Mr. David Raymond Division of Environmental Remediation NYS Department of Environmental Conservation SUNY at Stony Brook 50 Circle Road Stony Brook, NY 11790-3409

Re: Long Island Horticultural Research Site #V00234 Voluntary Cleanup Agreement No.: D1-0002-01-03

Dear Mr. Raymond:

Regarding the Long Island Horticultural Research Site #V00234, I am writing to certify that the institutional controls and engineering controls put in place, pursuant to the executed voluntary agreement, are still in place, have not been altered and are still effective.

Please feel free to contact me at 607-255-0485 should you have any questions about this certification.

Sincerely.

Eric Harrington

Periodic Review Report for Cornell LIHREC

I. Executive Summary

A. The Long Island Horticulture Research and Extension Center (LIHREC) is a horticultural research center administered by Cornell University and the State University of New York. Horticultural research conducted at the facility includes the planting and care of diverse crops in small experimental land plots located both in open fields and in greenhouses. Various pesticides, including proprietary products, were mixed and applied to crops in different experimental plots. Upon completing a specific pesticide application, the application tank was rinsed clean. The rinse water from the application tank was discharged into an evaporation pit and overflow drywell system for disposal. Prior to the construction of the evaporation pit/overflow drywell system, rinse water was reportedly discharged to a rock drain area.

Results of previous NYSDEC laboratory analyses indicated that endosulfan I, endosulfan II, endosulfan sulfate and chlordane were detected in an evaporation pit liquid sample at concentrations ranging from 80 to 320 micrograms per liter (ug/l). NYSDEC laboratory analyses of a sediment sample collected from the bottom of the evaporation pit detected heptachlor, alpha chlordane, and gamma chlordane at concentrations of 720, 1,900 and 2,000 milligrams per kilogram (mg/kg) respectively. Other NYSDEC evaporation pit bottom sample analyses detected endosulfan I, endosulfan II and chlordane at 7,900, 2,900 and 4,000 mg/kg respectively. Finally, NYSDEC analyses of a bottom sediment sample from the overflow drywell indicated the presence of endosulfan I, endosulfan II and chlordane. Analyses performed by an LIHREC-contracted laboratory indicated the presence of chlordane in an evaporation pit liquid sample (529 ug/l), evaporation bottom sediments (251 mg/kg) and overflow drywell sediments (75.3 mg/kg).

In consideration of the above, Cornell submitted a work plan to NYSDEC for removal of all liquids and sludge from both the evaporation pit and overflow drywell in approximately January 1994. The remediation work plan was approved by the NYSDEC in November 1994 with the remediation work conducted in December 1994. The remediation work included removing liquid phase waste material from the evaporation pit and removing all sludge/solids from both the evaporation pit and overflow drywell. After all of the sludge/solids were removed, the evaporation pit and overflow piping were decontaminated utilizing a high-pressure water tri-sodium phosphate rinse. A total of twenty-one (21) drums of liquid waste and three (3) drums of sludge/solids were generated as a result of the remediation work.

In 1997, Cornell retained H2M to conduct a Preliminary Site Assessment

(PSA) to evaluate the nature and extent of the potential impacts associated with the past disposal of pesticide residues in the evaporation pit/overflow drywell system and former rock drain area. The report was submitted to NYSDEC and is the basis for the proposed soil remediation program.

As part of the PSA, H2M conducted two soil borings in each of the two source areas. At the evaporation pit/overflow drywell, one boring was advanced directly through the evaporation pit and one directly through the overflow drywell. Although several pesticides were detected in the soils beneath the evaporation pit, because none were detected at concentrations above the NYSDEC Recommended Soil Cleanup Objectives (RSCOs). remediation of soils beneath the evaporation pit was deemed unnecessary. A second soil boring was conducted through the center of the overflow drywell. Aldrin, chlordane, DDE, endosulfan I, endosulfan II, endosulfan sulfate and heptachlor were detected at concentrations above their respective RSCOs. The highest reported pesticide concentrations were detected in the soils immediately below the bottom of the drywell, approximately 10 feet below grade surface (bgs). Results of the two soil borings completed through the rock drain area indicated elevated levels of pesticides to a total depth of ten to twelve feet below grade. DDT, endosulfan I. endosulfan II. endosulfan sulfate and methoxychlor were detected at concentrations above their respective RSCOs.

