# ENVIRONMENTAL SITE ASSESSMENT FORMER CITY OF BUFFALO MUNICIPAL PIER PROPOSED SHOOTERS RESTAURANT BUFFALO, NEW YORK

#### I. INTRODUCTION

#### A. General

Empire Soils Investigations, Inc. (ESI) was retained to complete an environmental site assessment on property (former City of Buffalo Municipal Pier) for the proposed Shooters Restaurant located along the Buffalo Waterfront, west of Fuhrmann Boulevard near the foot of Michigan Avenue, in the City of Buffalo, (Erie County), New York. A project location plan is presented as Drawing No. 1 in Appendix A.

The environmental site assessment was completed in conjunction with an ESI companion report entitled "Geotechnical Investigation, Proposed Shooters Restaurant, Buffalo, New York" which presents the results of our subsurface exploration and geotechnical engineering recommendations for the proposed construction. The environmental site assessment was requested and authorized by Mr. Jerry Holcombe, representing Holcombe Associates, Inc. (HAI) in Niagara Falls, New York.

#### B. Purpose and Scope

ESI was engaged by HAI to render an opinion if significant quantities of oil and hazardous materials, as defined by the Comprehensive Environmental Response Compensation and Liability Act (CERCLA) are present in the soil and ground water beneath the site. To accomplish this objective, ESI completed the fol-

lowing scope of services:

S-5167 SOUTH PARK AVENUE, P.O. BOX 0913, HAMBURG, NY 14075, 716-649-8110

- o Made a site visit and reviewed the present site use;
- o Discussed the project with Mr. Holcombe and reviewed site plans (provided by HAI) of the subject property;
- o Planned a subsurface exploration and sampling program for an environmental site assessment;
- o Monitored the drilling of ten (10) test borings and installation of one (1) ground water monitoring well at the subject property (refer to Drawing No. 2 for location in Appendix A);
- o Determined organic vapor concentrations during the exploration phase of the project;
- o Measured relative ground surface elevations at the ten (10) test boring locations;
- o Prepared the test boring logs;
- o Engaged a New York State Department of Health (NYSDOH) certified analytical testing laboratory to analyze soil and ground water samples collected from selected test borings and the monitoring well, respectively;
- o Evaluated data collected and;
- o Summarized the environmental assessment and analytical test results in this report.

Limitations to this report are presented in Appendix B.

#### II. SITE CONDITIONS

#### A. Physical Setting

The site discussed in this report occupies approximately 6.2 acres of land (based on dimensions from site maps prepared by Mussachio Architects, Wiliamsville, New York, dated November 1988 and supplied by Mr. Holcombe of HAI), in the City of Buffalo, (Erie County) New York. We understand that the subject property is being leased from the Niagara Frontier Transportation Authority (NFTA). The site is bordered on the north by a water filled slip located between the subject property and the Seaway Piers to the north. The Buffalo Outer Harbor borders the property on the west and Fuhrmann Boulevard borders the property on the east. South of the subject site is vacant land which is presently owned by the NFTA and was previously used as a dredge disposal area.

The site topography is relatively level with a slight slope down to the south-southwest. Based on considerations of area topography and drainage, it appears that ground water beneath the site is generally level with a slight slope down towards Lake Erie and the Outer Harbor which exists about 100-feet to the north and to the west of the site.

# B. Site History

Information regarding site history was obtained from the City of Buffalo Engineering and Survey Department, the Erie County Public Library and the Buffalo Historical Society. The discussion below is based solely on information obtained from these limited sources.

In the early 1800's, the Lake Erie Shoreline was approximately east of the Fuhrmann Boulevard and the present day Buffalo Skyway. In about 1840, a seawall was constructed along the shoreline approximately at the location of the present Buffalo Skyway. The outer harbor break wall was constructed approximately 2000-feet off shore from about 1865 to 1890. During this period, the area northeast of the subject site (i.e. near the foot of Michigan Avenue), was occupied by numerous railroad facilities, storage yards, elevators and warehouses related to various water front businesses such as shipbuilding, coal storage and transfer, grain and lumber.

