1.0 INTRODUCTION

The Hanna Furnace Site in South Buffalo encompasses approximately 131 acres, including the 10-acre Union Ship Canal and the 35-acre former railroad yard. Previous investigations performed by various agencies and consultants have generally characterized the site; however, the former rail yard has been the subject of minimal investigation (see Figure 1). The City of Buffalo is planning to redevelop the former rail yard as a commercial/light industrial park. Prior to redevelopment, the former rail yard must be adequately characterized to verify that public health and the environment are adequately protected. In the fall of 1998 and winter of 1999, Malcolm Pirnie performed a characterization of the former railroad yard.

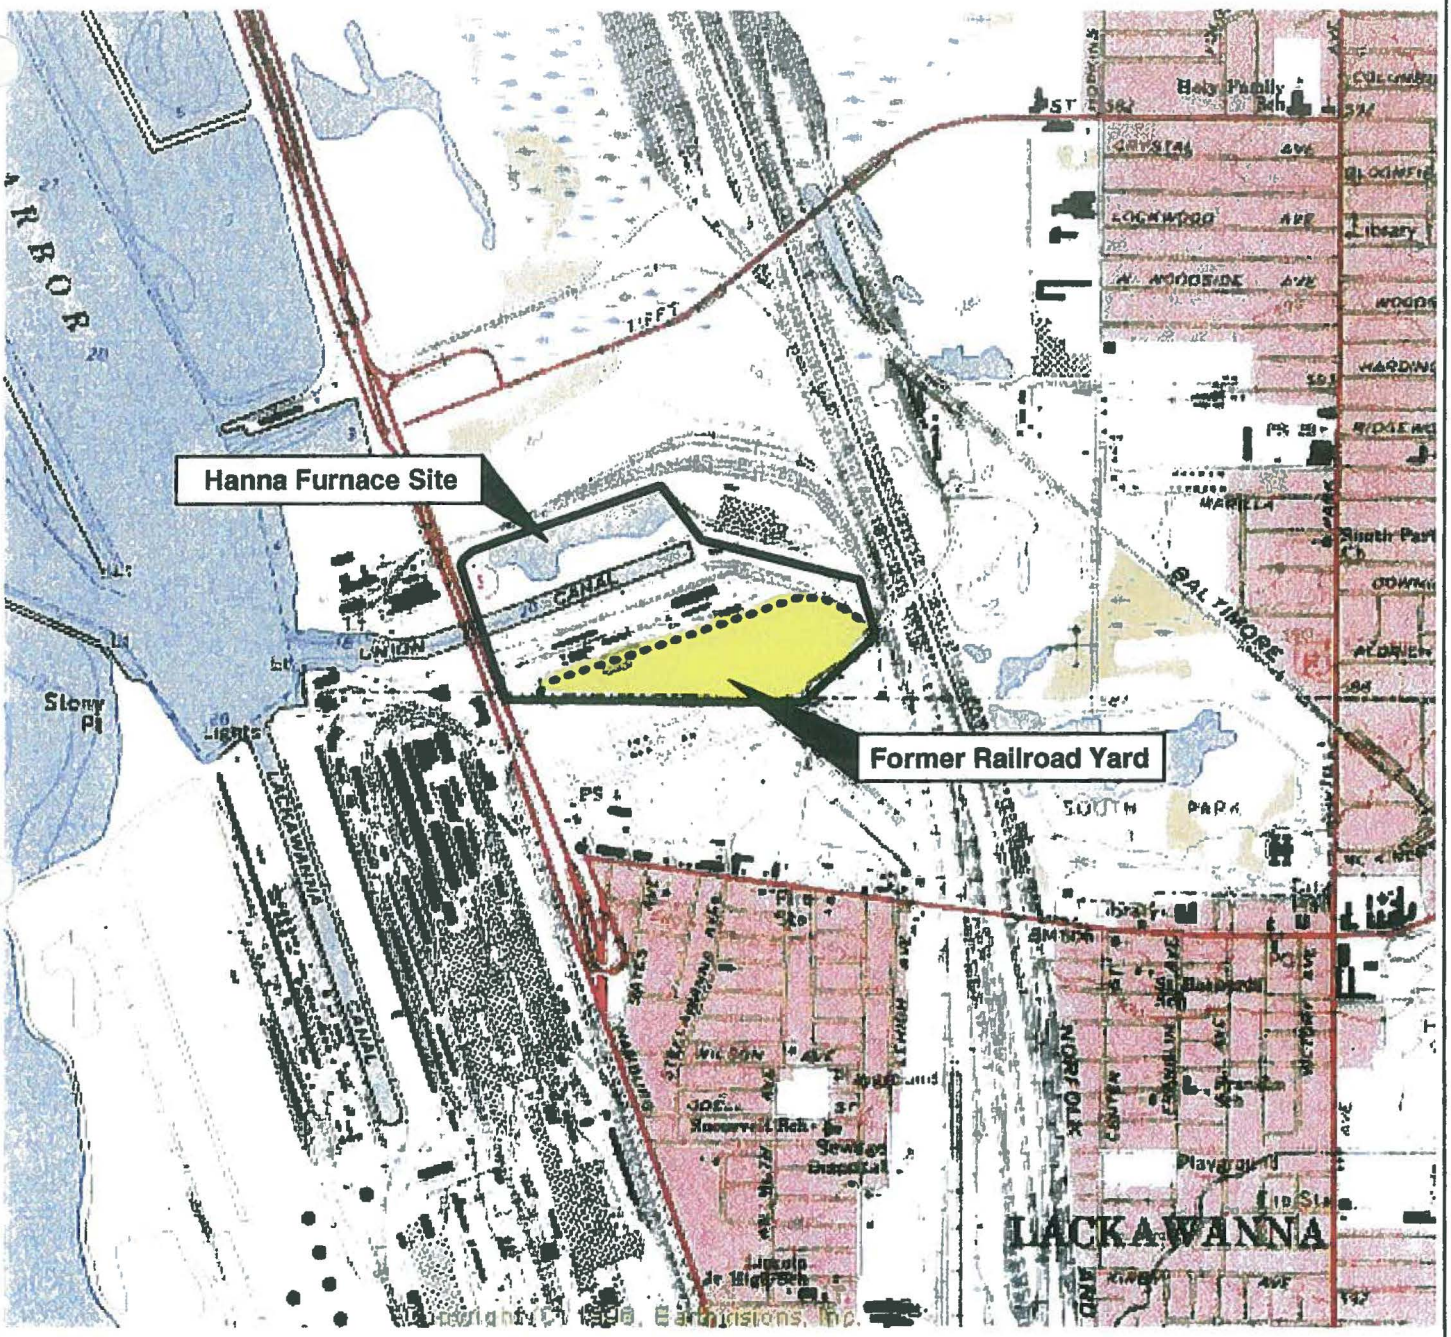

1.1 PREVIOUS SAMPLING

The Hanna Furnace Site has had several environmental investigations performed over the last 20 years by various agencies, none of which concluded that remedial action was necessary. The area of investigation at the Hanna Furnace site varies between investigation; therefore, it is important to keep in mind the area of investigation when evaluating and comparing data results and recommendations. Because there is no significant historic evidence of contamination of concern on the former railroad yard, most investigations at the Hanna Furnace site included little or no sampling within the railroad yard. The following is a chronological summary of the significant site investigations performed at the Hanna Furnace site and the results or recommendations of each:

- In 1979 Rupley, Bahler, and Blake, Consulting Engineers prepared a Solid Waste Management Facility Report. This report was limited to evaluation of surface water quality in the Union Ship Canal and an on-site pond. The water samples contained phenols and soluble iron at concentrations above NYSDEC Class GA groundwater standards.

HANNA FURNACE SITE - FORMER RAILROAD YARD
SUPPLEMENTAL INVESTIGATION

SITE LOCATION MAP

SEPTEMBER 1999

- In April 1982, after the cessation of pig iron manufacturing at the site, the Erie County Department of Environmental Protection inspected the site and prepared a report entitled "Inactive Site Profile Report". The report recommended that the NYSDEC downgrade the classification of the site to a "class F" which pertains to a site where no further action is warranted and little to no environmental hazard potential exists.