Upon completing the PSA, Cornell/LIHREC entered into a Voluntary Agreement with the NYSDEC to conduct additional investigations and to remediate two areas documented to contain elevated levels of pesticides (i.e., Overflow Drywell and Rock Drain Area). In accordance with the Voluntary Agreement, a work plan describing the additional investigation and remediation was submitted to and approved by the NYSDEC.

D. Annual certification will be provided until the NYSDEC notifies Cornell in writing that this certification is no longer needed.

II. Site Overview

According to LIHREC records, the evaporation pit/drywell system was constructed in 1979 and consisted of a rectangular poured-concrete treatment pit with dimensions of 10 x 6 x 6 feet. The walls and bottom of the pit were constructed with 6-inch thick concrete. A valved 4-inch diameter overflow line, set one foot off the bottom of the evaporation pit, connected the pit with an adjacent drywell (i.e., leaching pool) consisting of two 8-foot diameter, 4-foot high leaching pool rings and one 8-foot diameter, 4-foot high chimney. The base of the leaching pool structure is approximately 12 feet below ground surface (bgs) according to the LIHREC-supplied drawings. When the liquid level in the evaporation pit exceeded one foot, the rinse waters would overflow into the drywell. When originally constructed, the evaporation pit

had an open top allowing rain water to enter. In 1981, a rain hood was constructed over the evaporation pit, thereby, preventing rain water from entering. In 1989, the overflow line was valved closed to prevent further overflow discharge to the drywell. The location of the evaporation pit/drywell system is approximately 1,700 feet south of the lab's main buildings and 280 feet east of Horton Road.

The location of the rock-drain area is approximately 1,700 feet south of the lab's main buildings and is marked by an area of one- to two-inch diameter gravel along the east side of Horton Avenue. According to LIHREC personnel, rinsate waters were disposed of in the rock-drain area prior to the construction of the evaporation pit/drywell system.

In November 1993, the NYSDEC collected a liquid and sediment sample from the evaporation pit and a sediment sample from the bottom of the overflow drywell, and analyzed the samples for pesticides by EPA Method 8080. Five inches of sediment and 12 inches of liquid were present in the bottom of the evaporation pit at the time the samples were collected.

The samples were submitted to two NYSDEC-contracted laboratories and to a LIHREC-contracted laboratory. Endosulfan I, Endosulfan II, Endosulfan Sulfate and Chlordane were detected in the liquid sample collected from the evaporation pit at 80, 80, 80, and 320 micrograms per liter (ug/l,), respectively by one of the NYSDEC-contracted laboratories. Pesticides were not detected above contract-required detection limits (CRDLs) in the liquid sample analyzed by the other NYSDEC contracted laboratory. Chlordane, at 529 ug/l, was the only pesticide detected in the evaporation pit liquid sample submitted to the LIHREC-contracted laboratory.

Heptachlor, Alpha Chlordane, and Gamma Chlordane were detected in the bottom sediment collected from the evaporation pit by one of the NYSDEC-contracted laboratories (Weston) at 720,000, 1,900,000, and 2,000,000J micrograms per kilogram (ug/kg), respectively.

The second NYSDEC-contracted laboratory (NYSDOH) detected Endosulfan I, Endosulfan II, and Chlordane in the bottom sediments from the evaporation pit at 7,900,000, 2,900,000, and 4,000,000 ug/kg, respectively. Chlordane, at 251,000 ug/kg, was the only pesticide detected by the LIHREC-contracted laboratory in the evaporation pit sediments.

Both NYSDEC-contracted laboratories detected high concentrations of Endosulfan I, Endosulfan II and Chlordane in the bottom sediments collected from the bottom of the leaching pool. Chlordane (75,300 ug/kg) was the only pesticide detected in the bottom sediments from the leaching pool by the LIHREC-contracted laboratory.

