meeting provided an opportunity for citizens to discuss their concerns, ask questions and comment on the proposed remedy. These comments have become part of the Administrative Record for this site. The public comment period for the PRAP ended on March 28, 2005.

This responsiveness summary responds to all questions and comments raised during the public comment period. The following are the comments received, with the NYSDEC's responses:

COMMENT 1: How do you define commercial uses?

RESPONSE 1: "Commercial use" generally means a land use for the primary purpose of buying, selling or trading of merchandise or services. Examples of commercial land uses include, but are not limited to, warehouses; building supply facilities; retail gasoline stations; automobile service stations; automobile dealerships; retail warehouses; repair and service establishments for appliances and other goods; professional offices; banks and credit unions; office buildings; retail businesses selling food or merchandise; golf courses; hospitals and clinics; religious institutions; hotels; motels; parking facilities and passive recreational uses, e.g., bike or walking paths, tennis courts, green space or other public uses with lower potential for soil contact. People who would be present a commercial facilities include adult workers during a business day, and adults and children who are customers, patrons or visitors to commercial facilities during the business day.

COMMENT 2: Because contaminants are being left on site under this proposal, what type of liability will fall to future owners or contractors who may want to use this site or adjacent properties found to be affected by site contamination?

RESPONSE 2: The municipality and all successors in title, lessees, and lenders are released from remedial liability for hazardous substances that were on the property prior to entry into the Environmental Restoration Program (ERP). The State indemnifies these same persons in the amount of any settlements/judgements obtained regarding an action relating to hazardous substances that were on the property prior to the ERP. This also applies to off-site contamination that is related to the site.

COMMENT 3: If future contamination is found on or off site, what process is followed to remediate it? Does the NYSDEC step in, hire a contractor, and handle all the paperwork?

RESPONSE 3: If future contamination is found on site, the current site owner has the burden of proof to show that the contamination is historical. If contamination is found to be historically related to the site, the NYSDEC would pay for the cost of investigation and remediation of the contamination. If historical contamination is found off-site, the NYSDEC would perform the necessary investigation and remediation to address it.

COMMENT 4: Does Alternative 5 clean the property to such an extent that there would be no restrictions as to future use?

RESPONSE 4: Alternative 5 would excavate all VOC and SVOC-impacted soil to SCGs and treat groundwater to standards. Provided these remedial objectives are achieved, there would be no restrictions on future use of the site, i.e., the site could be used for any purpose including single family homes. This alternative was not selected, however, since the removal of the SVOC-impacted soil is not considered to be justified due to the relatively high cost to remove this soil as opposed to application of a site cover. Both the selected remedy and Alternative 5 are considered to be protective of human health and the environment.

COMMENT 5: Because the proposed remedy leaves some contamination in place, restricts the future use, and requires institutional controls, how does the City handle the following scenarios:

Who is responsible for ensuring proper implementation of the site management plan (SMP)?

Does the NYSDEC or NYSDOH get involved in the permitting process normally handled by the municipality, or are there any special permitting requirements for future construction?

Who determines that a future soil vapor suppression system needs to be installed?

Who handles the installation?

Who determines if any future soil vapor suppression system installed at the site is working properly?

RESPONSE 5: To address residual contamination remaining on site after remediation, the property owner must develop and implement a SMP. The SMP sets forth the institutional and engineering controls to address remaining contamination, as required in Section 8 of the ROD. The SMP is submitted to the NYSDEC for review and approval and requires submittal of

periodic certifications regarding the continued effectiveness of the controls specified in the plan. The SMP would also specify other submittals to the NYSDEC required under the plan which may include site monitoring data and reports. The NYSDEC will oversee the implementation of the plan as the need arises. Beyond the controls specified in the SMP, there are no special permits required by the NYSDEC. Local permits are obtained through normal permit processes under the appropriate local entities. If future buildings are constructed on the site, however, the potential for vapor intrusion must be evaluated by the property owner, as specified by the SMP, with results submitted to the NYSDEC. The NYSDEC will assist the owner in determining if any vapor intrusion controls are necessary. The owner would then be responsible for the proper installation, operation, maintenance and monitoring of the system to insure it complies with the guidelines set forth prior to installation. The owner is also responsible for monitoring the system to verify that it is operating properly with submission of this data to the NYSDEC.

COMMENT 6: Does the NYSDEC have engineers to review any construction plans that may be submitted to the city?

RESPONSE 6: The City should, in the first instance, confirm that the plans are consistent with the remedial program and SMP. The NYSDEC will review the City's determination and the plans, to the extent necessary, to insure compliance with the SMP. Also see Response 5, above.

COMMENT 7: What if the city determines that residential use is the best use of this site, what would we have to do with the NYSDEC to get the restriction vs. residential use lifted.

RESPONSE 7: The proposed remedy was based on commercial use of the site as proposed by the City in the ERP application. Based on the City's comment on the proposed remedy, the NYSDEC has slightly modified the remedy to allow "restricted residential" use, with the requirement that vegetated areas are covered by a two foot soil cover underlain by a demarcation layer. "Restricted residential" means a land use where there is common control of the property, e.g., apartment complexes, townhouse developments, mixed use high rise development, etc., where there is a single property owner. Single family housing is not generally considered for this category of land use. Restricted residential use shall at a minimum prohibit any vegetable gardens on a property, although community gardens may be considered with NYSDEC approval. Examples of such land uses include, but are not limited to: residences; day care facilities; schools, colleges and other educational institutions; nursing homes, elder care and other long-term health care facilities and active recreational uses, e.g., playgrounds, picnic areas, playing fields or other public uses where there is a higher potential for soil contact.

COMMENT 8: What kind of timetable are we talking about regarding the completion of the ROD, the finalizing of the RD and the actual remedial construction?

RESPONSE 8: After issuance of the ROD, the City must submit an ERP application for the remedial design and construction of the selected remedy. Once the application is approved, the remedial design and bidding documents are prepared by the City's consultant and submitted for NYSDEC review and approval. After this, the project is bid for remedial construction. Based on similar projects, this process is estimated to take approximately one year. The construction phase of the remedy is estimated to take approximately one year to complete.

COMMENT 9: If the proposed remedy is implemented and the city should find a willing developer, is it possible for the City's implementation of the remedy and the developers plans for the site to proceed on parallel tracks?

RESPONSE 9: Yes. In general, it is beneficial to all parties involved to work on a parallel track. Specific needs of the developer can be incorporated into the design and construction performed by the City to minimize any duplication of work. The developer, however, would have to meet the remediation schedules.