The shoreline near the subject site remained the same (i.e. along Fuhrmann Boulevard) until the construction of the two (2) municipal piers in about 1926. The shoreline configuration south of the subject site changed considerably as dumping by previous owners gradually filled the area between Fuhrmann Boulevard and the Buffalo Outer Harbor. This area was used as a storage yard for new automobiles shipped by Lake freighters from points west (refer to the photograph presented as Drawing No. 3 in Appendix A taken in the mid 1950's). The shoreline south of the municipal piers moving south

continued to change (i.e. westward towards the Outer Harbor) during the late 1950's, 1960's and early 1970's. During this period the subject area was used as a dredge disposal site for outer harbor sediments. The shoreline has remained generally the same from the end of dredge spoil dumping in the mid 1970's until present. The area south of the subject area has recently been used stock piling coal, salt and sand.

Aerial photographs of the subject property were obtained for review from the City of Buffalo Survey Department, Erie County Department of Environment and Planning and the Buffalo Historical Society. The photographs reviewed (1940 through 1982) verified the changes in the basic shoreline configuration (as discussed previously) for the subject site and remained generally the same until present day.

# C. Site Visit

ESI visited the site during the field explorations program which was completed from November 30, 1988 to December 7, 1988. The purpose of the site visit was to observe current conditions at the site with respect to the potential presence of hazardous materials in the soils and/or ground water beneath the subject site.

subject site is generally level land covered by asphaltic pavement, short grass and miscellaneous debris from former stock piles of coal, salt and sand. Two (2) existing structures are lothe approximate center of the property. One (about 100-feet by 175-feet) is located about 50-feet from the north property line along the edge of the water. The building is vacant and on the north and has a concrete floor which is somewhat deteriorated. It appears that the structure was used to stockpile material (ì.e. salt) from the weather. The second (80-feet by 120-feet) is located east of the larger structure

about 140-feet from the edge of water along the north property line. The building also has a concrete floor and is vacant except for a construction trailer stored inside. Along the western property border (edge of the outer harbor) miscellaneous rubble fill and construction debris were observed from the existing ground surface downward to the edge of the water. The area surrounding the two (2) existing buildings is covered with asphaltic pavement. It appears that surface water run-off is towards the outer harbor, north and west, and towards a catch basin located south of the existing buildings.

Based on field observations made during the site visit, there are existing sewer, water, gas, electric and telephone service lines bordering the subject property northeast of the subject site along Fuhrmann Boulevard. However, the field locations of utilities on the site were not confirmed as part of this study.

#### D. Regulatory Agency Information

ESI contacted Mr. John Tygert of the New York State Department of Environmental Conservation (NYSDEC) and Mr. Melvin Szymanski of the Erie County Department of Environment and Planning (ECDEP). The purpose of the inquiries was to request information with regards to the potential presence of hazardous materials, known environmental releases, prior environmental studies done on property and prior environmental citations on the property.

NYSDEC and ECDEP stated, after a careful review of their respective records, that there are no known waste disposal activities located on the subject property. However, there are three (3) inactive industrial waste disposal site within approximately 2000-feet of the subject site. The Times Beach/Fuhrmann Boulevard, waste site in Buffalo, New York (I.D. No. NYD915080) is about 2000-feet north of the subject site. A waste site known as the City Ship Canal,

west Bank, South Michigan Street, Buffalo, New York is located about 1000-feet northeast of the subject site. The Niagara Frontier Transportation Authority's (NFTA) Outer Harbor disposal property (I.D. No. NYD915026) borders the subject on the southeast. The NFTA Outer Harbor property is registered as a 2A hazardous waste site. A Phase II Site investigation is presently being contemplated by the NFTA to change the site's present 2A listing. The NFTA Outer property is immediately adjacent to the subject property to the southeast.

The NYSDEC and ECDEP also stated that there are no known records of environmental releases at the subject site. It should be noted that the NYSDEC and ECDEP files only reflect those sites where inquiry and/or investigation by NYSDEC, the United States Environmental Protection Agency (USEPA), local health/environmental department, or by input from the public at large, have revealed the possibility of hazardous waste and/or associated activities involvhazardous materials have taken place. It should be further noted that answers to inquiries of this nature only reflect the formation currently in the NYSDEC and ECDEP files.

The following local agencies and city departments were also contacted for information regarding known environmental concerns at the site: Erie County Health Department, City of Buffalo Police Department and City of Buffalo Fire Department. Information obtained from these sources indicates that there are no known records of hazardous materials being released at the site.

#### III. SUBSURFACE EXPLORATION

ESI made ten (10) test borings (B-1 through B-10) and installed a ground water monitoring well in one (1) of the test borings (B-6). The drilling of test borings and the installation of the monitoring well was done from November 30, 1988 to December 7, 1988. The test

boring locations are plotted on Drawing No. 2 in Appendix A.