Figures attached [2] illustrating site location, boundaries, significant features and surrounding area.

III. Evaluate Remedy Performance, Effectiveness, and Protectiveness

A. Initial work including cleaning and removal of a pesticidecontaminated sump, removal of visually-impacted soils, and development and testing of groundwater wells was completed under an Interim Remedial Measure (IRM). This IRM work occurred in 1994.

Following the IRM work, the following remediation was conducted:

Collection and analysis of water samples from five wells, four of which existed prior to the work plan approval and one additional well installed and developed as part of the Work Plan scope.

Removal and disposal of an overflow drywell (precast structure) and rock drain, as well as contaminated soils beneath the drywell and drain structures, including the following sub-tasks:

- Installation of sheeting and shoring in the two work areas.
- Excavation of pesticide-impacted soils from beneath the Overflow Drywell (to approximately 16' below grade) and from the Rock Drain Area (to approximately 12' below grade).
- Waste characterization sampling and analysis.
- Confirmatory soil sampling at the terminus (bottom and sidewalls) of the excavations to document the level of pesticide residuals that remained in the soil.
- o Transportation and disposal of pesticide-impacted media.
- o Removal and decontamination of sheeting and shoring.
- o Backfilling of the excavated Overflow Drywell and Rock Drain Area.

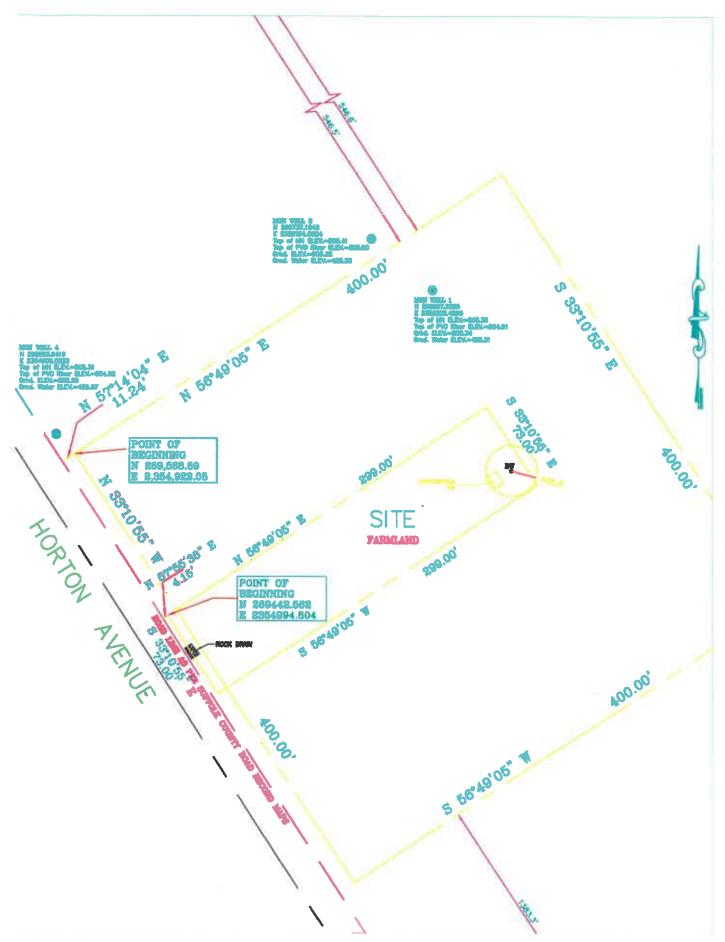

Removal of impacted soil and structures during the IRM and remedial work eliminated principal areas of contamination at the site and severely reduced the potential of future migration of contaminants from these areas into surrounding soils or groundwater.

The remedial action as described continues to protect human health and the environment.

- V. Not Applicable
- VI. Not Applicable

VII. Overall PRR Conclusions and Recommendations

C.1. Cornell will continue to provide certification that the institutional and engineering controls put in place, pursuant to the executed voluntary cleanup agreement, are still in place, have not been altered and are still effective. Annual certification will be provided until the NYSDEC notifies Cornell in writing that this certification is no longer needed.