- In 1983, the NYSDEC, after inspection of the site, prepared an "Inactive Hazardous Waste Disposal Site Report". The on-site inactive landfill was assigned a site number (# 915029).

- Also in 1983, the United States Geological Survey (USGS) drilled and sampled seven test borings on the north side of the Union Ship canal. Samples from these borings were analyzed for a short list of heavy metals. In their report entitled "Draft Report of Preliminary Evaluation of Chemical Migration to the Niagara River from Hazardous Waste Disposal Sites in Erie and Niagara Counties," the USGS concluded that there was potential for lateral migration of contaminants at and away from the site.

- In 1985, a site inspection and Phase I investigation was performed for the NYSDEC by Engineering-Science and Dames & Moore. The Phase I investigation was limited to areas north of the Union Ship Canal and included a records search and scoring the site using the Hazard Ranking Scoring (HRS) system. The study area was assigned a score of 8.73 in the Phase I report. Additional data needs were identified by the Phase I investigation and a Phase II investigation was recommended and outlined.

- In 1988, Recra Environmental, Inc. performed a "Site Characterization and Environmental Assessment" for the New York State Department of Transportation. The characterization and assessment included the entire 131-acre site. The work involved collecting samples of surface and subsurface soil/fill, surface water, sediment and groundwater, performance of a risk assessment and evaluation of remedial alternatives. Five (SS-20 through SS-24) of 15 surface soil/fill samples (.5 to 1.5-feet bgs) were collected from the railroad yard portion of the site (see Figure 2). Analytical results of the surface soils indicated elevated levels of heavy metals and very low (<2 ppm) concentrations of PCBs. Groundwater from the only one of seven wells (MW-4) installed at the site that is within the former railroad yard contained PCB 1242, arsenic, chromium, lead, and cyanide at concentrations above the class "GA" standards. The pH of the groundwater was also above the range of the class "GA" standard. The HRS score of the Hanna Furnace site was recalculated using the data collected from the site characterization. The revised HRS, as scored by Recra, remained rather low at 12.28 which

Printed on Recycled Paper

indicates that the site does not pose an immediate concern to human health and the environment.

- In 1995, ABB Environmental Services performed a Preliminary Site Assessment (PSA) for the NYSDEC at the site. The PSA included not only the 131-acre Hanna Furnace site but also the adjacent Chenango Steel site. The purpose of the PSA was to re-score the site using the HRS system and to reclassify the site. Only one soil and one groundwater sample were collected from the former railroad yard during the Hanna Furnace PSA. The soil sample was collected from a soil boring (BS-104) in the south-central portion of the property and the groundwater sample was collected from a monitoring well (MW-104) installed at the same location (see Figure 2). The soil sample was collected from fill material at a depth of 6 to 8 feet below grade, and the well was screened from 5 to 15 feet below grade. Groundwater level measurements from this one well indicated that the water table was present at a depth of approximately 8.7 feet below grade at the time of the PSA. Both the soil and groundwater samples were analyzed for Target Compound List (TCL) volatile organic compounds (VOCs), SVOCs, pesticides/PCBs, and Target Analyte List (TAL) metals and cyanide. Analytical results indicated that the metals aluminum, beryllium, calcium, and magnesium were present in the soil sample at concentrations exceeding, by up to four times, the upper limit of the range found in Eastern United States Background concentrations listed in the TAGM 4046 soil cleanup guidelines. Cyanide was detected at a concentration of 32.1 ppm in the soil sample.

  Analysis of the groundwater sample indicated that only cyanide (240 µg/L) and sodium (26,300 µg/L) were detected at concentrations exceeding the NYSDEC Glass GA Groundwater Quality Standards (100 and 20,000 µg/L, respectively). TCL VOCs, SVOCs, and pesticides/PCBs were not detected in either the soil or groundwater sample. No disposal of listed or characteristic hazardous waste was documented at the site. Also, the site was recommended for delisting from the NYSDEC Registry of Inactive Hazardous Waste Disposal Sites.

- In 1997, Ecology and Environment, Inc., performed an Environmental Site Assessment for the Buffalo Urban Renewal Agency. The objective of the assessment was to summarize all available and pertinent environmental information, to identify variations in current site conditions relative to those defined in earlier investigations, and to identify potential areas of concern. The assessment involved a review of records as well as the performance of three site inspections.