The ground surface elevation at each of the test boring locations was measured in the field by ESI using optical survey methods. The ground surface elevations were referenced to a bench mark established on the rim of a catch basin located in the approximate center of the property along the south property line. Based on data from a site plan provided by HAI and prepared by Pratt and Huth Associates, the elevation at this point is 579.76. The bench mark location is plotted on Drawing No. 2 presented in Appendix A.

The test borings were advanced to determine subsurface conditions for geotechnical evaluation of the soils and ground water with respect to the proposed consutrction. Based on the configuration of the proposed restaurant, Mussachio Architects generally located six (6) of the geotechnical test borings (B-1 through B-6) within the proposed building area and four (4) test borings (B-7, B-8, B-9 and B-10) in the proposed parking areas. Two (2) test borings, B-4 and B-6 were used as environmental sampling points, with a ground water monitoring well being installed in test boring B-6.

Test boring procedures and ground water monitoring well installation details are discussed in detail in the companion geotechnical report entitled "Geotechnical Investigation, Proposed Shooters Restaurant, Buffalo, New York". The test boring logs and details of the ground water monitoring well installation are presented in Appendix C of this report.

#### IV. FIELD AND LABORATORY TESTING AND RESULTS

#### A. General

In conjunction with the environmental assessment and geotechnical exploration at this site, various field and laboratory measurements were taken by ESI and a NYSDOH certified analytical testing laboratory to evaluate air, soil and water quality. Test

procedures and results are summarized in subsequent paragraphs.

### B. Air Quality Testing and Results

Organic vapor monitoring was conducted during the subsurface investigation and compared to background measurements to indicate potential hazardous substances below ground. Organic vapor measurements were taken at the top of the hollow stem augers with the augers set at various depths during drilling and as the soil samples were removed from the split-spoon and placed in sample jars.

Organic vapor measurements were taken using a photoionization detector (PID). The PID used to measure ionizable organic vapors was a Hnu PI101 manufactured by Hnu Systems, Inc. of Newton Highlands, Massachusetts with a 10.2 eV ultraviolet light source. The Hnu measures organic vapors up to about 2000 parts per million (ppm). The instrument was calibrated before the start of field work using the manufacturer's recommended calibration standard of Benzene.

Ambient "background" organic vapor measurements were taken approximately 20-feet upwind of each test boring location prior to drilling to establish site conditions. The range of these "background" readings during the monitored period (November 30, 1988 through December 7, 1988) were 0.0 to 0.4 ppm.

PID measurements made during drilling operations near the top of borehole and near the split-spoon samples generally indicated organic vapors less than 0.4 ppm, with a peak reading of 6 ppm measured near the ground surface in test boring B-6. Organic vapor measurements should be compared to ambient background readings ranging from about 0.0 to 0.4 ppm. Field air quality monitoring data are presented on the boring logs in Appendix C.

# C. Soil and Analytical Testing and Results

ESI collected composite soil samples from test borings B-4 and B-6 for analytical soil analysis of the Superfund Target Compound List (TCL) which includes Organochlorine Pesticides and PCB's (Test Method 8080), semi-volatile TCL Pollutants (Test Method 8240), semi-volatile TCL Pollutants (Acid and base/neutral extractables, Test Method 8270), Priority Pollutant Metals and Cyanide (Test Method 335.2). We point out that a summary of the Superfund Target Compound List (TCL) compounds and parameters is presented in Appendix E for reference. The results of the chemical analyses done on the composite soil samples collected from test borings B-4 and B-6 are presented in Appendix D.

Composite soil samples were collected from test borings B-4 and B-6 during drilling from December 6, 1988 to December 7, 1988. The sample collection procedure consisted of compositing representative soil from split-spoon samples taken within the fill material encountered in each of the test borings.

The soil samples were placed into pre-cleaned 40 ml septum vials filled to capacity to prevent air space. The containers were tightly sealed and placed in an ice cooler. The containers were then returned to Huntingdon Analytical Services, Inc. (HAS) in Middleport, New York for testing immediately following collection.

The analytical results indicate that no significant TCL Organochlorine Pesticides and PCB's (USEPA Test Method 8080), semi-volatile TCL Pollutants (Test Method 8240), and semi-volatile TCL pollutants (acid base/ neutral extractables) were detected in the soil samples collected from the two (2) test borings. A concentration of 4400 ug/kg (parts per billion) of acetone was detected in the composite soil sample collected from test boring B-6. The measured concentration of acetone is probably the result of the

decontamination of the soil mixing equipment used to composite the soil samples (Note: boring B-6 was sampled after B-4, with equipment being decontaminated in the field between borings). Minor detectable concentrations of several base neutral extractables detected in Test Method 8270 are not a result of any current activities at the site and are not indicative of widespread or gross contamination across the site and could generally be considered insignificant with respect to the proposed development.