Printed on Recycled Paper

The assessment report presented the findings in order of environmental concern by area. The only environmental concern associated with the railroad yard area was solid waste disposal. Several waste piles of railroad ties, tires, C&D debris, household trash, firebrick and black material were noted in the report. Only those debris piles with black material were considered potential contamination by E & E.

Based on the historical use of the site as a rail yard and historical analytical results of sampling in and near the rail yard, Malcolm Pirnie developed an investigation scope to more thoroughly characterize the former rail yard commensurate with the property's proposed intended end use. The field investigation was performed in six days between December 22, 1998 and January 29, 1999, and included the surveying and marking of the proposed sampling locations and the collection of surface and subsurface samples (see Figure 2).

HANNA FURNACE SITE
FORMER RAIL YARD CHARACTERIZATION

BORING LOCATION MAP

BUFFALO ECONOMIC RENAISSANCE CORPORATION

FEBRUARY 1999

2.0 SCOPE OF WORK

2.1 SURVEYING

The surveying firm TVGA divided the site into increments approximately one (1) acre in size using standard surveying methods on December 22 and 23, 1998. To denote each acre, stakes and flags were placed at 200-foot intervals. The borings were completed at 200-foot spacing or as close as possible to each stake.

2.2 SITE WALKOVER

Malcolm Pirnie performed a site walkover on September 11, 1998 in order to assess present site conditions. A significant amount of material was observed in the former rail yard in mounds generally 3 to 5 feet in height. Reportedly, demolition contractors dumped the mounds without a City permit. The mounds reportedly contain demolition debris from projects in Buffalo, New York and possible West Seneca, New York. Debris, including tires, scrap metal, wood, and appliances, was observed throughout the site. Railroad ties were observed in piles as well as in place in the former rail yard.

2.3 SURFACE SOIL SAMPLING

Surface and subsurface soil samples were collected at two foot intervals using split-spoon samples advanced by a drilling rig owned and operated by Maxim Technologies. A total of 36 locations generally spaced 200 feet apart were sampled. Samples were composited from two adjacent locations per sample for a total of 18 composite surface soil and 18 composite subsurface soil samples for submission to the laboratory for analyses.

To characterize the surface soil conditions in the former rail yard, 18 surface soil samples (A1 through R1) were collected as one composite from every two soil boring

Printed on Recycled Paper

locations. The sampling locations are shown on Figure 1, and the locations from which each composite sample was collected are shown in Table 1. The samples were collected from depths of 0 to 2 feet below grade. The composite surface soil samples were analyzed for polycyclic aromatic compounds (PAHs), phenols, cyanide, and TAL metals.

Upon opening each split spoon, a portion of each soil sample was immediately placed in a bottle supplied by the laboratory for analysis of VOCs, and a portion of the sample was placed in a plastic bag for VOC screening. The VOC headspace screening was completed with a photo-ionization detector (PID) on each bagged sample after allowing a minimum of 30 minutes for volatilization. The three surface soil samples with the highest recorded PID measurements were submitted to the laboratory for analysis of TCL VOCs.

The individual surface soil samples were also analyzed for PCBs using DTECH immunoassay test kits. The test kits use antibodies that preferentially bind to the target compounds (in this case, PCBs), and the amount of target compound present is indicated by varying degrees of color change in the antibodies. The test kits determine PCB presence or absence in concentration ranges of 0 to 25 ppm. The test kit results have been considered accurate for establishing the presence or absence of PCBs in those ranges by the New York State Department of Conservation (NYSDEC). For QA/QC purposes and acceptance of the results by the New York State Department of Health (NYSDOH) as protective of public health, five surface soil samples were selected for submittal to the laboratory for analysis of PCBs to confirm the results of the immunoassay test kits. The laboratory analytical results are included in Appendix B.

2.4 SUBSURFACE SOIL SAMPLING

A total of 36 borings (designated SB-1 through SB-36) were completed at the site. One boring was completed at each stake using standard hollow stem auger techniques. The boring locations are shown on Figure 2. Soil samples were collected at 2-foot intervals continuously using decontaminated split spoons two feet in length. The borings

Printed on Recycled Paper

were advanced until native material was encountered, typically 8 to 10 feet bgs. The split spoon samples were described on boring logs by a Malcolm Pirnie geologist and the boring logs are presented in Appendix B. A portion of each split spoon sample was immediately placed in a bottle supplied by the laboratory for analysis of VOCs, and a portion of the sample was placed in a plastic bag for VOC screening. The three subsurface soil samples with the highest recorded PID measurements were submitted to the laboratory for analysis of TCL VOCs. Composite samples were created by mixing the entire vertical column of fill material from each of two adjacent borings, and the resulting samples (A2 through R2) were analyzed for PAHs, phenols, cyanide, and TAL metals. Five composite samples (B2, E2, K2, L2 and O2) were submitted to the laboratory for full TCLP analysis to determine if onsite fill material constitutes a hazardous waste. Table 1 and Figure 2 show which borings were used in each of the composite samples.

Because blue colored fill material was encountered in most of the borings and a blue color is often an indication of the presence of cyanide, one sample was collected of the blue material in boring SB-20 at the 7- to 10-foot depth. The sample was analyzed for total cyanide and reactive cyanide.

Printed on Recycled Paper

3.0 SITE CHARACTERIZATION RESULTS

As described in the boring logs, fill material up to 12 feet thick covers the site. The fill material is generally comprised of tan to brown silty sand with gravel (often slag). At depths of 6 to 10 feet below grade, a blue angular coarse sand size material was generally observed throughout the site in layers 0.5 to 4 feet thick. A layer of peat 6 to 12 inches thick underlay this blue material. Immediately beneath the native peat layer was a dark gray clay and silt.

The discussion of the surface and subsurface soil sample analytical results is based on the Recommended Soil Cleanup Guidelines in the NYSDEC January 1994 Technical Administrative Guideline Memorandum (TAGM) 4046. Where no cleanup guideline for an inorganic analyte is included in TAGM 4046, the highest value of the Eastern United States of America Background Concentrations listed in TAGM 4046 is used for comparison for that analyte. Because the NYSDEC does not have soil cleanup guidelines for lead and cyanide, the USEPA Region III Soil Screening Levels of 400 and 1,600 mg/kg, respectively, were used for comparison. The United States Environmental Protection Agency's Maximum Concentrations for Toxicity Characteristics are used for the Toxicity Characteristic Leaching Procedure results.

3.1 ANALYTICAL RESULTS - VOCs

The PID screening indicated that VOCs were detected at low concentrations in 8 of the 36 borings. The screening results indicated the presence of VOCs at concentrations of up to 4.5 ppm in the borings, and the highest VOC screening concentration was detected in the 2 to 4 foot interval of boring SB-14.

The three surface samples and the three subsurface samples with the highest PID measurements were submitted to the laboratory for analysis of TCL VOCs. No VOCs were detected in the six soil samples.

Printed on Recycled Paper

3.2 ANALYTICAL RESULTS - PCBs

The results of the DTECH PCB test kit analysis indicate that PCBs are sometimes present at very low concentrations in the surface soils at some locations throughout the site. The PCB concentrations detected by the DTECH kits ranged from less than 0.5 to 4.0 parts per million (ppm). The NYSDEC recommended soil cleanup objective (TAGM 4046) for PCBs is 1.0 ppm in surface soil and 10 ppm in subsurface samples. Table 2 summarizes the results of the DTECH PCB analysis.

Five surface soil samples were submitted to the laboratory for PCB analysis to confirm the DTECH test kit results. Sample SB-22 was collected from an interval with DTECH results of less than 0.5 ppm to confirm the low concentrations. Samples SB-16 and SB-27 were collected from intervals with DTECH results of 0.5 to 1.0 ppm to confirm that concentrations in these samples do not exceed the soil cleanup guidelines. Samples SB-15 and SB-33 was collected from the interval with the highest measured DTECH results of 1 to 4 ppm to assess the performance of the kits at higher concentrations. PCBs were not detected in the 5 samples submitted to the laboratory for PCB analysis. Laboratory analysis of all 5 surface samples for PCBs indicates that the DTECH test kits provided false positive results of the PCB concentrations in these samples.