The analytical test results for Priority Pollutant Metals and Cyanide indicate concentrations that are generally considered to be within background levels.

# D. Ground Water Analytical Testing and Results

ESI collected a representative water sample from monitoring well B-6 for water quality analysis using USEPA TCL Test Methods for Organochlorine Pesticides and PCB's (Test Method 608), Semi-volatile TCL Pollutants (Test Method 624), Semi-volatile TCL Pollutants (Test Method 625), Priority Pollutant Metals and Cyanide. The results of the chemical analyses done on the water samples collected from monitoring well B-6 are presented in Appendix D.

Ground water samples were collected on December 12, 1988 from the monitoring well installed in test boring B-6. We point out that the monitoring well was "developed" using evacuation techniques following installation. A Brainard-Kilman, hand operated, positive displacement pump was used to evacuate the well. Approximately one (1) hour after three (3) well volumes were purged from the well, a dedicated, pre-cleaned, 3-feet long by 1-inch outside diameter teflon bailer with a teflon check valve was used to purge and sample the well. The sample collection procedure consisted of purging three (3) well volumes from the well and allowing the well to recover prior to sampling. The water sample was collected by lowering

the bailer into the water and allowing it to fill. The bailer was then removed and the contents emptied into pre-cleaned 40 ml glass septum vials filled to capacity to prevent air bubbles. The vials were tightly sealed and placed in an ice cooler and returned to HAS for testing immediately following collection.

The analytical results indicate that TCL Organochlorine Pesticides and PCB's, semi-volatile TCL Pollutants, semi-volatile TCL Pollutants semi-volatile TCL pollutants (acid, base/neutral extractables) were not detected in the ground water samples collected from the monitoring well (B-6). Priority Pollutant Metals and Cyanide were detected at concentrations generally below those specified for New York State Class GA (potable) ground water.

#### V. SUMMARY AND CONCLUSIONS

The conclusion presented below are subject to the limitations contained in Appendix B. An environmental site assessment and geotechnical investigation were performed for HAI at the site of the proposed Shooters Restaurant, which is located southwest of Fuhrmann Boulevard in Buffalo, New York. This assessment was limited to data obtained during a site visit, a brief review of site history and a field exploration and chemical analysis program. Based on the limited studies conducted and the information made available to ESI, relevant findings are summarized below:

- o The site includes approximately 6.2 acres of waterfront property in Buffalo, New York, southwest of Fuhrmann Boulevard. The site is presently level land occupied by two (2) buildings.
- o The property will be leased from the NFTA.
- O Based on the review of site history, the subject property was covered by water until about 1926 when the City of Buffalo constructed the City Municipal Piers. Land area south of the piers increased through the years as the area was filled with dredge materials from the Buffalo Outer Harbor. The subject property was used for storage of new automobiles, coal, salt and sand.

- o Personnel from NYSDEC, ECDEP and local agencies (previously listed) were contacted. No record of releases of hazardous materials or soil/ground water remediations was found for the site. It should be noted that records from ECDEP indicate that three (3) inactive waste disposal sites are within 2000-feet of the subject site.
- o Organic vapor concentrations were not detected during the subsurface investigation at the subject site.
- o Chemical test results indicate that concentrations of TCL Organochlorine Pesticides and PCB's, semi-volatile TCL Pollutants and semi-volatile TCL Pollutants (acid, base/neutral Extractables) were not detected in water samples collected from the monitoring well installed in boring B-6.
- o Chemical test results also indicated that concentrations of TCC Organochlorine Pesticides and PCB's and semi-volatile TCL Pollutants were not detected in composite soil samples collected from borings B-4 and B-6.
- O Chemical test results indicated that minor concentrations of some semi-volatile TCL Pollutants (acid, base/neutral extractables) were detected in composite soil samples collected from borings B-4 and B-6.

In summary, ESI has not found any information that indicates that significant quantities of hazardous materials are present in the soil and ground water at the subject site. It is our opinion, based on the data collected and reviewed as part of this environmental site assessment, that significant quantities of hazardous substances are, or have not been, present at the subject site. Evaluation of the possible impact of practices at neighboring locations on the subject site was beyond our contracted scope of services.