3.3 ANALYTICAL RESULTS - PAHs/PHENOLIC COMPOUNDS

The PAH and phenolic compound analyses indicate that phenolic compounds were not detected, and that some PAHs were detected at concentrations above the soil cleanup guidelines. Table 3 presents the analytical results for the composite surface soil samples, and Table 4 presents the analytical results for the composite subsurface soil samples. The elevated PAH concentrations in the surface soils are consistent with previous sampling performed at the Hanna Furnace Site.

The PAH concentrations detected in the subsurface soil samples were significantly lower than those in the surface soil composite samples. The soil cleanup

Shading indicates that concentration exceeds Guidance Value, and the background range is used when there is no Guidance Value.

guidelines were contravened for at least one PAH compound in 17 of the 18 surface soil composite samples, but in only 5 of the 18 subsurface soil composite samples. In the surface soil samples, concentrations of indeno(1,2,3-cd)pyrene and benzo(k)fluoranthene were slightly above the soil cleanup guidelines, while concentrations of benzo(a)anthracene, chrysene, benzo(b)fluoranthene, benzo(a)pyrene, and dibenzo(a,h)anthracene were significantly above the guidelines. The results of the subsurface soil samples indicated that concentrations of benzo(a)anthracene and chrysene slightly exceeded the soil cleanup guidelines, and concentrations of benzo(a)pyrene were significantly above the guidelines.

The concentrations of PAHs detected in both surface and subsurface soils at this site are primarily within the range typically found in urban soils. Because PAHs are formed through anthropogenic combustion processes such as the burning of coal, oil and gasoline, they are generally ubiquitous in soils, especially urban soils.

The presence of PAH's at this site is consistent with its urban location and past use as a railroad yard.

3.4 ANALYTICAL RESULTS - INORGANIC ANALYTES

The analysis of composite soil samples for inorganic analytes (TAL metals plus cyanide) indicated that a number of metals were detected at concentrations above the soil cleanup guidelines. Table 3 shows the analytical results for the surface samples, and Table 4 shows the analytical results for the subsurface samples. The elevated metals concentrations in the surface soils are generally consistent with previous sampling performed at the Hanna Furnace Site.

Surface Soils

The analysis of the surface soil composite samples indicated that aluminum, arsenic, beryllium, cadmium, calcium, chromium, copper, lead, magnesium, manganese, mercury, nickel, and zinc were detected in at least one sample at concentrations exceeding the soil cleanup guidelines and/or the Eastern U.S. background concentrations.

Printed on Recycled Paper

Maximum detected concentrations of aluminum, manganese, and mercury were less than 2 times the Eastern U.S. soil background concentrations. Maximum chromium, copper, lead and nickel concentrations were less than 4 times the background concentrations; and maximum arsenic, beryllium, cadmium, calcium, and magnesium concentrations were equal to or less than 8 times the background concentrations. The highest detected concentration of zinc was 24 times the background concentrations.

Barium and iron were detected in the surface soil samples at concentrations above the soil cleanup guidelines, but below the Eastern U.S. background concentrations. Cadmium, cobalt, mercury, potassium, sodium, selenium, silver, and thallium were detected at concentrations at or below the guidelines, or were not detected in the composite surface soil samples.

Subsurface Soils

The concentrations of metals in the composite subsurface soil samples were generally lower than or similar to those of the surface soil samples. Aluminum, arsenic, beryllium, cadmium, calcium, magnesium, manganese, nickel, and zinc were detected in at least one composite surface sample at concentrations exceeding the soil cleanup guidelines and/or the Eastern U.S. background concentrations.

Maximum detected concentrations of aluminum, manganese, and nickel were less than 2 times the Eastern U.S. soil background concentrations. Maximum arsenic, beryllium, and magnesium concentrations were less than 6 times the background concentrations; and maximum cadmium and calcium concentrations were less than 9 times the background concentrations. The highest detected concentration of zinc was 34 times the background concentrations.

Barium and iron were detected in the subsurface samples at concentrations above the soil cleanup guidelines, but below the Eastern U.S. background concentrations. Cadmium, chromium, cobalt, copper, lead, mercury, potassium, sodium, selenium, silver, and thallium were detected at concentrations at or below the applicable guidelines, or were not detected in the composite subsurface soil samples.