Respectfully submitted, EMPIRE SOILS INVESTIGATIONS, INC.

APPENDIX B

LIMITATIONS

#### APPENDIX B

#### LIMITATIONS

- 1. The observations described in this report were made under conditions stated therein. The conclusions presented in the report were based solely upon the services described therein and not tasks and procedures beyond the scope of described services or the time and budgetary constraints imposed by the client.
- 2. In preparing the limited site history, ESI has relied on certain information provided by State, County and City officials and other parties referenced herein. ESI did not attempt to independently verify the accuracy or completeness of information reviewed or received during the course of the collection of this site history.
- 3. No specific attempt was made to check on the compliance of present or past owners or operators of the site with Federal, State, or Local laws and regulations, environmental or otherwise.
- 4. Observations were made of the site and of structures on the site as indicated within the report. Where access to portions of the site or to structures was limited or unavailable, ESI renders no opinion as to the presence of hazardous materials or to the presence of indirect evidence relating to hazardous material in that portion of the site or structure.
- 5. Unless otherwise specified in the report, ESI did not perform testing or analyses to determine the presence or concentrations of asbestos or radon at the site.
- 6. This report has been prepared for the exclusive use of HAI and its designated agents for the specific application to the Proposed Shooters Restaurant site in Buffalo, New York in accordance with generally accepted engineering practice. No other warranty expressed or implied, is made.

APPENDIX C

SUBSURFACE LOGS

# **GENERAL INFORMATION & KEY TO SUBSURFACE LOGS**

The Subsurface Logs attached to this report present the observations and mechanical data collected by the driller at the site, supplemented by classification of the material removed from the borings as determined through visual identification by technicians in the laboratory. It is cautioned that the materials removed from the borings represent only a fraction of the total volume of the deposits at the site and may not necessarily be representative of the subsurface conditions between adjacent borings or between the sampled intervals. The data presented on the Subsurface Logs together with the recovered samples will provide a basis for evaluating the character of the subsurface conditions relative to the project. The evaluation must consider all the recorded details and their significance relative to each other. Often analyses of standard boring data indicate the need for additional testing or sampling procedures to more accurately evaluate the subsurface conditions. Any evaluation of the contents of this report and the recovered samples must be performed by Professionals. The information presented in the following defines some of the procedures and terms used on the Subsurface Logs to describe the conditions encountered.

- 1. The figures in the Depth column defines the scale of the Subsurface Log.
- 2. The sample column shows, graphically, the depth range from which a sample was recovered. See Table 1 for a description of the symbols used to signify the various types of samples.
- 3. The Sample No. is used for identification on sample containers and/or Laboratory Test Reports.
- 4. Blows on Sampler shows the results of the "Penetration Test", recording the number of blows required to drive a split spoon sampler into the soil. The number of blows required for each six inches of penetration is recorded. The first 6 inches of penetration is considered to be a seating drive. The number of blows required for the second and third 6 inches of penetration is termed the penetration resistance, N. The outside diameter of the sampler, the hammer weight and the length of drop are noted at the bottom of the Subsurface Log.
- 5. Blows on Casing shows the number of blows required to advance the casing a distance of 12 inches. The casing size, the hammer weight and the length of drop are noted at the bottom of the Subsurface Log. If the casing is advanced by means other than driving, the method of advancement will be indicated in the Notes column or under the Method of Investigation at the bottom of the Subsurface Log.
- 6. All recovered soil samples are reviewed in the laboratory by an engineering technician, geologist or geotechnical engineer, unless note otherwise. The visual descriptions are made on the basis of a combination of the driller's field descriptions and observations and the sample as received in the laboratory. The method of visual classification is based primarily on the Unified Soil Classification (ASTM D 2487-83) with regard to the particle size and plasticity. (See Table No. II) Additionally, the relative portion, by weight, of two or more soil types is described for granular soils in accordance with "Suggested Methods of Test for Identification of Soils" by D. M. Burmister, ASTM Special Technical Publication 479, June 1970. (See Table No. III) The description of the relative soil density or consistency is based upon the penetration records as defined on Table No. IV. The description of the soil moisture is based upon the relative wetness of the soil as recovered and is described as dry, moist, wet and saturated. Water introduced in the boring either naturally or during drilling may have affected the moisture condition of the recovered sample. Special terms are used as required to describe materials in greater detail; several such terms are listed in Table V. When sampling gravelly soils with a standard two inch diameter split spoon, the true percentage of gravel is often not recovered due to the relatively small sampler diameter. The presence of boulders and large gravel is sometimes, but not necessarily, detected by an evaluation of the casing and samplers blows or through the "action" of the drill rig as reported by the driller.
- 7. The description of the rock shown is based on the recovered rock core and the driller's observations. The terms frequently used in the description are included in Table VI.
- 8. The stratification lines represent the approximate boundary between soil types and the transition may be gradual. Solid stratification lines are based on the driller's field observations.
- 9. Miscellaneous observations and procedures noted by the driller are shown in this column, including water level observations. It is important to realize the reliability of the water level observations depends upon the soil type (water does not readily stabilize in a hole through fine grained soils), and that drill water used to advance the boring may have influenced the observations. The ground water level typically will fluctuate seasonally. One or more perched or trapped water levels may exist in the ground seasonally. All the available readings should be evaluated. If definite conclusions cannot be made, it is often prudent to examine the conditions more thoroughly through test pit excavations or water observation wells.
- 10. The length of core run is defined as the length of penetration of the core barrel. Core recovery is the length of core recovered divided by the core run. The RQD (Rock Quality Designation) is the total pieces of NX core exceeding 4 inches in length divided by the core run. The size core barrel used is also noted.