Printed on Recycled Paper

Total cyanide concentrations in the composite surface and subsurface soil samples ranged from 1 to 33 mg/kg. Analysis of the sample of blue sandy material collected from boring SB-20 revealed that no reactive cyanide was detected in the sample, and that the total cyanide concentration was 38.8 mg/kg. Although there currently is no NYSDEC soil cleanup guideline for cyanide, the USEPA soil screening level (SSL) can be used for comparison. The SSL for amenable cyanide is 1600 mg/kg. Amenable cyanide is that portion which is amenable to chlorination. The susceptibility of cyanide complexes to chlorination is indicative of its availability to organisms. Total cyanide includes the cyanide that is amenable and that is not amenable to chlorination. Because the total cyanide concentrations detected in the samples from the site are less than 40 mg/kg, the concentrations detected in the soil at the Former Rail Yard are well below the USEPA soil screening levels for amenable cyanide.

3.5 ANALYTICAL RESULTS - TOXICITY CHARACTERISTIC LEACHING PROCEDURE (TCLP)

The TCLP analysis of 5 subsurface composite samples indicated that only barium is present in leachable quantities. Barium concentrations ranged from 0.2 to 0.6 µg/L in the samples of fill material, well below the USEPA Maximum Concentration Value for Toxicity Characteristics of 100 µg/L for barium.

Printed on Recycled Paper

4.0 SUMMARY AND CONCLUSIONS

The characterization of the Former Rail Yard at the Hanna Furnace Site revealed that fill material is present at the site at an average thickness of 9 feet and a maximum thickness of approximately 12 feet. Underlying the fill material is native material consisting of a layer of peat underlain by gray silt and clay. Staining and odors were absent in the soil borings, and PID measurements were detected in only 8 out of 36 borings.

The laboratory analytical results indicate that VOCs, PCBs, and phenols were not detected in the samples from the Former Rail Yard. Additionally, cyanide concentrations were well below the USEPA soil screening levels. A number of metals and PAHs were detected at concentrations above the NYSDEC soil cleanup guidelines, with higher concentrations generally occurring in the samples collected from the 0 to 2 foot interval. The TCLP analysis indicated that only barium was present in leachable quantities in the fill material at the site, and that the concentrations of barium in the TCLP samples were well below the applicable guidelines.

These results indicate that the rail yard is suitable for re-development as a commercial/light industrial park provided that certain precautions are taken to limit exposure to the metals and PAHs present in the on-site fill material. Minimum precautions should include:

- Establishment of health and safety protocols for specific re-development activities to minimize exposure potential.
- Development of a protocol for dealing with excavated fill material
- Placement of a minimum of 1-foot of clean soil over the surface following or during development to minimize the potential for exposure following site re-development.
- Establishment of a protocol for digging required to maintain or enhance utilities following completion of site redevelopment including health and safety requirements and excavated soil handling/disposal requirements.

PO Box 1938
Buffalo, NY 14219-0138

SAMPLE SOURCE	HANNA FURNACE, 3587-001
ORIGIN	02
DESCRIPTION	COMPOSITE
SAMPLED ON	29-JAN-99 00:00 by CLIENT
DATE RECEIVED	02-FEB-99 11:00
P.O. NO.	N/A

CAS #	Analysis Performed	Result	Units	Detection Limit	Date Analyzed	Method	Notebook Reference
	Phenol-d5	75	%				97-186-10976
	Nitrobenzene-d5	86	%				97-186-10976
	2-Fluorobiphenyl	85	%				97-186-10976
	2,4,6-Tribromophenol	25	%				97-186-10976
	Terphenyl-d14	86	%				97-186-10976

Analysis Comment: Results Calculated on a dry weight basis.

U = None Detected

QC NY 10252 NJ 73168 PA 68180 EPA NY 00033

Approved by: Lab Director

KEY: ND or U = None Detected < = less than
mg/L = milligrams per liter (equivalent to parts per million)
B = analyte was detected in the method or trip blank
ug/L = micrograms per liter (equivalent to parts per billion)
mg/kg = milligrams per kilogram (equivalent to parts per million)
J = result estimated below the quantitation limit