#### ENVIRONMENTAL ANALYTICAL REPORT

HAS Ref. #30-796

DECEMBER 1988

### HUNTINGDON ANALYTICAL SERVICES ENVIRONMENTAL REPORT

HAS Reference Number: #30-796

December

1988

#### Statement of Work Performed

I hereby declare that the work was performed under my supervision according to the procedures outlined by the following references and that this report provides a correct and faithful record of the results obtained.

- 40 CFR Part 136, "Guidelines Establishing Test Procedures for the Analysis of Pollutants Under the Clean Water Act," October 26, 1984 (Federal Register) U.S. Environmental Protection Agency.
- U.S. Environmental Protection Agency, "Test Methods of Evaluating Solid Waste Physical/Chemical Methods," Office of Solid Waste and Emergency Response, SW-846, 2nd Edition and 3rd Edition.
- New York State Department of Health, Analytical Toxicology Laboratory Handbook, August 1982.

Richard D. Fitzpatrick

Environmental Laboratory Director

#### REPORT CODE LEGEND:

<DL = Less than detection limit</pre>

ND = Not detected

NA = Not applicable

<IQ = Response not statistically significant
 from laboratory background values</pre>

\*Medium Soil/Sediment Contract Required Quantitation Limits (CRQL) for Volatile TCL Compounds are 100 times the individual Low Soil/Sediment CRQL.

\*Specific quantitation limits are highly matrix dependent. The quantitation limits listed herein are provided for guidance and may not always be achievable.

\*\*Quantitation Limits listed for soil/sediment are based on wet weight. The

\*Quantitation Limits listed for soil/sediment are based on wet weight. The quantitation limits calculated by the laboratory for soil/sediment, calculated on dry weight basis, as required by the protocol, will be higher.

Medium Soil/Sediment Contract Required Detection Limits (CRDL) for Semi-Volatile HSL Compounds are 60 times the individual Low Soil/Sediment CRDL.

<sup>\*</sup>Specific quantitation limits are highly matrix dependent. The quantitation limits listed herein are provided for guidance and may not always be achievable.

<sup>\*\*</sup>Quantitation limits listed for soil/sediment are based on wet weight. The quantitation limits calculated by the laboratory for soil/sediment, calculated on dry weight basis as required by the contract, will be higher.

## CLP Inorganics (continued)

1: Any analytical method specified in Exhibit D, CLP-Inorganics may be utilized as long as the documented instrument or method detection limits meet the Contract Required Quantitation Level (CRQL) requirements. Higher quantitation levels may only be used in the following circumstance:

If the sample concentration exceeds two times the quantitation limit of the instrument or method in use, the value may be reported even though the instrument or method detection limit may not equal the contract required quantitation level. This is illustrated in the example below:

For lead:
Method in use = ICP
Instrument Detection Limit (IDL) = 40
Sample concentration = 85
Contract Required Quantitation Level (CRQL) = 5

The value of 85 may be reported even though instrument detection limit is greater than Contract Required Quantitation Limit. The instrument or method detection limit must be documented as described in Exhibit E.

2: These CROL are the instrument detection limits obtained in pure water that must be met using the procedure in Exhibit E. The quantitation limits for samples may be considerably higher depending on the sample matrix.
